1: Mode selection is controlled by SDMMC_0

2: Bypass mode

3: Mode selection is controlled by SDMMC_1

(R/W)

PMU_0P1A_XPD_1 Configures whether software enables VO2 regulator.

0: Disable

1: Enable

(R/W)

PMU_0P1A_TIEH_SEL_1 Configures mode for VO2.

0: Mode is controlled by PMU_0P1A_TIEH_1.

1: Mode is controlled by SDMMC_0

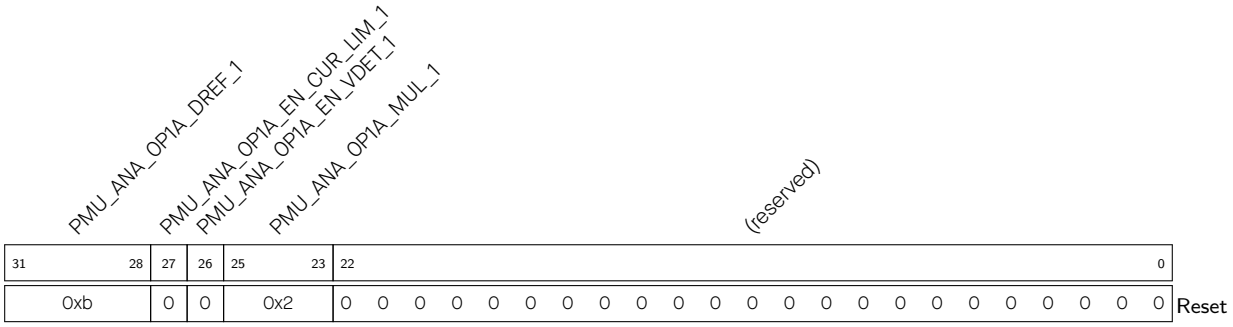
2: Bypass mode

3: Mode is controlled by SDMMC_1

(R/W)

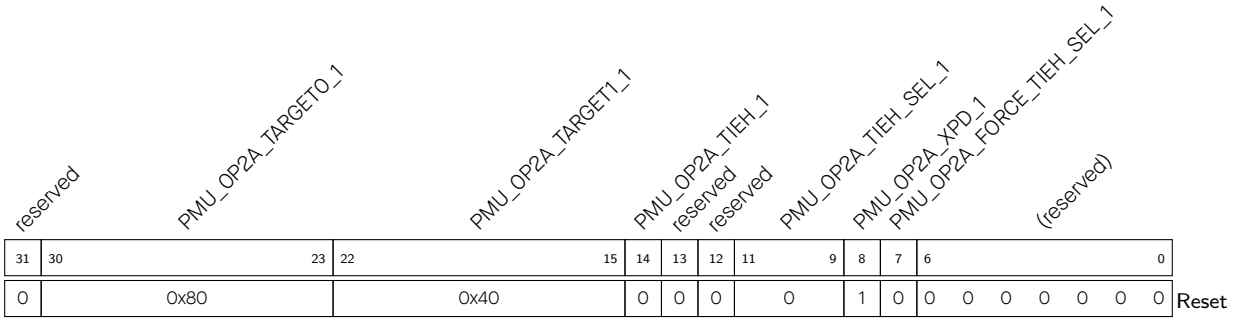
PMU_0P1A_TIEH_1 Configures mode for VO2.

0: LDO mode



1: Bypass mode

(R/W)



PMU_0P1A_TARGET1_1 Configures the timeout for stage 2 of the VO2 regulator wait counter, with the unit being a 16 division of LP_DYN_SLOW_CLK. (R/W)

PMU_0P1A_TARGET0_1 Configures the timeout for stage 1 of the VO2 regulator wait counter, with the unit being a 16 division of LP_DYN_SLOW_CLK. (R/W)

Register 15.63. PMU_EXT_LDO_P1_0P1A_ANA_REG (0x01D4)

PMU_ANA_0P1A_DREF_1
PMU_ANA_0P1A_EN_CUR_LIM_1
PMU_ANA_0P1A_EN_VDET_1
PMU_ANA_0P1A_MUL_1
(reserved)
31 28 27 26 25 23 22 0
0xb 0 0 0x2 0 0 0

Register 15.64. PMU_EXT_LDO_P1_0P2A_REG (0x01D8)

PMU_0P2A_FORCE_TIEH_SEL_1 Configures which of the following controls the mode selection for VO4 regulator.

1: Mode selection is controlled by PMU_0P2A_TIEH_SEL_1

1: Mode selection is controlled by SDMMC_0

2: Bypass mode

3: Mode selection is controlled by SDMMC_1

(R/W)

PMU_0P2A_XPD_1 Configures whether software enables VO4 regulator.

0: Disable

1: Enable

(R/W)

PMU_0P2A_TIEH_SEL_1 Configures mode for VO4.

0: Mode is controlled by PMU_0P2A_TIEH_1.

1: Mode is controlled by SDMMC_0

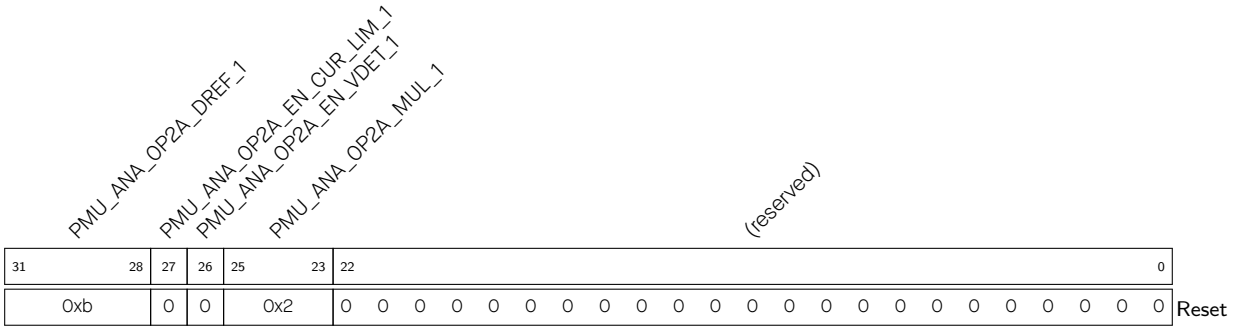
2: Bypass mode

3: Mode is controlled by SDMMC_1

(R/W)

PMU_0P2A_TIEH_1 Configures mode for VO4.

0: LDO mode



1: Bypass mode

(R/W)

PMU_0P2A_TARGET1_1 Configures the timeout for stage 2 of the VO4 regulator wait counter, with the unit being a 16 division of LP_DYN_SLOW_CLK. (R/W)

PMU_0P2A_TARGET0_1 Configures the timeout for stage 1 of the VO4 regulator wait counter, with the unit being a 16 division of LP_DYN_SLOW_CLK. (R/W)

Register 15.65. PMU_EXT_LDO_P1_0P2A_ANA_REG (0x01DC)

PMU_ANA_0P2A_MUL_1 Configures the MUL, where the output voltage of the regulator is MUL × Vref.

0-7: MUL ranges from 1 to 2.75, with a step of 0.25.

(R/W)

PMU_ANA_0P2A_EN_VDET_1 Configures whether to enable VO4 voltage detection.

0: Do not enable

1: Enable

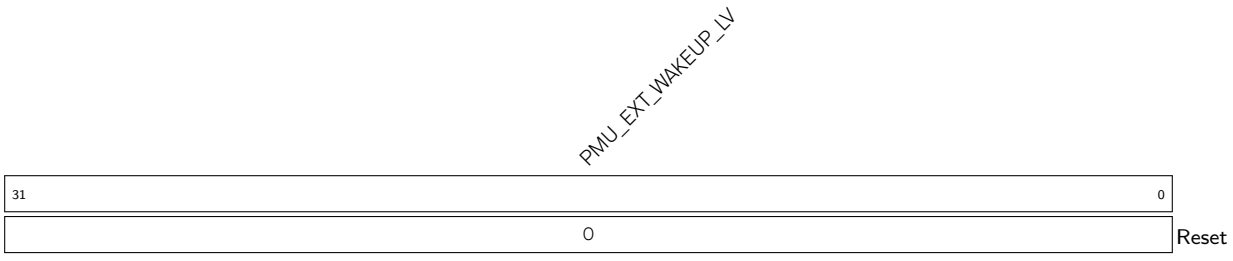
(R/W)

PMU_ANA_0P2A_EN_CUR_LIM_1 Configures whether to enable over current protection for VO4.

0: Do not enable

1: Enable

(R/W)



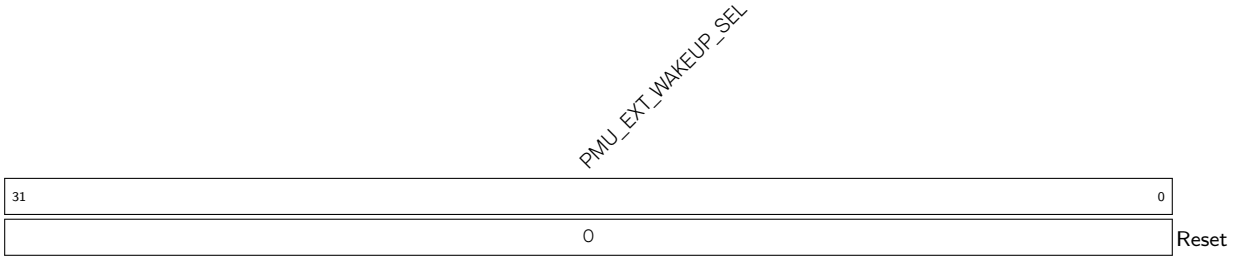
PMU_ANA_0P2A_DREF_1 Configures the LDO Vref, where the output voltage of the regulator is MUL × Vref.

0-8: Vref = 0.5 V - 0.9 V, with a step of 50 mV

9-15: Vref = 1.0 V - 1.6 V, with a step of 100 mV

(R/W)

Register 15.66. PMU_EXT_WAKEUP_LV_REG (0x01E8)



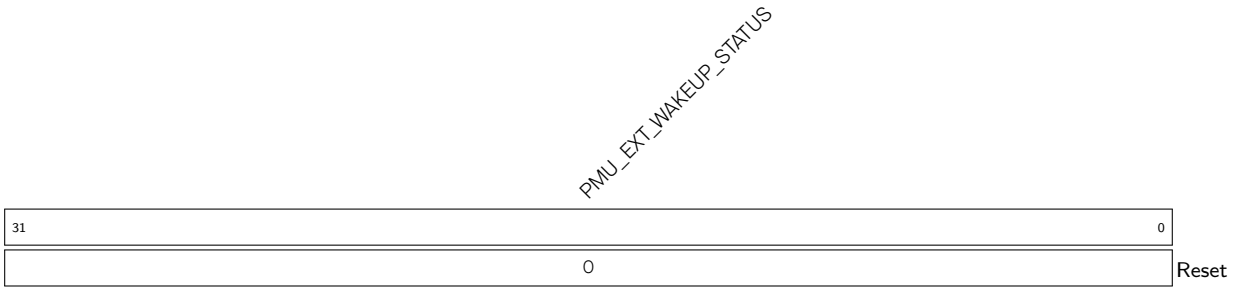
PMU_EXT_WAKEUP_LV Configures the wake level for EXT wake-up.

0: Low level wake-up

1: High level wake-up

(R/W)

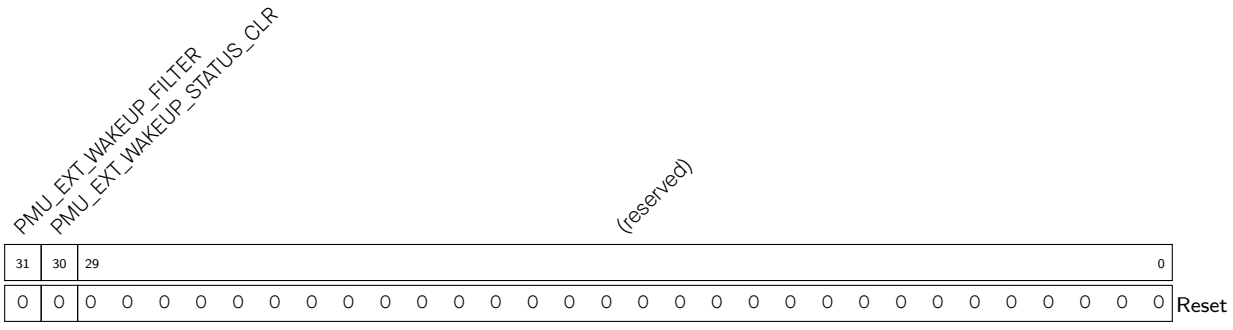
Register 15.67. PMU_EXT_WAKEUP_SEL_REG (0x01EC)



PMU_EXT_WAKEUP_SEL Configures whether to enable EXT wake-up.

0: Disable

1: Enable



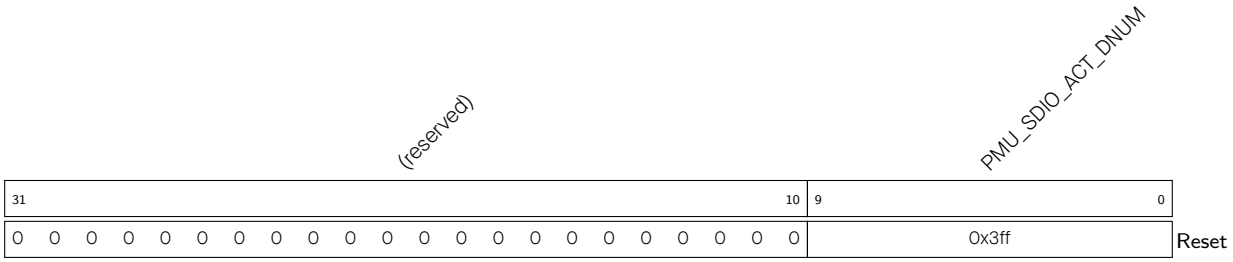
(R/W)

Register 15.68. PMU_EXT_WAKEUP_ST_REG (0x01F0)

PMU_EXT_WAKEUP_STATUS Gets the GPIO number for wake-up. 0 corresponds to GPIO0, 1 corresponds to GPIO1, and so on. (RO)

Register 15.69. PMU_EXT_WAKEUP_CNTL_REG (0x01F4)

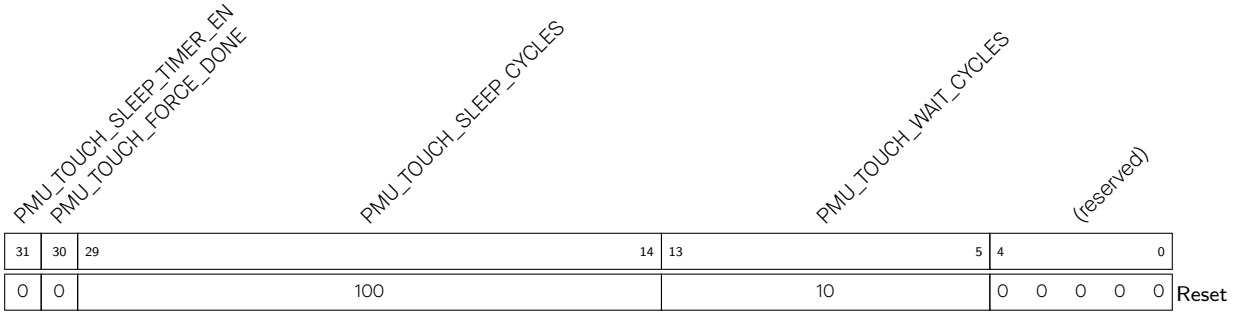
PMU_EXT_WAKEUP_STATUS_CLR Clears the wake-up records. (R/W)



PMU_EXT_WAKEUP_FILTER Configures whether to enable the wake-up filter.

0: Disable

1: Enable

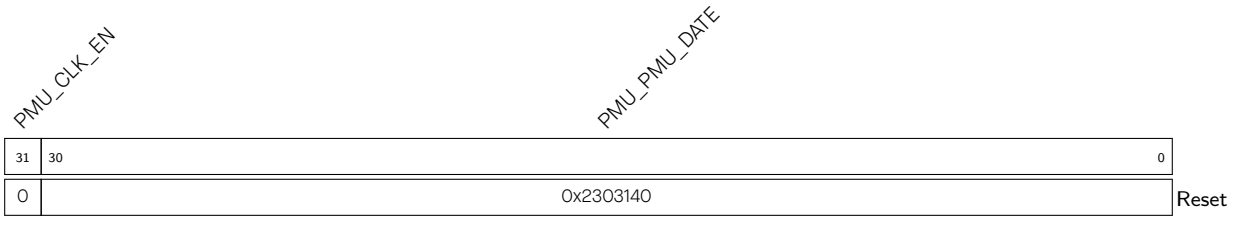


(R/W)

Register 15.70. PMU_SDIO_WAKEUP_CNTL_REG (0x01F8)

PMU_SDIO_ACT_DNUM Configures the duration for maintaining the working state of SDIO. The unit is LP_DYN_FAST_CLK. (R/W)

Register 15.71. PMU_TOUCH_PWR_CNTL_REG (0x0210)



PMU_TOUCH_WAIT_CYCLES Configures the waiting time for the PMU to wake up from the TOUCH timer, with the unit of LP_DYN_SLOW_CLK. (R/W)

PMU_TOUCH_SLEEP_CYCLES Configure the sleep time for TOUCH, with the unit of LP_DYN_SLOW_CLK. (R/W)

PMU_TOUCH_FORCE_DONE Force return to the working state of the TOUCH timer. (R/W)

PMU_TOUCH_SLEEP_TIMER_EN Enables the TOUCH timer to start working. (R/W)

Register 15.72. PMU_DATE_REG (0x03FC)

PMU_PMU_DATE Version control register. (R/W)

PMU_CLK_EN Force enables the automatic clock gating of the register. (R/W)

Chapter 16

System Timer

16.1 Overview

ESP32-P4 provides a 52-bit system timer, which can be used to generate tick interrupts for the operating system, or be used as a general timer to generate periodic interrupts or one-time interrupts.

16.2 Features

The system timer has the following features:

- Two 52-bit counters and three 52-bit comparators
- Software accessing registers clocked by APB_CLK
- CNT_CLK used for counting, with an average frequency of 16 MHz in two counting cycles
- 40 MHz XTAL_CLK as the clock source of CNT_CLK
- 52-bit alarm values (t) and 26-bit alarm periods (δt)
- Two modes to generate alarms:
  - Target mode: only a one-time alarm is generated based on the alarm value (t)
  - Period mode: periodic alarms are generated based on the alarm period (δt)
- Three comparators generating three independent interrupts based on configured alarm value (t) or alarm period (δt)
- Software configuring the reference count value. For example, the system timer is able to load back the sleep time recorded by RTC timer via software after Light-sleep
- Able to stall or continue running when CPU stalls or enters the on-chip-debugging mode
- Alarm for Event Task Matrix (ETM) event

16.3 System Timer Structure

The timer consists of two counters: UNIT0 and UNIT1. The count values can be monitored by three comparators, COMP0, COMP1, and COMP2. See the timer block diagram in Figure 16.3-1.

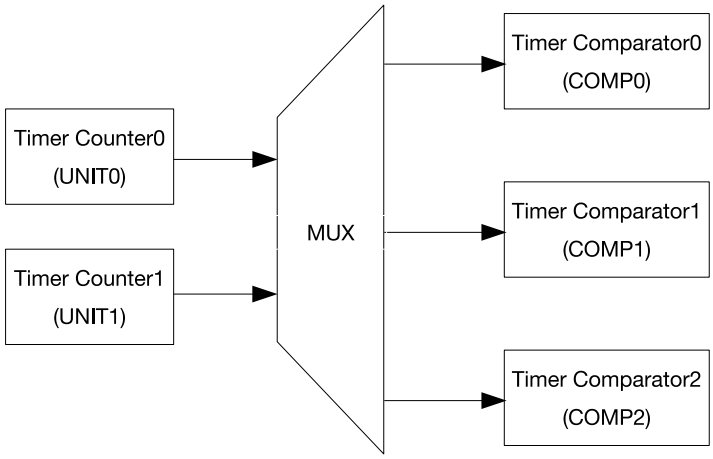


Figure 16.3-1. System Timer Structure

16.4 Clock Source Selection

The counters and comparators use XTAL_CLK or RC_FAST_CLK as the clock sources. The clock source can be selected by configuring field HP_SYS_CLKRST_SYSTIMER_CLK_SRC_SEL in register HP_SYS_CLKRST_PERI_CLK_CTRL21_REG. After XTAL_CLK is scaled by 2.5, a counter clock signal CNT_CLK clock is generated with a frequency of $f_{XTAL_CLK}/2.5$. The average clock frequency of CNT_CLK is 16 MHz, as shown in Figure 16.5-1. The timer counter is incremented by 1/16 μs on each CNT_CLK cycle.

Software operation such as configuring registers is clocked by APB_CLK. For more information about APB_CLK, see Chapter 11 *Reset and Clock*.

The following two bits of system registers are also used to control the system timer:

- Set HP_SYS_CLKRST_SYSTIMER_APB_CLK_EN in register HP_SYS_CLKRST_SOC_CLK_CTRL2_REG to enable APB_CLK signal to the system timer.
- Set HP_SYS_CLKRST_RST_EN_SYSTIMER in register HP_SYS_CLKRST_HP_RST_EN1_REG to reset the system timer.

Note that if the timer is reset, its registers will be restored to their default values. For more information, please refer to Chapter 11 *Reset and Clock*.

16.5 Functional Description

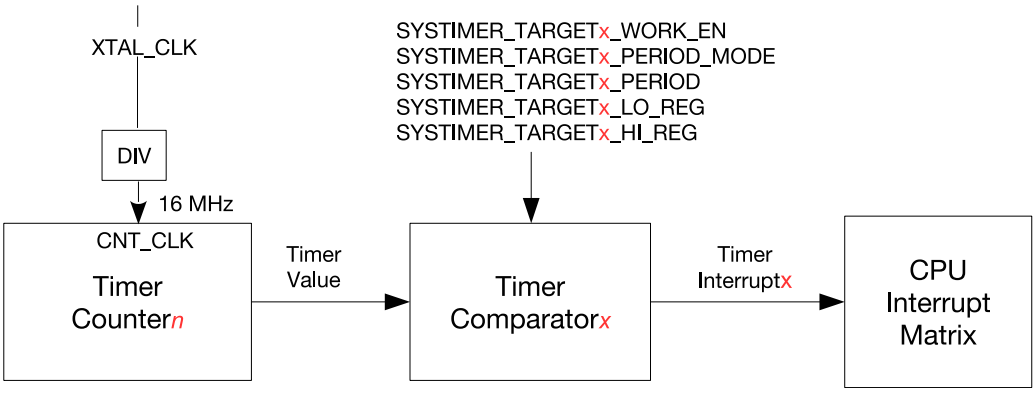

Figure 16.5-1. System Timer Alarm Generation

Figure 16.5-1 shows the procedure to generate alarm in system timer. In this process, one timer counter and one timer comparator are used. An alarm interrupt will be generated accordingly based on the comparison result in the comparator.

16.5.1 Counter

The system timer has two 52-bit timer counters, shown as UNIT*n* (*n* = 0 or 1). Their counting clock source is a 16 MHz clock, i.e., CNT_CLK. Whether UNIT*n* works or not is controlled by three bits in register SYSTIMER_CONF_REG:

- SYSTIMER_TIMER_UNIT*n*_WORK_EN: set this bit to enable the counter UNIT*n* in the system timer.
- SYSTIMER_TIMER_UNIT*n*_CORE0_STALL_EN: if this bit is set, the counter UNIT*n* stops when CPU0 is stalled. The counter continues its counting after the CPU resumes.
- SYSTIMER_TIMER_UNIT*n*_CORE1_STALL_EN: if this bit is set, the counter UNIT*n* stops when CPU1 is stalled. The counter continues its counting after the CPU resumes.

The configuration of the bits to control the counter UNIT*n* is shown below, assuming that CPU is stalled.

Table 16.5-1. UNIT*n* Configuration Bits

SYSTIMER_TIMER_ UNIT*n*_WORK_EN	SYSTIMER_TIMER_ UNIT*n*_CORE0_STALL_EN	SYSTIMER_TIMER_ UNIT*n*_CORE1_STALL_EN	Counter UNIT*n*
0	x *	x *	Not at work
1	1	x	Stop counting, but will continue its counting after the CPU0 resumes
1	x	1	Stop counting, but will continue its counting after the CPU1 resumes
1	0	0	Keep counting

* x: Don't-care.

When the counter UNIT*n* is at work, the count value is incremented on each counting cycle. When the counter UNIT*n* is stopped, the count value stops increasing and keeps unchanged.

The lower 32 and higher 20 bits of the initial count value are loaded from the registers SYSTIMER_TIMER_UNIT*n*_LOAD_LO and SYSTIMER_TIMER_UNIT*n*_LOAD_HI. Writing 1 to the bit SYSTIMER_TIMER_UNIT*n*_LOAD will trigger a reload event, and the current count value will be changed immediately. If UNIT*n* is at work, the counter will continue to count up from the new reloaded value.

Writing 1 to SYSTIMER_TIMER_UNIT*n*_UPDATE will trigger an update event. The lower 32 and higher 20 bits of the current count value will be locked into the registers SYSTIMER_TIMER_UNIT*n*_VALUE_LO and SYSTIMER_TIMER_UNIT*n*_VALUE_HI, and then SYSTIMER_TIMER_UNIT*n*_VALUE_VALID is asserted. Before the next update event, the values of SYSTIMER_TIMER_UNIT*n*_VALUE_LO and SYSTIMER_TIMER_UNIT*n*_VALUE_HI remain unchanged.

16.5.2 Comparator and Alarm

The system timer has three 52-bit comparators, shown as COMP*x* (*x* = 0, 1, or 2). The comparators can generate independent interrupts based on different alarm values (t) or alarm periods (δt).

Configure SYSTIMER_TARGET*x*_PERIOD_MODE to choose from the two alarm modes for each COMP*x*:

- 1: period mode
- 0: target mode

In period mode, the alarm period (δt) is provided by the register SYSTIMER_TARGET*x*_PERIOD. Assuming that current count value is t1, when it reaches (t1 + δt), an alarm interrupt will be generated. When the count value reaches (t1 + 2*δt), another alarm interrupt also will be generated. By such way, periodic alarms are generated.

In target mode, the lower 32 bits and higher 20 bits of the alarm value (t) are provided by SYSTIMER_TIMER_TARGET*x*_LO and SYSTIMER_TIMER_TARGET*x*_HI. Assuming that current count value is t2 (t2 <= t), an alarm interrupt will be generated when the count value reaches the alarm value (t). Unlike in period mode, only one alarm interrupt is generated in target mode.

SYSTIMER_TARGET*x*_TIMER_UNIT_SEL is used to choose the count value from which timer counter to be compared to generate alarms:

- 1: Use the count value from UNIT*1*
- 0: Use the count value from UNIT*0*

Finally, set SYSTIMER_TARGET*x*_WORK_EN and COMP*x* starts to compare the count value:

- In target mode, COMP*x* compares it with the alarm value (t).
- In period mode, COMP*x* compares it with the alarm period (t1 + n*δt).

An alarm is generated when the count value equals to the alarm value (t) in target mode or to the start value + n*alarm period δt (n = 1, 2, 3...) in period mode. But if the alarm value (t) set in registers is less than the current count value, i.e., the target has already passed, when the current count value is larger than the alarm value (t) within a range (0 ~ 2^{51} - 1), an alarm interrupt will also be generated immediately. No matter in target mode or period mode, the low 32 bits and high 20 bits of the real alarm value can always be read from SYSTIMER_TARGET*x*_LO_RO and SYSTIMER_TARGET*x*_HI_RO. The alarm trigger point and the relationship between current count value t_c and the alarm value t_t are shown below.

Table 16.5-2. Trigger Point

Relationship Between t_c and t_t	Trigger Point
t_c- t_t <= 0	t_c = t_t, an alarm is triggered.
0 <= t_c - t_t < 2^{51} - 1 (t_c < 2^{51} and t_t < 2^{51}, or t_c >= 2^{51} and t_t >= 2^{51})	An alarm is triggered immediately.
t_c - t_t >= 2^{51} - 1	t_c overflows after counting to its maximum value 52'hfffffffffffff, and then starts counting up from 0. When its value reaches t_t, an alarm is triggered.

16.5.3 Event Task Matrix

The system timer on ESP32-P4 supports the Event Task Matrix (ETM) function, which allows the system timer's ETM tasks to be triggered by any peripherals' ETM events, or system timer's ETM events to trigger any peripherals' ETM tasks. This section introduces the ETM tasks and events related to the system timer. For more information, please refer to Chapter 14 Event Task Matrix (ETM).

The system timer can generate the following ETM event:

- SYSTIMER_EVT_CNT_CMP*x*: Indicates the alarm events generated by COMP*x*.

When SYSTIMER_ETM_EN is set to 1, the alarm events can trigger the ETM event.

16.5.4 Synchronization Operation

The frequency of the clock used for software configuration is different from that of the clock driving the timer counters and comparators. Therefore, synchronization is required for configuring some registers. The steps are as follows:

1. Software writes specific values to configuration fields. See the first column in Table 16.5-3.
2. Software writes 1 to corresponding bits to start synchronization. See the second column in Table 16.5-3.

Table 16.5-3. Synchronization Operation for Configuration Registers

Configuration Fields	Synchronization Enable Bit
SYSTIMER_TIMER_UNIT*n*_LOAD_LO SYSTIMER_TIMER_UNIT*n*_LOAD_HI	SYSTIMER_TIMER_UNIT*n*_LOAD
SYSTIMER_TARGET*x*_PERIOD SYSTIMER_TIMER_TARGET*x*_HI SYSTIMER_TIMER_TARGET*x*_LO	SYSTIMER_TIMER_COMP*x*_LOAD

The frequency of the clock used for software reading is different from that of the clock driving the timer counters and comparators. Therefore, synchronization is also needed for reading some registers. The steps are as follows:

1. Software writes specific values to the updating register SYSTIMER_TIMER_UNIT*n*_UPDATE.

2. Software reads the corresponding bit SYSTIMER_TIMER_UNIT*n*_VALUE_VALID to be valid to confirm synchronization is done.
3. Software reads the corresponding status registers SYSTIMER_TIMER_UNIT*n*_VALUE_HI and SYSTIMER_TIMER_UNIT*n*_VALUE_LO.

16.6 Interrupts

ESP32-P4's system timer can generate the following interrupt signals that will be sent to the Interrupt Matrix.

- SYSTIMER_TARGET0_INT
- SYSTIMER_TARGET1_INT
- SYSTIMER_TARGET2_INT

There are several internal interrupt sources from the system timer that can generate the above interrupt signals. The interrupt sources from the system timer are listed with their trigger conditions and the resulted interrupt signals in Table 16.6-1.

Table 16.6-1. System Timer's Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
SYSTIMER_INT0	When COMP0 alarms	SYSTIMER_TARGET0_INT
SYSTIMER_INT1	When COMP1 alarms	SYSTIMER_TARGET1_INT
SYSTIMER_INT2	When COMP2 alarms	SYSTIMER_TARGET2_INT

The above interrupts are level-type alarm interrupts. The interrupt signal is asserted high when the comparator starts to alarm. Until the software clears the interrupt, it remains high. To enable interrupts, set the bit SYSTIMER_TARGET*x*_INT_ENA.

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 16.8 *Register Summary*.

16.7 Programming Procedure

When configuring COMP*x* and UNIT*n*, please ensure the corresponding COMP and UNIT are at work.

16.7.1 Read Current Count Value

1. Set SYSTIMER_TIMER_UNIT*n*_UPDATE to fill the current count value of COMP*x* into SYSTIMER_TIMER_UNIT*n*_VALUE_HI and SYSTIMER_TIMER_UNIT*n*_VALUE_LO.

2. Poll the reading of SYSTIMER_TIMER_UNIT*n*_VALUE_VALID till it is 1. Then, user can read the count value from SYSTIMER_TIMER_UNIT*n*_VALUE_HI and SYSTIMER_TIMER_UNIT*n*_VALUE_LO.
3. Read the lower 32 bits and higher 20 bits from SYSTIMER_TIMER_UNIT*n*_VALUE_LO and SYSTIMER_TIMER_UNIT*n*_VALUE_HI respectively.

16.7.2 Configure a One-Time Alarm in Target Mode

1. Set SYSTIMER_TARGET*x*_TIMER_UNIT_SEL to select the counter (UNIT*0* or UNIT*1*) used for comparison with COMP*x*.
2. Read the current count value with reference to Section 16.7.1. This value will be used to calculate the alarm value (t) in Step 4.
3. Clear SYSTIMER_TARGET*x*_PERIOD_MODE to enable target mode.
4. Set an alarm value (t), and fill its lower 32 bits into SYSTIMER_TIMER_TARGET*x*_LO, and the higher 20 bits into SYSTIMER_TIMER_TARGET*x*_HI.
5. Set SYSTIMER_TIMER_COMP*x*_LOAD to synchronize the alarm value (t) to COMP*x*, i.e., load the alarm value (t) to the COMP*x*.
6. Set SYSTIMER_TARGET*x*_WORK_EN to enable the selected COMP*x*. COMP*x* starts comparing the count value with the alarm value (t).
7. Set SYSTIMER_TARGET*x*_INT_ENA to enable the timer interrupt. When UNIT*n* reaches the alarm value (t), a SYSTIMER_TARGET*x*_INT interrupt is triggered.

16.7.3 Configure Periodic Alarms in Period Mode

1. Set SYSTIMER_TARGET*x*_TIMER_UNIT_SEL to select the counter (UNIT*0* or UNIT*1*) used for comparison with COMP*x*.
2. Set an alarm period (δt), and fill it into SYSTIMER_TARGET*x*_PERIOD.
3. Set SYSTIMER_TIMER_COMP*x*_LOAD to synchronize the alarm period (δt) to COMP*x*, i.e., load the alarm period (δt) to COMP*x*.
4. Clear and then set SYSTIMER_TARGET*x*_PERIOD_MODE to configure COMP*x* into period mode.
5. Set SYSTIMER_TARGET*x*_WORK_EN to enable the selected COMP*x*. COMP*x* starts comparing the count value with the sum of (start value + n*δt) (n = 1, 2, 3...).
6. Set SYSTIMER_TARGET*x*_INT_ENA to enable the timer interrupt. A SYSTIMER_TARGET*x*_INT interrupt is triggered when UNIT*n* reaches start value + n*δt (n = 1, 2, 3...) set in Step 2.

16.7.4 Update After Light-sleep

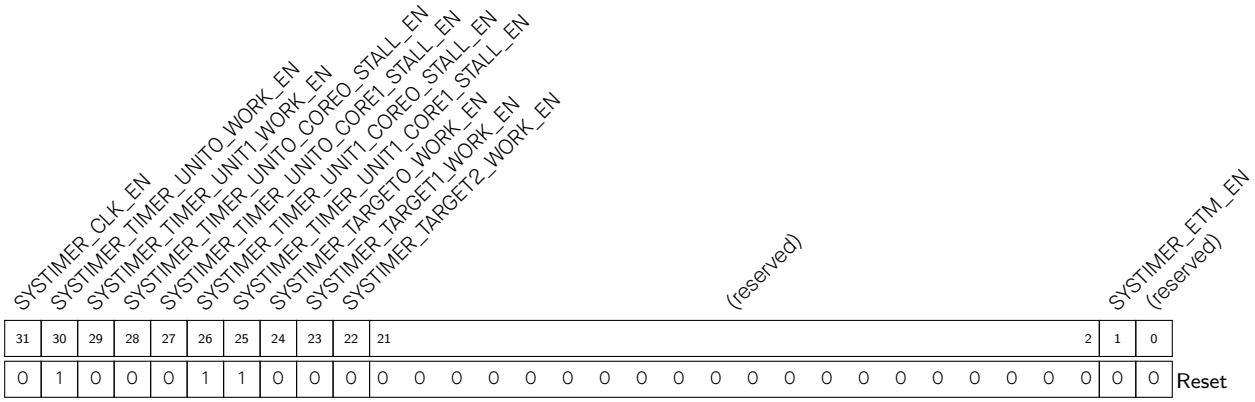
1. Configure RTC timer before the chip goes to Light-sleep mode, to record the exact sleep time. For more information, see Chapter 15 *Low-Power Management*.
2. Read the sleep time from the RTC timer when the chip wakes up from Light-sleep mode.
3. Read the current count value of system timer, see Section 16.7.1.

4. Convert the time value recorded by RTC timer from the clock cycles based on RTC_SLOW_CLK to that based on 16 MHz CNT_CLK. For example, if the frequency of RTC_SLOW_CLK is 32 kHz, the recorded RTC timer value should be converted by multiplying by 500.
5. Add the converted RTC value to the current count value of system timer:
   - Fill the new value into SYSTIMER_TIMER_UNIT*n*_LOAD_LO (low 32 bits) and SYSTIMER_TIMER_UNIT*n*_LOAD_HI (high 20 bits).
   - Set SYSTIMER_TIMER_UNIT*n*_LOAD to load the new timer value into the system timer. By such way, the system timer is updated.

16.8 Register Summary

The addresses in this section are relative to system timer base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Clock Control Register			
SYSTIMER_CONF_REG	Configure system timer clock	0x0000	R/W
UNIT*0* Control and Configuration Registers			
SYSTIMER_UNIT0_OP_REG	Read UNIT0 value to registers	0x0004	varies
SYSTIMER_UNIT0_LOAD_HI_REG	High 20 bits to be loaded to UNIT0	0x000C	R/W
SYSTIMER_UNIT0_LOAD_LO_REG	Low 32 bits to be loaded to UNIT0	0x0010	R/W
SYSTIMER_UNIT0_VALUE_HI_REG	UNIT0 value, high 20 bits	0x0040	RO
SYSTIMER_UNIT0_VALUE_LO_REG	UNIT0 value, low 32 bits	0x0044	RO
SYSTIMER_UNIT0_LOAD_REG	UNIT0 synchronization register	0x005C	WT
UNIT*1* Control and Configuration Registers			
SYSTIMER_UNIT1_OP_REG	Read UNIT1 value to registers	0x0008	varies
SYSTIMER_UNIT1_LOAD_HI_REG	High 20 bits to be loaded to UNIT1	0x0014	R/W
SYSTIMER_UNIT1_LOAD_LO_REG	Low 32 bits to be loaded to UNIT1	0x0018	R/W
SYSTIMER_UNIT1_VALUE_HI_REG	UNIT1 value, high 20 bits	0x0048	RO
SYSTIMER_UNIT1_VALUE_LO_REG	UNIT1 value, low 32 bits	0x004C	RO
SYSTIMER_UNIT1_LOAD_REG	UNIT1 synchronization register	0x0060	WT
Comparator*0* Control and Configuration Registers			
SYSTIMER_TARGET0_HI_REG	Alarm value to be loaded to COMP0, high 20 bits	0x001C	R/W
SYSTIMER_TARGET0_LO_REG	Alarm value to be loaded to COMP0, low 32 bits	0x0020	R/W
SYSTIMER_TARGET0_CONF_REG	Configure COMP0 alarm mode	0x0034	R/W
SYSTIMER_COMP0_LOAD_REG	COMP0 synchronization register	0x0050	WT
Comparator*1* Control and Configuration Registers			
SYSTIMER_TARGET1_HI_REG	Alarm value to be loaded to COMP1, high 20 bits	0x0024	R/W
SYSTIMER_TARGET1_LO_REG	Alarm value to be loaded to COMP1, low 32 bits	0x0028	R/W
SYSTIMER_TARGET1_CONF_REG	Configure COMP1 alarm mode	0x0038	R/W
SYSTIMER_COMP1_LOAD_REG	COMP1 synchronization register	0x0054	WT
Comparator*2* Control and Configuration Registers			
SYSTIMER_TARGET2_HI_REG	Alarm value to be loaded to COMP2, high 20 bits	0x002C	R/W
SYSTIMER_TARGET2_LO_REG	Alarm value to be loaded to COMP2, low 32 bits	0x0030	R/W
SYSTIMER_TARGET2_CONF_REG	Configure COMP2 alarm mode	0x003C	R/W
SYSTIMER_COMP2_LOAD_REG	COMP2 synchronization register	0x0058	WT
Interrupt Registers			
SYSTIMER_INT_ENA_REG	Interrupt enable register of system timer	0x0064	R/W
SYSTIMER_INT_RAW_REG	Interrupt raw register of system timer	0x0068	R/WTC/SS
SYSTIMER_INT_CLR_REG	Interrupt clear register of system timer	0x006C	WT

Name	Description	Address	Access
SYSTIMER_INT_ST_REG	Interrupt status register of system timer	0x0070	RO
COMP*0* Status Registers			
SYSTIMER_REAL_TARGET0_LO_REG	Actual target value of COMP0, low 32 bits	0x0074	RO
SYSTIMER_REAL_TARGET0_HI_REG	Actual target value of COMP0, high 20 bits	0x0078	RO
COMP*1* Status Registers			
SYSTIMER_REAL_TARGET1_LO_REG	Actual target value of COMP1, low 32 bits	0x007C	RO
SYSTIMER_REAL_TARGET1_HI_REG	Actual target value of COMP1, high 20 bits	0x0080	RO
COMP*2* Status Registers			
SYSTIMER_REAL_TARGET2_LO_REG	Actual target value of COMP2, low 32 bits	0x0084	RO
SYSTIMER_REAL_TARGET2_HI_REG	Actual target value of COMP2, high 20 bits	0x0088	RO
Version Register			
SYSTIMER_DATE_REG	Version control register	0x00FC	R/W

16.9 Registers

The addresses in this section are relative to system timer base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

Register 16.1. SYSTIMER_CONF_REG (0x0000)

SYSTIMER_CLK_EN
SYSTIMER_TIMER_UNIT0_WORK_EN
SYSTIMER_TIMER_UNIT1_WORK_EN
SYSTIMER_TIMER_UNIT0_CORE0_STALL_EN
SYSTIMER_TIMER_UNIT0_CORE1_STALL_EN
SYSTIMER_TIMER_UNIT1_CORE0_STALL_EN
SYSTIMER_TIMER_UNIT1_CORE1_STALL_EN
SYSTIMER_TARGET0_WORK_EN
SYSTIMER_TARGET1_WORK_EN
SYSTIMER_TARGET2_WORK_EN
(reserved)
SYSTIMER_ETM_EN
(reserved)
31 30 29 28 27 26 25 24 23 22 21 2 1 0
0 1 0 0 0 1 1 0 0 0

Register 16.1. SYSTIMER_CONF_REG (0x0000)

Continued from the previous page...

SYSTIMER_TIMER_UNIT1_WORK_EN Configures whether to enable UNIT1.

0: Disable

1: Enable

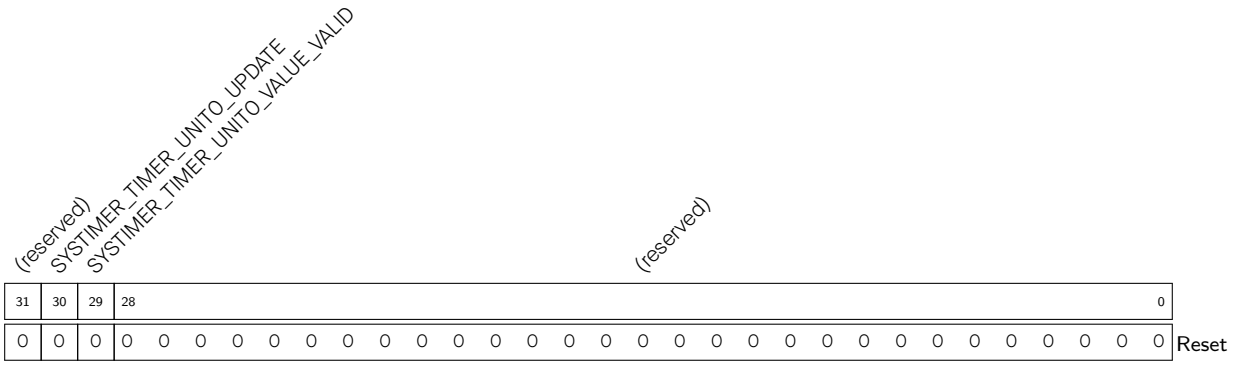
(R/W)

SYSTIMER_TIMER_UNIT0_WORK_EN Configures whether to enable UNIT0.

0: Disable

1: Enable

(R/W)



SYSTIMER_CLK_EN Configures register clock gating.

0: Only enable needed clock for register read or write operations.

1: Register clock is always enabled for read and write operations.

(R/W)

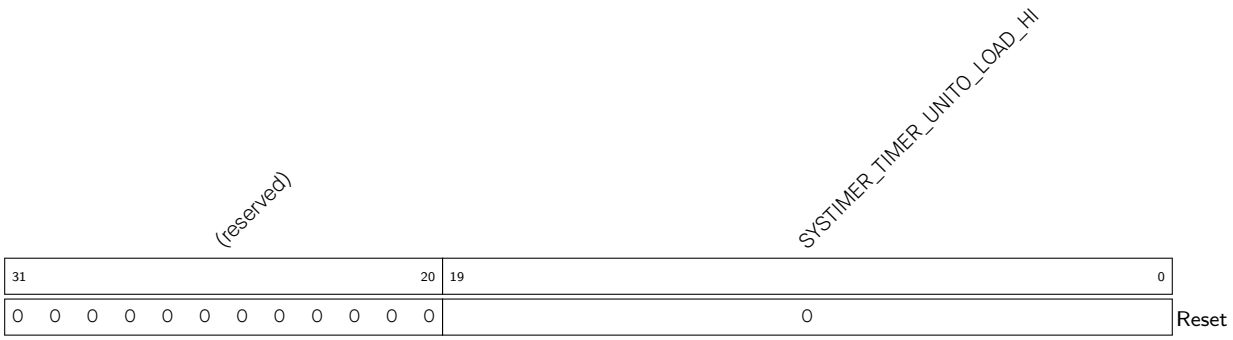
Register 16.2. SYSTIMER_UNIT0_OP_REG (0x0004)

SYSTIMER_TIMER_UNIT0_VALUE_VALID Represents whether UNIT0 value is synchronized and valid.

0: UNIT0 value is neither synchronized nor valid

1: UNIT0 value is synchronized and valid

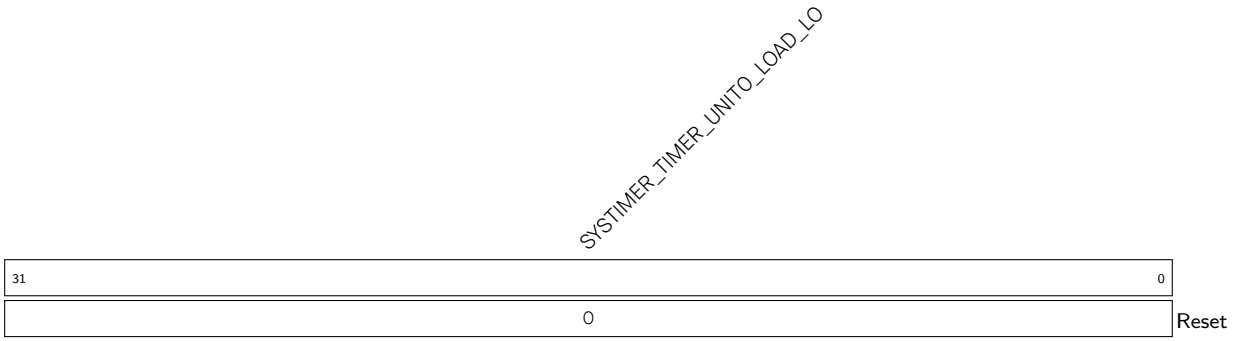
(R/SS/WTC)



SYSTIMER_TIMER_UNIT0_UPDATE Configures whether to update timer UNIT0, i.e., reads the UNIT0 count value to SYSTIMER_TIMER_UNIT0_VALUE_HI and SYSTIMER_TIMER_UNIT0_VALUE_LO.

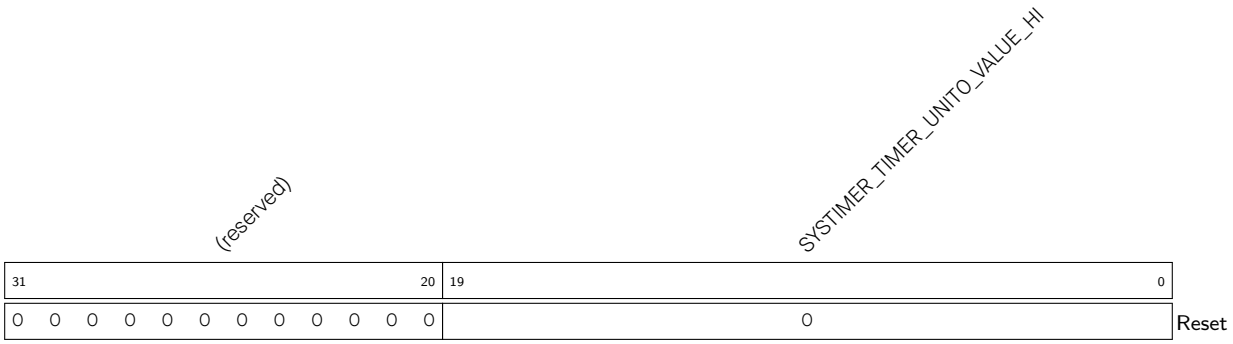
0: No effect

1: Update timer UNIT0



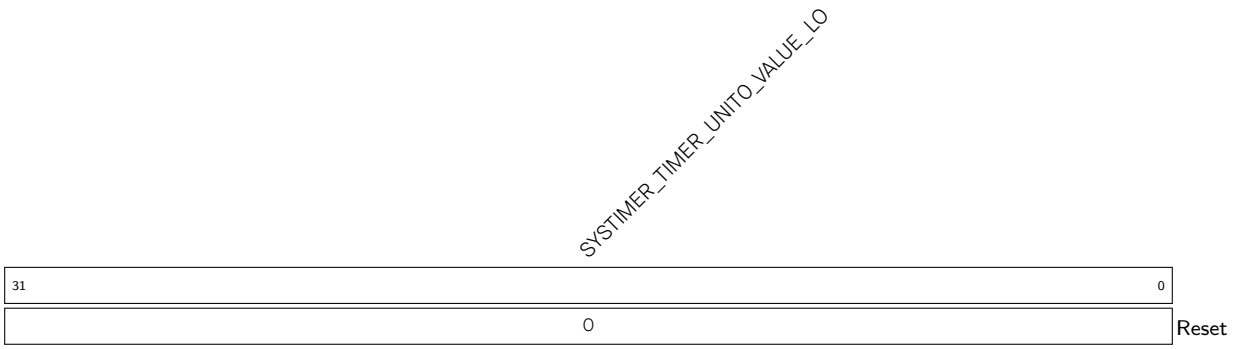
(WT)

Register 16.3. SYSTIMER_UNIT0_LOAD_HI_REG (0x000C)



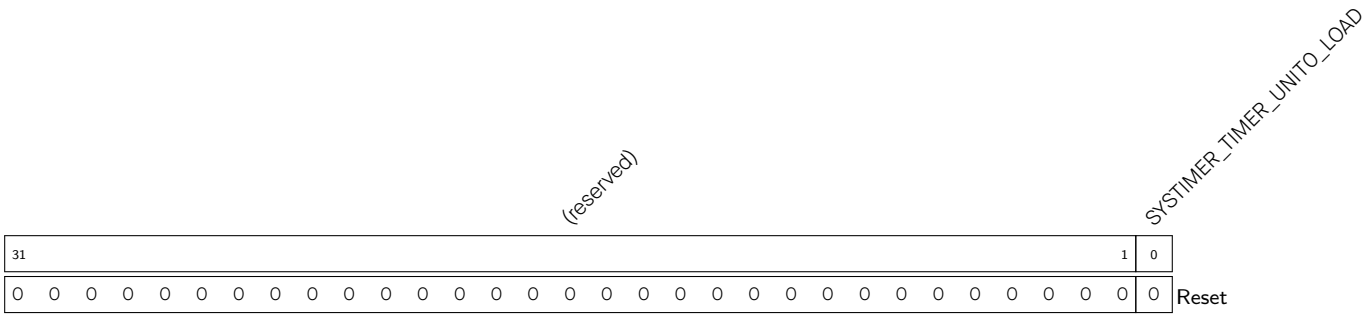
SYSTIMER_TIMER_UNIT0_LOAD_HI Configures the value to be loaded to UNIT0, high 20 bits. (R/W)

Register 16.4. SYSTIMER_UNIT0_LOAD_LO_REG (0x0010)



SYSTIMER_TIMER_UNIT0_LOAD_LO Configures the value to be loaded to UNIT0, low 32 bits. (R/W)

Register 16.5. SYSTIMER_UNIT0_VALUE_HI_REG (0x0040)

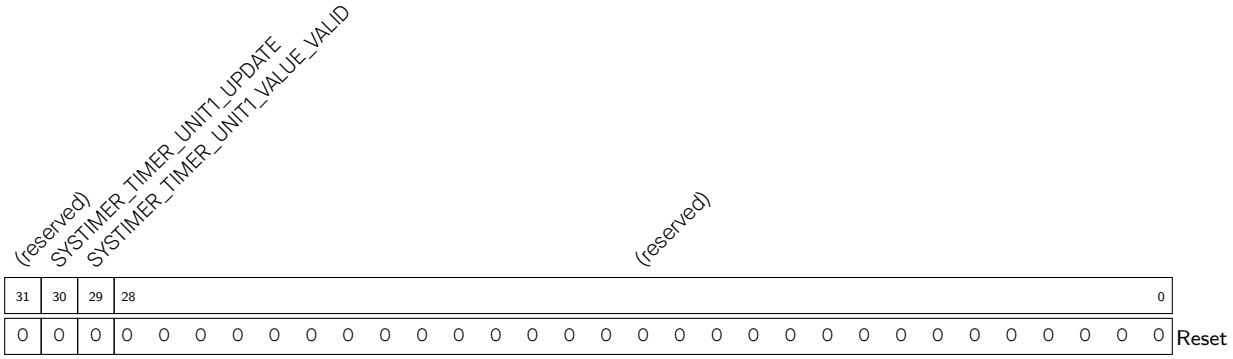


SYSTIMER_TIMER_UNIT0_VALUE_HI Represents UNIT0 read value, high 20 bits. (RO)

Register 16.6. SYSTIMER_UNIT0_VALUE_LO_REG (0x0044)

SYSTIMER_TIMER_UNIT0_VALUE_LO Represents UNIT0 read value, low 32 bits. (RO)

Register 16.7. SYSTIMER_UNIT0_LOAD_REG (0x005C)



SYSTIMER_TIMER_UNIT0_LOAD Configures whether to reload the value of UNIT0, i.e., reloads the values of SYSTIMER_TIMER_UNIT0_VALUE_HI and SYSTIMER_TIMER_UNIT0_VALUE_LO to UNIT0.

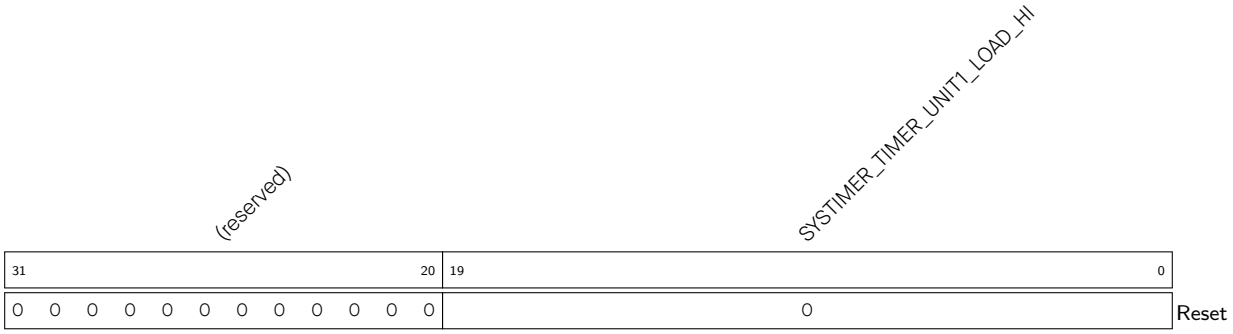
0: No effect

1: Reload the value of UNIT0

(WT)

Register 16.8. SYSTIMER_UNIT1_OP_REG (0x0008)

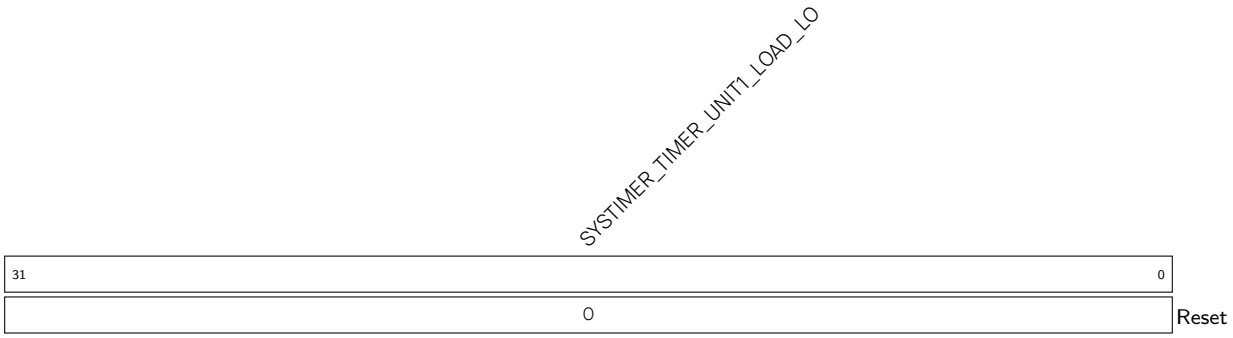
SYSTIMER_TIMER_UNIT1_VALUE_VALID Represents UNIT1 value is synchronized and valid. (R/SS/WTC)



SYSTIMER_TIMER_UNIT1_UPDATE Configures whether to update timer UNIT1, i.e., reads the UNIT1 count value to SYSTIMER_TIMER_UNIT1_VALUE_HI and SYSTIMER_TIMER_UNIT1_VALUE_LO.

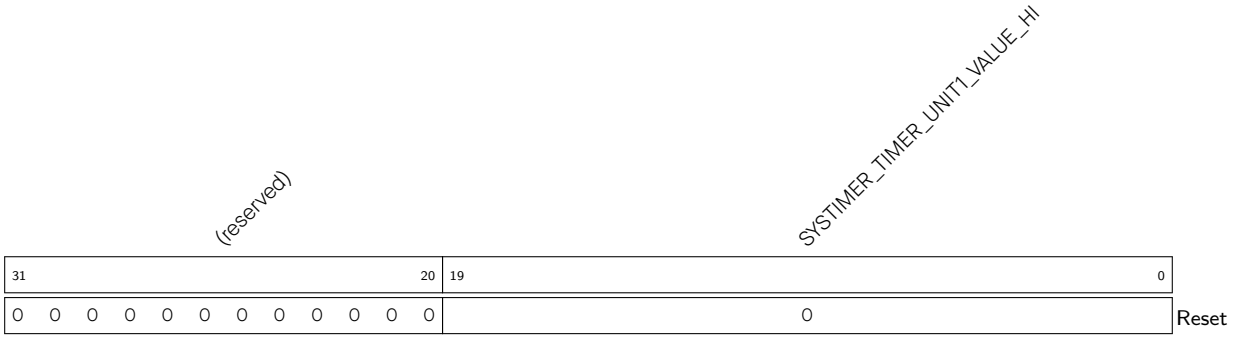
0: No effect

1: Update timer UNIT1



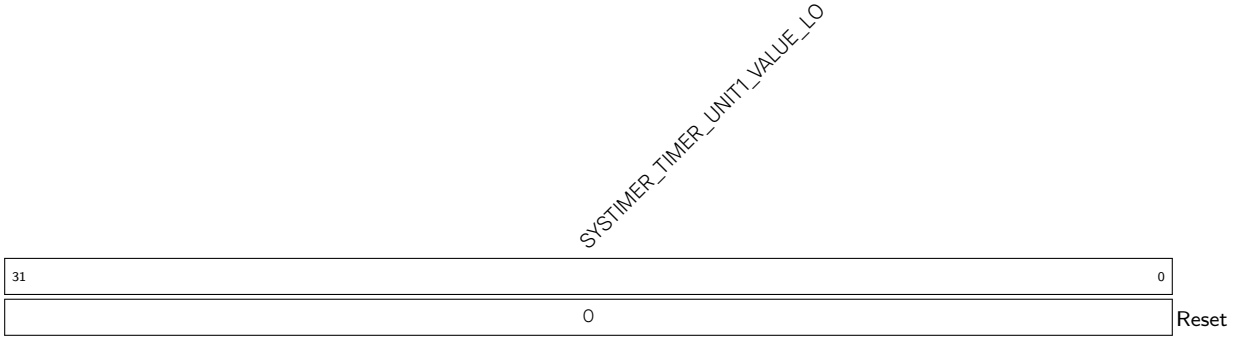
(WT)

Register 16.9. SYSTIMER_UNIT1_LOAD_HI_REG (0x0014)



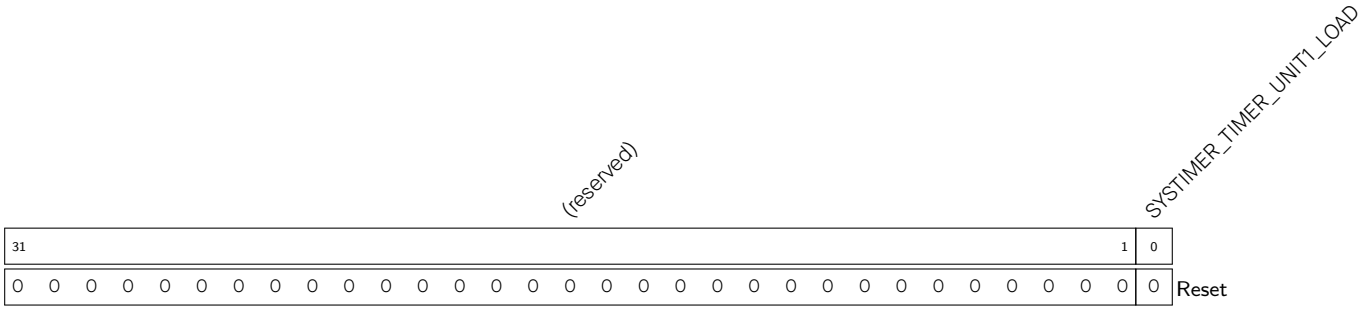
SYSTIMER_TIMER_UNIT1_LOAD_HI Configures the value to be loaded to UNIT1, high 20 bits. (R/W)

Register 16.10. SYSTIMER_UNIT1_LOAD_LO_REG (0x0018)



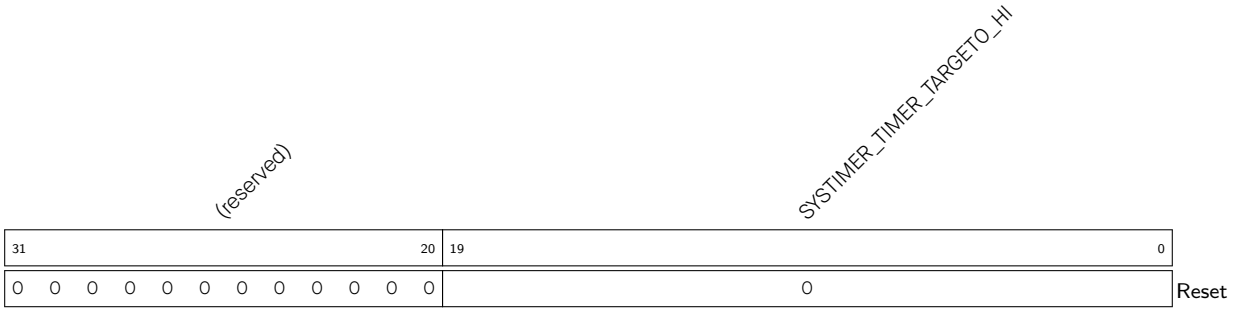
SYSTIMER_TIMER_UNIT1_LOAD_LO Configures the value to be loaded to UNIT1, low 32 bits. (R/W)

Register 16.11. SYSTIMER_UNIT1_VALUE_HI_REG (0x0048)



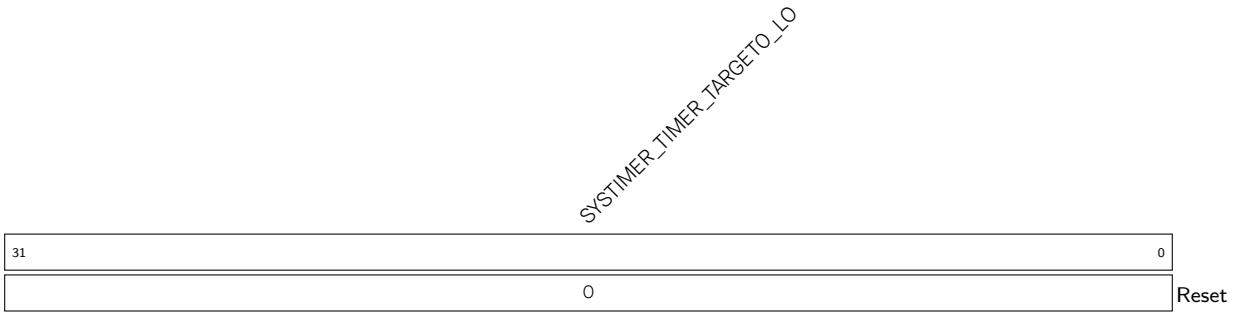
SYSTIMER_TIMER_UNIT1_VALUE_HI Represents UNIT1 read value, high 20 bits. (RO)

Register 16.12. SYSTIMER_UNIT1_VALUE_LO_REG (0x004C)



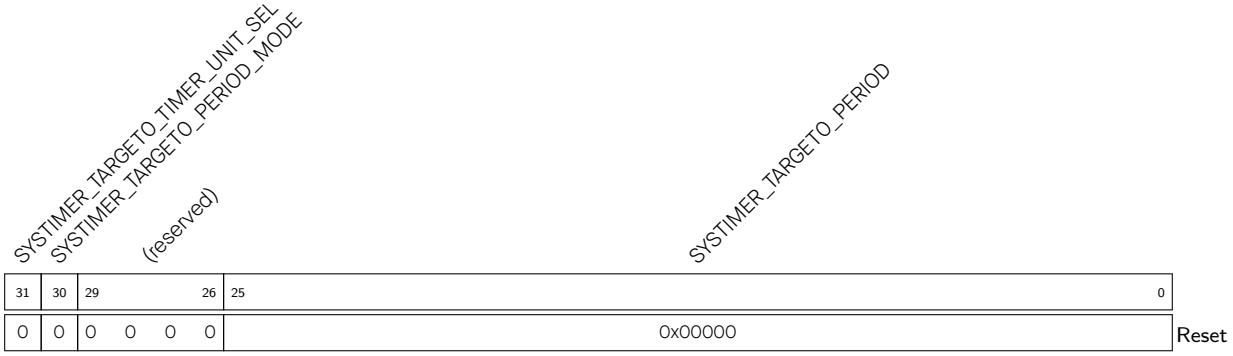
SYSTIMER_TIMER_UNIT1_VALUE_LO Represents UNIT1 read value, low 32 bits. (RO)

Register 16.13. SYSTIMER_UNIT1_LOAD_REG (0x0060)



SYSTIMER_TIMER_UNIT1_LOAD Configures whether to reload the value of UNIT1, i.e., reload the values of SYSTIMER_TIMER_UNIT1_VALUE_HI and SYSTIMER_TIMER_UNIT1_VALUE_LO to UNIT1.
0: No effect
1: Reload the value of UNIT1
(WT)

Register 16.14. SYSTIMER_TARGET0_HI_REG (0x001C)



SYSTIMER_TIMER_TARGET0_HI Configures the alarm value to be loaded to COMP0, high 20 bits. (R/W)

Register 16.15. SYSTIMER_TARGET0_LO_REG (0x0020)

SYSTIMER_TIMER_TARGET0_LO Configures the alarm value to be loaded to COMP0, low 32 bits. (R/W)

Register 16.16. SYSTIMER_TARGET0_CONF_REG (0x0034)

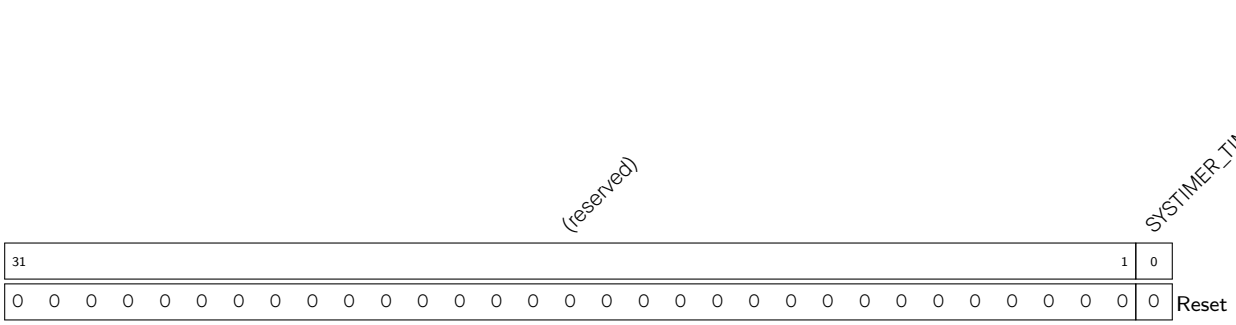
SYSTIMER_TARGET0_PERIOD Configures COMP0 alarm period. (R/W)

SYSTIMER_TARGET0_PERIOD_MODE Selects the two alarm modes for COMP0.

0: Target mode

1: Period mode

(R/W)



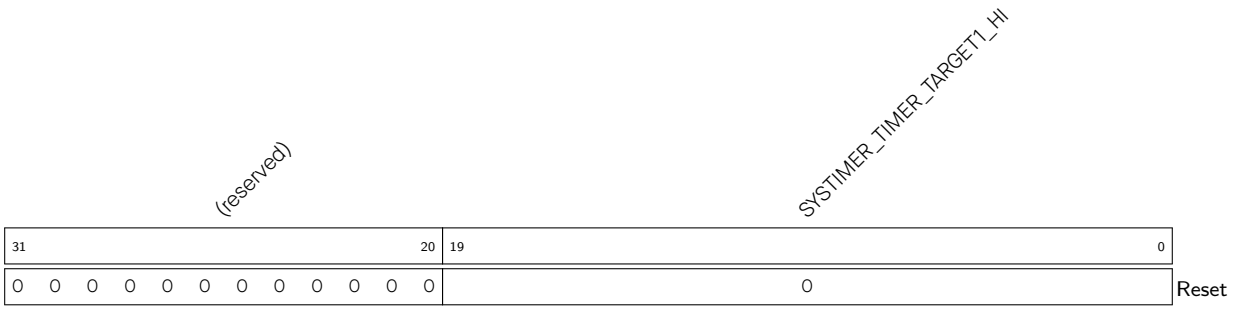
SYSTIMER_TARGET0_TIMER_UNIT_SEL Chooses the count value for comparison with COMP0.

0: Use the count value from UNIT*0*

1: Use the count value from UNIT*1*

(R/W)

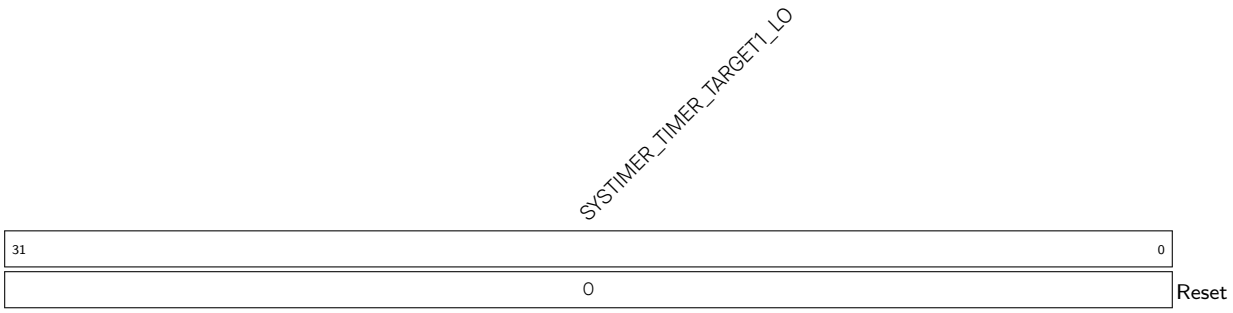
Register 16.17. SYSTIMER_COMP0_LOAD_REG (0x0050)



SYSTIMER_TIMER_COMP0_LOAD Configures whether to enable COMP0 synchronization, i.e., reload the alarm value/period to COMP0.

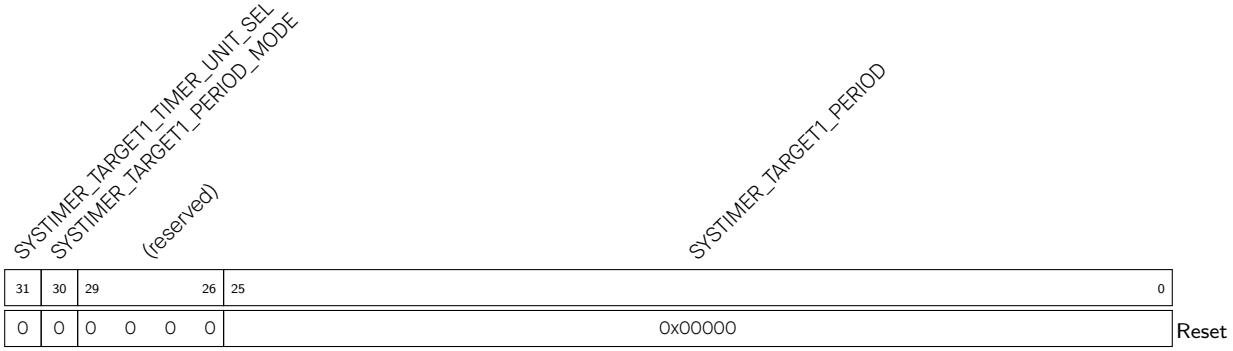
0: No effect

1: Enable COMP0 synchronization



(WT)

Register 16.18. SYSTIMER_TARGET1_HI_REG (0x0024)

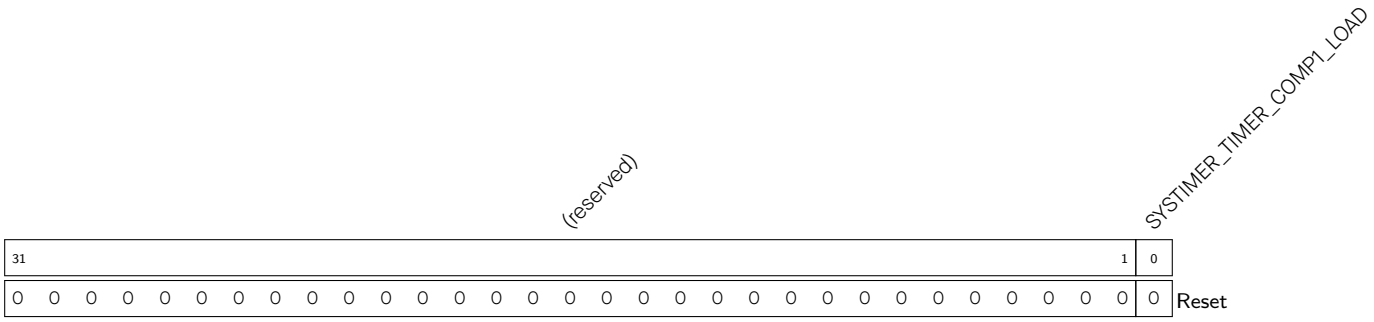


SYSTIMER_TIMER_TARGET1_HI Configures the alarm value to be loaded to COMP1, high 20 bits. (R/W)

Register 16.19. SYSTIMER_TARGET1_LO_REG (0x0028)

SYSTIMER_TIMER_TARGET1_LO Configures the alarm value to be loaded to COMP1, low 32 bits. (R/W)

Register 16.20. SYSTIMER_TARGET1_CONF_REG (0x0038)

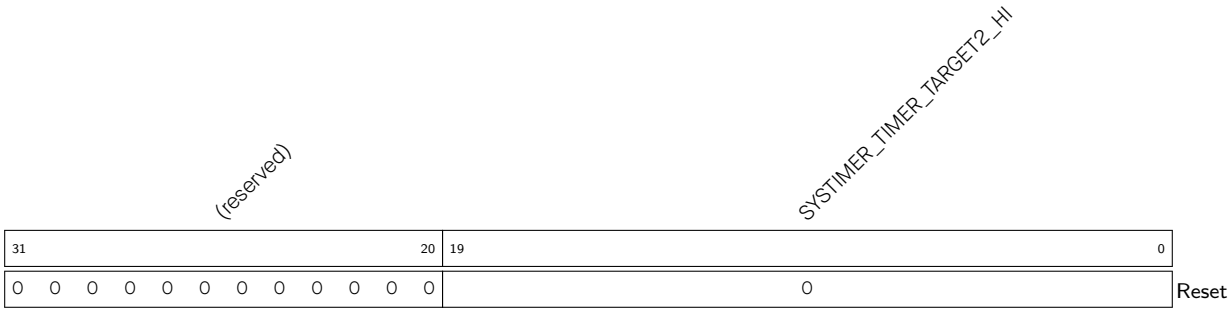


SYSTIMER_TARGET1_PERIOD Configures COMP1 alarm period. (R/W)

SYSTIMER_TARGET1_PERIOD_MODE Selects the two alarm modes for COMP1. See details in SYSTIMER_TARGET0_PERIOD_MODE. (R/W)

SYSTIMER_TARGET1_TIMER_UNIT_SEL Chooses the count value for comparison with COMP1. See details in SYSTIMER_TARGET0_TIMER_UNIT_SEL. (R/W)

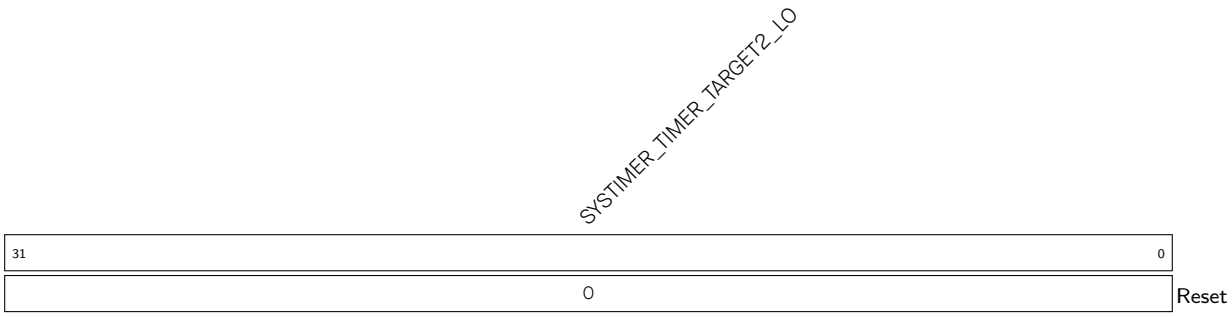
Register 16.21. SYSTIMER_COMP1_LOAD_REG (0x0054)



SYSTIMER_TIMER_COMP1_LOAD Configures whether to enable COMP1 synchronization, i.e., reload the alarm value/period to COMP1.

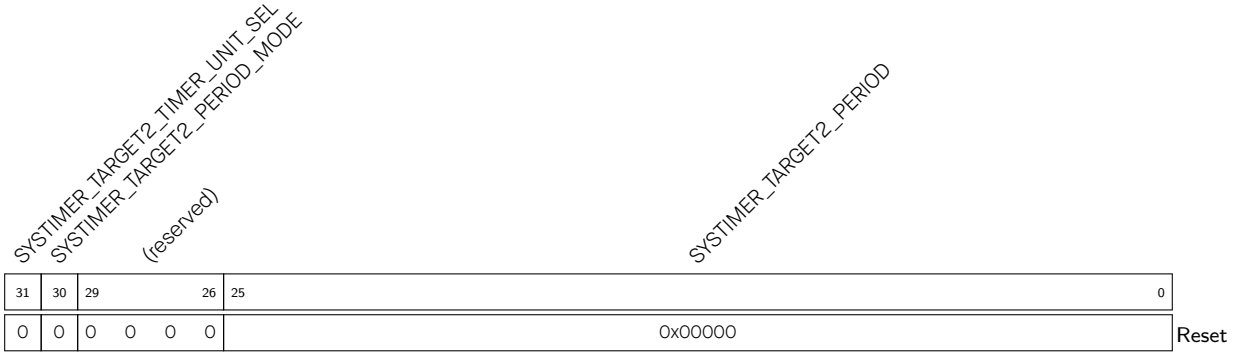
0: No effect

1: Enable COMP1 synchronization



(WT)

Register 16.22. SYSTIMER_TARGET2_HI_REG (0x002C)

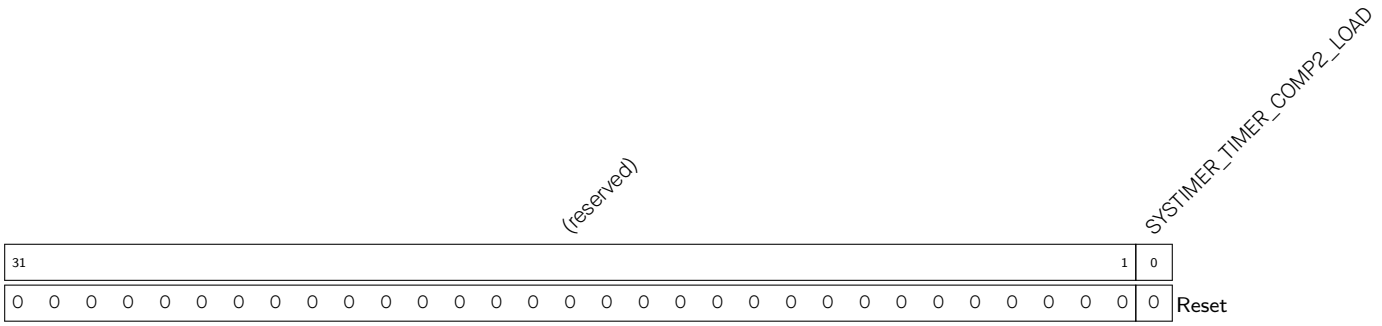


SYSTIMER_TIMER_TARGET2_HI Configures the alarm value to be loaded to COMP2, high 20 bits. (R/W)

Register 16.23. SYSTIMER_TARGET2_LO_REG (0x0030)

SYSTIMER_TIMER_TARGET2_LO Configures the alarm value to be loaded to COMP2, low 32 bits. (R/W)

Register 16.24. SYSTIMER_TARGET2_CONF_REG (0x003C)

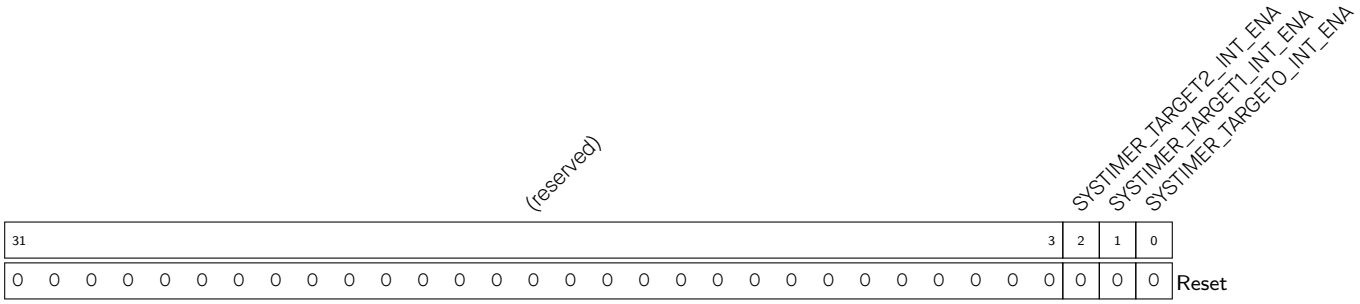


SYSTIMER_TARGET2_PERIOD Configures COMP2 alarm period. (R/W)

SYSTIMER_TARGET2_PERIOD_MODE Configures Configures the two alarm modes for COMP2. See details in SYSTIMER_TARGET0_PERIOD_MODE. (R/W)

SYSTIMER_TARGET2_TIMER_UNIT_SEL Chooses the count value for comparison with COMP2. See details in SYSTIMER_TARGET0_TIMER_UNIT_SEL. (R/W)

Register 16.25. SYSTIMER_COMP2_LOAD_REG (0x0058)



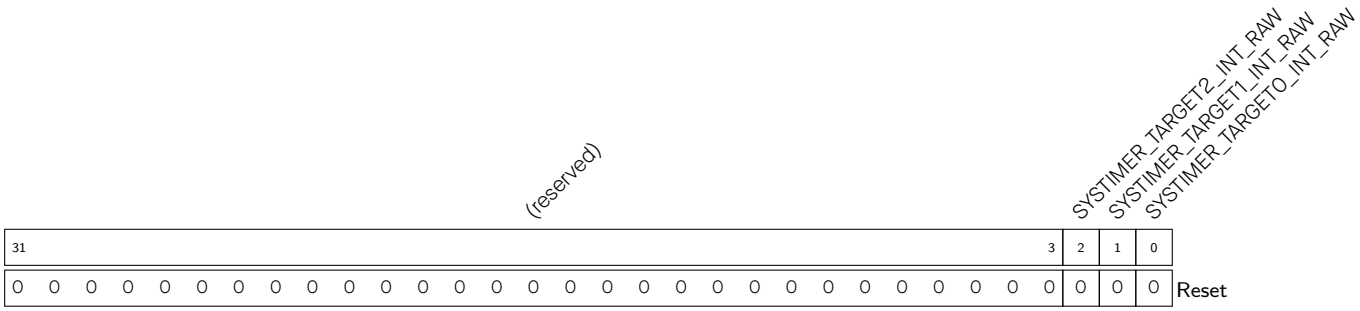
SYSTIMER_TIMER_COMP2_LOAD Configures whether to enable COMP2 synchronization, i.e., reload the alarm value/period to COMP2.

0: No effect

1: Enable COMP2 synchronization

(WT)

Register 16.26. SYSTIMER_INT_ENA_REG (0x0064)

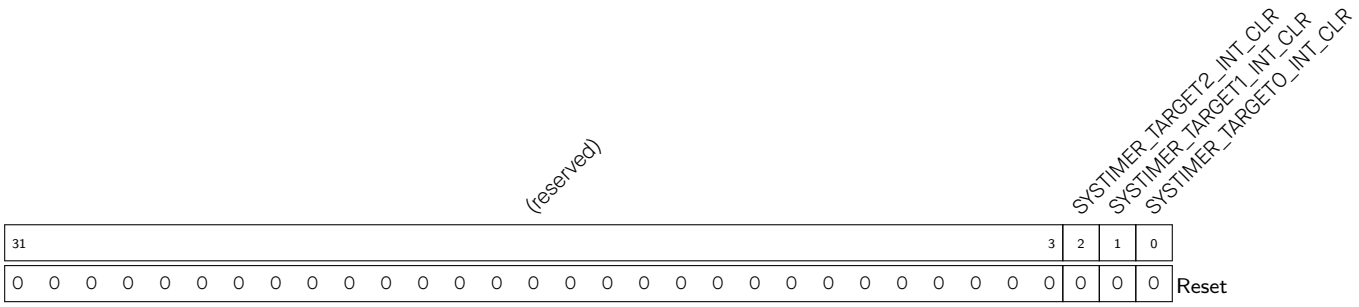


SYSTIMER_TARGET0_INT_ENA Write 1 to enable SYSTIMER_TARGET0_INT. (R/W)

SYSTIMER_TARGET1_INT_ENA Write 1 to enable SYSTIMER_TARGET1_INT. (R/W)

SYSTIMER_TARGET2_INT_ENA Write 1 to enable SYSTIMER_TARGET2_INT. (R/W)

Register 16.27. SYSTIMER_INT_RAW_REG (0x0068)

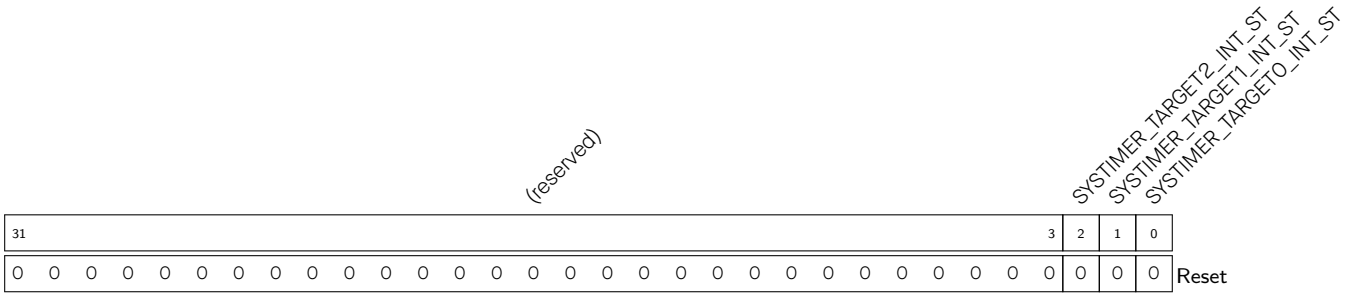


SYSTIMER_TARGET0_INT_RAW The raw interrupt status of SYSTIMER_TARGET0_INT. (R/WTC/SS)

SYSTIMER_TARGET1_INT_RAW The raw interrupt status of SYSTIMER_TARGET1_INT. (R/WTC/SS)

SYSTIMER_TARGET2_INT_RAW The raw interrupt status of SYSTIMER_TARGET2_INT. (R/WTC/SS)

Register 16.28. SYSTIMER_INT_CLR_REG (0x006C)

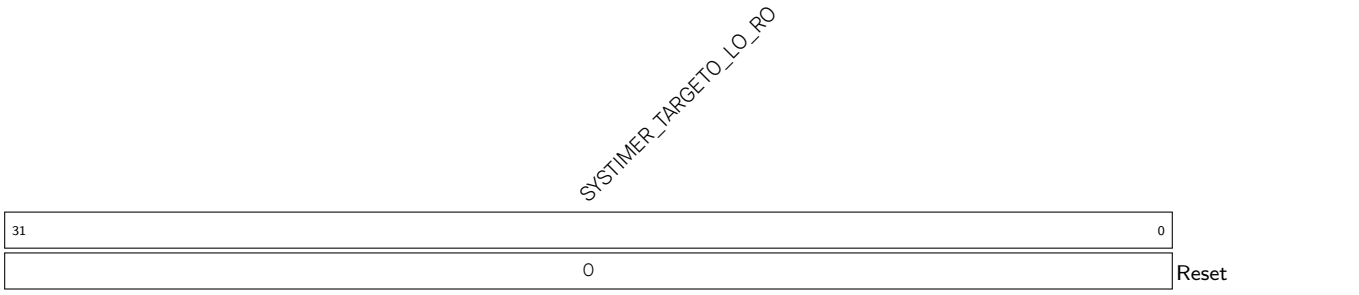


SYSTIMER_TARGET0_INT_CLR Write 1 to clear SYSTIMER_TARGET0_INT. (WT)

SYSTIMER_TARGET1_INT_CLR Write 1 to clear SYSTIMER_TARGET1_INT. (WT)

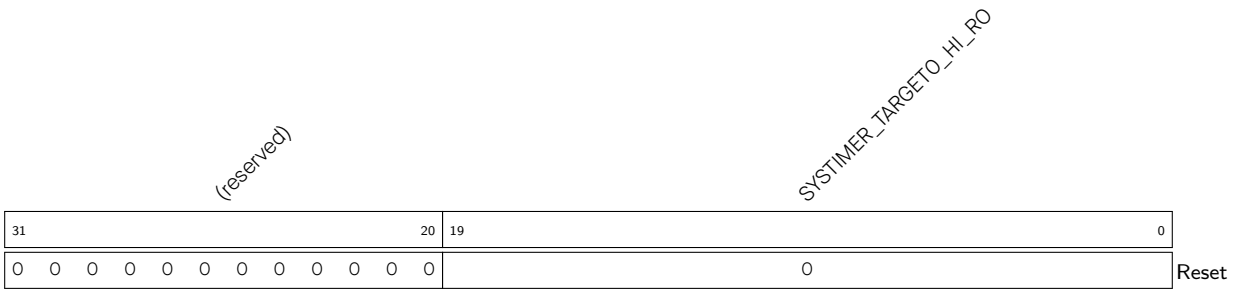
SYSTIMER_TARGET2_INT_CLR Write 1 to clear SYSTIMER_TARGET2_INT. (WT)

Register 16.29. SYSTIMER_INT_ST_REG (0x0070)



SYSTIMER_TARGET0_INT_ST The masked interrupt status of SYSTIMER_TARGET0_INT. (RO)

SYSTIMER_TARGET1_INT_ST The masked interrupt status of SYSTIMER_TARGET1_INT. (RO)

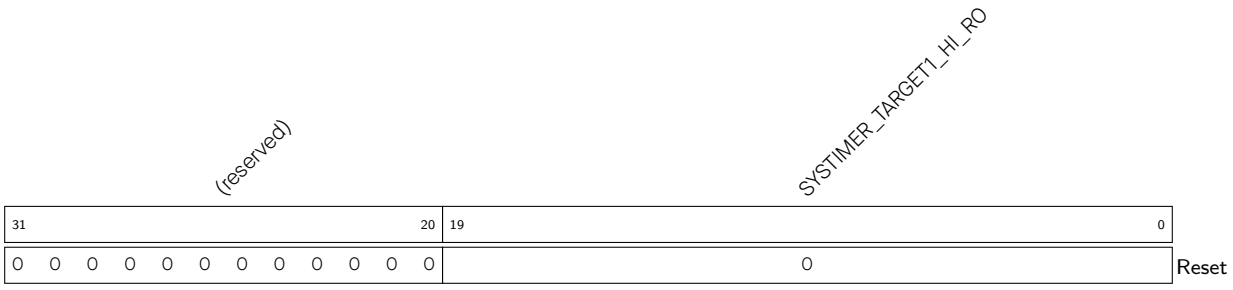


SYSTIMER_TARGET2_INT_ST The masked interrupt status of SYSTIMER_TARGET2_INT. (RO)

Register 16.30. SYSTIMER_REAL_TARGET0_LO_REG (0x0074)

SYSTIMER_TARGET0_LO_RO Represents the actual target value of COMP0, low 32 bits. (RO)

Register 16.31. SYSTIMER_REAL_TARGET0_HI_REG (0x0078)



SYSTIMER_TARGET0_HI_RO Represents the actual target value of COMP0, high 20 bits. (RO)

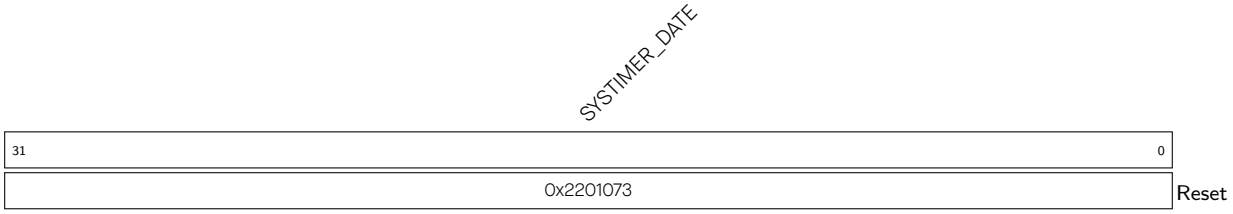
Register 16.32. SYSTIMER_REAL_TARGET1_LO_REG (0x007C)

SYSTIMER_TARGET1_LO_RO Represents the actual target value of COMP1, low 32 bits. (RO)

Register 16.33. SYSTIMER_REAL_TARGET1_HI_REG (0x0080)

SYSTIMER_TARGET1_HI_RO Represents the actual target value of COMP1, high 20 bits. (RO)

Register 16.34. SYSTIMER_REAL_TARGET2_LO_REG (0x0084)



SYSTIMER_TARGET2_LO_RO Represents the actual target value of COMP2, low 32 bits. (RO)

Register 16.35. SYSTIMER_REAL_TARGET2_HI_REG (0x0088)

SYSTIMER_TARGET2_HI_RO Represents the actual target value of COMP2, high 20 bits. (RO)

Register 16.36. SYSTIMER_DATE_REG (0x00FC)

SYSTIMER_DATE Version control register. (R/W)

Chapter 17

Timer Group (TIMG)

17.1 Overview

General-purpose timers can be used to precisely time an interval, trigger an interrupt after a particular interval (periodically and aperiodically), or act as a hardware clock. As shown in Figure 17.1-1, the ESP32-P4 chip contains two timer groups, namely timer group 0 and timer group 1 (hereinafter referred to as TIMG*n*, where *n* can be 0 or 1). Each timer group consists of two general-purpose timers (hereinafter referred to as T*x*, where *x* can be 0 or 1) and one Main System Watchdog Timer (MWDT). The general-purpose timer is based on a 16-bit prescaler and a 54-bit auto-reload-capable up-down counter.

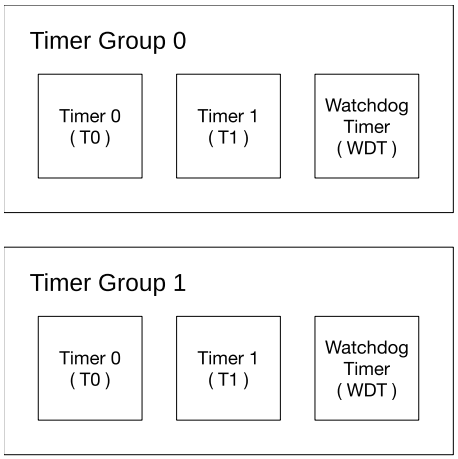


Figure 17.1-1. Timer Group Overview

Note that while the Main System Watchdog Timer registers are described in this chapter, their functional description is included in Chapter 18 *Watchdog Timers (WDT)*. Therefore, the term "timer" within this chapter refers to the general-purpose timer.

17.2 Features

The timer's features are summarized as follows:

- A 54-bit time-base counter programmable to incrementing or decrementing
- Three clock sources: PLL_F80M_CLK or XTAL_CLK or RC_FAST_CLK
- A 16-bit clock prescaler, from 2 to 65536
- Able to read real-time value of the time-base counter
- Able to halt and resume the time-base counter

- Programmable alarm generation
- Timer value reload — Auto-reload at alarm or software-controlled instant reload
- Calculate clock frequency — Calculate the measured frequency of the clock, which can be called TIMG0_CALI_CLK, based on the crystal clock
- Level interrupt generation
- Support several ETM tasks and events

17.3 Functional Description

Figure 17.3-1 shows Timer T*x* in timer group TIMG*n*. T*x* contains a 16-bit integer divider as a prescaler, a timer-based counter, and a comparator for alarm generation.

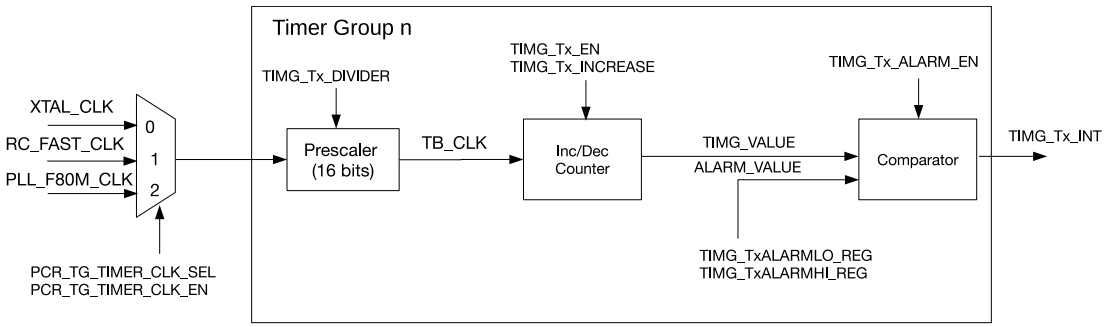

Figure 17.3-1. Timer Group Architecture

17.3.1 16-bit Prescaler and Clock Selection

Take the Timer T*x* in timer group TIMG*n* as an example:

- The timer can select its clock source by setting the HP_SYS_CLKRST_TIMERGRP*n*_T*x*_SRC_SEL field of the HP_SYS_CLKRST_PERI_CLK_CTRL20_REG register or the HP_SYS_CLKRST_PERI_CLK_CTRL21_REG register. When the field is 0, XTAL_CLK is selected; when the field is 1, RC_FAST_CLK is selected and when the field is 2, PLL_F80M_CLK is selected.
- The selected clock can be switched on by setting HP_SYS_CLKRST_TIMERGRP*n*_T*x*_CLK_EN field of the HP_SYS_CLKRST_PERI_CLK_CTRL20_REG register or the HP_SYS_CLKRST_PERI_CLK_CTRL21_REG register to 1 and switched off by setting it to 0. The clock is then divided by a 16-bit prescaler to generate the time-base counter clock (TB_CLK) used by the time-base counter. The divisor of the prescaler can be configured through the TIMG_T*x*_DIVIDER field.

TIMG_T*x*_DIVIDER field can be configured as 0 ~ 65535 for a divisor range of 2 ~ 65536. To be more specific, when TIMG_T*x*_DIVIDER is configured as:

- 0: the divisor is 65536
- 1: the divisor is 2
- 2: the divisor is also 2
- 3 ~ 65535: the divisor is 3 ~ 65535

To modify the 16-bit prescaler, please first configure the TIMG_T*x*_DIVIDER field, and then set TIMG_T*x*_DIVCNT_RST to 1. Meanwhile, the timer must be disabled (i.e., TIMG_T*x*_EN should be cleared). Otherwise, the result can be unpredictable.

17.3.2 54-bit Time-base Counter

The 54-bit time-base counter is based on TB_CLK and can be configured to increment or decrement via the TIMG_T*x*_INCREASE field. The time-base counter can be enabled or disabled by setting or clearing the TIMG_T*x*_EN field, respectively. When enabled, the time-base counter increments or decrements on each cycle of TB_CLK. When disabled, the time-base counter is essentially frozen. Note that the TIMG_T*x*_INCREASE field can be changed no matter whether TIMG_T*x*_EN is set or not, and this will cause the time-base counter to change direction instantly.

To read the 54-bit value of the time-base counter, the timer value must be latched to two registers before being read by the CPU (due to the CPU being 32-bit). By writing any value to the TIMG_T*x*UPDATE_REG, the current value of the 54-bit timer starts to be latched into the TIMG_T*x*LO_REG and TIMG_T*x*HI_REG registers containing the lower 32-bits and higher 22-bits, respectively. When TIMG_T*x*UPDATE_REG is cleared by hardware, it indicates the latch operation has been completed and current timer value can be read from the TIMG_T*x*LO_REG and TIMG_T*x*HI_REG registers. TIMG_T*x*LO_REG and TIMG_T*x*HI_REG registers will remain unchanged for the CPU to read in its own time until TIMG_T*x*UPDATE_REG is written to again.

17.3.3 Alarm Generation

A timer can be configured to trigger an alarm when the timer's current value matches the alarm value. An alarm will cause an interrupt to occur and (optionally) an automatic reload of the timer's current value (see Section 17.3.4).

The 54-bit alarm value is configured using TIMG_T*x*ALARMLO_REG and TIMG_T*x*ALARMHI_REG, which represent the lower 32-bits and higher 22-bits of the alarm value, respectively. However, the configured alarm value is ineffective until the alarm is enabled by setting the TIMG_T*x*_ALARM_EN field. To avoid alarm being enabled "too late" (i.e., the timer value has already passed the alarm value when the alarm is enabled), the hardware will trigger the alarm immediately if the current timer value is:

- higher than the alarm value (within a defined range) when the up-down counter increments
- lower than the alarm value (within a defined range) when the up-down counter decrements

Table 17.3-1 and Table 17.3-2 show the relationship between the current value of the timer, the alarm value, and when an alarm is triggered. The current time value and the alarm value are defined as follows:

- TIMG_VALUE = {TIMG_T*x*HI_REG, TIMG_T*x*LO_REG}
- ALARM_VALUE = {TIMG_T*x*ALARMHI_REG, TIMG_T*x*ALARMLO_REG}

Table 17.3-1. Alarm Generation When Up-Down Counter Increments

Scenario	Range	Alarm
1	ALARM_VALUE − TIMG_VALUE $> 2^{53}$	Triggered
2	0 < ALARM_VALUE − TIMG_VALUE $\leq 2^{53}$	Triggered when the up-down counter counts TIMG_VALUE up to ALARM_VALUE
3	0 $\leq$ TIMG_VALUE − ALARM_VALUE $< 2^{53}$	Triggered
4	TIMG_VALUE − ALARM_VALUE $\geq 2^{53}$	Triggered when the up-down counter restarts counting up from 0 after reaching the timer's maximum value and counts TIMG_VALUE up to ALARM_VALUE

Table 17.3-2. Alarm Generation When Up-Down Counter Decrements

Scenario	Range	Alarm
5	TIMG_VALUE − ALARM_VALUE $> 2^{53}$	Triggered
6	0 < TIMG_VALUE − ALARM_VALUE $\leq 2^{53}$	Triggered when the up-down counter counts TIMG_VALUE down to ALARM_VALUE
7	0 $\leq$ ALARM_VALUE − TIMG_VALUE $< 2^{53}$	Triggered
8	ALARM_VALUE − TIMG_VALUE $\geq 2^{53}$	Triggered when the up-down counter restarts counting down from the timer's maximum value after reaching the minimum value and counts TIMG_VALUE down to ALARM_VALUE

When an alarm occurs, the TIMG_T*x*_ALARM_EN field is automatically cleared and no alarm will occur again until the TIMG_T*x*_ALARM_EN is set next time.

17.3.4 Timer Reload

A timer is reloaded when a timer's current value is overwritten with a reload value stored in the TIMG_T*x*_LOAD_LO and TIMG_T*x*_LOAD_HI fields that correspond to the lower 32-bits and higher 22-bits of the timer's new value, respectively. However, writing a reload value to TIMG_T*x*_LOAD_LO and TIMG_T*x*_LOAD_HI will not cause the timer's current value to change. Instead, the reload value is ignored by the timer until a reload event occurs. A reload event can be triggered either by a software instant reload or an auto-reload at alarm.

A software instant reload is triggered by the CPU writing any value to TIMG_T*x*LOAD_REG, which causes the timer's current value to be instantly reloaded. If TIMG_T*x*_EN is set, the timer will continue incrementing or decrementing from the new value. In this case if TIMG_T*x*_ALARM_EN is set, the timer will still trigger alarms in scenarios listed in Table 17.3-1 and 17.3-2. If TIMG_T*x*_EN is cleared, the timer will remain frozen at the new value until counting is re-enabled.

An auto-reload at alarm will cause a timer reload when an alarm occurs, thus allowing the timer to continue incrementing or decrementing from the reload value. This is generally useful for resetting the timer's value when using periodic alarms. To enable auto-reload at alarm, the TIMG_T*x*_AUTORELOAD field should be set. If not enabled, the timer's value will continue to increment or decrement past the alarm value after an alarm.

17.3.5 Event Task Matrix Feature

The TIMG*n* on ESP32-P4 supports the Event Task Matrix (ETM) function, which allows TIMG*n*'s ETM tasks to be triggered by any peripherals' ETM events, or TIMG*n*'s ETM events to trigger any peripherals' ETM tasks. This section introduces the ETM tasks and events related to TIMG*n*. For more information, please refer to Chapter 14 Event Task Matrix (ETM).

TIMG*n* can receive the following ETM tasks:

- TG0_TASK_CNT_START_TIMER0: When triggered, it will enable the time-base counter.
- TG1_TASK_CNT_START_TIMER0: When triggered, it will enable the time-base counter.
- TG0_TASK_CNT_STOP_TIMER0: When triggered, it will disable the time-base counter.
- TG1_TASK_CNT_STOP_TIMER0: When triggered, it will disable the time-base counter.

> **Note:**
> The above two ETM tasks have the same function as the APB configuration TIMG_T0_EN. When these operations occur at the same time, the priority of each operation from high to low is as follows:
>
> 1. TG0_TASK_CNT_START_TIMER0 and TG1_TASK_CNT_START_TIMER0: When triggered, it will enable the time-base counter;
> 2. TG0_TASK_CNT_STOP_TIMER0 and TG1_TASK_CNT_STOP_TIMER0: When triggered, it will disable the time-base counter;
> 3. APB configuration TIMG_T0_EN: Enable or disable the time-base counter.

- TG0_TASK_ALARM_START_TIMER0: When triggered, it will enable the alarm generation.
- TG1_TASK_ALARM_START_TIMER0: When triggered, it will enable the alarm generation.

> **Note:**
> Alarm generation can also be enabled through APB method configuring TIMG_T0_ALARM_EN and hardware events. When these operations occur at the same time, the priority of each operation from high to low is as follows:
>
> 1. TG0_TASK_ALARM_START_TIMER0 and TG1_TASK_ALARM_START_TIMER0: When triggered, it will enable the alarm generation;
> 2. Alarm events: When triggered, it will disable the alarm generation;
> 3. APB configuration TIMG_T0_ALARM_EN: Enable or disable the alarm generation.

- TG0_TASK_CNT_CAP_TIMER0: When triggered, it will update the current counter value to the TIMG_T0LO_REG and TIMG_T0HI_REG registers.
- TG1_TASK_CNT_CAP_TIMER0: When triggered, it will update the current counter value to the TIMG_T0LO_REG and TIMG_T0HI_REG registers.
- TG0_TASK_CNT_RELOAD_TIMER0: When triggered, it will overwrite the current counter value with the reload value stored in TIMG_T0_LOAD_LO and TIMG_T0_LOAD_HI.
- TG1_TASK_CNT_RELOAD_TIMER0: When triggered, it will overwrite the current counter value with the

reload value stored in TIMG_T0_LOAD_LO and TIMG_T0_LOAD_HI.

TIMG*n* can generate the following ETM events:

- TG0_EVT_CNT_CMP_TIMER0: Indicates the interrupt event of T0 in TIMG0.
- TG1_EVT_CNT_CMP_TIMER0: Indicates the interrupt event of T0 in TIMG1.

> **Note:**
> All the ETM tasks and events of TIMG*n* will not take effect until the TIMG*n*_ETM_EN is set to 1.

In practical applications, timer groups' ETM events can trigger their own ETM tasks.

For example, TG0_TASK_ALARM_START_TIMER0 and TG1_TASK_ALARM_START_TIMER0 can be triggered respectively by TG0_EVT_CNT_CMP_TIMER0 and TG1_EVT_CNT_CMP_TIMER0 to realize periodic alarm. For configuration steps, please refer to 17.4.4 Timer as Periodic Alarm by ETM.

17.3.6 RTC_SLOW_CLK Frequency Calculation

Using XTAL_CLK as a reference, it is possible to calculate the frequency of clock sources for RTC_SLOW_CLK (i.e., RC_SLOW_CLK, RC_FAST_DIV_CLK, and XTAL32K_CLK) as follows:

1. Start periodic or one-shot frequency calculation (see Section 17.4.5 for details);
2. Once receiving the signal to start calculation, the counter of XTAL_CLK and the counter of RTC_SLOW_CLK begin to work at the same time. When the counter of RTC_SLOW_CLK counts to C0, the two counters stop counting simultaneously;
3. Assume the value of XTAL_CLK's counter is C1, and the frequency of RTC_SLOW_CLK would be calculated as: $f_rtc = \frac{C0 \times f_XTAL_CLK}{C1}$

17.3.7 Interrupts

ESP32-P4's TIMG*n* can generate the following interrupt signal(s) that will be sent to the Interrupt Matrix.

- TG*n*_T*x*_INT
- TG*n*_WDT_INT

There are several internal interrupt sources from TIMG*n* that can generate the above interrupt signal(s). The interrupt sources from TIMG*n* are listed with their trigger conditions and the resulted interrupt signal(s) in Table 17.3-3.

Table 17.3-3. TIMG*n*'s Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
TIMG_T*x*_INT	Alarm generated by T*x*	TG*n*_T*x*_INT
TIMG_WDT_INT	Alarm generated by WDT	TG*n*_WDT_INT

> **Note:**
> For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 17.5 *Register Summary*.

17.4 Configuration and Usage

17.4.1 Timer as a Simple Clock

1. Configure the time-base counter
   - Select clock source by configuring the HP_SYS_CLKRST_TIMERGRP0_TGRT_CLK_SRC_SEL field of the HP_SYS_CLKRST_PERI_CLK_CTRL21_REG register.
   - Configure the 16-bit prescaler by setting TIMG_T*x*_DIVIDER.
   - Configure the timer direction by setting or clearing TIMG_T*x*_INCREASE.
   - Set the timer's starting value by writing the starting value to TIMG_T*x*_LOAD_LO and TIMG_T*x*_LOAD_HI, then reloading it into the timer by writing any value to TIMG_T*x*LOAD_REG.
2. Start the timer by setting TIMG_T*x*_EN.
3. Get the timer's current value.
   - Write any value to TIMG_T*x*UPDATE_REG to latch the timer's current value.
   - Wait until TIMG_T*x*UPDATE_REG is cleared by hardware.
   - Read the latched timer value from TIMG_T*x*LO_REG and TIMG_T*x*HI_REG.

17.4.2 Timer as One-shot Alarm

1. Configure the time-base counter following step 1 of Section 17.4.1.
2. Configure the alarm.
   - Configure the alarm value by setting TIMG_T*x*ALARMLO_REG and TIMG_T*x*ALARMHI_REG.
   - Enable interrupt by setting TIMG_T*x*_INT_ENA.
3. Disable auto reload by clearing TIMG_T*x*_AUTORELOAD.
4. Start the alarm by setting TIMG_T*x*_ALARM_EN.
5. Handle the alarm interrupt.
   - Clear the interrupt by setting the timer's corresponding bit in TIMG_T*x*_INT_CLR.
   - Disable the timer by clearing TIMG_T*x*_EN.

17.4.3 Timer as Periodic Alarm by APB

1. Configure the time-base counter following step 1 in Section 17.4.1.
2. Configure the alarm following step 2 in Section 17.4.2.
3. Enable auto reload by setting TIMG_T*x*_AUTORELOAD and configure the reload value via TIMG_T*x*_LOAD_LO and TIMG_T*x*_LOAD_HI.

4. Start the alarm by setting TIMG_Tx_ALARM_EN.
5. Handle the alarm interrupt (repeat on each alarm iteration).
   - Clear the interrupt by setting the timer's corresponding bit in TIMG_Tx_INT_CLR.
   - If the next alarm requires a new alarm value and reload value (i.e., different alarm interval per iteration), then TIMG_TxALARMLO_REG, TIMG_TxALARMHI_REG, TIMG_Tx_LOAD_LO, and TIMG_Tx_LOAD_HI should be reconfigured as needed. Otherwise, the aforementioned registers should remain unchanged.
   - Re-enable the alarm by setting TIMG_Tx_ALARM_EN.
6. Stop the timer (on final alarm iteration).
   - Clear the interrupt by setting the timer's corresponding bit in TIMG_Tx_INT_CLR.
   - Disable the timer by clearing TIMG_Tx_EN.

17.4.4 Timer as Periodic Alarm by ETM

1. Enable the ETM module's clock
2. Map ETM event to ETM task (which means using the event to trigger the task)
   - If TIMG_T0_AUTORELOAD is set to 1, map TG0_EVT_CNT_CMP_TIMER0 and TG1_EVT_CNT_CMP_TIMER0 to the TG0_TASK_ALARM_START_TIMER0 and TG1_TASK_ALARM_START_TIMER0 respectively by one ETM channel.
   - If TIMG_T0_AUTORELOAD is set to 0, in addition to mapping TG0_EVT_CNT_CMP_TIMER0 and TG1_EVT_CNT_CMP_TIMER0 to the TG0_TASK_ALARM_START_TIMER0 and TG1_TASK_ALARM_START_TIMER0, the TG0_EVT_CNT_CMP_TIMER0 and TG1_EVT_CNT_CMP_TIMER0 should also be mapped to TG0_TASK_CNT_RELOAD_TIMER0 and TG1_TASK_CNT_RELOAD_TIMER0 by another ETM channel.
3. Choose to enable the one or two ETM channels.
4. Set TIMER_ETM_EN to 1 to enable timer group's ETM events and tasks.
5. Configure the time-base counter following step 1 in Section 17.4.1.
6. Configure the alarm following step 2 in Section 17.4.2.
7. Configure the reload value via TIMG_T0_LOAD_LO and TIMG_T0_LOAD_HI.
8. Handle the TG0_EVT_CNT_CMP_TIMER0 and TG1_EVT_CNT_CMP_TIMER0.
   - When alarm generates, the TG0_EVT_CNT_CMP_TIMER0 and TG1_EVT_CNT_CMP_TIMER0 also generate, and the alarm generation will be disabled by the alarm.
   - If TIMG_T0_AUTORELOAD is 1, the current counter value is overwritten by the reloaded value. The alarm generation will be reopened by TG0_TASK_ALARM_START_TIMER0 and TG1_TASK_ALARM_START_TIMER0.
   - If TIMG_T0_AUTORELOAD is 0, the current counter value is overwritten by the reloaded value because of the TG0_TASK_CNT_RELOAD_TIMER0 and TG1_TASK_CNT_RELOAD_TIMER0. The alarm generation will be reopened by TG0_TASK_ALARM_START_TIMER0 and TG1_TASK_ALARM_START_TIMER0.

9. Stop the timer (on final alarm iteration).
    - Disable the ETM channels used to map timer group's event and task
    - Set TIMER_ETM_EN to 0.
    - Clear the interrupt by setting the timer's corresponding bit in TIMG_TO_INT_CLR.
    - Disable the timer by clearing TIMG_TO_EN.

17.4.5 RTC_SLOW_CLK Frequency Calculation

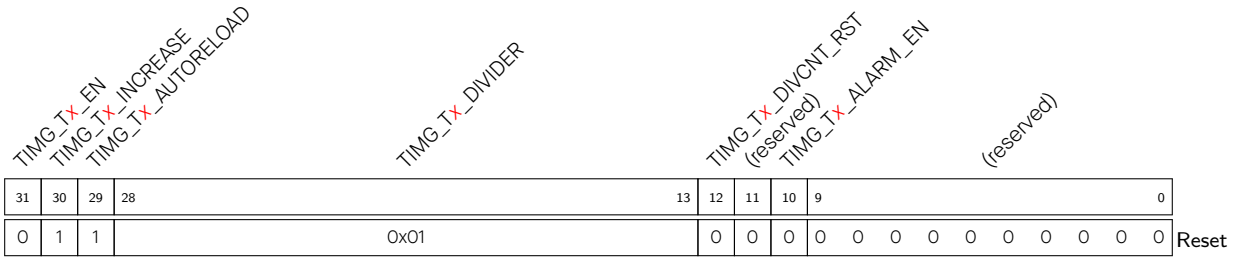
1. One-shot frequency calculation
    - Configure HP_SYS_CLKRST_TIMERGRP0_TGRT_CLK_EN to enable clock gate of TIMG0_CALI_CLK.
    - Configure HP_SYS_CLKRST_TIMERGRP0_TGRT_CLK_SRC_SEL to select one clock as the clock source of TIMG0_CALI_CLK.
    - Configure HP_SYS_CLKRST_TIMERGRP0_TGRT_CLK_DIV_NUM to output TIMG0_CALI_CLK after integer prescaler.
    - Configure the time of calculation via TIMG_RTC_CALI_MAX.
    - Select one-shot frequency calculation by clearing TIMG_RTC_CALI_START_CYCLING, and enable the two counters via TIMG_RTC_CALI_START.
    - Once TIMG_RTC_CALI_RDY becomes 1, read TIMG_RTC_CALI_VALUE to get the value of XTAL_CLK's counter, and calculate the frequency of RTC_SLOW_CLK according to the formula in Section 17.3.6.
2. Periodic frequency calculation
    - Select the clock whose frequency is to be calculated (clock source of RTC_SLOW_CLK) via HP_SYS_CLKRST_TIMERGRP0_TGRT_CLK_SRC_SEL, and configure the time of calculation via TIMG_RTC_CALI_MAX.
    - Select periodic frequency calculation by enabling TIMG_RTC_CALI_START_CYCLING.
    - When TIMG_RTC_CALI_CYCLING_DATA_VLD is 1, TIMG_RTC_CALI_VALUE is valid.
3. Timeout
   If the counter of RTC_SLOW_CLK cannot finish counting in TIMG_RTC_CALI_TIMEOUT_RST_CNT cycles, TIMG_RTC_CALI_TIMEOUT will be set to indicate a timeout.

17.5 Register Summary

The addresses in this section are relative to Timer Group base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
T0 Control and configuration registers			
TIMG_TOCONFIG_REG	Timer 0 configuration register	0x0000	varies
TIMG_TOLO_REG	Timer 0 current value, low 32 bits	0x0004	RO
TIMG_TOHI_REG	Timer 0 current value, high 22 bits	0x0008	RO
TIMG_TOUPDATE_REG	Write to copy current timer value to TIMG_TOLO_REG or TIMG_TOHI_REG	0x000C	R/W/SC
TIMG_TOALARMLO_REG	Timer 0 alarm value, low 32 bits	0x0010	R/W
TIMG_TOALARMHI_REG	Timer 0 alarm value, high 22 bits	0x0014	R/W
TIMG_TOLOADLO_REG	Timer 0 reload value, low 32 bits	0x0018	R/W
TIMG_TOLOADHI_REG	Timer 0 reload value, high 22 bits	0x001C	R/W
TIMG_TOLOAD_REG	Write to reload timer from TIMG_TOLOADLO_REG or TIMG_TOLOADHI_REG	0x0020	WT
T1 Control and configuration registers			
TIMG_T1CONFIG_REG	Timer 1 configuration register	0x0024	varies
TIMG_T1LO_REG	Timer 1 current value, low 32 bits	0x0028	RO
TIMG_T1HI_REG	Timer 1 current value, high 22 bits	0x002C	RO
TIMG_T1UPDATE_REG	Write to copy current timer value to TIMG_T1LO_REG or TIMG_T1HI_REG	0x0030	R/W/SC
TIMG_T1ALARMLO_REG	Timer 1 alarm value, low 32 bits	0x0034	R/W
TIMG_T1ALARMHI_REG	Timer 1 alarm value, high 22 bits	0x0038	R/W
TIMG_T1LOADLO_REG	Timer 1 reload value, low 32 bits	0x003C	R/W
TIMG_T1LOADHI_REG	Timer 1 reload value, high 22 bits	0x0040	R/W
TIMG_T1LOAD_REG	Write to reload timer from TIMG_T1LOADLO_REG or TIMG_T1LOADHI_REG	0x0044	WT
WDT Control and configuration registers			
TIMG_WDTCONFIG0_REG	Watchdog timer configuration register	0x0048	varies
TIMG_WDTCONFIG1_REG	Watchdog timer prescaler register	0x004C	varies
TIMG_WDTCONFIG2_REG	Watchdog timer stage 0 timeout value	0x0050	R/W
TIMG_WDTCONFIG3_REG	Watchdog timer stage 1 timeout value	0x0054	R/W
TIMG_WDTCONFIG4_REG	Watchdog timer stage 2 timeout value	0x0058	R/W
TIMG_WDTCONFIG5_REG	Watchdog timer stage 3 timeout value	0x005C	R/W
TIMG_WDTFEED_REG	Write to feed the watchdog timer	0x0060	WT
TIMG_WDTWPROTECT_REG	Watchdog write protect register	0x0064	R/W
RTC CALI Control and configuration registers			
TIMG_RTCCALICFG_REG	RTC calibration configure register	0x0068	varies
TIMG_RTCCALICFG1_REG	RTC calibration configure register 1	0x006C	RO
TIMG_RTCCALICFG2_REG	RTC calibration configure register 2	0x0080	varies



Name	Description	Address	Access
Interrupt registers			
TIMG_INT_ENA_TIMERS_REG	Interrupt enable bits	0x0070	R/W
TIMG_INT_RAW_TIMERS_REG	Raw interrupt status	0x0074	R/SS/WTC
TIMG_INT_ST_TIMERS_REG	Masked interrupt status	0x0078	RO
TIMG_INT_CLR_TIMERS_REG	Interrupt clear bits	0x007C	WT
Version register			
TIMG_NTIMERS_DATE_REG	Timer version control register	0x00F8	R/W
Clock configuration registers			
TIMG_REGCLK_REG	Timer group clock gate register	0x00FC	R/W

17.6 Registers

The addresses in this section are relative to Timer Group base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 17.1. TIMG_TxCONFIG_REG (x: 0-1) (0x0000+0x24*x)

TIMG_Tx_ALARM_EN Configures whether to enable Timer Tx alarm function. This bit will be automatically cleared once an alarm occurs.

0: Disable

1: Enable

(R/W/SC)

TIMG_Tx_DIVCNT_RST Configures to reset Timer Tx's clock divider counter.

0: No effect

1: Reset

(WT)

TIMG_Tx_DIVIDER Represents Timer *x* clock (Tx_clk) prescaler value. (R/W)

TIMG_Tx_AUTORELOAD Configures to enable Timer Tx auto-reload function at the time of alarm.

0: No effect

1: Enable

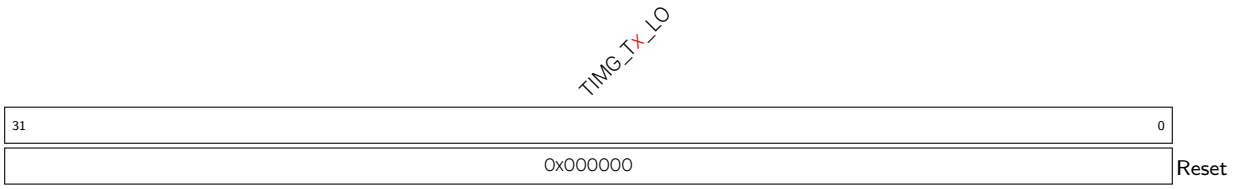
(R/W)

TIMG_Tx_INCREASE Configures the counting direction of Timer Tx time-base counter.

0: Decrement

1: Increment

(R/W)



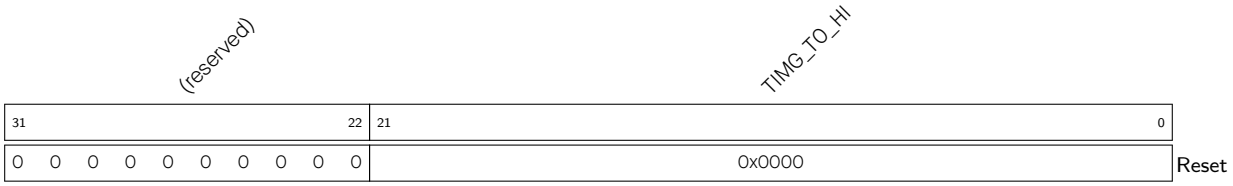
TIMG_Tx_EN Configures whether to enable Timer Tx time-base counter.

0: Disable

1: Enable

(R/W/SS/SC)

Register 17.2. TIMG_T*x*LO_REG (*x*: 0-1) (0x0004+0x24x*)**

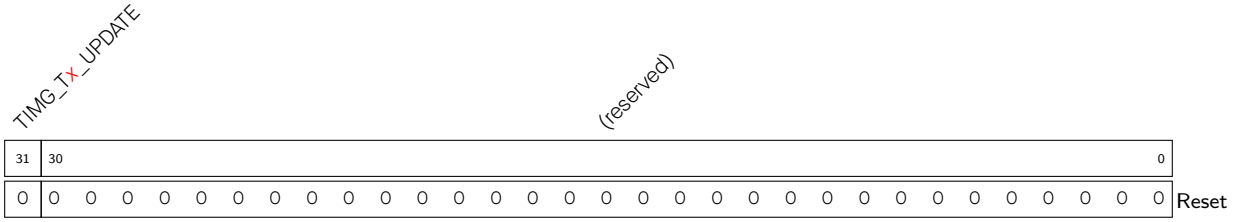


TIMG_T*x*_LO Represents the low 32 bits of the time-base counter of Timer T*x*. Valid only after writing to TIMG_T*x*UPDATE_REG.

Measurement unit: T*x*_clk.

(RO)

Register 17.3. TIMG_T*x*HI_REG (*x*: 0-1) (0x0008+0x24x*)**

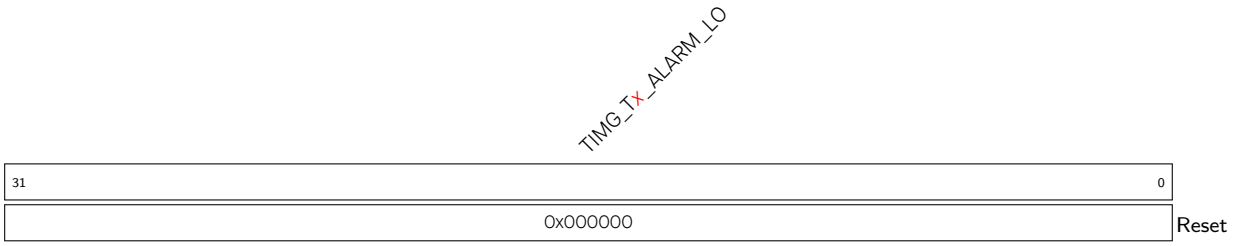


TIMG_T*x*_HI Represents the high 22 bits of the time-base counter of Timer T*x*. Valid only after writing to TIMG_T*x*UPDATE_REG.

Measurement unit: T*x*_clk.

(RO)

Register 17.4. TIMG_T*x*UPDATE_REG (*x*: 0-1) (0x000C+0x24x*)**



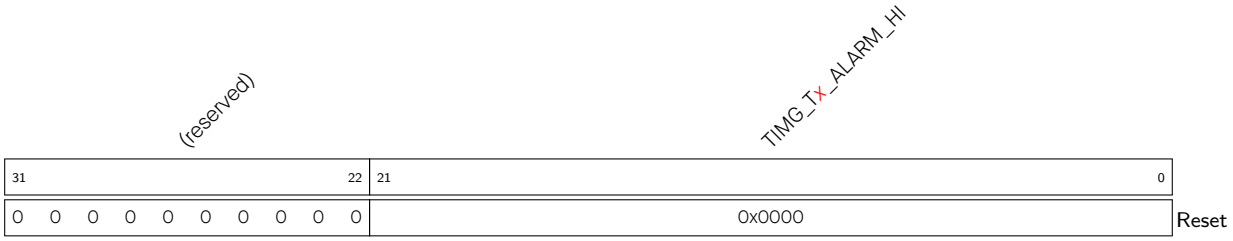
TIMG_T*x*_UPDATE Configures to latch the counter value.

0: Latch

1: Latch

(R/W/SC)

Register 17.5. TIMG_TxALARMLO_REG (x: 0-1) (0x0010+0x24*x)

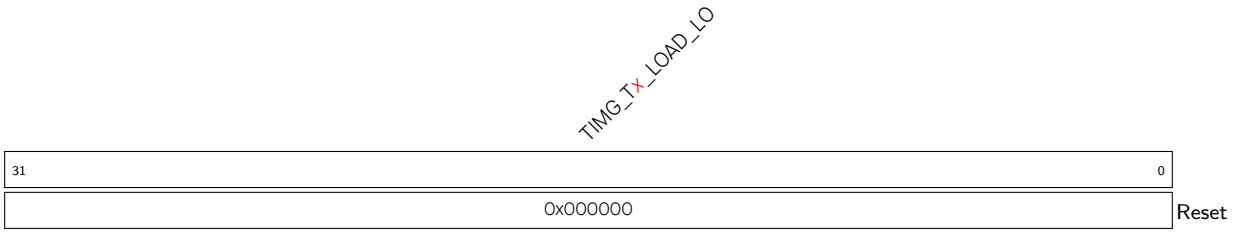


TIMG_Tx_ALARM_LO Configures the low 32 bits of Timer Tx alarm trigger time-base counter value. Valid only when TIMG_Tx_ALARM_EN is 1.

Measurement unit: Tx_clk.

(R/W)

Register 17.6. TIMG_TxALARMHI_REG (x: 0-1) (0x0014+0x24*x)

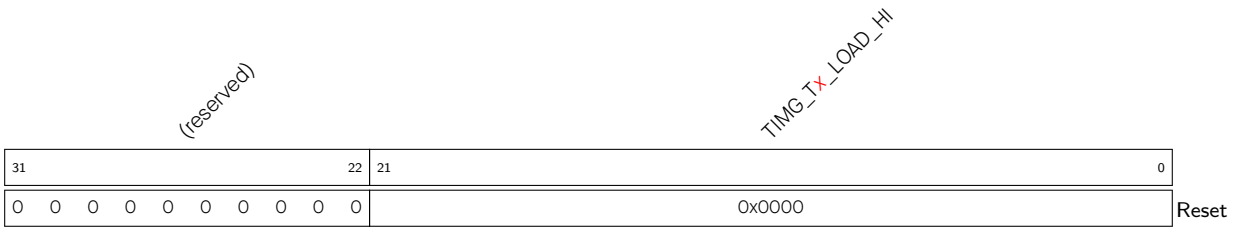


TIMG_Tx_ALARM_HI Configures the high 22 bits of Timer Tx alarm trigger time-base counter value. Valid only when TIMG_Tx_ALARM_EN is 1.

Measurement unit: Tx_clk.

(R/W)

Register 17.7. TIMG_TxLOADLO_REG (x: 0-1) (0x0018+0x24*x)

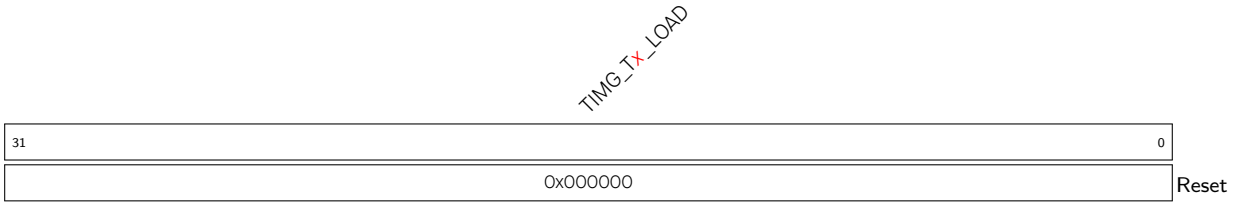


TIMG_Tx_LOAD_LO Configures low 32 bits of the value that a reload will load onto Timer Tx time-base counter.

Measurement unit: Tx_clk.

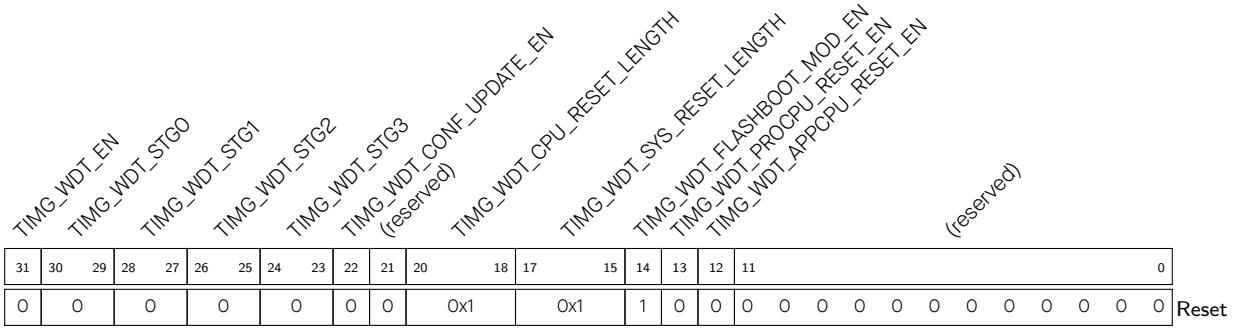
(R/W)

Register 17.8. TIMG_TxLOADHI_REG (x: 0-1) (0x001C+0x24*x)



TIMG_Tx_LOAD_HI Configures high 22 bits of the value that a reload will load onto Timer Tx time-base counter.

Measurement unit: Tx_clk.



(R/W)

Register 17.9. TIMG_TxLOAD_REG (x: 0-1) (0x0020+0x24*x)

TIMG_Tx_LOAD Write any value to trigger Timer Tx time-base counter reload. (WT)

Register 17.10. TIMG_WDTCONFIG0_REG (0x0048)

TIMG_WDT_APPCPU_RESET_EN Configures whether to mask the APP CPU reset generated by MWDT. Valid only when write protection is disabled.

0: Mask

1: Unmask

(R/W)

TIMG_WDT_PROCPU_RESET_EN Configures whether to mask the PRO CPU reset generated by MWDT. Valid only when write protection is disabled.

0: Mask

1: Unmask

(R/W)

TIMG_WDT_FLASHBOOT_MOD_EN Configures whether to enable flash boot protection.

0: Disable

1: Enable

(R/W)

TIMG_WDT_SYS_RESET_LENGTH Configures the system reset signal length. Valid only when write protection is disabled.

Measurement unit: mwdt_clk.

0: 100 ns

1: 200 ns

2: 300 ns

3: 400 ns

4: 500 ns

5: 800 ns

6: 1.6 μs

7: 3.2 μs

(R/W)

Continued on the next page...

Register 17.10. TIMG_WDTCONFIG0_REG (0x0048)

Continued from the previous page...

TIMG_WDT_CPU_RESET_LENGTH Configures the CPU reset signal length. Valid only when write protection is disabled.
Measurement unit: mwdt_clk.

0: 100 ns
1: 200 ns
2: 300 ns
3: 400 ns
4: 500 ns
5: 800 ns
6: 1.6 μs
7: 3.2 μs

(R/W)

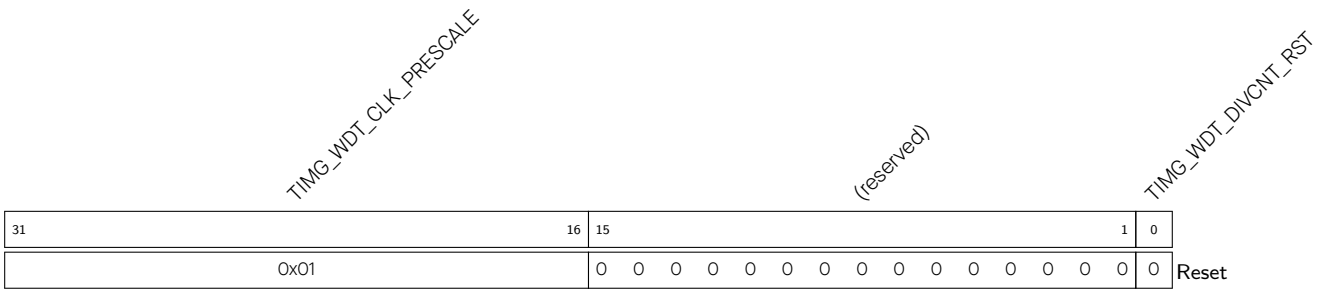
TIMG_WDT_CONF_UPDATE_EN Configures to update the WDT configuration registers.
0: No effect
1: Update
(WT)

TIMG_WDT_STG3 Configures the timeout action of stage 3. Valid only when write protection is disabled.
0: No effect
1: Interrupt
2: Reset CPU
3: Reset system
(R/W)

TIMG_WDT_STG2 Configures the timeout action of stage 2. Valid only when write protection is disabled.
0: No effect
1: Interrupt
2: Reset CPU
3: Reset system
(R/W)

TIMG_WDT_STG1 Configures the timeout action of stage 1. Valid only when write protection is disabled.
0: No effect
1: Interrupt
2: Reset CPU
3: Reset system
(R/W)

Continued on the next page...



Register 17.10. TIMG_WDTCONFIG0_REG (0x0048)

Continued from the previous page...

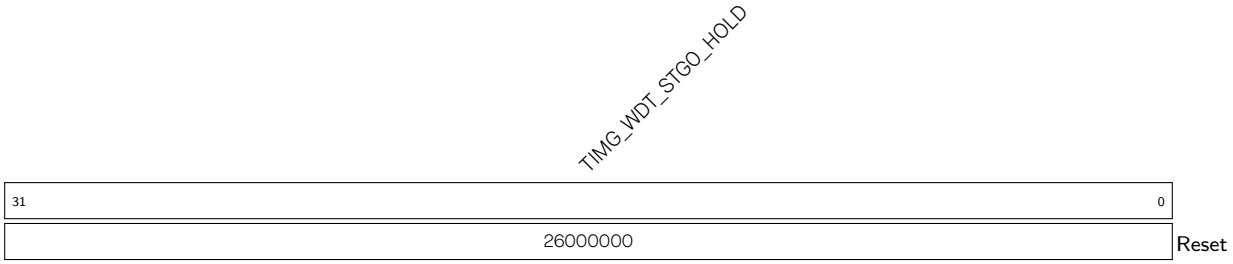
TIMG_WDT_STG0 Configures the timeout action of stage 0. Valid only when write protection is disabled.
0: No effect
1: Interrupt
2: Reset CPU
3: Reset system
(R/W)

TIMG_WDT_EN Configures whether or not to enable the MWDT. Valid only when write protection is disabled.
0: Disable
1: Enable
(R/W)

Register 17.11. TIMG_WDTCONFIG1_REG (0x004C)

TIMG_WDT_DIVCNT_RST Configures whether to reset WDT's clock divider counter.

0: No effect



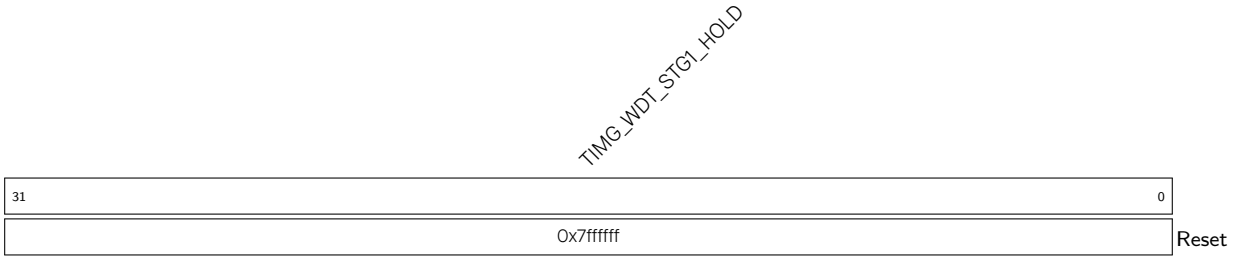
1: Reset

(WT)

TIMG_WDT_CLK_PRESCALE Configures MWDT clock prescaler value. Valid only when write protection is disabled.

MWDT clock period = 12.5 ns *TIMG_WDT_CLK_PRESCALE. (R/W)

Register 17.12. TIMG_WDTCONFIG2_REG (0x0050)

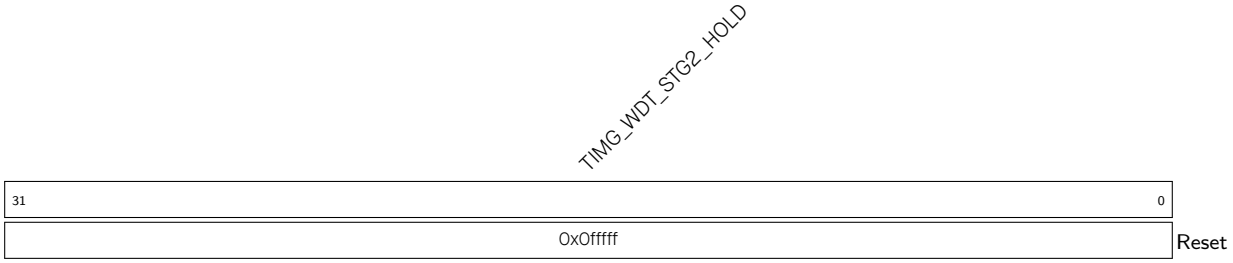


TIMG_WDT_STG0_HOLD Configures the stage 0 timeout value. Valid only when write protection is disabled.

Measurement unit: mwdt_clk.

(R/W)

Register 17.13. TIMG_WDTCONFIG3_REG (0x0054)

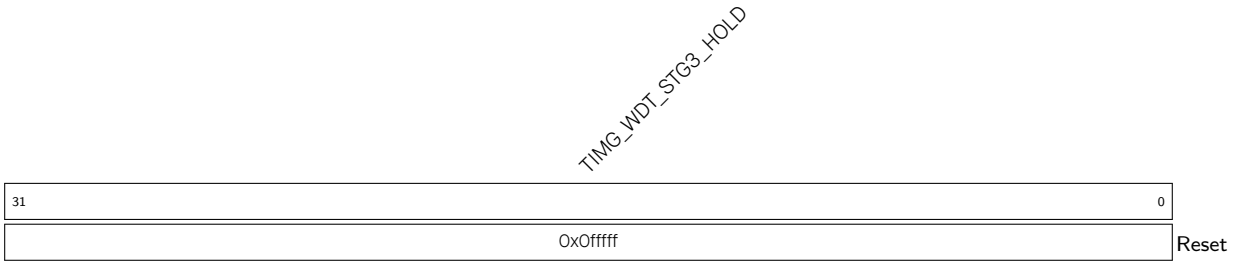


TIMG_WDT_STG1_HOLD Configures the stage 1 timeout value. Valid only when write protection is disabled.

Measurement unit: mwdt_clk.

(R/W)

Register 17.14. TIMG_WDTCONFIG4_REG (0x0058)

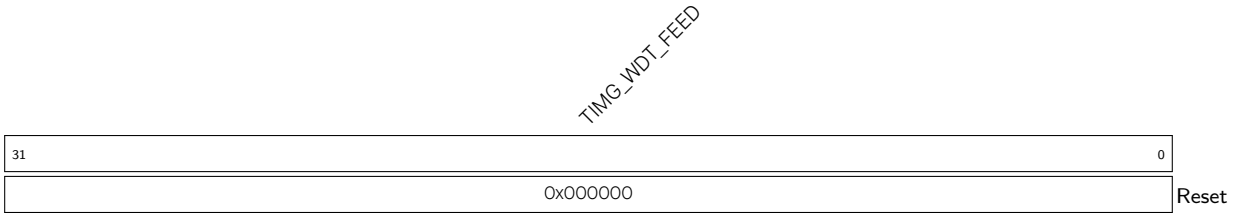


TIMG_WDT_STG2_HOLD Configures the stage 2 timeout value. Valid only when write protection is disabled.

Measurement unit: mwdt_clk.

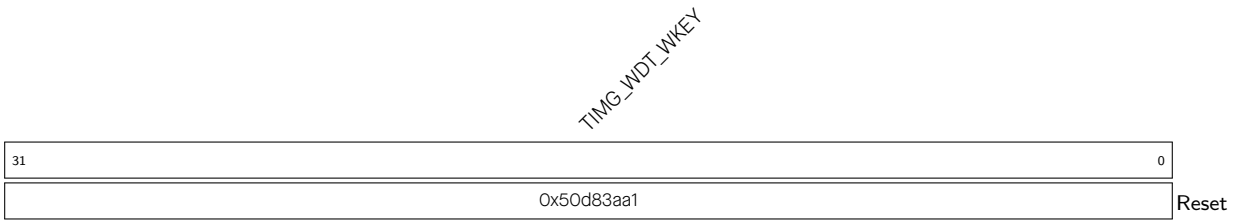
(R/W)

Register 17.15. TIMG_WDTCONFIG5_REG (0x005C)



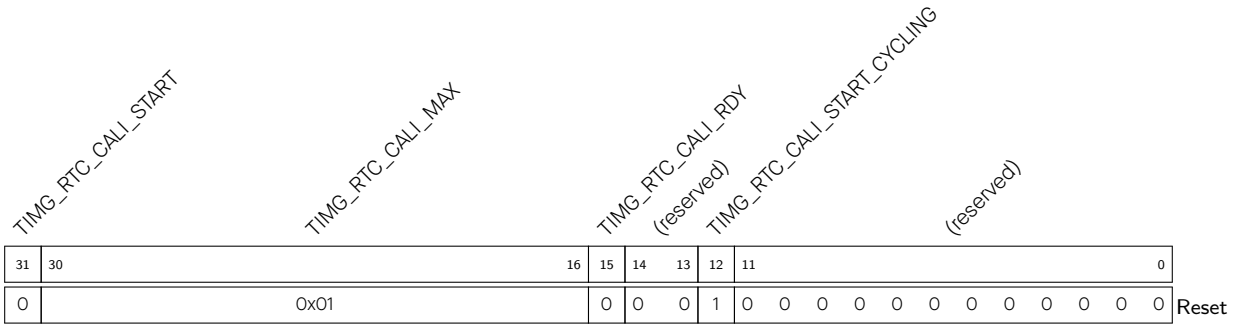
TIMG_WDT_STG3_HOLD Configures the stage 3 timeout value. Valid only when write protection is disabled.

Measurement unit: mwdt_clk.



(R/W)

Register 17.16. TIMG_WDTFEED_REG (0x0060)



TIMG_WDT_FEED Write any value to feed the MWDT. Valid only when write protection is disabled. (WT)

Register 17.17. TIMG_WDTWPROTECT_REG (0x0064)

TIMG_WDT_WKEY Configures a different value than its reset value to enable write protection. (R/W)

Register 17.18. TIMG_RTCCALICFG_REG (0x0068)

TIMG_RTC_CALI_START_CYCLING Configures the frequency calculation mode.

0: One-shot frequency calculation

1: Periodic frequency calculation.

(R/W)

TIMG_RTC_CALI_RDY Represents whether one-shot frequency calculation is done.

0: Not done

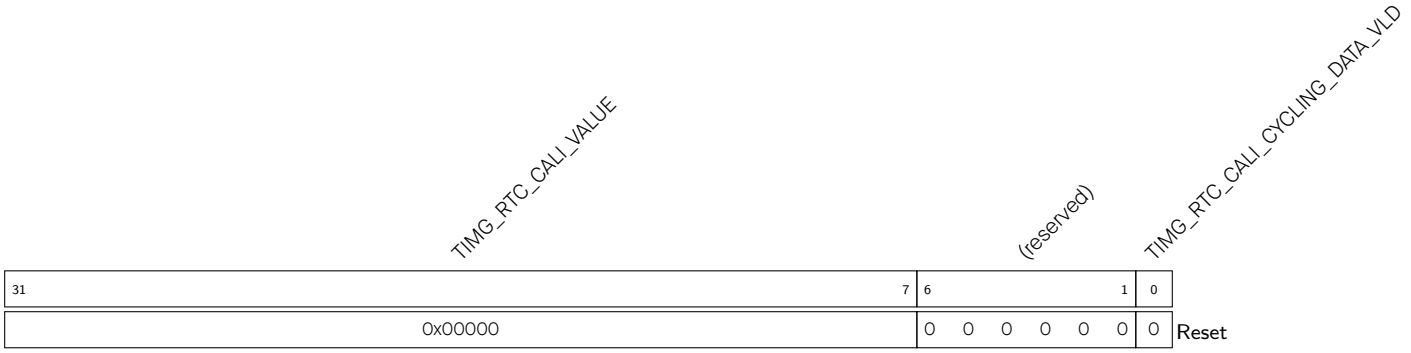
1: Done

(RO)

TIMG_RTC_CALI_MAX Configures the time to calculate RTC slow clock's frequency.

Measurement unit: XTAL_CLK.

(R/W)



TIMG_RTC_CALI_START Configures whether to enable one-shot frequency calculation.

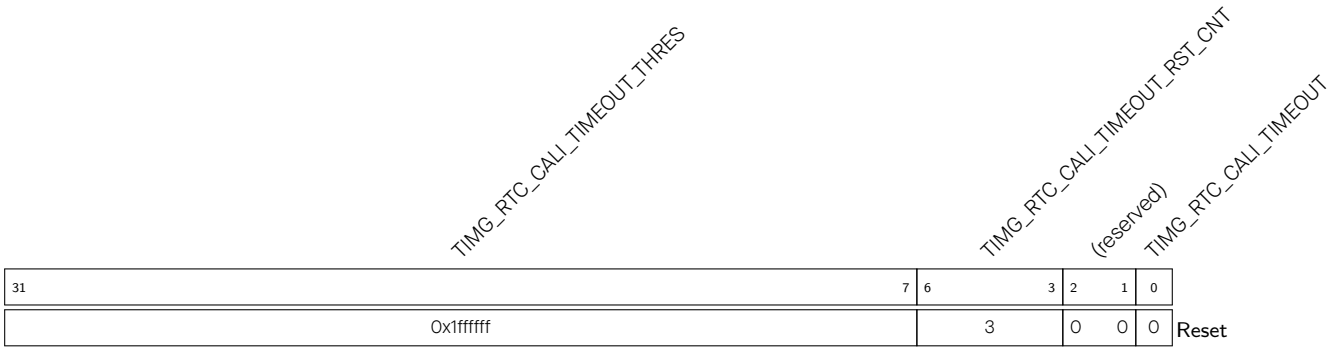
0: Disable

1: Enable

(R/W)

Register 17.19. TIMG_RTCCALICFG1_REG (0x006C)

TIMG_RTC_CALI_CYCLING_DATA_VLD Represents whether periodic frequency calculation is done.



0: Not done

1: Done

(RO)

TIMG_RTC_CALI_VALUE Represents the value countered by XTAL_CLK when one-shot or periodic frequency calculation is done. It is used to calculate RTC slow clock's frequency. (RO)

Register 17.20. TIMG_RTCCALICFG2_REG (0x0080)

TIMG_RTC_CALI_TIMEOUT Represents whether RTC frequency calculation is timeout.

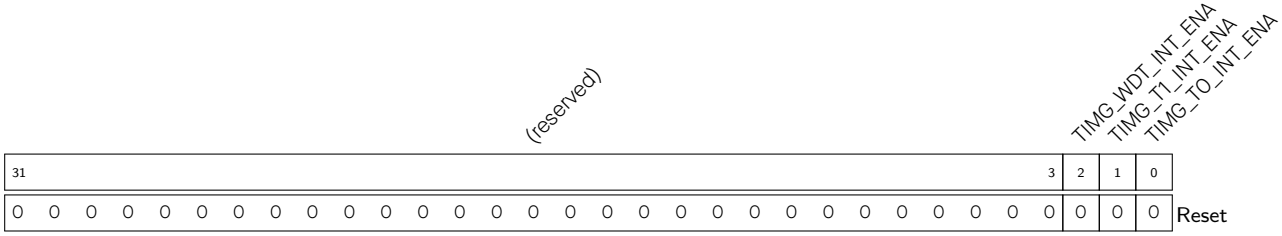
0: No timeout

1: Timeout

(RO)

TIMG_RTC_CALI_TIMEOUT_RST_CNT Configures the cycles that reset frequency calculation timeout.

Measurement unit: XTAL_CLK.

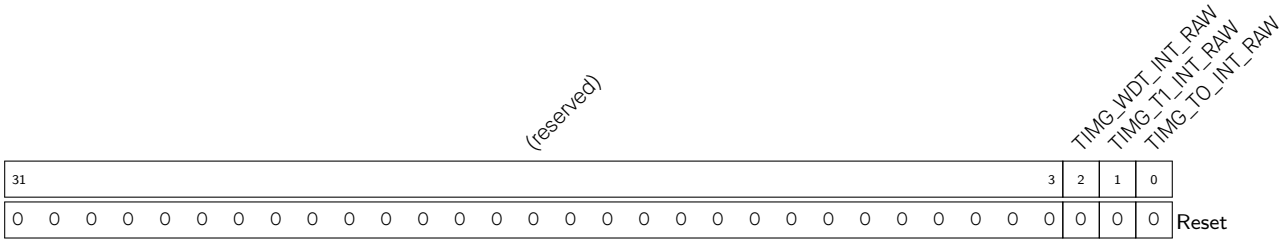


(R/W)

TIMG_RTC_CALI_TIMEOUT_THRES Configures the threshold value for the RTC frequency calculation timer. If the timer's value exceeds this threshold, a timeout is triggered.

Measurement unit: XTAL_CLK.

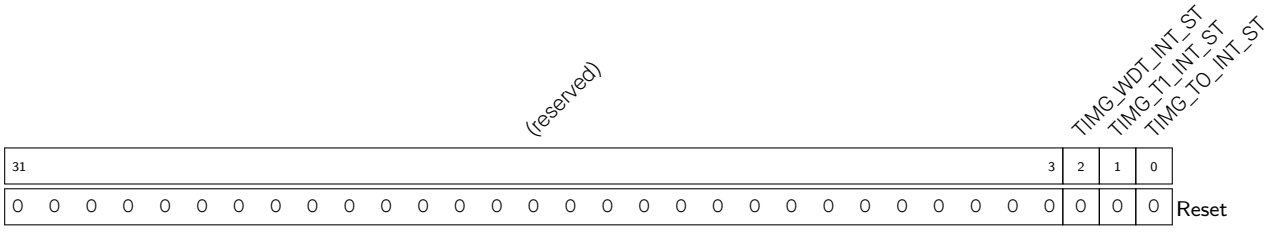
(R/W)



Register 17.21. TIMG_INT_ENA_TIMERS_REG (0x0070)

TIMG_T*x*_INT_ENA (*x*: 0-1) Write 1 to enable the TIMG_T*x*_INT interrupt. (R/W)

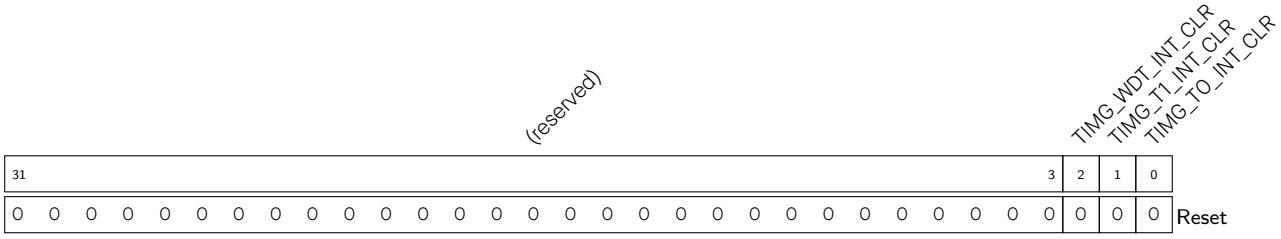
TIMG_WDT_INT_ENA Write 1 to enable the TIMG_WDT_INT interrupt. (R/W)



Register 17.22. TIMG_INT_RAW_TIMERS_REG (0x0074)

TIMG_T*x*_INT_RAW (*x*: 0-1) The raw interrupt status bit of the TIMG_T*x*_INT interrupt. (R/SS/WTC)

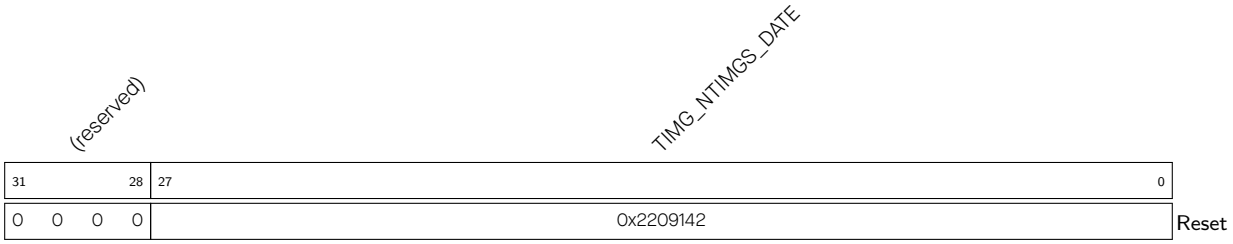
TIMG_WDT_INT_RAW The raw interrupt status bit of the TIMG_WDT_INT interrupt. (R/SS/WTC)



Register 17.23. TIMG_INT_ST_TIMERS_REG (0x0078)

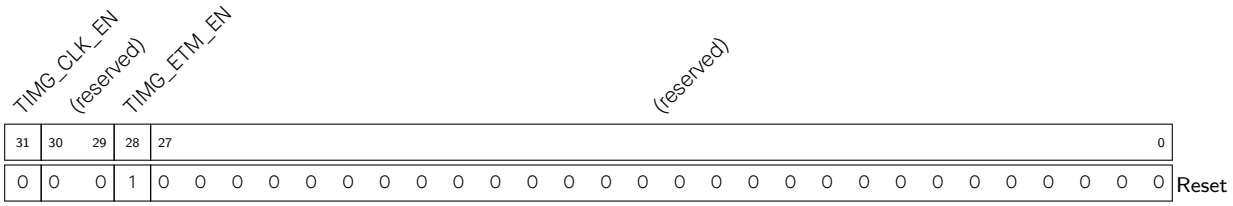
TIMG_T*x*_INT_ST (*x*: 0-1) The masked interrupt status bit of the TIMG_T*x*_INT interrupt. (RO)

TIMG_WDT_INT_ST The masked interrupt status bit of the TIMG_WDT_INT interrupt. (RO)



Register 17.24. TIMG_INT_CLR_TIMERS_REG (0x007C)

TIMG_T*x*_INT_CLR (*x*: 0-1) Write 1 to clear the TIMG_T*x*_INT interrupt. (WT)



TIMG_WDT_INT_CLR Write 1 to clear the TIMG_WDT_INT interrupt. (WT)

Register 17.25. TIMG_NTIMERS_DATE_REG (0x00F8)

TIMG_NTIMGS_DATE Version control register (R/W)

Register 17.26. TIMG_REGCLK_REG (0x00FC)

TIMG_ETM_EN Configures whether to enable timer's ETM task and event.

0: Disable

1: Enable

(R/W)

TIMG_CLK_EN Configures whether to enable gate clock signal for registers.

0: Force clock on for registers

1: Support clock only when registers are read or written to by software.

(R/W)

Chapter 18

Watchdog Timers (WDT)

18.1 Overview

Watchdog timers are hardware timers used to detect and recover from malfunctions. They must be periodically fed (reset) to prevent a timeout. A system/software that is behaving unexpectedly (e.g., is stuck in a software loop or in overdue events) will fail to feed the watchdog, thus the watchdog timer will time out and trigger an interrupt or reset, directing the system to a known state for exception handling or a restart. Therefore, watchdog timers are useful for detecting and handling erroneous system/software behavior.

As shown in Figure 18.1-1, ESP32-P4 contains three digital watchdog timers: one in each of the two timer groups in Chapter 17 *Timer Group (TIMG)* (called Main System Watchdog Timers, or MWDT) and one in the LP system (called the RTC Watchdog Timer, or RWDT). Each digital watchdog timer allows for four separately configurable stages, and each stage can be programmed to take one action upon timeout, unless the watchdog is fed or disabled. MWDT supports three timeout actions: interrupt, HP CPU reset, and HP core reset, while RWDT supports four timeout actions: interrupt, HP CPU reset, HP core reset, and system reset (see details in Section 18.2.2.2 *Stages and Timeout Actions*). A timeout value can be set for each stage individually.

In SPI Boot mode, RWDT and the MWDT in timer group 0 are enabled automatically in order to detect errors that may occur during the flash boot process and facilitate recovery.

ESP32-P4 also has one analog watchdog timer: Super watchdog (SWD). It is an ultra-low-power circuit in analog domain that helps to prevent the system from operating in a sub-optimal state and resets the system if required.

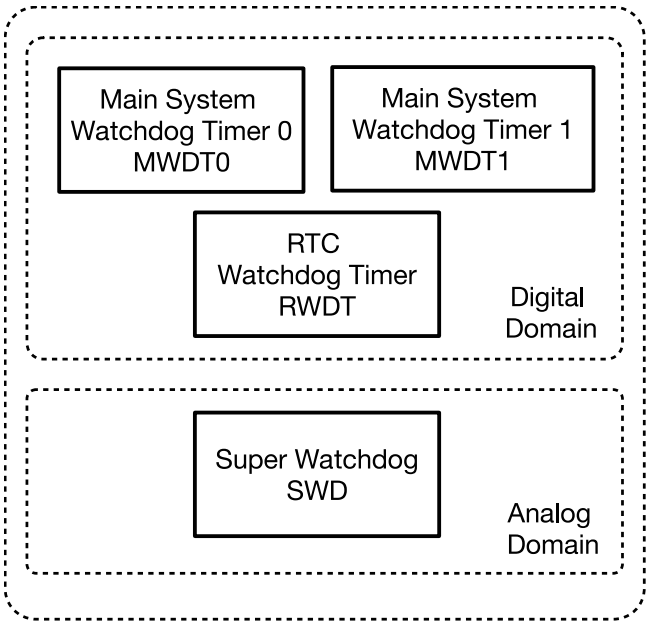


Figure 18.1-1. Watchdog Timers Overview

Note that while this chapter provides the functional descriptions of the watchdog timer's, MWDT register descriptions are detailed in Chapter 17 *Timer Group (TIMG)*, and the RWDT and SWD register descriptions are detailed in Section 18.5 *Register Summary*.

18.2 Digital Watchdog Timers

18.2.1 Features

Watchdog timers have the following features:

- Four stages, each with a separately programmable timeout value and timeout action
- Timeout actions:
  - MWDT: interrupt, HP CPU reset, HP core reset
  - RWDT: interrupt, HP CPU reset, HP core reset, system reset
- Flash boot protection under SPI Boot mode at stage 0:
  - MWDT0: HP core reset upon timeout
  - RWDT: system reset upon timeout
- Write protection that makes WDT register read only unless unlocked
- 32-bit timeout counter
- Clock source:
  - MWDT: PLL_F80M_CLK, RC_FAST_CLK or XTAL_CLK
  - RWDT: LP_DYN_SLOW_CLK

18.2.2 Functional Description

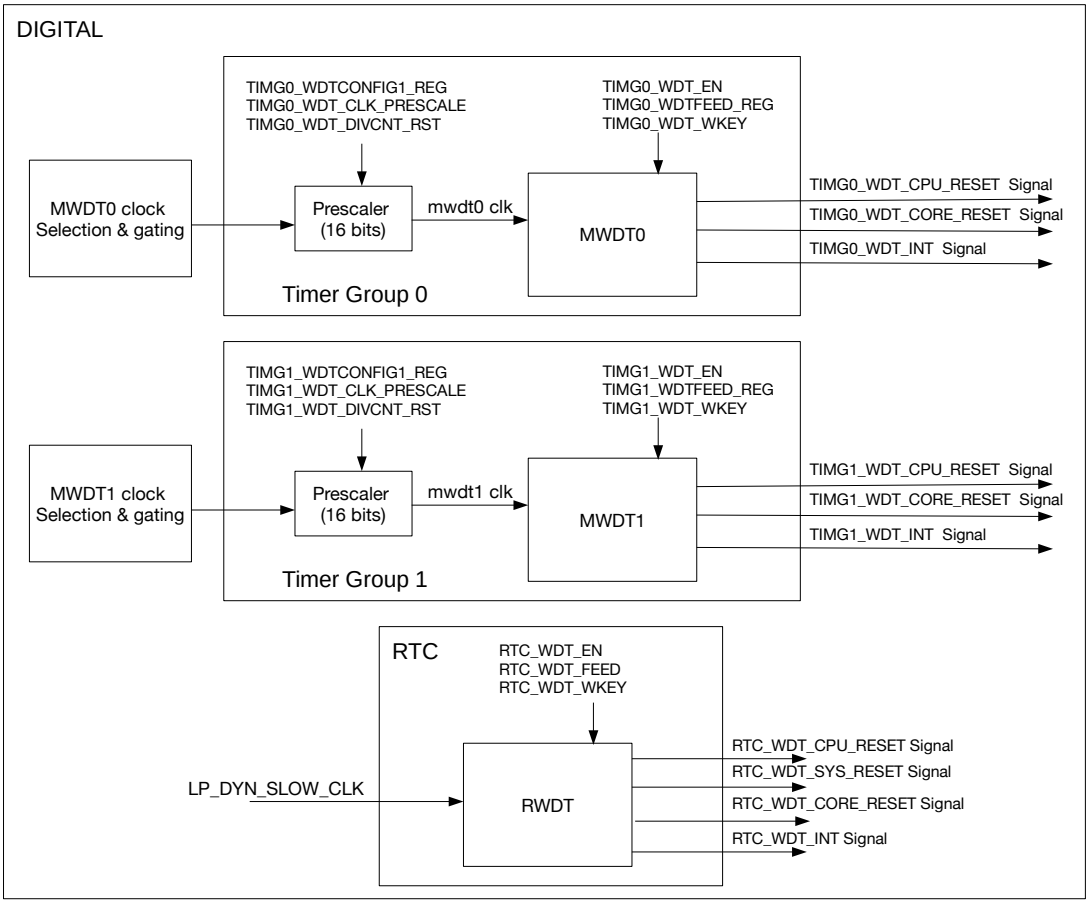

Figure 18.2-1. Digital Watchdog Timers in ESP32-P4

Figure 18.2-1 shows the three watchdog timers in ESP32-P4 digital systems.

18.2.2.1 Clock Source and 32-Bit Counter

At the core of each watchdog timer is a 32-bit counter.

Take MWDT0 as an example:

- MWDT0 can select between the PLL_F80M_CLK, RC_FAST_CLK or XTAL_CLK (external) clock as its clock source by setting the HP_SYS_TIMERGRP0_WDT_SRC_SEL field of the HP_SYS_CLKRST_PERI_CLK_CTRL20_REG register.
- The selected clock is switched on by setting HP_SYS_TIMERGRP0_WDT_CLK_EN field of the HP_SYS_CLKRST_PERI_CLK_CTRL20_REG register to 1 and switched off by setting it to 0. Then the selected clock is divided by a 16-bit configurable prescaler. See more details in Table 11.2-1 of Chapter 11.
- The 16-bit prescaler for MWDT is configured via the TIMG_WDT_CLK_PRESCALE field of TIMG_WDTCONFIG1_REG. When TIMG_WDT_DIVCNT_RST field is set, the prescaler is reset and it can be re-configured at once.

In contrast, the clock source of RWDT is derived directly from LP_DYN_SLOW_CLK (see details in Chapter 11

Reset and Clock).

MWDT and RWDT are enabled by setting the TIMG_WDT_EN and RTC_WDT_EN fields respectively. When enabled, the 32-bit counters of the watchdog will increment on each source clock cycle until the timeout value of the current stage is reached (i.e., timeout of the current stage). When this occurs, the current counter value is reset to zero and the next stage will become active. If a watchdog timer is fed by software, the timer will return to stage 0 and reset its counter value to zero. Software can feed a watchdog timer by writing any value to TIMG_WDTFEED_REG for MDWT and by writing 1 to RTC_WDT_FEED for RWDT.

18.2.2.2 Stages and Timeout Actions

Timer stages allow for a timer to have a series of different timeout values and corresponding timeout action. When one stage times out, the timeout action is triggered, the counter value is reset to zero, and the next stage becomes active.

MWDT/RWDT offers four stages (referred to as stages 0 to 3). The watchdog timers will progress through each stage in a loop (i.e., from stage 0 to 3, then back to stage 0).

Timeout values of each stage for MWDT are configured in TIMG_WDTCONFIG*i*_REG (where *i* ranges from 2 to 5), whilst timeout values for RWDT are configured using RTC_WDT_STG*j*_HOLD field (where *j* ranges from 0 to 3).

Please note that the timeout value of stage 0 for RWDT ($Thold_0$) is determined by the combination of the
EFUSE_WDT_DELAY_SEL field of eFuse register EFUSE_RD_REPEAT_DATA0_REG and RTC_WDT_STG0_HOLD field. The relationship is as follows:

$$T_{hold0} = RTC_WDT_STG0_HOLD << (EFUSE_WDT_DELAY_SEL + 1)$$

where $<<$ is a left-shift operator. For example, if RTC_WDT_STG0_HOLD is configured as 100 and EFUSE_WDT_DELAY_SEL is 1, the $Thold_0$ will be 400 cycles.

Upon the timeout of each stage, one of the following timeout actions will be executed:

Table 18.2-1. Timeout Actions

Timeout Action	Description
Interrupt	Trigger an interrupt
HP CPU reset	Reset the HP CPU0 and HP CPU1
HP core reset	HP core reset resets HP CPU0, HP CPI1, HP peripherals, HP GPIO, etc.
System reset	Reset the whole digital system, including the LP system.
Disabled	No effect on the system

For MWDT, the timeout action of all stages is configured in TIMG_WDTCONFIG0_REG. Likewise for RWDT, the timeout action is configured in RTC_WDT_CONFIG0_REG.

18.2.2.3 Write Protection

Watchdog timers are critical to detecting and handling erroneous system/software behavior, thus should not be disabled easily (e.g., due to a misplaced register write). Therefore, MWDT and RWDT incorporate a write

protection mechanism that prevent the watchdogs from being disabled or tampered with due to an accidental write.

The write protection mechanism is implemented using a write-key field for each timer (TIMG_WDT_WKEY for MWDT, RTC_WDT_WKEY for RWDT). The value 0x50D83AA1 must be written to the watchdog timer's write-key field before any other register of the same watchdog timer can be changed. Any attempts to write to a watchdog timer's registers (other than the write-key field itself) whilst the write-key field's value is not 0x50D83AA1 will be ignored. The recommended procedure for accessing a watchdog timer is as follows:

1. Disable the write protection by writing the value 0x50D83AA1 to the timer's write-key field.
2. Make the required modification of the watchdog such as feeding or changing its configuration.
3. Re-enable write protection by writing any value other than 0x50D83AA1 to the timer's write-key field.

18.2.2.4 Flash Boot Protection

Under the SPI boot mode, MWDT0 as well as RWDT, are automatically enabled. Stage 0 for the enabled MWDT0 is automatically configured as HP core reset action upon timeout, known as HP core reset. Likewise, stage 0 for RWDT is configured to system reset, which resets the main system and RTC when it times out. After SPI booting, TIMG_WDT_FLASHBOOT_MOD_EN and RTC_WDT_FLASHBOOT_MOD_EN should be cleared to stop the flash boot protection procedure for both MWDT0 and RWDT respectively. After this, MWDT0 and RWDT can be configured by software.

18.3 Super Watchdog

Super watchdog (SWD) is an ultra-low-power circuit in analog domain that helps to prevent the system from operating in a sub-optimal state and resets the system (system reset) if required. SWD contains a watchdog circuit that needs to be fed for at least once during its timeout period, which is slightly less than one second. About 100 ms before watchdog timeout, it will also send out a WD_INTR signal as a request to remind the system to feed the watchdog.

If the system doesn't respond to SWD feed request and watchdog finally times out, SWD will generate a system level signal SWD_RSTB to reset whole digital circuits on the chip (system reset) .

The source of the clock for SWD is constant and can not be selected.

18.3.1 Features

SWD has the following features:

- Ultra-low power
- Interrupt to indicate that the SWD is about to time out
- Various dedicated methods for software to feed SWD, which enables SWD to monitor the working state of the whole operating system

18.3.2 Super Watchdog Controller

18.3.2.1 Structure

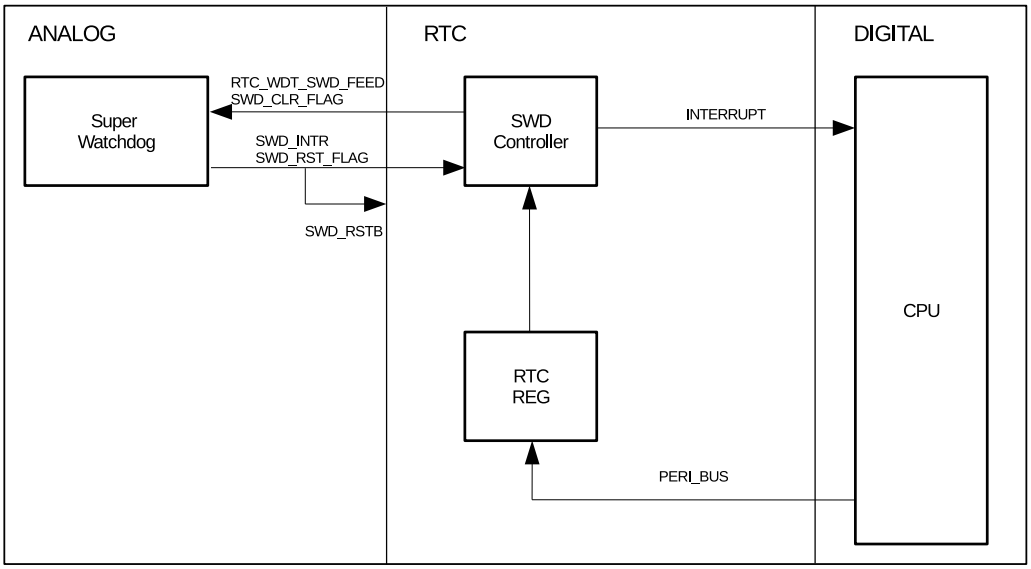

Figure 18.3-1. Super Watchdog Controller Structure

18.3.2.2 Workflow

In normal state:

- SWD controller receives feed request from SWD.
- SWD controller can send an interrupt to main CPU.
- Main CPU can feed SWD directly by setting RTC_WDT_SWD_FEED.
- When trying to feed SWD, CPU needs to disable SWD controller's write protection by writing 0x50D83AA1 to RTC_WDT_SWD_WKEY. This prevents SWD from being fed by mistake when the system is operating in sub-optimal state.
- If setting RTC_WDT_SWD_AUTO_FEED_EN to 1, SWD controller can also feed SWD itself without any interaction with CPU.

After reset:

- Check LP_AONCLKRST_LPCORE_RESET_CAUSE[4:0] for the cause of HP CPU reset.
  If LP_AONCLKRST_LPCORE_RESET_CAUSE[4:0] == 0x12, it indicates that the cause is SWD reset.
- Set RTC_WDT_SWD_RST_FLAG_CLR to clear the SWD reset flag.

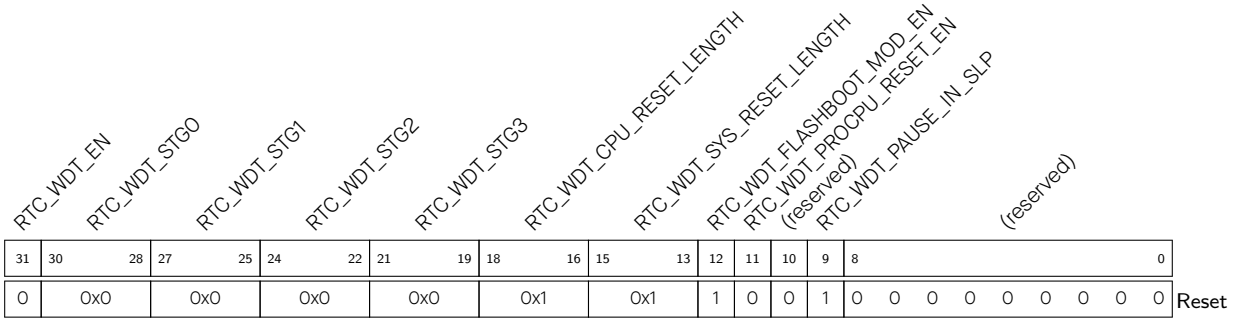
18.4 Interrupts

For watchdog timer interrupts, please refer to Section 17.3.7 *Interrupts* in Chapter 17 *Timer Group (TIMG)*.

18.5 Register Summary

The addresses in this section are relative to RTC_WDT base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
configuration register			
RTC_WDT_CONFIG0_REG	Configure the RWDT operation	0x0000	R/W
RTC_WDT_CONFIG1_REG	Configure the RWDT timeout time of stage0	0x0004	R/W
RTC_WDT_CONFIG2_REG	Configure the RWDT timeout time of stage1	0x0008	R/W
RTC_WDT_CONFIG3_REG	Configure the RWDT timeout time of stage2	0x000C	R/W
RTC_WDT_CONFIG4_REG	Configure the RWDT timeout time of stage3	0x0010	R/W
RTC_WDT_FEED_REG	Configure the feed function of RWDT	0x0014	WT
RTC_WDT_WPROTECT_REG	Configure the lock function of RWDT	0x0018	R/W
RTC_WDT_SWD_CONFIG_REG	Configure the SWD operation	0x001C	varies
RTC_WDT_SWD_WPROTECT_REG	Configure the lock function of SWD	0x0020	R/W
RTC_WDT_INT_RAW_REG	Configure whether to generate timeout interrupt	0x0024	R/WTC/SS
RTC_WDT_INT_ST_REG	The interrupt status register of WDT	0x0028	RO
RTC_WDT_INT_ENA_REG	The interrupt enable register of WDT	0x002C	R/W
RTC_WDT_INT_CLR_REG	The interrupt clear register of WDT	0x0030	WT
RTC_WDT_DATE_REG	Version control register	0x03FC	R/W

18.6 Registers

MWDT registers are part of the timer submodule and are described in Section 17.5 *Register Summary* in Chapter 17 *Timer Group (TIMG)*.

The addresses of RWDT and SWD registers in this section are relative to RTC_WDT base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

Register 18.1. RTC_WDT_CONFIG0_REG (0x0000)

RTC_WDT_PAUSE_IN_SLP Configure whether or not pause RWDT when chip is in sleep mode.

0: Enable

1: Disable

(R/W)

RTC_WDT_PROCPU_RESET_EN Configure whether or not to enable RWDT to reset CPU.

0: Disable

1: Enable

(R/W)

RTC_WDT_FLASHBOOT_MOD_EN Configure whether or not to enable RWDT when chip is in SPI boot mode.

0: Disable

1: Enable

(R/W)

RTC_WDT_SYS_RESET_LENGTH Configure the HP core reset time.

Measurement unit: LP_DYN_FAST_CLK

(R/W)

RTC_WDT_CPU_RESET_LENGTH Configure the HP CPU reset time.

Measurement unit: LP_DYN_FAST_CLK

(R/W)

RTC_WDT_STG3 Configure the timeout action of stage3.

0: No operation

1: Generate interrupt

2: Generate HP CPU reset

3: Generate HP core reset

4: Generate system reset

(R/W)

Continued on the next page...

Register 18.1. RTC_WDT_CONFIG0_REG (0x0000)

Continued from the previous page...

RTC_WDT_STG2 Configure the timeout action of stage2.

0: No operation

1: Generate interrupt

2: Generate HP CPU reset

3: Generate HP core reset

4: Generate system reset

(R/W)

RTC_WDT_STG1 Configure the timeout action of stage1.

0: No operation

1: Generate interrupt

2: Generate HP CPU reset

3: Generate HP core reset

4: Generate system reset

(R/W)

RTC_WDT_STG0 Configure the timeout action of stage0.

0: No operation

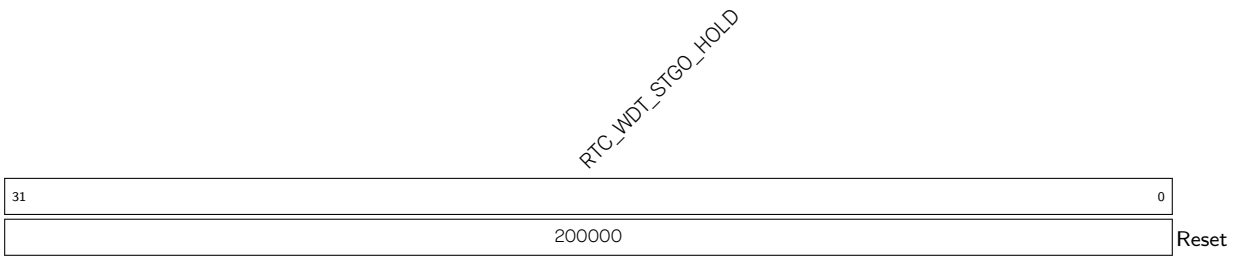
1: Generate interrupt

2: Generate HP CPU reset

3: Generate HP core reset

4: Generate system reset

(R/W)



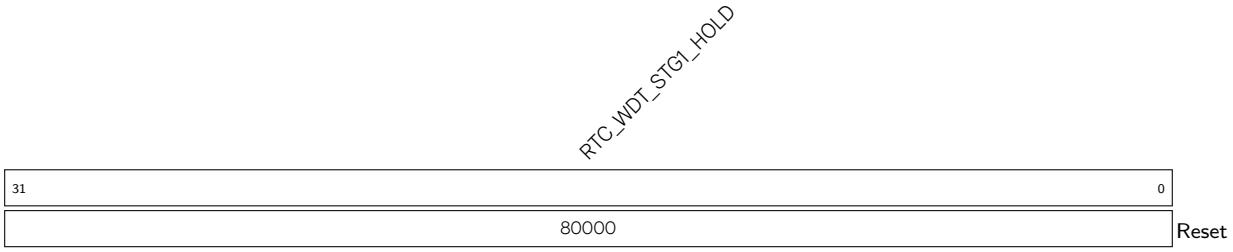
RTC_WDT_EN Configure whether or not enable RWDT.

0: Disable RWDT

1: Enable RWDT

(R/W)

Register 18.2. RTC_WDT_CONFIG1_REG (0x0004)

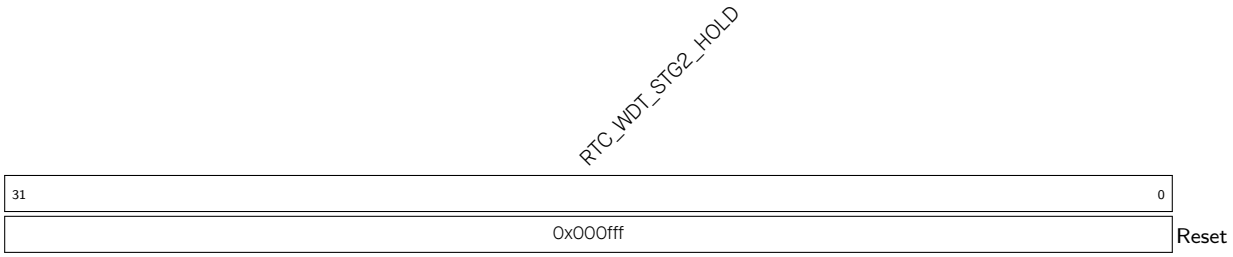


RTC_WDT_STG0_HOLD Configure the timeout time for stage0.

Measurement unit: LP_DYN_SLOW_CLK

(R/W)

Register 18.3. RTC_WDT_CONFIG2_REG (0x0008)

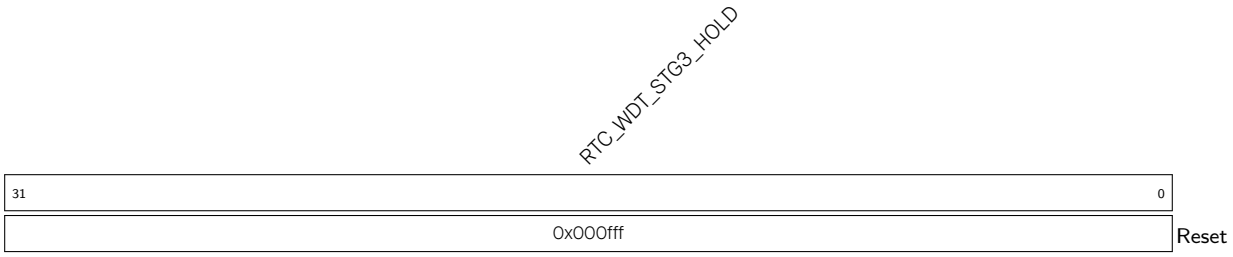


RTC_WDT_STG1_HOLD Configure the timeout time for stage1.

Measurement unit: LP_DYN_SLOW_CLK

(R/W)

Register 18.4. RTC_WDT_CONFIG3_REG (0x000C)

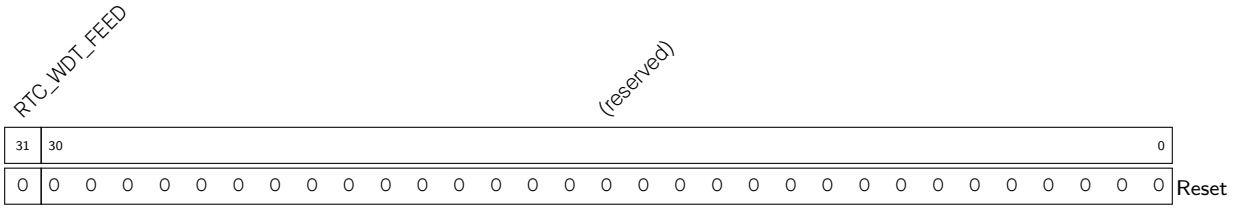


RTC_WDT_STG2_HOLD Configure the timeout time for stage2.

Measurement unit: LP_DYN_SLOW_CLK

(R/W)

Register 18.5. RTC_WDT_CONFIG4_REG (0x0010)

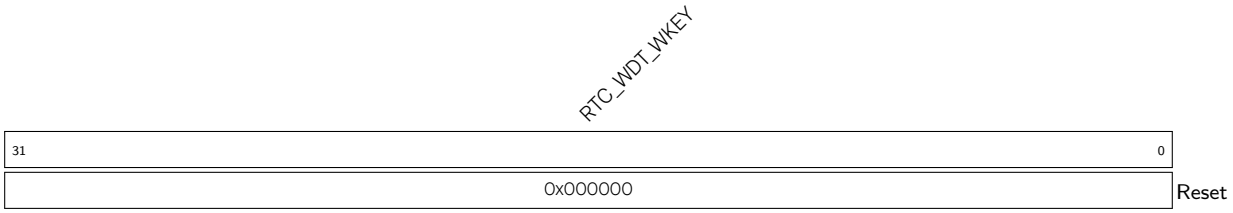


RTC_WDT_STG3_HOLD Configure the timeout time for stage3.

Measurement unit: LP_DYN_SLOW_CLK

(R/W)

Register 18.6. RTC_WDT_FEED_REG (0x0014)



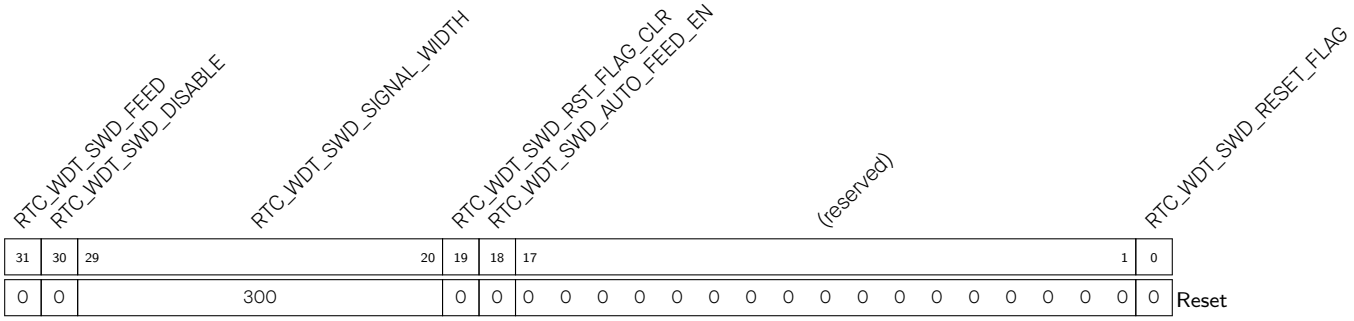
RTC_WDT_FEED Configure this bit to feed the RWDT.

0: Invalid

1: Feed RWDT

(WT)

Register 18.7. RTC_WDT_WPROTECT_REG (0x0018)



RTC_WDT_WKEY Configure this field to lock or unlock RWDT's configuration registers.

0x50D83AA1: unlock the RWDT configuration register

Others value: lock the RWDT configuration register which can't be modified by software.

(R/W)

Register 18.8. RTC_WDT_SWD_CONFIG_REG (0x001C)

RTC_WDT_SWD_RESET_FLAG Represents the SWD whether has generated the reset signal

0: No

1: Yes

(RO)

RTC_WDT_SWD_AUTO_FEED_EN Configure this bit to enable to feed SWD automatically by hardware.

0: Disable

1: Enable

(R/W)

RTC_WDT_SWD_RST_FLAG_CLR Configure this bit to clear SWD reset flag

0: Invalid

1: Clear the reset flag

(WT)

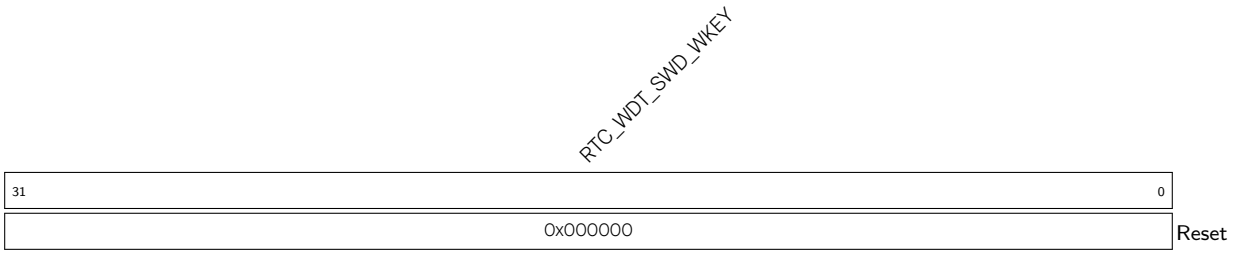
RTC_WDT_SWD_SIGNAL_WIDTH Configure the SWD signal length that output to analog circuit. Measurement unit: LP_DYN_FAST_CLK (R/W)

RTC_WDT_SWD_DISABLE Configure this bit to disable the SWD.

0: Enable the SWD

1: Disable the SWD

(R/W)



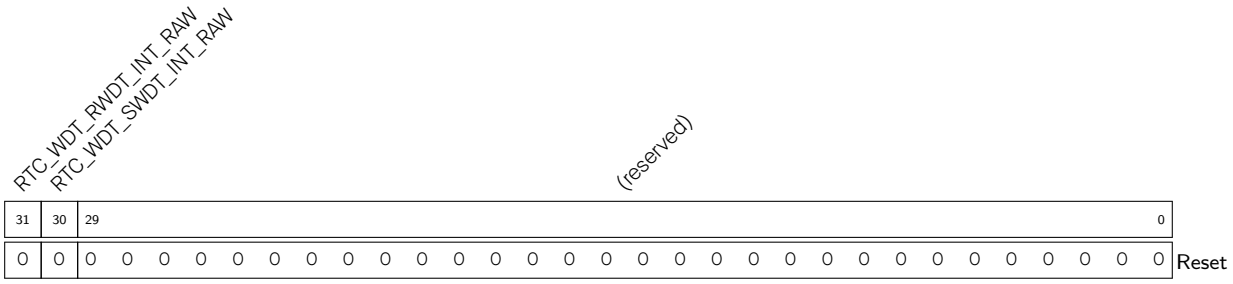
RTC_WDT_SWD_FEED Configure this bit to feed the SWD.

0: Invalid

1: Feed SWD

(WT)

Register 18.9. RTC_WDT_SWD_WPROTECT_REG (0x0020)



RTC_WDT_SWD_WKEY Configure this field to lock or unlock SWD's configuration registers.

0x50D83AA1: unlock the SWD configuration register.

Others value: lock the SWD configuration register which can't be modified by the software.

(R/W)

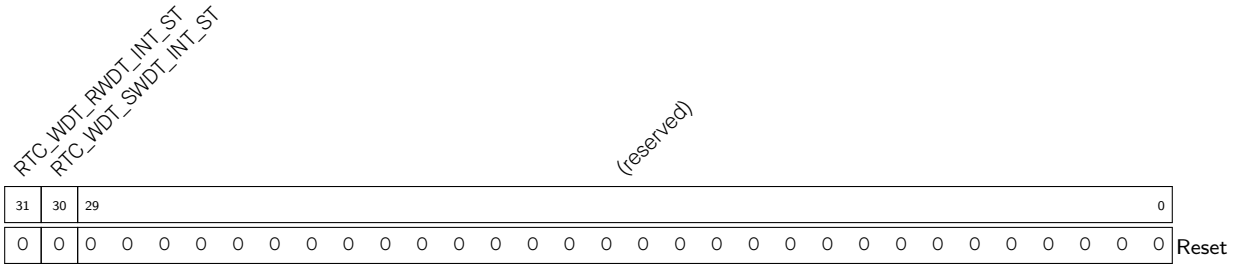
Register 18.10. RTC_WDT_INT_RAW_REG (0x0024)

RTC_WDT_SWDT_INT_RAW Represents the SWD whether or not has generated timeout interrupt.

0: No

1: Yes

(R/WTC/SS)



RTC_WDT_RWDT_INT_RAW Represents the RWDT whether or not generates timeout interrupt.

0: No

1: Yes

(R/WTC/SS)

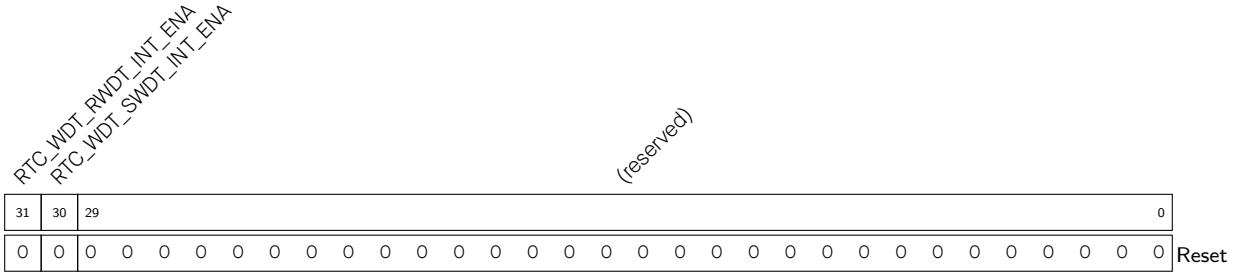
Register 18.11. RTC_WDT_INT_ST_REG (0x0028)

RTC_WDT_SWDT_INT_ST Represents the SWD whether or not has generated and sent timeout interrupt to CPU.

0: No

1: Yes

(RO)



RTC_WDT_RWDT_INT_ST Represents the RWDT whether or not generates and sends timeout interrupt to CPU.

0: No

1: Yes

(RO)

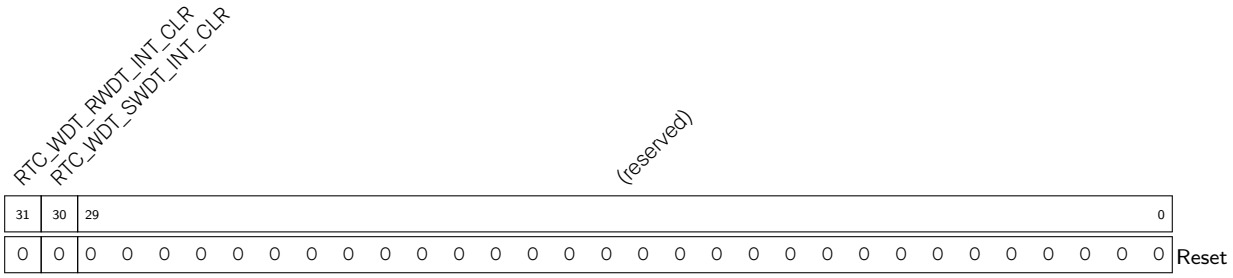
Register 18.12. RTC_WDT_INT_ENA_REG (0x002C)

RTC_WDT_SWDT_INT_ENA Configure whether or not to enable the SWD to send timeout interrupt.

0: Disable

1: Enable

(R/W)



RTC_WDT_RWDT_INT_ENA Configure whether or not to enable the RWDT to send timeout interrupt.

0: Disable

1: Enable

(R/W)

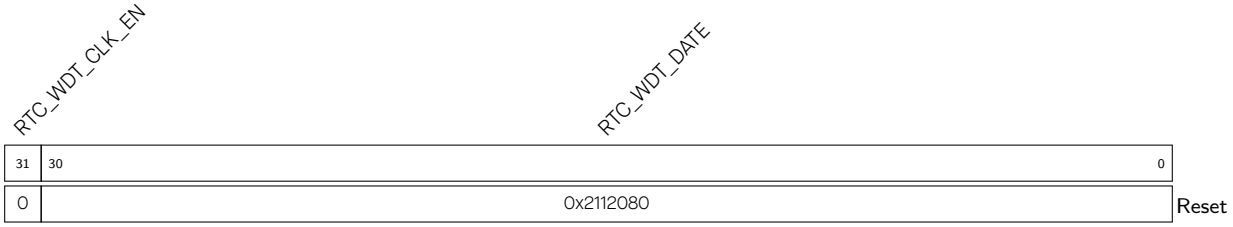
Register 18.13. RTC_WDT_INT_CLR_REG (0x0030)

RTC_WDT_SWDT_INT_CLR Configure whether to clear the timeout interrupt signal sent by SWD to CPU.

0: No

1: Yes

(WT)



RTC_WDT_RWDT_INT_CLR Configure whether to clear the timeout interrupt signal sent by RWDT to CPU.

0: No

1: Yes

(WT)

Register 18.14. RTC_WDT_DATE_REG (0x03FC)

RTC_WDT_DATE Version control register. (R/W)

RTC_WDT_CLK_EN Reserved. (R/W)

Chapter 19

RTC Timer

19.1 Introduction

RTC Timer is an important module for implementing low power management of ESP32-P4. Based on a 48-bit readable counter, RTC Timer is mainly used as a system timer in low power mode when the timer peripheral in the HP system is unavailable. It also allows for configuring timer interrupts and logging the time when specific events happen in the system. The supported events are described in the 19.3 Functional Description.

19.2 Feature List

RTC Timer has the following features:

- 48-bit counter
- Time logging when one of the following events happens:
  - HP system reset
  - CPU enters stall state
  - CPU exits stall state
  - Crystal powers up
  - Crystal powers down
- Time logging through register configuration
- Occurrence time cached of the most recent two specific events
- Generation of interrupts at target times, which are configurable. It is also possible to configure two target times simultaneously.
- Uninterrupted operation during any reset or sleep mode, except for power-on reset of LP system.

19.3 Functional Description

- 48-bit counter
  - The implementation of the RTC Timer is based on a 48-bit counter, driven by the RC_SLOW_CLK in the AlwaysOn power domain. It uses continuous loop counting (except during LP system reset), and an overflow interrupt is generated when the 48-bit counter overflows.
- Log the occurrence time of specific events
  - RTC Timer supports logging the occurrence time of three types of events:

    * HP system reset
    * CPU enters or exits stall state
    * Crystal powers up or down
  - The above three types of events have their own independent configuration registers. When the configuration registers are enabled, if the corresponding events occur, the hardware pulse generated will trigger the RTC Timer to log the current time. The corresponding configuration registers are shown in the table below.

Table 19.3-1. Configure RTC Timer to Log the Occurrence Time of Specific Events

Configuration Register	Description
RTC_TIMER_MAIN_TIMER_SYS_RST	Enable the RTC Timer to log the time of system reset.
RTC_TIMER_MAIN_TIMER_SYS_STALL	Enable the RTC Timer to log the time when the CPU enters or exits the stall state.
RTC_TIMER_MAIN_TIMER_XTAL_OFF	Enable the RTC Timer to log the time when the crystal powers up or down.

- Log the current time through software configuration.
  - In addition to the above three specific events that can trigger the RTC Timer to log the time, the RTC Timer can also record the current time through the configuration register RTC_TIMER_MAIN_TIMER_UPDATE.
  - A pulse signal will be generated by configuring the RTC_TIMER_MAIN_TIMER_UPDATE, which will trigger the RTC Timer to record the current time.
- Generate counting interrupts at target times
  - RTC Timer supports configuring two target times simultaneously, referred to as target time 0 and target time 1. When the timer reaches target time 0, it will trigger the RTC_TIMER_CMP0_INT interrupt. Similarly, when the timer reaches Target Moment 1, it will trigger the RTC_TIMER_CMP1_INT interrupt.
  - Configure the target times through the registers below:

Table 19.3-2. Target times Configuration

Configuration Register	Description
RTC_TIMER_MAIN_TIMER_TAR_EN*n*	*n* = 0 or 1, enable target time configuration.
RTC_TIMER_MAIN_TIMER_TAR_LOW*n*	*n* = 0 or 1, configure the low 32 bits of the target time.
RTC_TIMER_MAIN_TIMER_TAR_HIGH*n*	*n* = 0 or 1, configure the high 16 bits of the target time.

- Read the time cached in the RTC Timer
  - There are two sets of registers used to cache the occurrence time of specific events, namely register group 0 and register group 1.
  - Register group 0 includes register RTC_TIMER_MAIN_BUF0_LOW_REG and RTC_TIMER_MAIN_BUF1_HIGH_REG which are used to cache the count value of the RTC Timer under the current trigger.

- Register group 1 includes register RTC_TIMER_MAIN_BUF1_LOW_REG and RTC_TIMER_MAIN_BUF1_HIGH_REG, which are used to cache the count value of the RTC Timer from the last trigger.
- On a new trigger, the record from the previous trigger will be moved from register group 0 to register group 1 (and the previous record in register group 1 will be overwritten), and the record of this trigger will be stored in register group 0. Therefore, only the last two triggers can be logged at any time.

19.4 Event Task Matrix Feature

The RTC Timer on ESP32-P4 supports the Event Task Matrix (ETM) function, which allows RTC Timer's ETM tasks to be triggered by any peripherals' ETM events, or RTC Timer's ETM events to trigger any peripherals' ETM tasks. This section introduces the ETM tasks and events related to RTC Timer. For more information, please refer to Chapter 14 Event Task Matrix (ETM).

RTC Timer doesn't receive any ETM tasks:

RTC Timer can generate the following ETM events:

- RTC_EVT_CMP: Indicate that the RTC Timer reaches the target time 0 configured by RTC_TIMER_MAIN_TIMER_TAR_LOW0 and RTC_TIMER_MAIN_TIMER_TAR_HIGH0.
- RTC_EVT_OVF: Indicate the 48-bit counter overflow.
- RTC_EVT_TICK: Indicates the event that occurs when the RTC timer increments by 1.

19.5 Interrupts

ESP32-P4's RTC Timer can generate the following interrupt signal(s) that will be sent to the Interrupt Matrix.

- LP_TIMER_REG_0_INTR
- LP_TIMER_REG_1_INTR

There are several internal interrupt sources from RTC Timer that can generate the above interrupt signal(s). The interrupt sources from RTC Timer are listed with their trigger conditions and the resulted interrupt signal(s) in Table 19.5-1.

Table 19.5-1. RTC Timer's Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
RTC_TIMER_CMP0_INT	RTC Timer reaches the target time 0	LP_TIMER_REG_0_INTR
RTC_TIMER_CMP1_INT	RTC Timer reaches the target time 1	LP_TIMER_REG_1_INTR
RTC_TIMER_OVERFLOW_INT	48-bit counter overflow	LP_TIMER_REG_0_INTR LP_TIMER_REG_1_INTR

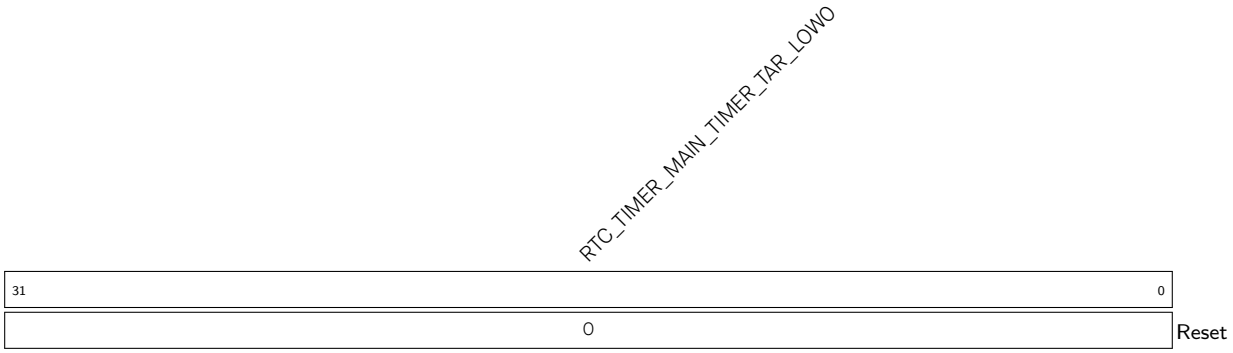
Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 19.6 *Register Summary*.

19.6 Register Summary

The addresses in this section are relative to RTC Timer base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

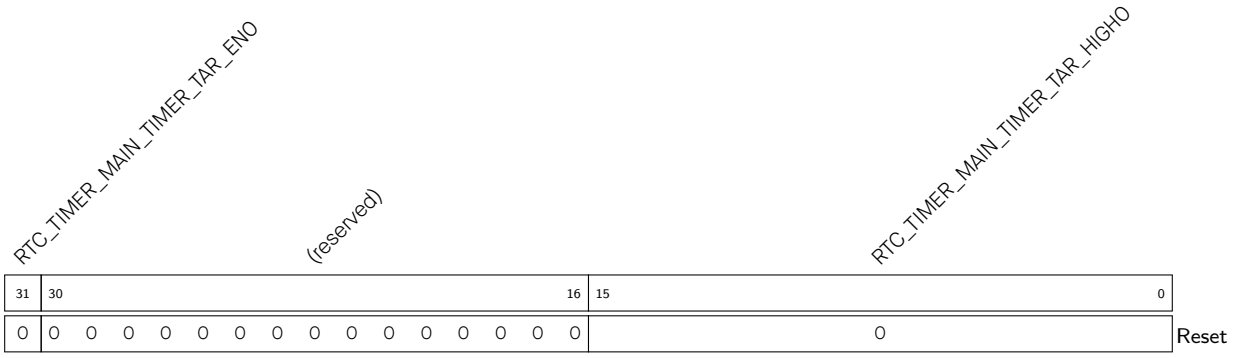
The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Configuration Registers			
RTC_TIMER_TAR0_LOW_REG	Configure the low 32 bits of the target time 0	0x0000	R/W
RTC_TIMER_TAR0_HIGH_REG	Configure the high 16 bits of the target time 0	0x0004	varies
RTC_TIMER_TAR1_LOW_REG	Configure the low 32 bits of the target time 1	0x0008	R/W
RTC_TIMER_TAR1_HIGH_REG	Configure the high 16 bits of the target time 1	0x000C	varies
RTC_TIMER_UPDATE_REG	Configure to enable the RTC Timer to latch current value	0x0010	varies
RTC_TIMER_MAIN_BUF0_LOW_REG	The low 32 bits of the cached value 0 in RTC Timer	0x0014	RO
RTC_TIMER_MAIN_BUF0_HIGH_REG	The high 16 bits of the cached value 0 in RTC Timer	0x0018	RO
RTC_TIMER_MAIN_BUF1_LOW_REG	The low 32 bits of the cached value 1 in RTC Timer	0x001C	RO
RTC_TIMER_MAIN_BUF1_HIGH_REG	The high 16 bits of the cached value 1 in RTC Timer	0x0020	RO
Interrupt Registers			
RTC_TIMER_INT_RAW_REG	The interrupt raw status register for the RTC Timer reaching the target time 0	0x0028	RO
RTC_TIMER_INT_ST_REG	The interrupt status register for the RTC Timer reaching the target time 0	0x002C	RO
RTC_TIMER_INT_ENA_REG	The interrupt enable register for the RTC Timer reaching the target time 0	0x0030	R/W
RTC_TIMER_INT_CLR_REG	The interrupt clear register for the RTC Timer reaching the target time 0	0x0034	WO
RTC_TIMER_LP_INT_RAW_REG	The interrupt raw status register for RTC Timer reaching the target time 1	0x0038	RO
RTC_TIMER_LP_INT_ST_REG	The interrupt status register for the RTC Timer reaching the target time 1	0x003C	RO
RTC_TIMER_LP_INT_ENA_REG	The interrupt enable register for the RTC Timer reaching the target time 1	0x0040	R/W
RTC_TIMER_LP_INT_CLR_REG	The interrupt clear register for the RTC Timer reaching the target time 1	0x0044	WO
Version Register			
RTC_TIMER_DATE_REG	Version control register	0x03FC	R/W

19.7 Registers

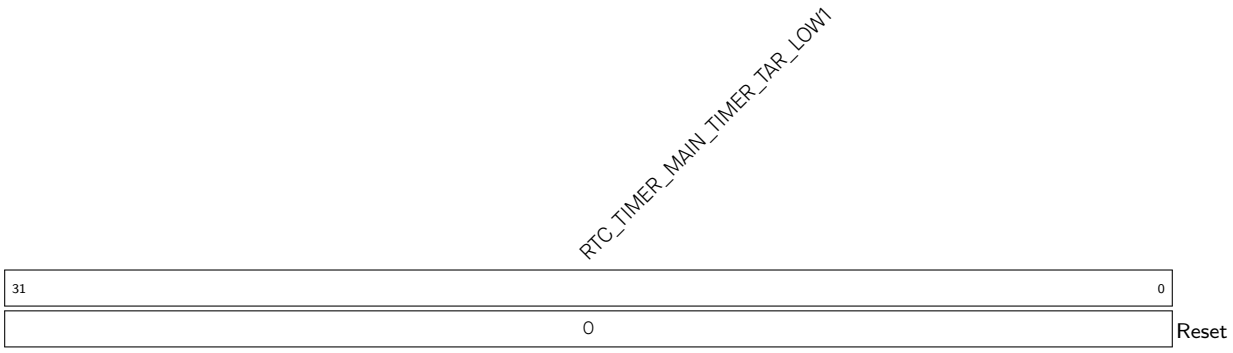
The addresses in this section are relative to RTC Timer base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



For how to program reserved fields, please refer to Section Programming Reserved Register Field.

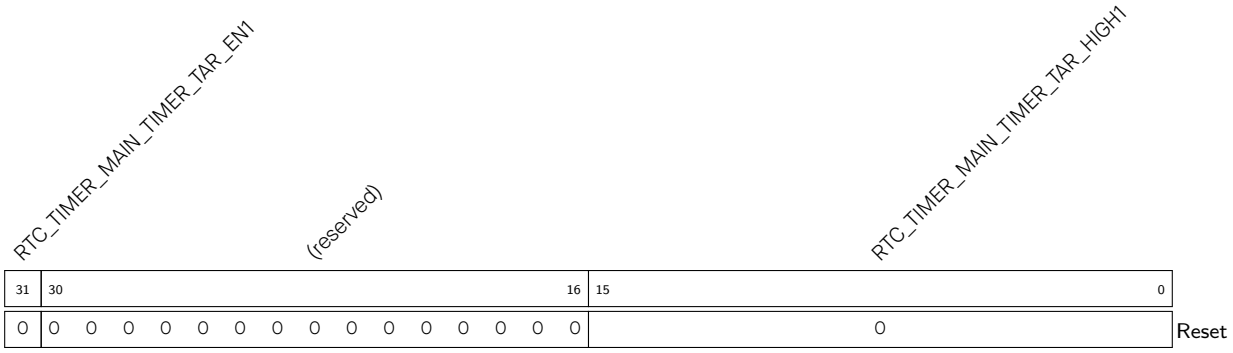
Register 19.1. RTC_TIMER_TAR0_LOW_REG (0x0000)

RTC_TIMER_MAIN_TIMER_TAR_LOW0 Configure the low 32 bits of the target time 0 of the RTC Timer. (R/W)



Register 19.2. RTC_TIMER_TAR0_HIGH_REG (0x0004)

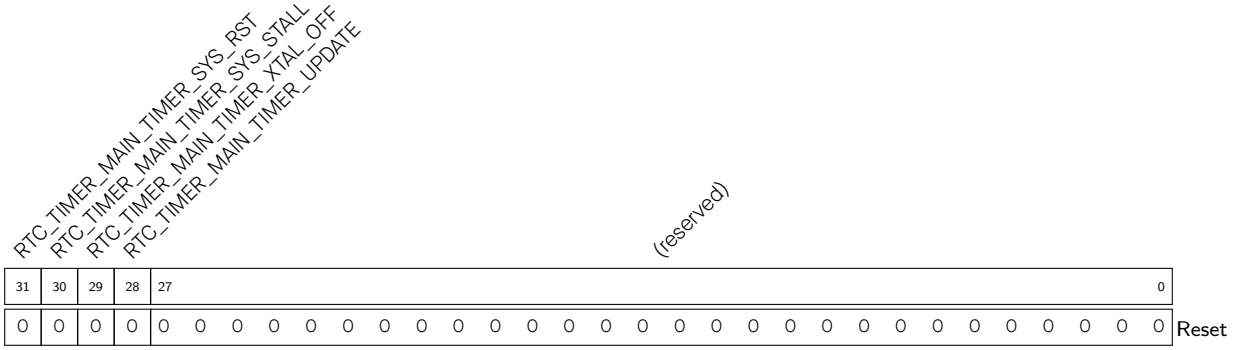
RTC_TIMER_MAIN_TIMER_TAR_HIGH0 Configure the high 16 bits of the target time 0. (R/W)



RTC_TIMER_MAIN_TIMER_TAR_EN0 Configure to enable the target time 0 of the RTC Timer. (WO)

Register 19.3. RTC_TIMER_TAR1_LOW_REG (0x0008)

RTC_TIMER_MAIN_TIMER_TAR_LOW1 Configure the low 32 bits of the target time 1. (R/W)

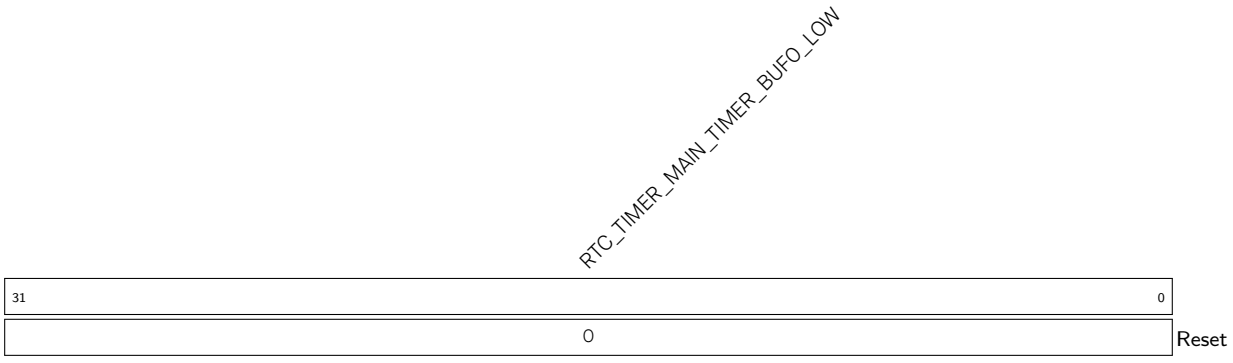


Register 19.4. RTC_TIMER_TAR1_HIGH_REG (0x000C)

RTC_TIMER_MAIN_TIMER_TAR_HIGH1 Configure the high 16 bits of the target time 1. (R/W)

RTC_TIMER_MAIN_TIMER_TAR_EN1 Configure to enable the target time 1 of the RTC Timer. (WO)

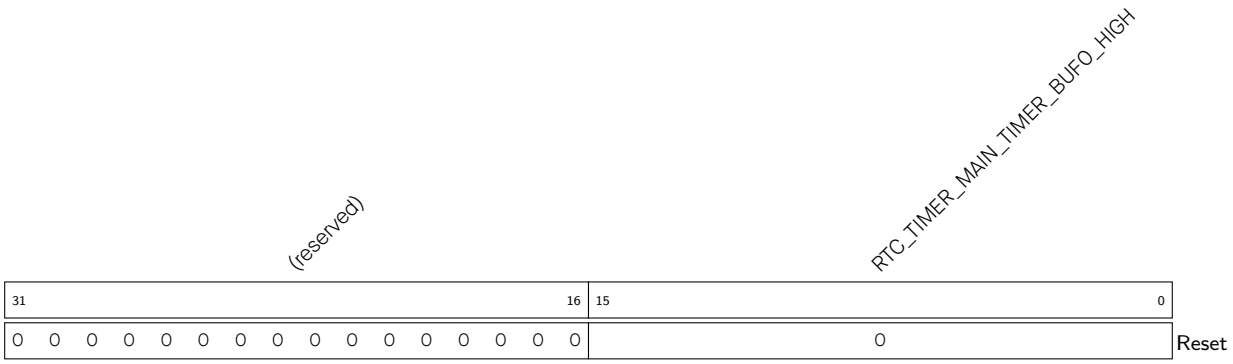
Register 19.5. RTC_TIMER_UPDATE_REG (0x0010)



RTC_TIMER_MAIN_TIMER_UPDATE Configure to log the current time through software configuration. (WO)

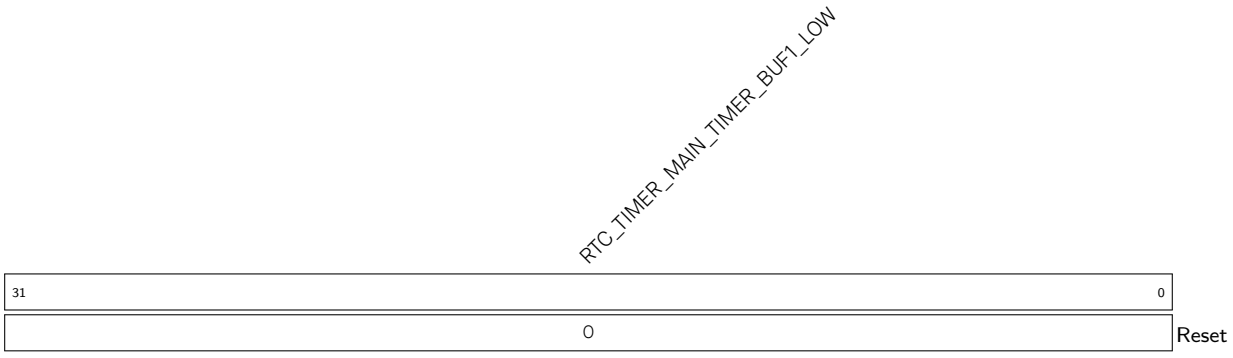
RTC_TIMER_MAIN_TIMER_XTAL_OFF Configure to enable RTC Timer to log the time when the crystal powers up or down. (R/W)

RTC_TIMER_MAIN_TIMER_SYS_STALL Configure to enable the RTC Timer to log the time when the CPU enters or exits the stall state. (R/W)



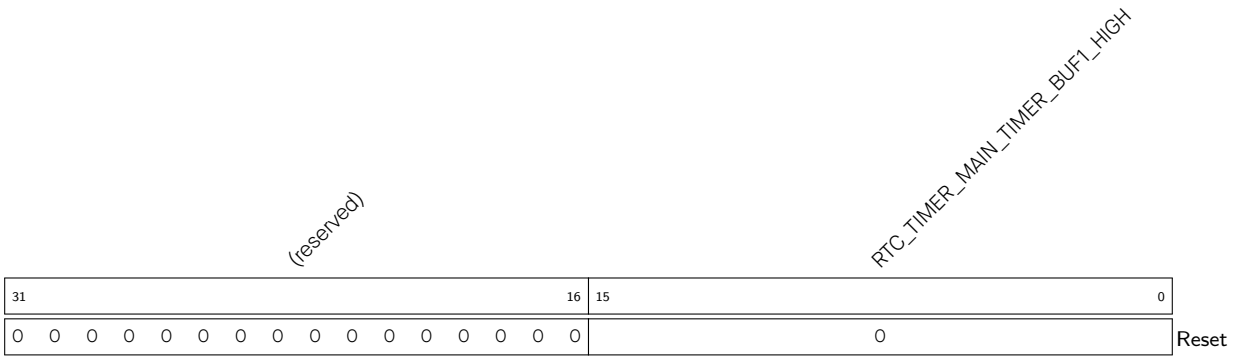
RTC_TIMER_MAIN_TIMER_SYS_RST Configure to enable RTC Timer to log the time of system reset. (R/W)

Register 19.6. RTC_TIMER_MAIN_BUF0_LOW_REG (0x0014)



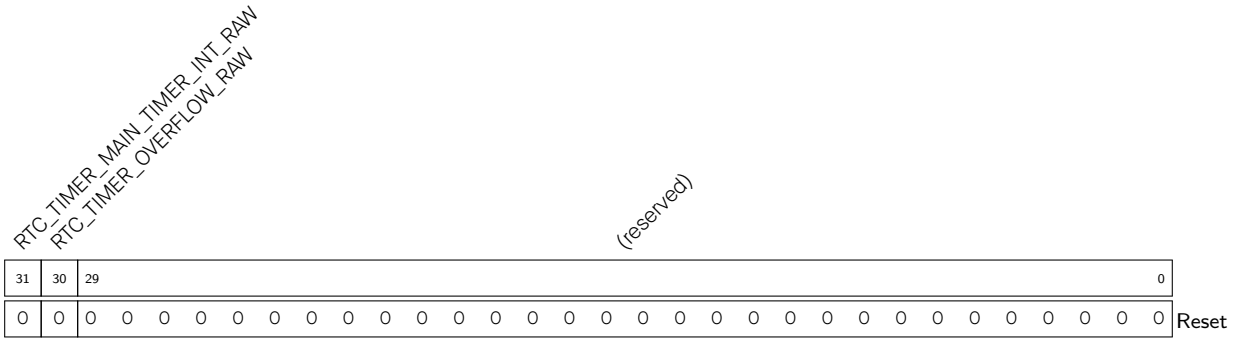
RTC_TIMER_MAIN_TIMER_BUF0_LOW Represent the low 32 bits of the cached value 0 in RTC Timer. (RO)

Register 19.7. RTC_TIMER_MAIN_BUF0_HIGH_REG (0x0018)



RTC_TIMER_MAIN_TIMER_BUF0_HIGH Represent the high 16 bits of the cached value 0 in RTC Timer. (RO)

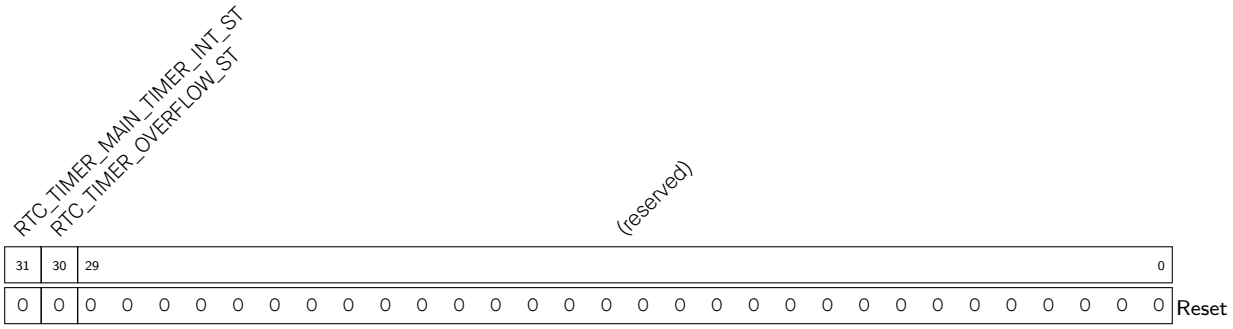
Register 19.8. RTC_TIMER_MAIN_BUF1_LOW_REG (0x001C)



RTC_TIMER_MAIN_TIMER_BUF1_LOW Represent the low 32 bits of the cached value 1 in RTC Timer. (RO)

Register 19.9. RTC_TIMER_MAIN_BUF1_HIGH_REG (0x0020)

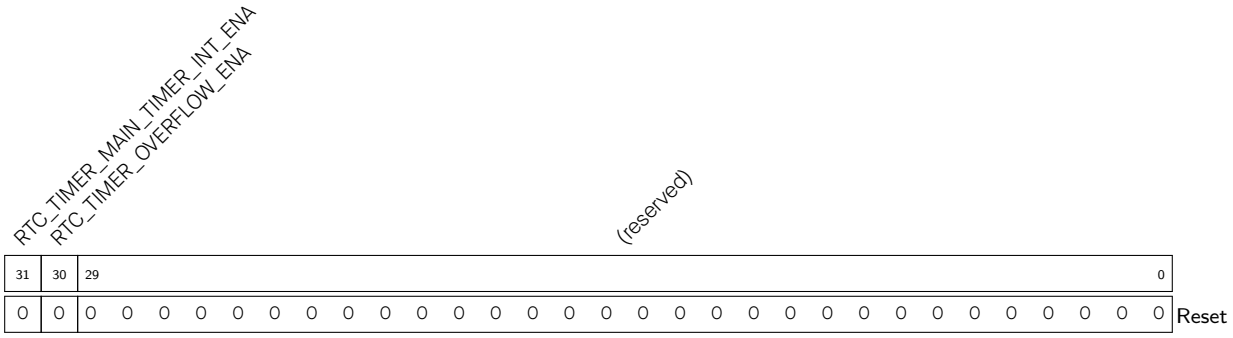
RTC_TIMER_MAIN_TIMER_BUF1_HIGH Represent the high 16 bits of the cached value 1 in RTC Timer. (RO)



Register 19.10. RTC_TIMER_INT_RAW_REG (0x0028)

RTC_TIMER_OVERFLOW_RAW The interrupt raw status for the 48-bit counter overflow. (RO)

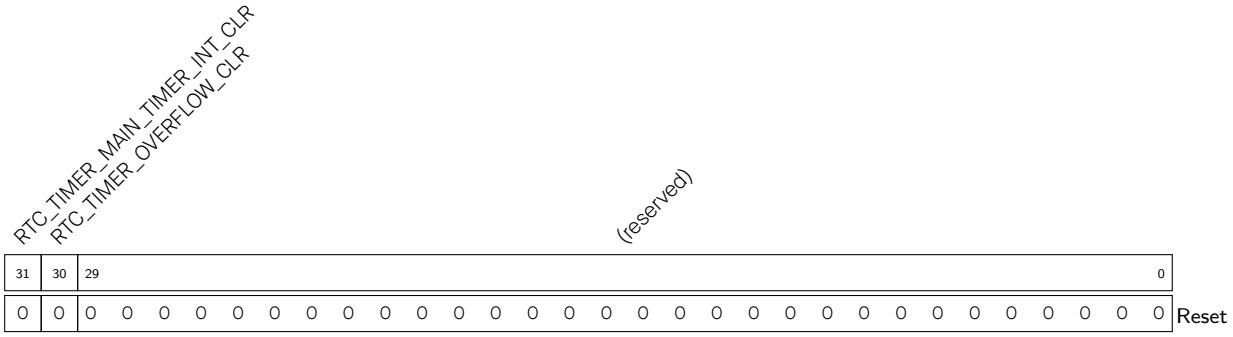
RTC_TIMER_MAIN_TIMER_INT_RAW The interrupt raw status for the RTC Timer reaching the target time 0. (RO)



Register 19.11. RTC_TIMER_INT_ST_REG (0x002C)

RTC_TIMER_OVERFLOW_ST The interrupt status for the 48-bit counter overflow. (RO)

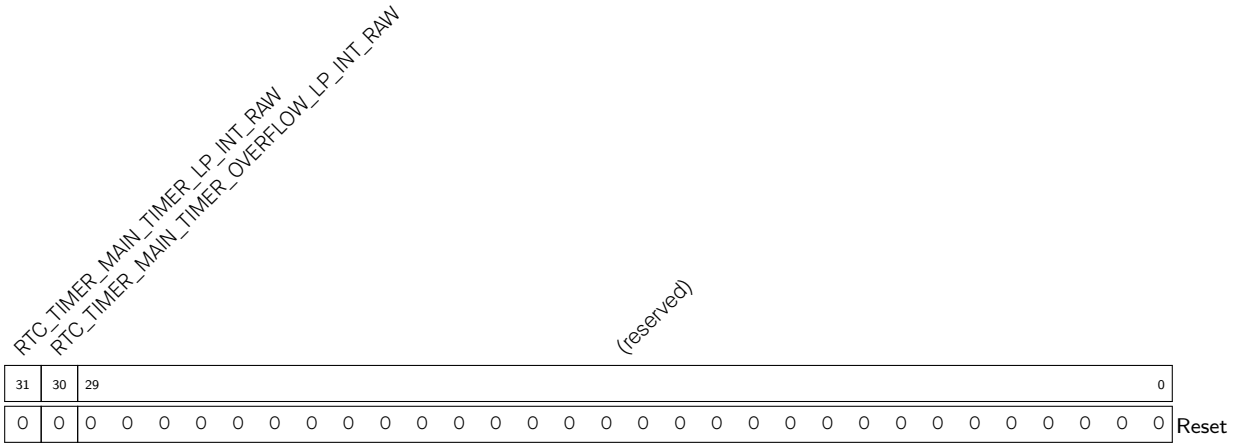
RTC_TIMER_MAIN_TIMER_INT_ST The interrupt status for the RTC Timer reaching the target time 0. (RO)



Register 19.12. RTC_TIMER_INT_ENA_REG (0x0030)

RTC_TIMER_OVERFLOW_ENA Configure to enable the interrupt for 48-bit counter overflow. (R/W)

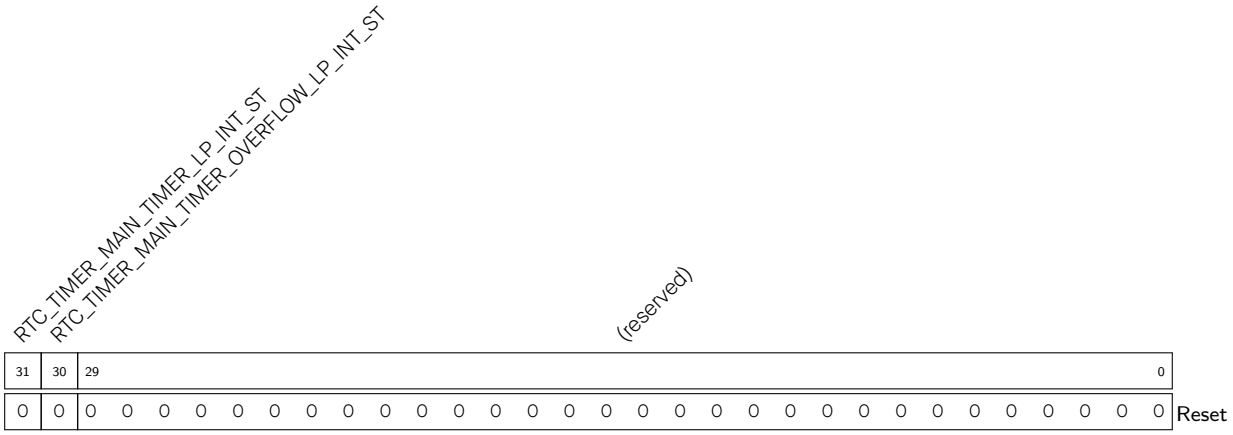
RTC_TIMER_MAIN_TIMER_INT_ENA Configure to enable the interrupt for the RTC Timer reaching the target time 0. (R/W)



Register 19.13. RTC_TIMER_INT_CLR_REG (0x0034)

RTC_TIMER_OVERFLOW_CLR Configure to clear the interrupt for 48-bit counter overflow. (WO)

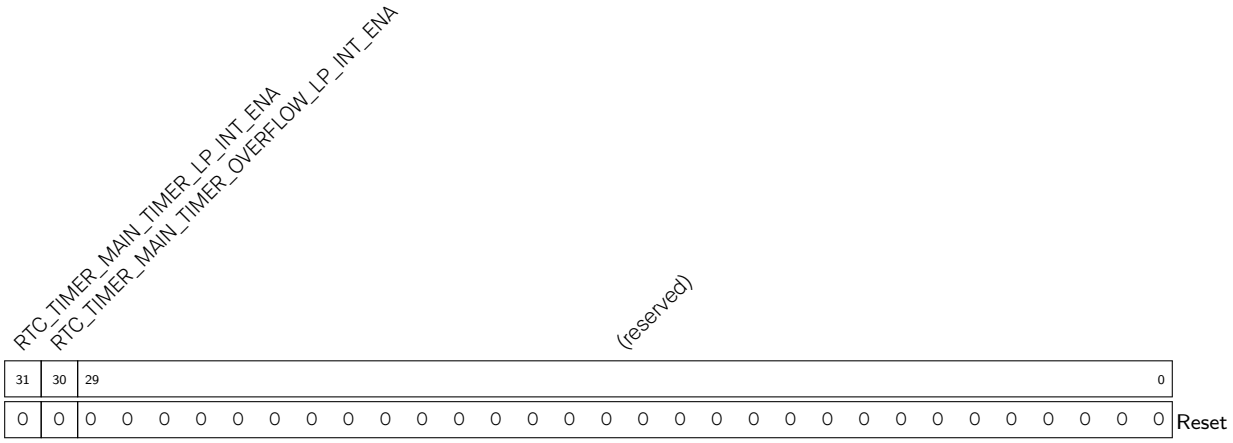
RTC_TIMER_MAIN_TIMER_INT_CLR Configure to clear the interrupt for the RTC Timer reaching the target time 0. (WO)



Register 19.14. RTC_TIMER_LP_INT_RAW_REG (0x0038)

RTC_TIMER_MAIN_TIMER_OVERFLOW_LP_INT_RAW The interrupt raw status for the 48-bit counter overflow. (RO)

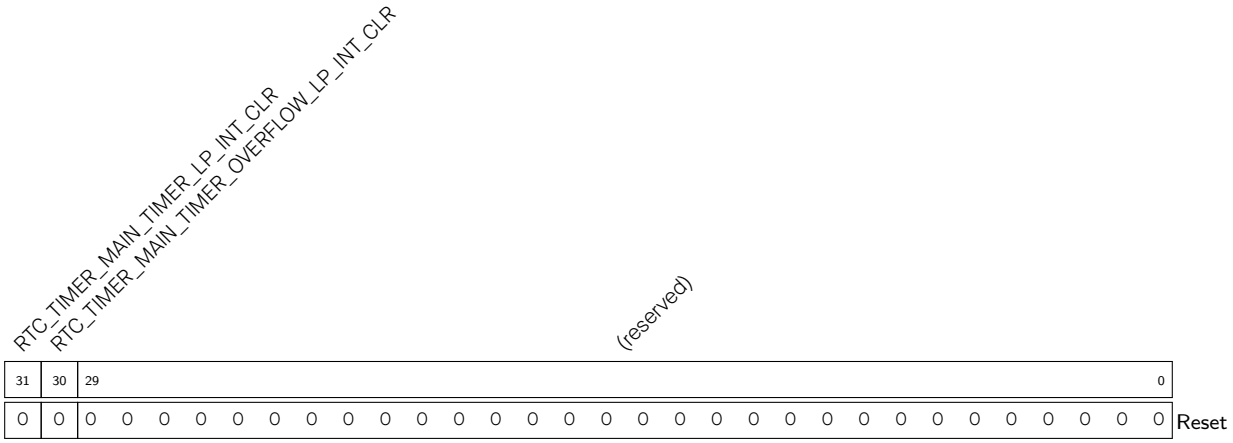
RTC_TIMER_MAIN_TIMER_LP_INT_RAW The interrupt raw status for the RTC Timer reaching the target time 1.(RO)



Register 19.15. RTC_TIMER_LP_INT_ST_REG (0x003C)

RTC_TIMER_MAIN_TIMER_OVERFLOW_LP_INT_ST The interrupt status for the 48-bit counter overflow. (RO)

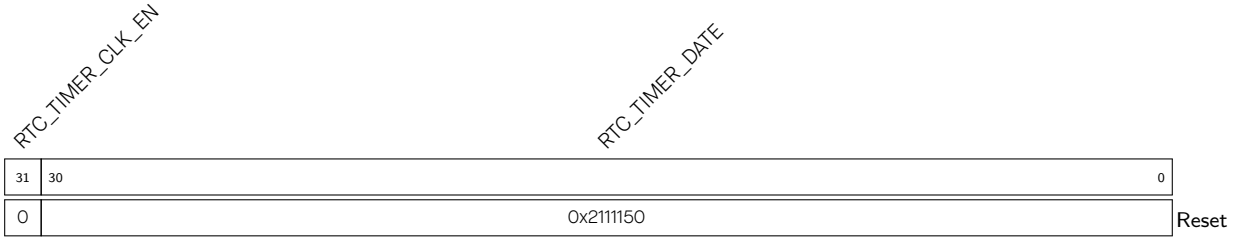
RTC_TIMER_MAIN_TIMER_LP_INT_ST The interrupt status for the RTC Timer reaching the target time 1.(RO)



Register 19.16. RTC_TIMER_LP_INT_ENA_REG (0x0040)

RTC_TIMER_MAIN_TIMER_OVERFLOW_LP_INT_ENA Configure to enable the interrupt for the 48-bit counter overflow. (R/W)

RTC_TIMER_MAIN_TIMER_LP_INT_ENA Configure to enable the interrupt for the RTC Timer reaching the target time 1. (R/W)



Register 19.17. RTC_TIMER_LP_INT_CLR_REG (0x0044)

RTC_TIMER_MAIN_TIMER_OVERFLOW_LP_INT_CLR Configure to clear the interrupt for 48-bit counter overflow. (WO)

RTC_TIMER_MAIN_TIMER_LP_INT_CLR Configure to clear the interrupt for the RTC Timer reaching the target time 1. (WO)

Register 19.18. RTC_TIMER_DATE_REG (0x03FC)

RTC_TIMER_DATE Version control register. (R/W)

RTC_TIMER_CLK_EN Configure to enable the register read/write clock. (R/W)

Chapter 20

Permission Control (PMS)

20.1 Overview

The permission control of ESP32-P4 consists of two parts: PMP (Physical Memory Protection) and APM (Access Permission Management).

PMP is located inside the HP CPUs and can control the HP CPUs' access to all address spaces. APM is an access permission management module located at the bus port, which can manage the permissions for the CPU (HP CPU0/1, LP CPU) to access the registers of all on-chip peripherals (see HP CPU PERI, HP PERI, and LP PERI in Table 20.1-1) and part of internal and external memory. The APM can also manage DMA masters like VDMA, USB OTG 2.0, to access parts of internal and external memory.

The APM module compares the configurable address range or the fixed address range, the access permissions of each address range, and the information carried on the bus like master ID, security mode, access address, access type, etc, to determine whether the access is allowed. With APM, users can precisely control the access of all masters to the memory and peripheral registers.

The distribution of management areas by PMP and APM is shown in Table 20.1-1. For HP CPU0/1, the control relationship between PMP and APM is shown in Figure 20.1-1.

Table 20.1-1. Management Areas by PMP and APM

Master / Slave	HP CPU0	HP CPU1	LP CPU	DMA Masters[1]
HP ROM[2]	PMP	PMP	HP APM	DMA APM
HP SPM	PMP	PMP	N/A	N/A
HP L2MEM[2]	PMP	PMP	HP APM	DMA APM
EXT MEM[2]	PMP	PMP	HP APM	DMA APM
Direct Access HP ROM[3]	PMP + HP APM	PMP + HP APM	N/A	N/A
Direct Access HP L2MEM[3]	PMP + HP APM	PMP + HP APM	N/A	N/A
Direct Access EXT MEM[3]	PMP + HP APM	PMP + HP APM	N/A	N/A
HP CPU PERI[4]	PMP + HP APM	PMP + HP APM	HP APM	N/A
HP PERI[5]	PMP + HP APM	PMP + HP APM	HP APM	N/A
LP PERI[6]	PMP + LP APM	PMP + LP APM	LP APM	N/A
LP ROM	N/A	N/A	N/A	N/A
LP SRAM	PMP + LP APM	PMP + LP APM	N/A	N/A

[1] DMA masters that support DMA transfers, such as VDMA, USB 2.0 OTG, MEM_MONITOR, etc.

[2]
- HP ROM (0x4FC0_0000 - 0x4FC1_FFFF)
- HP L2MEM (0x4FF0_0000 - 0x4FFB_FFFF)
- EXT MEM, including external flash (0x4000_0000 - 0x43FF_FFFF) and external RAM (0x4800_0000 - 0x4BFF_FFFF)

[3] "Direct access" means HP CPU0/1 accesses internal and external memory mapped into the following address spaces without going through the cache:
- HP ROM (0x8FC0_0000 - 0x8FC1_FFFF)
- HP L2MEM (0x8FF0_0000 - 0x8FFB_FFFF)
- EXT MEM, including external flash (0x8000_0000 - 0x83FF_FFFF) and external RAM (0x8800_0000 - 0x8BFF_FFFF)

[4] HP CPU peripheral registers (0x3FF0_0000 - 0x3FF1_FFFF)

[5] HP system peripheral registers (0x5000_0000 - 0x500F_FFFF)

[6] LP system peripheral registers (0x5011_0000 - 0x5012_FFFF)

[7] As can be seen from the table, APM includes HP APM, LP APM, and DMA APM, which will be described in the following sections.

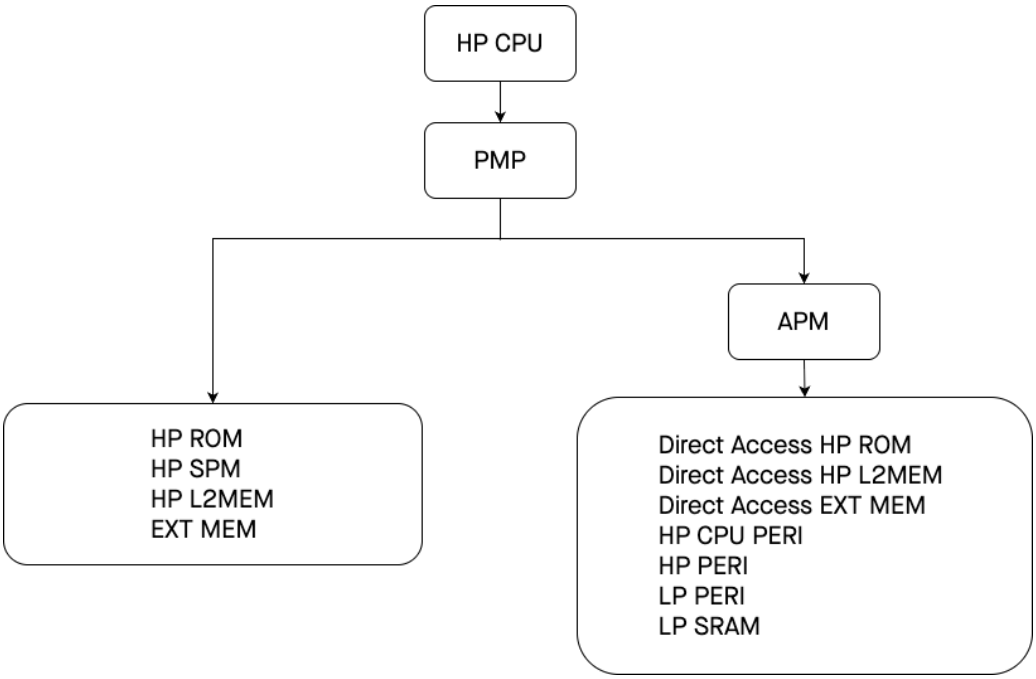


Figure 20.1-1. PMP-APM Management Relation

The diagram illustrates that when the HP CPUs access HP ROM, HP SPM, HP L2MEM, and EXT MEM, the access paths are solely managed by PMP. On the other hand, when the HP CPUs access the peripheral registers, HP ROM, HP L2MEM, and EXT MEM without going through the cache, the access paths are controlled by both PMP and APM. If the PMP check fails, the APM permission control will not be triggered.

PMP-related registers are located inside the HP CPUs and can be read or configured with special instructions. For how to configure PMP, please refer to Chapter 2 *High-Performance CPU* > 2.10.1 *Standard Physical Memory Protection*.

The following sections will provide a detailed introduction to the features, functions, and configurations of the APM module. When referring to HP CPU0/1, accessing HP ROM/HP L2MEM/EXT MEM always means direct access to HP ROM/HP L2MEM/EXT MEM.

20.2 Features

The APM module has the following features:

- Up to 32 configurable address ranges for each DMA master
- Access permission management for each CPU core to access internal memory, external memory, and peripheral registers
- Support for interrupts
- Support for exception information record

20.3 Functional Description

20.3.1 Architecture

The APM module contains three parts and five register modules as follows:

- **DMA APM**, containing register group HP_DMA_PMS_REG, responsible for:
  - configuring up to 32 address regions for DMA masters
  - managing the access permission to each address region for each DMA master
- **HP APM**, containing register groups HP_PERI_PMS_REG and LP2HP_PERI_PMS_REG, responsible for managing the access permissions to peripheral registers (HP CPU PERI, HP PERI), internal memory (HP ROM, HP L2MEM), and external memory (EXT MEM) in the HP system, specifically,
  - managing the access permissions for HP CPU0/1 in user mode to access all the above-mentioned slaves
  - managing the access permissions for HP CPU0/1 in machine mode to access all the above-mentioned slaves
  - managing the access permissions for LP CPU in machine mode to access all the above-mentioned slaves
- **LP APM**, containing register groups LP_PERI_PMS_REG and HP2LP_PERI_PMS_REG, responsible for managing the access permissions to peripheral registers (LP PERI) and internal memory (LP SRAM) in the LP system, specifically,
  - managing the access permissions for HP CPU0/1 in user mode to access LP PERI and LP SRAM
  - managing the access permissions for HP CPU0/1 in machine mode to access LP PERI and LP SRAM
  - managing the access permissions for LP CPU in machine mode to access LP PERI

Figure 20.3-1 shows the access paths managed by APM and the corresponding register groups.

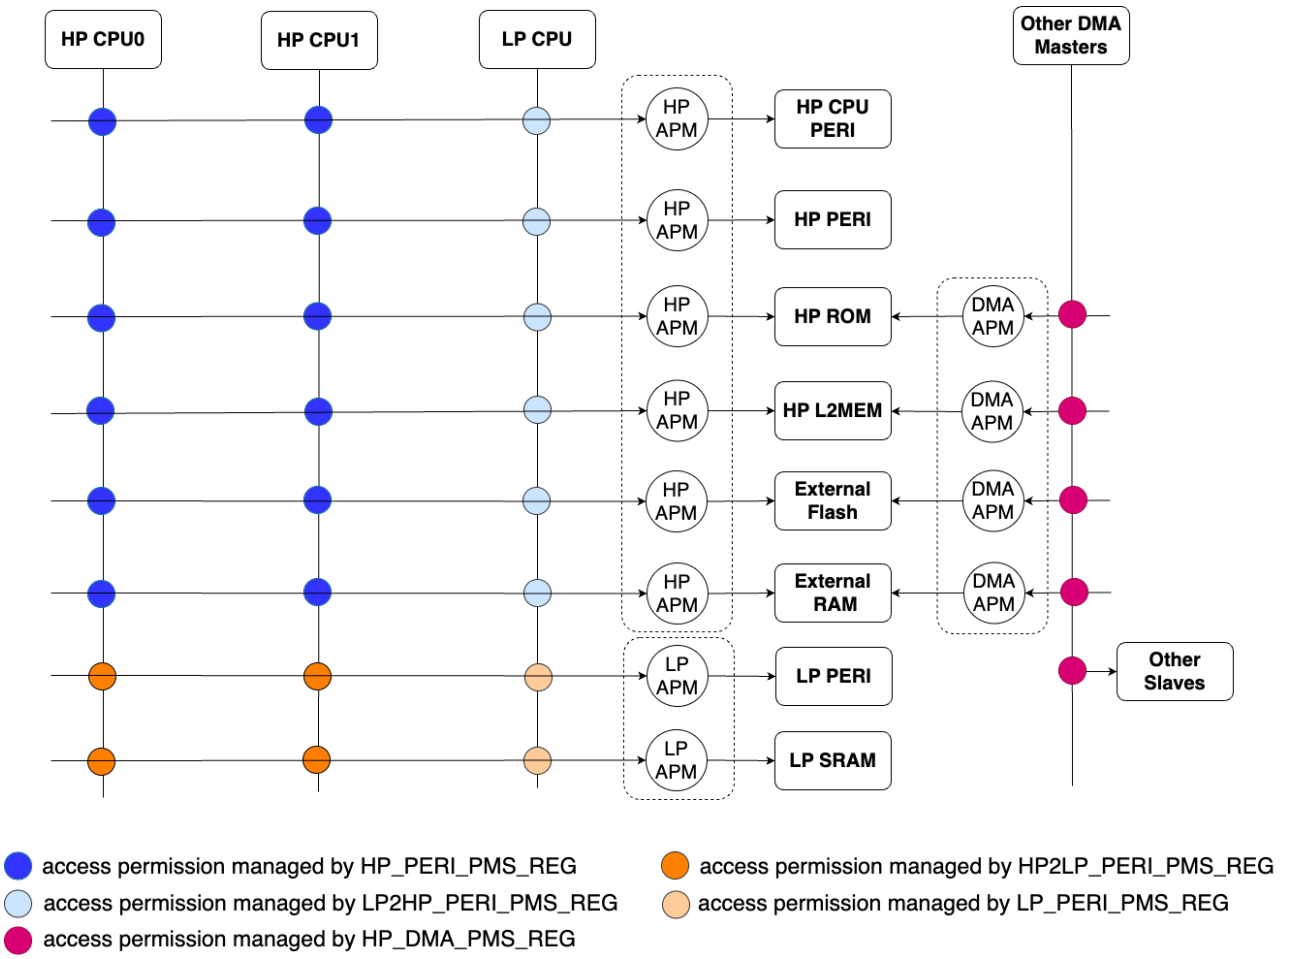

Figure 20.3-1. APM Architecture

Note:

- For register group names "HP2LP" and "LP2HP", the "HP" refers to HP CPU0/1, and "LP" refers to LP CPU.
- From Table 20.1-1, it can be seen that HP CPU and LP CPU access different address spaces of HP ROM, HP L2MEM, external flash, and external RAM. For HP CPU0/1, HP APM manages their direct access to internal and external memory without going through the cache.
- LP_PERI_PMS_REG includes eight additional configurable address ranges for HP APM and LP APM to manage the access permissions to peripheral registers, including HP CPU PERI, HP PERI, and LP PERI.

20.3.2 Address Ranges and Permissions Management

APM manages address ranges, which can be fixed or configurable. DMA APM can manage up to 32 configurable address ranges. In addition to the fixed address ranges, HP APM and LP APM can also manage in total eight configurable address ranges.

20.3.2.1 Address Ranges Managed by HP APM and LP APM

In the access paths controlled by HP APM and LP APM, the internal memory and external memory use fixed address ranges for access control, while peripheral registers not only support fixed address ranges permission control but also support eight configurable address ranges.

- Fixed address ranges
  - The fixed address ranges are the valid address spaces of peripheral registers, internal memory, and external memory. See the table notes under Table 20.1-1 for the address ranges of internal and external memory. Refer to Chapter 9 *System and Memory* > Table 9.3-2 for the address ranges of each peripheral.
  - To manage access to the fixed address ranges, please refer to Figure 20.3-1 for the access paths and their corresponding register groups.
- Configurable Address Range
  - APM can configure eight address ranges with PMS_PERI_REGION*n*/*m*_LOW_REG and PMS_PERI_REGION*n*/*m*_HIGH_REG (*n*/*m* = 0 ~ 7) in LP_PERI_PMS_REG. These configurable address ranges can be used by HP CPUs and LP CPU to access all on-chip peripheral registers (HP CPU PERI, HP PERI, LP PERI).
  - The access permissions are managed by PMS_PERI_REGION_PMS_REG in LP_PERI_PMS_REG.

When managing access permissions to peripheral registers, the permission management for the configurable address range should precede that of the fixed address range. Specifically:

- If the access address is within the configurable address range, then APM will check if this access is permitted to access the configurable address range.
  - If permitted, APM will continue to check if the access is permitted to the fixed address range.
  - If not permitted, the access will be denied and skip the permission check to the fixed address range.
- If the access address is outside the configurable address range, then it will skip the configurable address range check, but will continue to the fixed address range check.
- The management of configurable address ranges is a supplement to the management of fixed address ranges. For example, users can configure access permissions for a fixed address range, and deny access to two configurable ranges within the fixed range, resulting in a fixed address range containing two access-disabled address ranges.

20.3.2.2 Address Ranges Managed by DMA APM

The register group HP_DMA_PMS_REG provides 32 sets of registers (PMS_DMA_REGION*n*_LOW_REG ~ PMS_DMA_REGION*n*_HIGH_REG, *n* = 0 ~ 31) to configure address ranges for DMA masters to access. Note that since the address must be aligned to 4K bytes, the lowest 12 bits are set to 0.

HP_DMA_PMS_REG provides separate read and write permissions for each DMA master to access each address range.

20.4 Programming Procedure

As HP CPUs can work in either user mode or machine mode, HP APM and LP APM grant specific access permissions for each work mode. Therefore, users need to configure the work mode for HP CPUs first in order for the HP CPUs to access internal memory, external memory, and peripheral registers.

Since LP CPU only supports machine mode, HP APM and LP APM grant access permissions for the machine mode of LP CPU.

DMA masters can access slaves regardless of the CPUs' work mode. DMA APM provides separate read and write permissions for each DMA master.

20.4.1 Configuring Access Permissions for HP CPU0/1

The configuration process for HP CPU0/1 accessing internal memory, external memory, or peripheral registers is as follows:

1. Configure user mode or machine mode for HP CPU0/1. For how to configure the work mode, please refer to RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10.
2. If accessing peripheral registers, eight additional address ranges can be configured, please refer to Section 20.3.2 for details.
3. Configure access permissions:
   - Configure the access permissions to internal memory (HP L2MEM and HP ROM), external memory (External RAM and flash), and peripheral registers (HP PERI and HP CPU PERI) in the HP system through HP_PERI_PMS_REG:
     - Configure the permission of HP CPU*n* accessing the *MODULE_NAME* module in *MODE_NAME* mode using PMS_CORE*n*_*MODE_NAME*_*MODULE_NAME*_ALLOW, for example PMS_CORE*n*_MM_PSRAM_ALLOW.
   - Configure the access permissions to LP SRAM and LP PERI through HP2LP_PERI_PMS_REG:
     - Configure the permission of HP CPU*n* accessing the *MODULE_NAME* module in *MODE_NAME* mode using PMS_HP_CORE*n*_*MODE_NAME*_*MODULE_NAME*_ALLOW, for example PMS_HP_CORE*n*_MM_LP_SYSREG_ALLOW.

20.4.2 Configuring Access Permissions for LP CPU

LP CPU only supports machine mode. The configuration process for LP CPU accessing internal memory, external memory, or peripheral registers is as follows:

1. If accessing peripheral registers, eight additional address ranges can be configured, please refer to Section 20.3.2 for details.
2. Configure access permissions:
   - Configure the access permissions to internal memory (HP L2MEM and HP ROM), external memory (External RAM and flash), and peripheral registers (HP PERI and HP CPU PERI) in the HP system through LP2HP_PERI_PMS_REG:
     - Configure the permission of LP CPU accessing the *MODULE_NAME* module in machine mode using PMS_LP_MM_*MODULE_NAME*_ALLOW, for example PMS_LP_MM_PSRAM_ALLOW.
   - Configure the access permissions to peripheral registers (LP PERI) in the LP system through LP_PERI_PMS_REG:
     - Configure the permission of LP CPU accessing the *MODULE_NAME* module in machine mode using PMS_LP_MM_*MODULE_NAME*_ALLOW, for example PMS_LP_MM_LP_SYSREG_ALLOW.

20.4.3 Configuring Access Permission for DMA Masters

The configuration process for DMA masters accessing internal memory, external memory, and other address spaces is as follows:

1. Configure the address ranges accessible to all DMA masters:
   - Configure the high 20 bits of the starting address of region*n* using PMS_DMA_REGION*n*_LOW_REG.
   - Configure the high 20 bits of the ending address of region*n* using PMS_DMA_REGION*n*_HIGH_REG.
2. Configure the read and write permissions for each DMA master (*DMA_MASTER*) to access each address range:
   - Configure the read permissions using PMS_*DMA_MASTER*_PMS_R_REG, such as PMS_DMA_GMAC_PMS_R_REG.
   - Configure the write permissions using PMS_*DMA_MASTER*_PMS_W_REG, such as PMS_DMA_GMAC_PMS_W_REG.

20.5 Illegal Access and Interrupts

When the APM module manages access paths, it parses the information carried on the bus (e.g., master ID, access direction (read or write), access address, and working mode) and then determines the access permission. When the APM module confirms that the access lacks permission, ESP32-P4 will consider it as an unauthorized access and will take the following actions:

- Reject the access request and provide an error response.
- HP APM will trigger ICM_SYS_REG_INT interrupt signal.
- DMA APM will trigger ICM_SYS_REG_INT interrupt signal.
- LP APM will trigger LP_SYSREG_INT interrupt signal.

These interrupt signals are generated by the internal interrupt sources of the APM module. Table 20.5-1 lists the internal interrupt sources, interrupt trigger conditions, and the generated interrupt signals.

Table 20.5-1. APM Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
ICM_CPU_ADDRHOLE_INTR	Triggered when HP APM detects unauthorized access; or when DMA APM detects unauthorized access from USB 2.0 High-Speed OTG, USB 2.0 Full-Speed OTG, EMAC, SDMMC, Trace0/1, GDMA-AHB, L2MEM Monitor, or SPM Monitor.	ICM_SYS_REG_INT
ICM_SYS_ADDRHOLE_INTR	Triggered when DMA APM detects unauthorized access from VDMA, GDMA-AXI, 2D-DMA, or H264 DMA.	ICM_SYS_REG_INT
LP_ADDRHOLE_INTR	Triggered when LP APM detects unauthorized access.	LP_SYSREG_INTR

APM automatically records relevant information about illegal accesses, including master ID, access direction (read or write), access address, illegal access flags, etc. All this information can be retrieved from the relevant registers described in Chapter *21 System Registers (SYSREG)*.

20.6 Register Summary

20.6.1 HP_DMA_PMS_REG

The addresses in this section are relative to the HP_DMA_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Version Control Registers			
PMS_DMA_DATE_REG	Version control register	0x0000	R/W
Clock Gating Registers			
PMS_DMA_CLK_EN_REG	Clock gating register	0x0004	R/W
Region Configuration Registers			
PMS_DMA_REGION0_LOW_REG	Region0 start address configuration register	0x0008	R/W
PMS_DMA_REGION0_HIGH_REG	Region0 end address configuration register	0x000C	R/W
PMS_DMA_REGION1_LOW_REG	Region1 start address configuration register	0x0010	R/W
PMS_DMA_REGION1_HIGH_REG	Region1 end address configuration register	0x0014	R/W
PMS_DMA_REGION2_LOW_REG	Region2 start address configuration register	0x0018	R/W
PMS_DMA_REGION2_HIGH_REG	Region2 end address configuration register	0x001C	R/W
PMS_DMA_REGION3_LOW_REG	Region3 start address configuration register	0x0020	R/W
PMS_DMA_REGION3_HIGH_REG	Region3 end address configuration register	0x0024	R/W
PMS_DMA_REGION4_LOW_REG	Region4 start address configuration register	0x0028	R/W
PMS_DMA_REGION4_HIGH_REG	Region4 end address configuration register	0x002C	R/W
PMS_DMA_REGION5_LOW_REG	Region5 start address configuration register	0x0030	R/W
PMS_DMA_REGION5_HIGH_REG	Region5 end address configuration register	0x0034	R/W
PMS_DMA_REGION6_LOW_REG	Region6 start address configuration register	0x0038	R/W
PMS_DMA_REGION6_HIGH_REG	Region6 end address configuration register	0x003C	R/W
PMS_DMA_REGION7_LOW_REG	Region7 start address configuration register	0x0040	R/W

Name	Description	Address	Access
PMS_DMA_REGION7_HIGH_REG	Region7 end address configuration register	0x0044	R/W
PMS_DMA_REGION8_LOW_REG	Region8 start address configuration register	0x0048	R/W
PMS_DMA_REGION8_HIGH_REG	Region8 end address configuration register	0x004C	R/W
PMS_DMA_REGION9_LOW_REG	Region9 start address configuration register	0x0050	R/W
PMS_DMA_REGION9_HIGH_REG	Region9 end address configuration register	0x0054	R/W
PMS_DMA_REGION10_LOW_REG	Region10 start address configuration register	0x0058	R/W
PMS_DMA_REGION10_HIGH_REG	Region10 end address configuration register	0x005C	R/W
PMS_DMA_REGION11_LOW_REG	Region11 start address configuration register	0x0060	R/W
PMS_DMA_REGION11_HIGH_REG	Region11 end address configuration register	0x0064	R/W
PMS_DMA_REGION12_LOW_REG	Region12 start address configuration register	0x0068	R/W
PMS_DMA_REGION12_HIGH_REG	Region12 end address configuration register	0x006C	R/W
PMS_DMA_REGION13_LOW_REG	Region13 start address configuration register	0x0070	R/W
PMS_DMA_REGION13_HIGH_REG	Region13 end address configuration register	0x0074	R/W
PMS_DMA_REGION14_LOW_REG	Region14 start address configuration register	0x0078	R/W
PMS_DMA_REGION14_HIGH_REG	Region14 end address configuration register	0x007C	R/W
PMS_DMA_REGION15_LOW_REG	Region15 start address configuration register	0x0080	R/W
PMS_DMA_REGION15_HIGH_REG	Region15 end address configuration register	0x0084	R/W
PMS_DMA_REGION16_LOW_REG	Region16 start address configuration register	0x0088	R/W
PMS_DMA_REGION16_HIGH_REG	Region16 end address configuration register	0x008C	R/W
PMS_DMA_REGION17_LOW_REG	Region17 start address configuration register	0x0090	R/W
PMS_DMA_REGION17_HIGH_REG	Region17 end address configuration register	0x0094	R/W

Name	Description	Address	Access
PMS_DMA_REGION18_LOW_REG	Region18 start address configuration register	0x0098	R/W
PMS_DMA_REGION18_HIGH_REG	Region18 end address configuration register	0x009C	R/W
PMS_DMA_REGION19_LOW_REG	Region19 start address configuration register	0x00A0	R/W
PMS_DMA_REGION19_HIGH_REG	Region19 end address configuration register	0x00A4	R/W
PMS_DMA_REGION20_LOW_REG	Region20 start address configuration register	0x00A8	R/W
PMS_DMA_REGION20_HIGH_REG	Region20 end address configuration register	0x00AC	R/W
PMS_DMA_REGION21_LOW_REG	Region21 start address configuration register	0x00B0	R/W
PMS_DMA_REGION21_HIGH_REG	Region21 end address configuration register	0x00B4	R/W
PMS_DMA_REGION22_LOW_REG	Region22 start address configuration register	0x00B8	R/W
PMS_DMA_REGION22_HIGH_REG	Region22 end address configuration register	0x00BC	R/W

PMS_DMA_AXI_PDMA_DUMMY_W_PMS_REG	GDMA-AXI Dummy write permission control register	0x0220	R/W

20.6.2 HP_PERI_PMS_REG

The addresses in this section are relative to the HP_PERI_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Version Control Registers			
PMS_HP_PERI_PMS_DATE_REG	Version control register	0x0000	R/W
Clock Gating Registers			
PMS_HP_PERI_PMS_CLK_EN_REG	Clock gating register	0x0004	R/W
HP CPU Permission Control Registers			
PMS_COREO_MM_HP_PERI_PMS_REG0_REG	Permission control register0 for HP CPU0 in machine mode	0x0008	R/W
PMS_COREO_MM_HP_PERI_PMS_REG1_REG	Permission control register1 for HP CPU0 in machine mode	0x000C	R/W
PMS_COREO_MM_HP_PERI_PMS_REG2_REG	Permission control register2 for HP CPU0 in machine mode	0x0010	R/W
PMS_COREO_MM_HP_PERI_PMS_REG3_REG	Permission control register3 for HP CPU0 in machine mode	0x0014	R/W
PMS_COREO_UM_HP_PERI_PMS_REG0_REG	Permission control register0 for HP CPU0 in user mode	0x0018	R/W
PMS_COREO_UM_HP_PERI_PMS_REG1_REG	Permission control register1 for HP CPU0 in user mode	0x001C	R/W
PMS_COREO_UM_HP_PERI_PMS_REG2_REG	Permission control register2 for HP CPU0 in user mode	0x0020	R/W
PMS_COREO_UM_HP_PERI_PMS_REG3_REG	Permission control register3 for HP CPU0 in user mode	0x0024	R/W
PMS_CORE1_MM_HP_PERI_PMS_REG0_REG	Permission control register0 for HP CPU1 in machine mode	0x0028	R/W
PMS_CORE1_MM_HP_PERI_PMS_REG1_REG	Permission control register1 for HP CPU1 in machine mode	0x002C	R/W
PMS_CORE1_MM_HP_PERI_PMS_REG2_REG	Permission control register2 for HP CPU1 in machine mode	0x0030	R/W

Name	Description	Address	Access
PMS_CORE1_MM_HP_PERI_PMS_REG3_REG	Permission control register3 for HP CPU1 in machine mode	0x0034	R/W
PMS_CORE1_UM_HP_PERI_PMS_REG0_REG	Permission control register0 for HP CPU1 in user mode	0x0038	R/W
PMS_CORE1_UM_HP_PERI_PMS_REG1_REG	Permission control register1 for HP CPU1 in user mode	0x003C	R/W
PMS_CORE1_UM_HP_PERI_PMS_REG2_REG	Permission control register2 for HP CPU1 in user mode	0x0040	R/W
PMS_CORE1_UM_HP_PERI_PMS_REG3_REG	Permission control register3 for HP CPU1 in user mode	0x0044	R/W

20.6.3 LP2HP_PERI_PMS_REG

The addresses in this section are relative to the LP2HP_PERI_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Version Control Registers			
PMS_LP2HP_PERI_PMS_DATE_REG	Version control register	0x0000	R/W
Clock Gating Registers			
PMS_LP2HP_PERI_PMS_CLK_EN_REG	Clock gating register	0x0004	R/W
LP CPU Permission Control Registers			
PMS_LP_MM_PMS_REG0_REG	Permission control register0 for the LP CPU in machine mode	0x0008	R/W
PMS_LP_MM_PMS_REG1_REG	Permission control register1 for the LP CPU in machine mode	0x0030	R/W
PMS_LP_MM_PMS_REG2_REG	Permission control register2 for the LP CPU in machine mode	0x00A4	R/W
PMS_LP_MM_PMS_REG3_REG	Permission control register3 for the LP CPU in machine mode	0x011C	R/W

20.6.4 LP_PERI_PMS_REG

The addresses in this section are relative to the LP_PERI_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Version Control Registers			

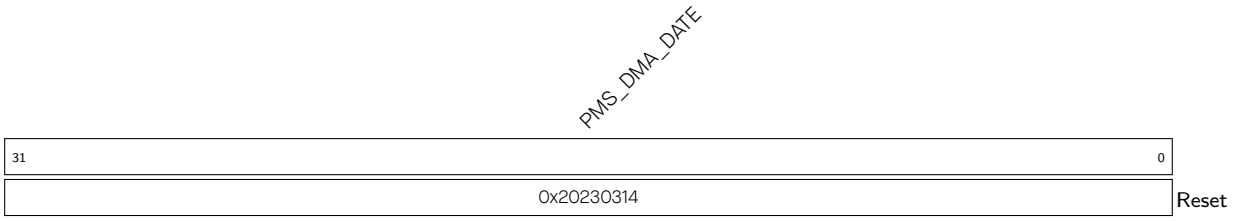
Name	Description	Address	Access
PMS_LP_PERI_PMS_DATE_REG	Version control register	0x0000	R/W
Clock Gating Registers			
PMS_LP_PERI_PMS_CLK_EN_REG	Clock gating register	0x0004	R/W
LP CPU Permission Control Registers			
PMS_LP_MM_LP_PERI_PMS_REG0_REG	Permission control register0 for LP CPU in machine mode	0x0008	R/W
Configurable Address Range Configuration Registers			
PMS_PERI_REGION0_LOW_REG	Region0 start address configuration register	0x000C	R/W
PMS_PERI_REGION0_HIGH_REG	Region0 end address configuration register	0x0010	R/W
PMS_PERI_REGION1_LOW_REG	Region1 start address configuration register	0x0014	R/W
PMS_PERI_REGION_PMS_REG	Permission control of access to address region 0-1	0x001C	R/W
PMS_PERI_REGION_2_TO_7_PMS_REG	Permission control of access to address region 2-7	0x0020	R/W
PMS_PERI_REGION2_LOW_REG	Address region 2 start address configuration register	0x0024	R/W
PMS_PERI_REGION2_HIGH_REG	Address region 2 end address configuration register	0x0028	R/W
PMS_PERI_REGION3_LOW_REG	Address region 3 start address configuration register	0x002C	R/W
PMS_PERI_REGION3_HIGH_REG	Address region 3 end address configuration register	0x0030	R/W
PMS_PERI_REGION4_LOW_REG	Address region 4 start address configuration register	0x0034	R/W
PMS_PERI_REGION4_HIGH_REG	Address region 4 end address configuration register	0x0038	R/W
PMS_PERI_REGION5_LOW_REG	Address region 5 start address configuration register	0x003C	R/W
PMS_PERI_REGION5_HIGH_REG	Address region 5 end address configuration register	0x0040	R/W
PMS_PERI_REGION6_LOW_REG	Address region 6 start address configuration register	0x0044	R/W
PMS_PERI_REGION6_HIGH_REG	Address region 6 end address configuration register	0x0048	R/W
PMS_PERI_REGION7_LOW_REG	Address region 7 start address configuration register	0x004C	R/W
PMS_PERI_REGION7_HIGH_REG	Address region 7 end address configuration register	0x0050	R/W
PMS_PERI_REGION1_HIGH_REG	Region1 end address configuration register	0x0018	R/W

20.6.5 HP2LP_PERI_PMS_REG

The addresses in this section are relative to the HP2LP_PERI_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

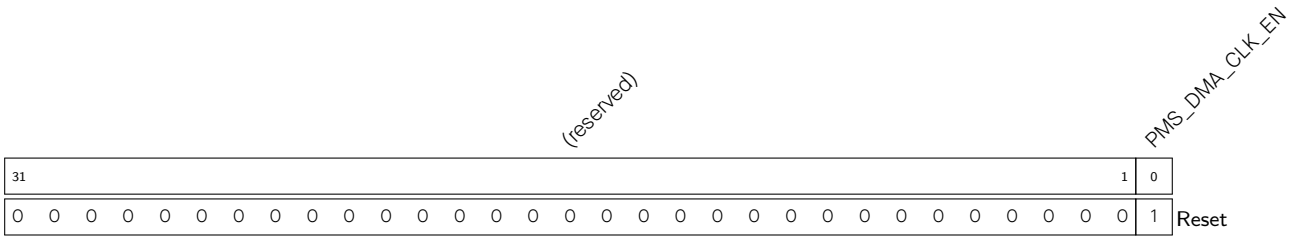
Name	Description	Address	Access
Version Control Registers			
PMS_HP2LP_PERI_PMS_DATE_REG	Version control register	0x0000	R/W
Clock Gating Registers			
PMS_HP2LP_PERI_PMS_CLK_EN_REG	Clock gating register	0x0004	R/W
HP CPU Permission Control Registers			
PMS_HP_CORE0_MM_PMS_REG0_REG	Permission control register0 for HP CPU0 in machine mode	0x0008	R/W
PMS_HP_CORE0_UM_PMS_REG0_REG	Permission control register0 for HP CPU0 in user mode	0x000C	R/W
PMS_HP_CORE1_MM_PMS_REG0_REG	Permission control register0 for HP CPU1 in machine mode	0x0010	R/W
PMS_HP_CORE1_UM_PMS_REG0_REG	Permission control register0 for HP CPU1 in user mode	0x0014	R/W



20.7 Registers

20.7.1 HP_DMA_PMS_REG

The addresses in this section are relative to the HP_DMA_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 20.1. PMS_DMA_DATE_REG (0x0000)

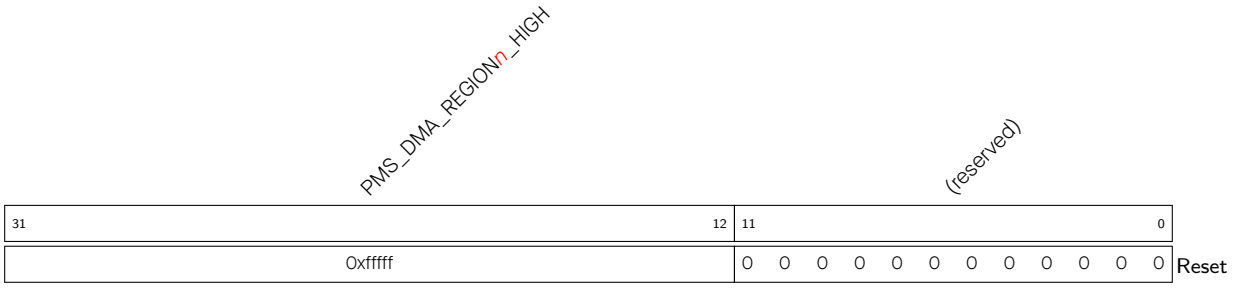
PMS_DMA_DATE Version control register. (R/W)

Register 20.2. PMS_DMA_CLK_EN_REG (0x0004)

PMS_DMA_CLK_EN Configures whether to keep the clock always on.

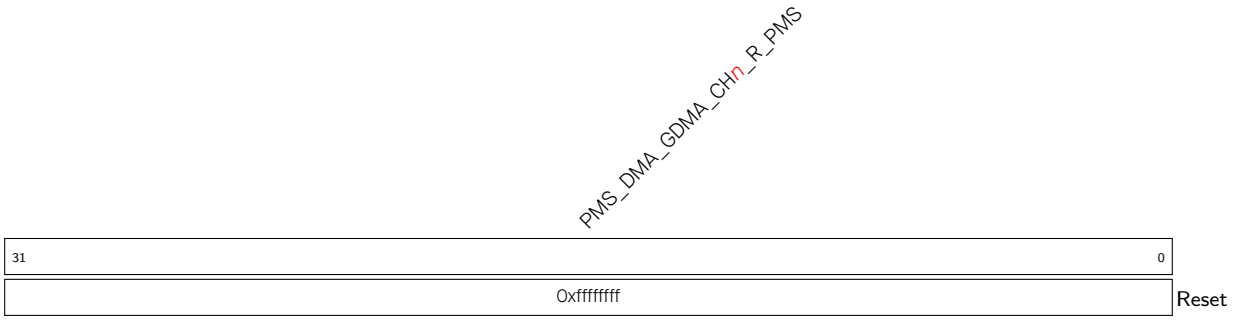
0: Enable automatic clock gating.

1: Keep the clock always on.



(R/W)

Register 20.3. PMS_DMA_REGION*n*_LOW_REG (*n*: 0-31) (0x0008+0x8n*)**

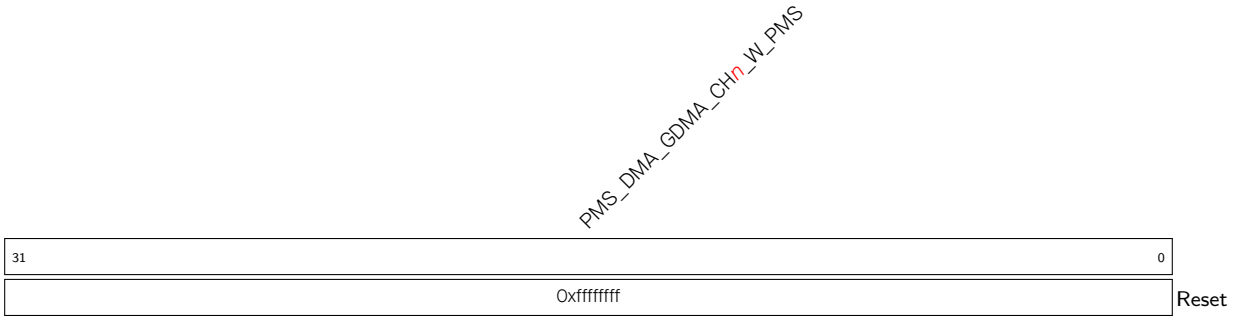


PMS_DMA_REGION*n*_LOW Configures the high 20 bits of the start address for region*n*. (R/W)

Register 20.4. PMS_DMA_REGIONn_HIGH_REG (n: 0-31) (0x000C+0x8*n)

PMS_DMA_REGIONn_HIGH Configures the high 20 bits of the end address for regionn. (R/W)

Register 20.5. PMS_DMA_GDMA_CHn_R_PMS_REG (n: 0-3) (0x0108+0x8*n)



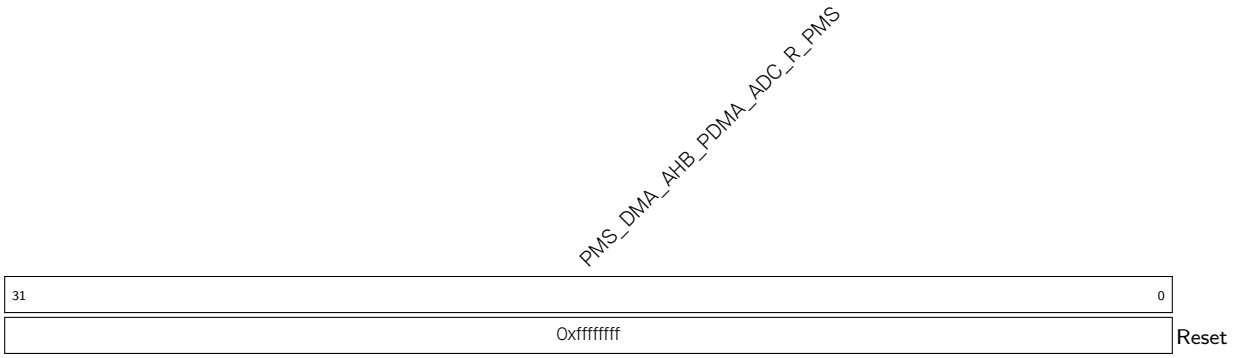
PMS_DMA_GDMA_CHn_R_PMS Configures the permission for GDMA chn to read 32 address regions. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.6. PMS_DMA_GDMA_CHn_W_PMS_REG (n: 0-3) (0x010C+0x8*n)



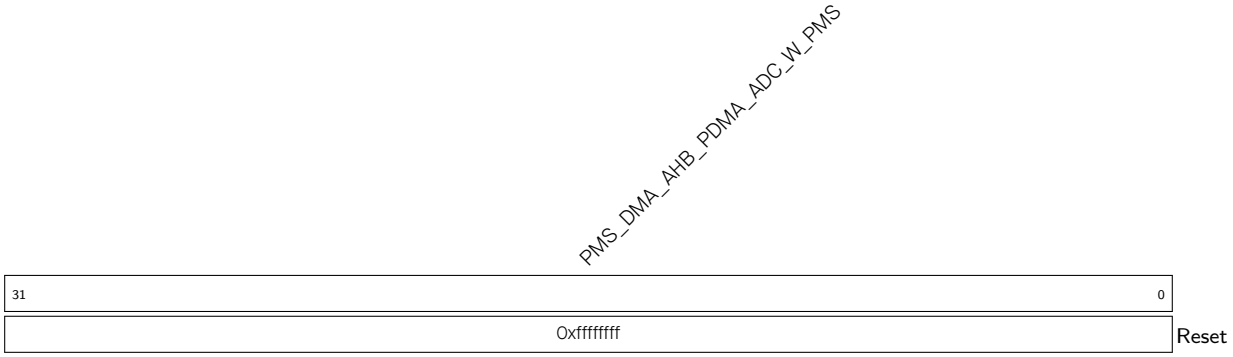
PMS_DMA_GDMA_CHn_W_PMS Configures the permission for GDMA chn to write 32 address regions. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.7. PMS_DMA_AHB_PDMA_ADC_R_PMS_REG (0x0128)



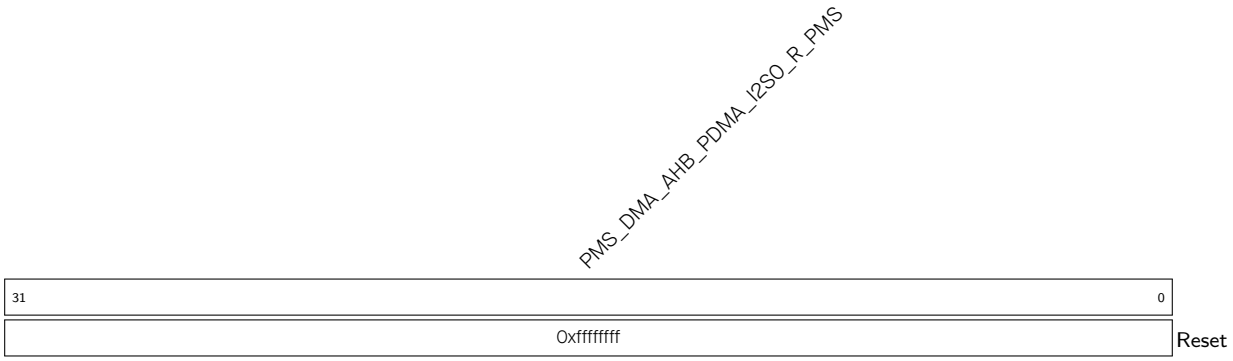
PMS_DMA_AHB_PDMA_ADC_R_PMS Configures GDMA-AHB permission to read 32 address ranges requested by ADC. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.8. PMS_DMA_AHB_PDMA_ADC_W_PMS_REG (0x012C)



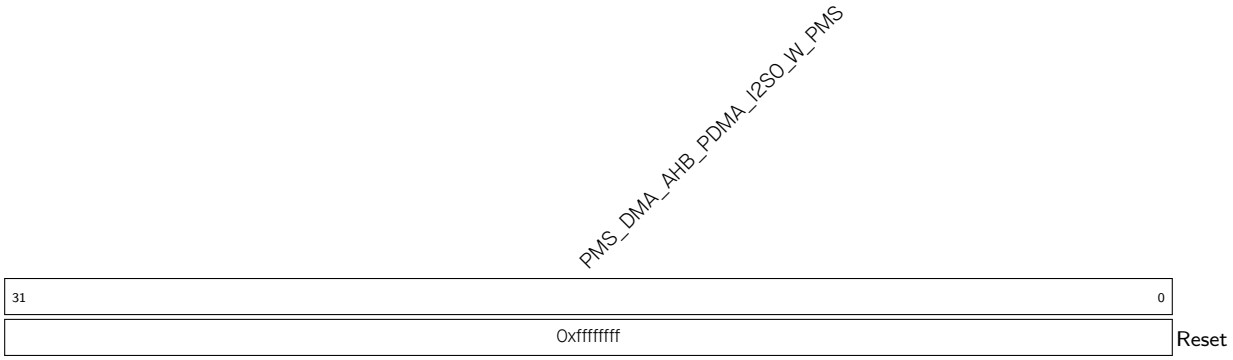
PMS_DMA_AHB_PDMA_ADC_W_PMS Configures GDMA-AHB permission to write 32 address ranges requested by ADC. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.9. PMS_DMA_AHB_PDMA_I2S0_R_PMS_REG (0x0130)



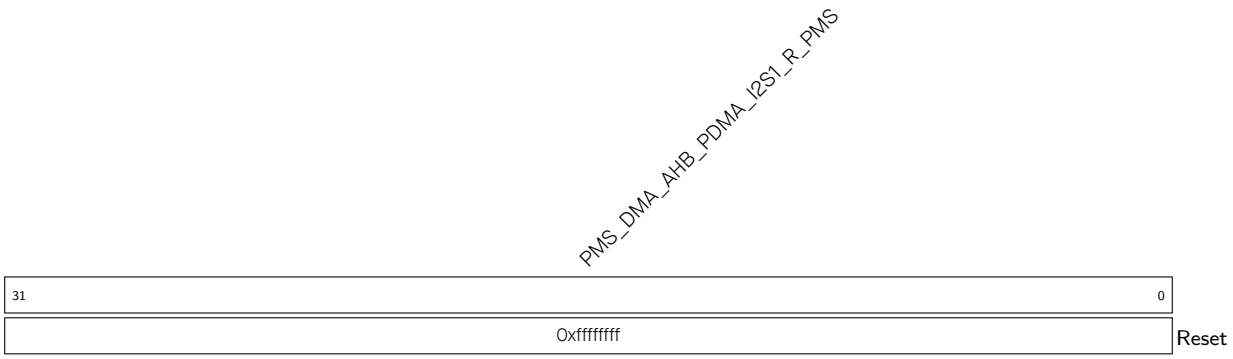
PMS_DMA_AHB_PDMA_I2S0_R_PMS Configures GDMA-AHB permission to read 32 address ranges requested by I2S0. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.10. PMS_DMA_AHB_PDMA_I2S0_W_PMS_REG (0x0134)



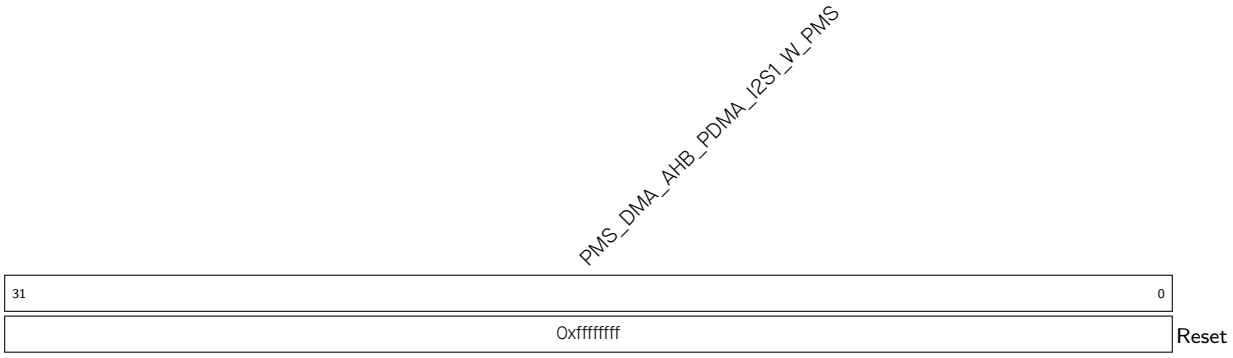
PMS_DMA_AHB_PDMA_I2S0_W_PMS Configures GDMA-AHB permission to write 32 address ranges requested by I2S0. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.11. PMS_DMA_AHB_PDMA_I2S1_R_PMS_REG (0x0138)



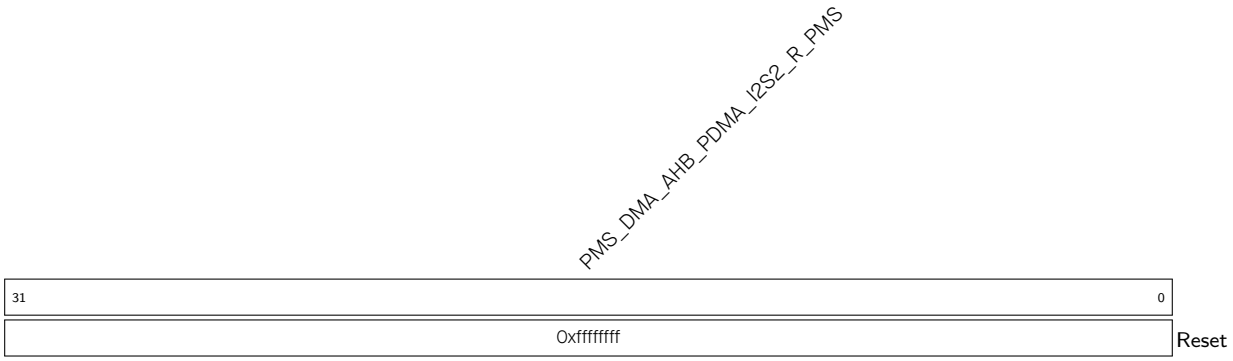
PMS_DMA_AHB_PDMA_I2S1_R_PMS Configures GDMA-AHB permission to read 32 address ranges requested by I2S1. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.12. PMS_DMA_AHB_PDMA_I2S1_W_PMS_REG (0x013C)



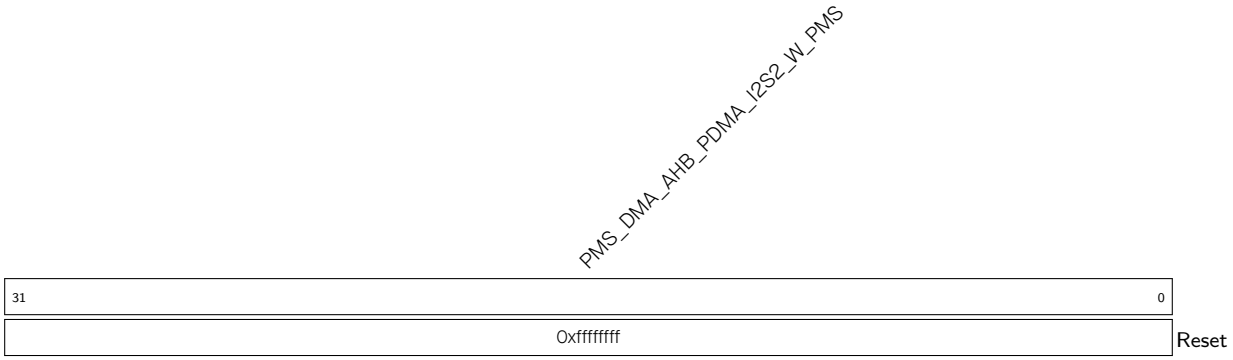
PMS_DMA_AHB_PDMA_I2S1_W_PMS Configures GDMA-AHB permission to write 32 address ranges requested by I2S1. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.13. PMS_DMA_AHB_PDMA_I2S2_R_PMS_REG (0x0140)



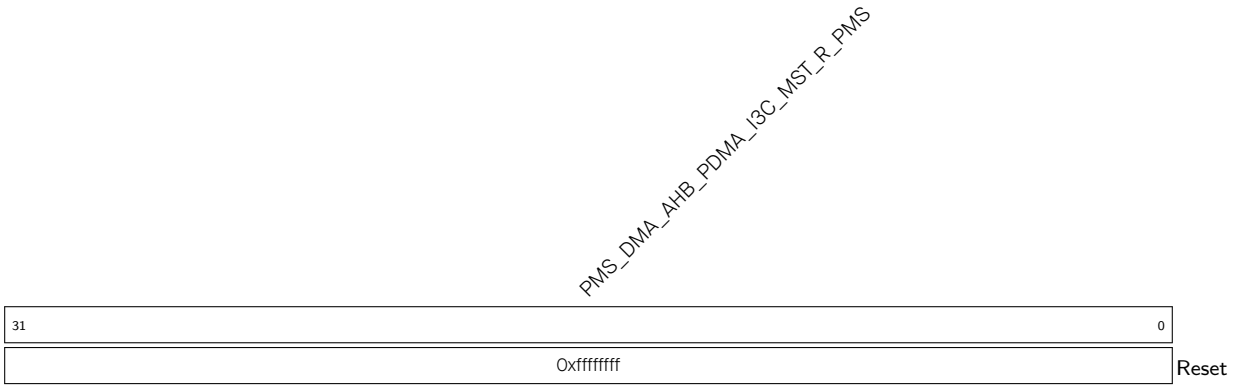
PMS_DMA_AHB_PDMA_I2S2_R_PMS Configures GDMA-AHB permission to read 32 address ranges requested by I2S2. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.14. PMS_DMA_AHB_PDMA_I2S2_W_PMS_REG (0x0144)



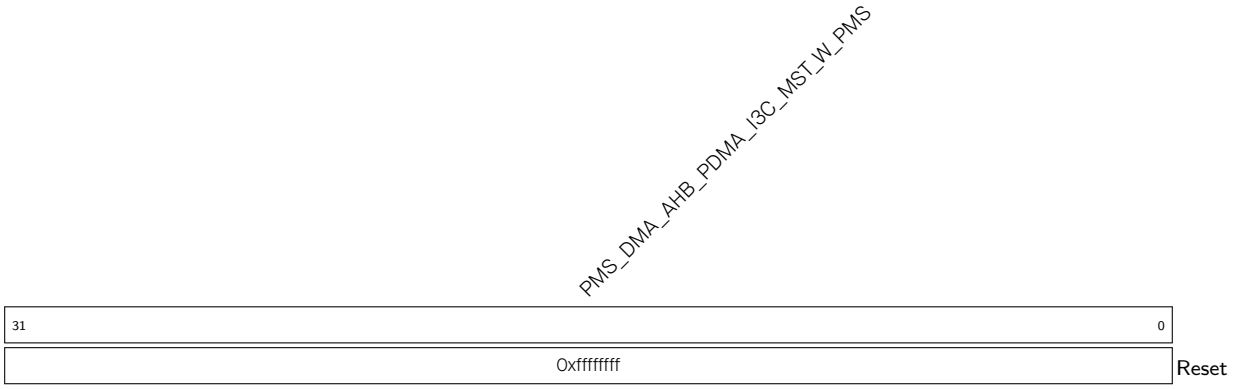
PMS_DMA_AHB_PDMA_I2S2_W_PMS Configures GDMA-AHB permission to write 32 address ranges requested by I2S2. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.15. PMS_DMA_AHB_PDMA_I3C_MST_R_PMS_REG (0x0148)



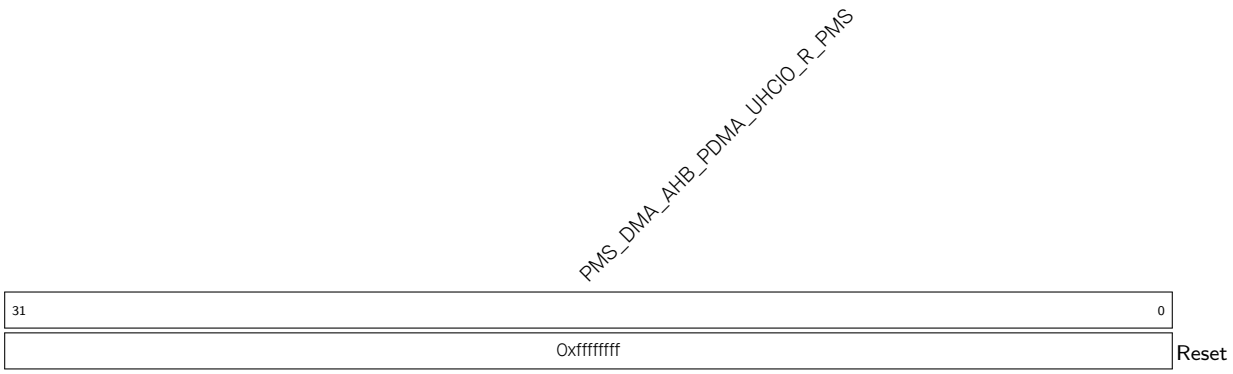
PMS_DMA_AHB_PDMA_I3C_MST_R_PMS Configures GDMA-AHB permission to read 32 address ranges requested by I3C master. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.16. PMS_DMA_AHB_PDMA_I3C_MST_W_PMS_REG (0x014C)



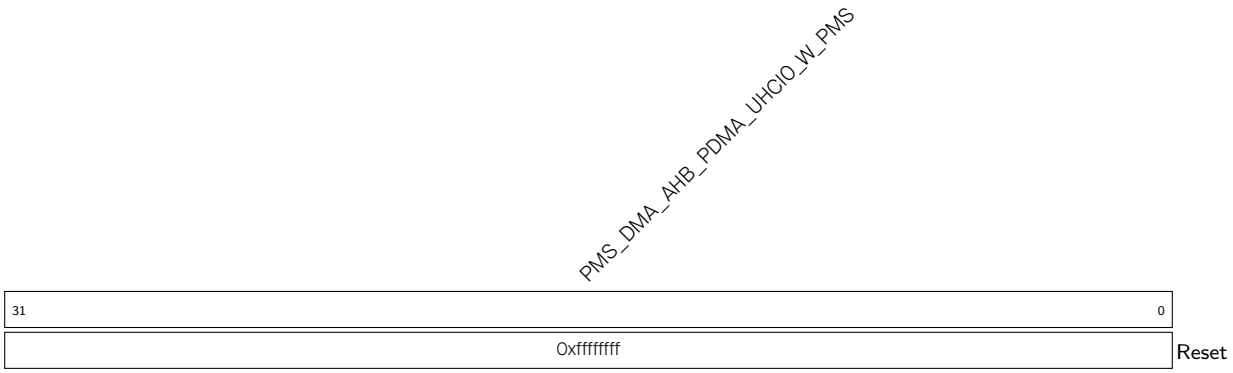
PMS_DMA_AHB_PDMA_I3C_MST_W_PMS Configures GDMA-AHB permission to write 32 address ranges requested by I3C master. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.17. PMS_DMA_AHB_PDMA_UHCI0_R_PMS_REG (0x0150)



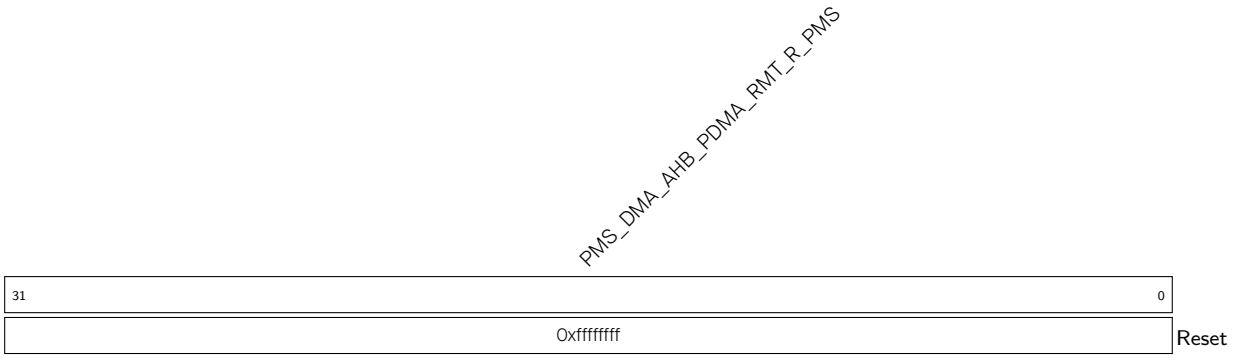
PMS_DMA_AHB_PDMA_UHCI0_R_PMS Configures GDMA-AHB permission to read 32 address ranges requested by UHCI. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.18. PMS_DMA_AHB_PDMA_UHCI0_W_PMS_REG (0x0154)



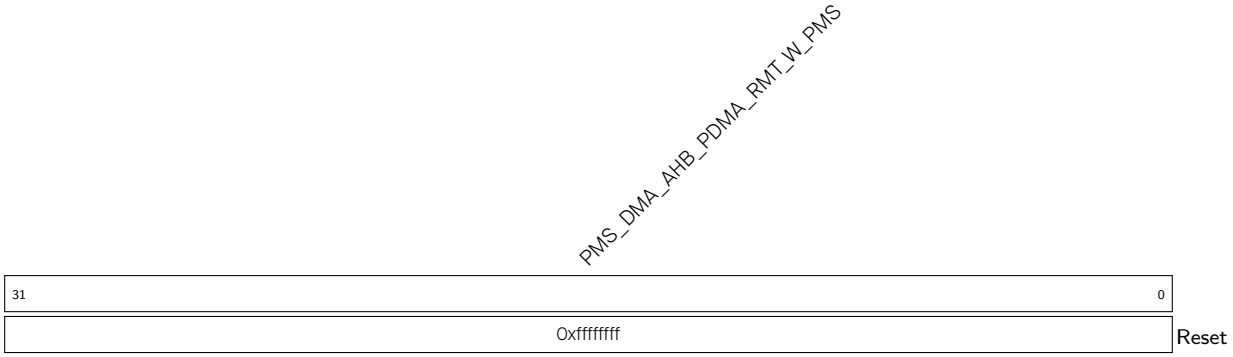
PMS_DMA_AHB_PDMA_UHCI0_W_PMS Configures GDMA-AHB permission to write 32 address ranges requested by UHCI. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.19. PMS_DMA_AHB_PDMA_RMT_R_PMS_REG (0x0158)



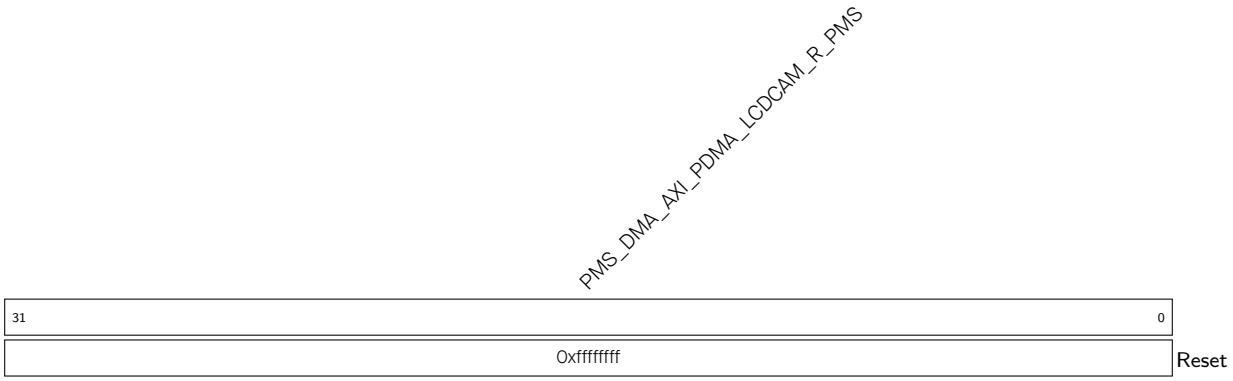
PMS_DMA_AHB_PDMA_RMT_R_PMS Configures GDMA-AHB permission to read 32 address ranges requested by RMT. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.20. PMS_DMA_AHB_PDMA_RMT_W_PMS_REG (0x0170)



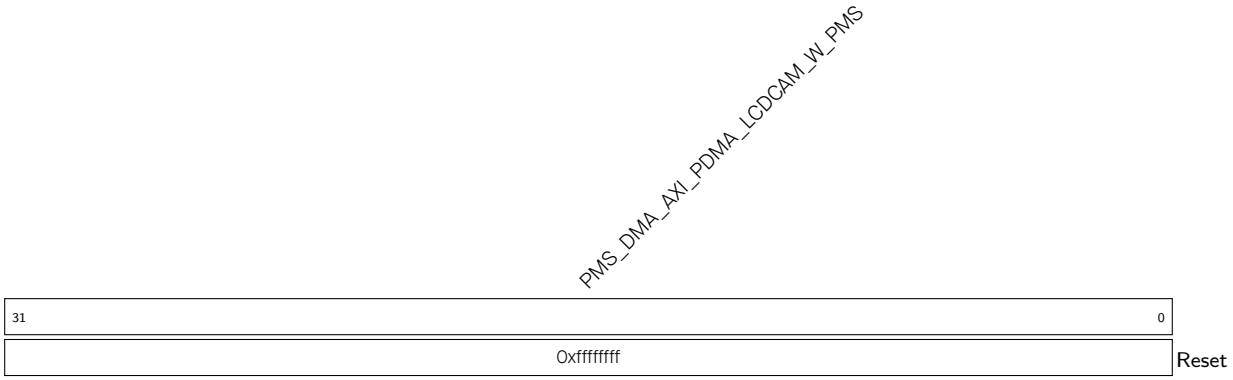
PMS_DMA_AHB_PDMA_RMT_W_PMS Configures GDMA-AHB permission to write 32 address ranges requested by RMT. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.21. PMS_DMA_AXI_PDMA_LCDCAM_R_PMS_REG (0x0174)



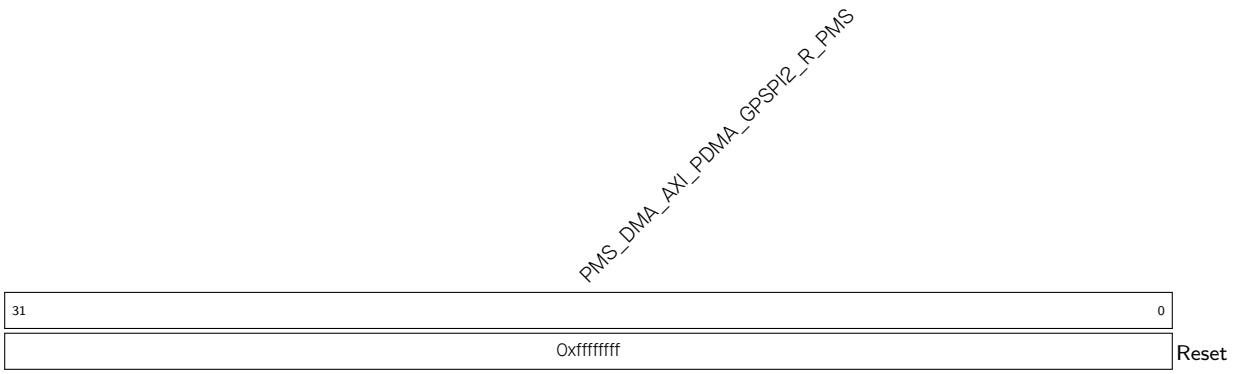
PMS_DMA_AXI_PDMA_LCDCAM_R_PMS Configures GDMA-AXI permission to read 32 address ranges requested by LCD_CAM. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.22. PMS_DMA_AXI_PDMA_LCDCAM_W_PMS_REG (0x0178)



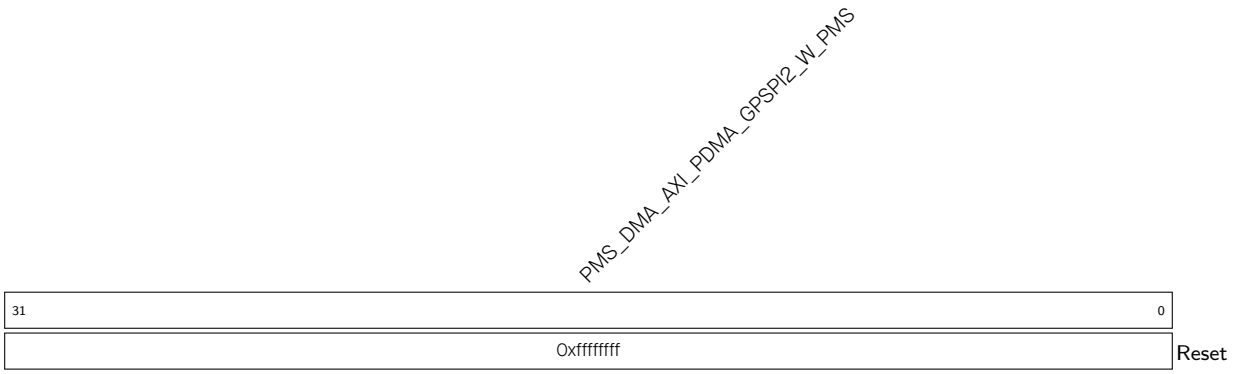
PMS_DMA_AXI_PDMA_LCDCAM_W_PMS Configures GDMA-AXI permission to write 32 address ranges requested by LCD_CAM. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.23. PMS_DMA_AXI_PDMA_GPSPI2_R_PMS_REG (0x017C)



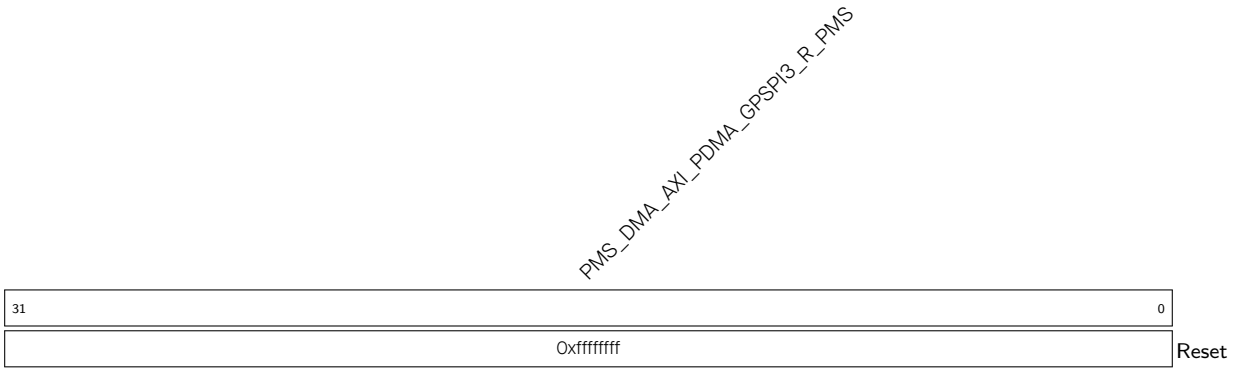
PMS_DMA_AXI_PDMA_GPSPI2_R_PMS Configures GDMA-AXI permission to read 32 address ranges requested by GP-SPI2. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.24. PMS_DMA_AXI_PDMA_GPSPI2_W_PMS_REG (0x0180)



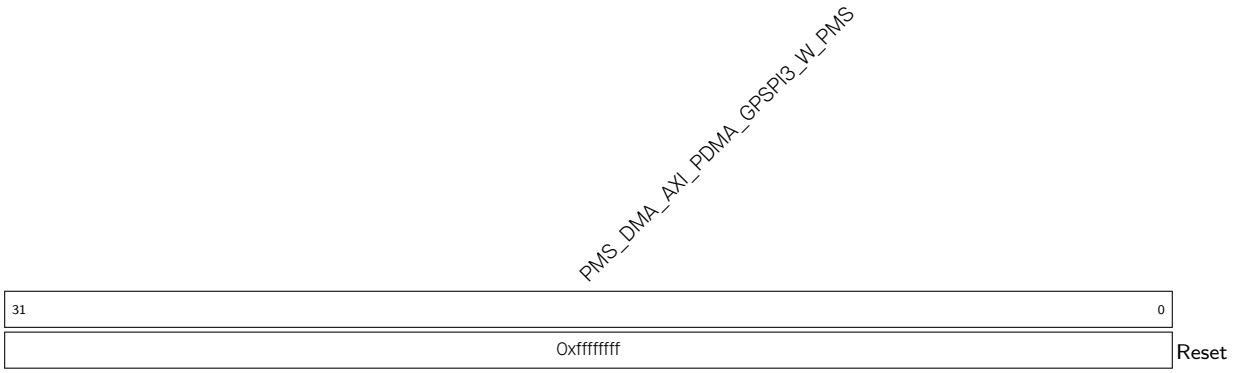
PMS_DMA_AXI_PDMA_GPSPI2_W_PMS Configures GDMA-AXI permission to write 32 address ranges requested by GP-SPI2. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.25. PMS_DMA_AXI_PDMA_GPSPI3_R_PMS_REG (0x0184)



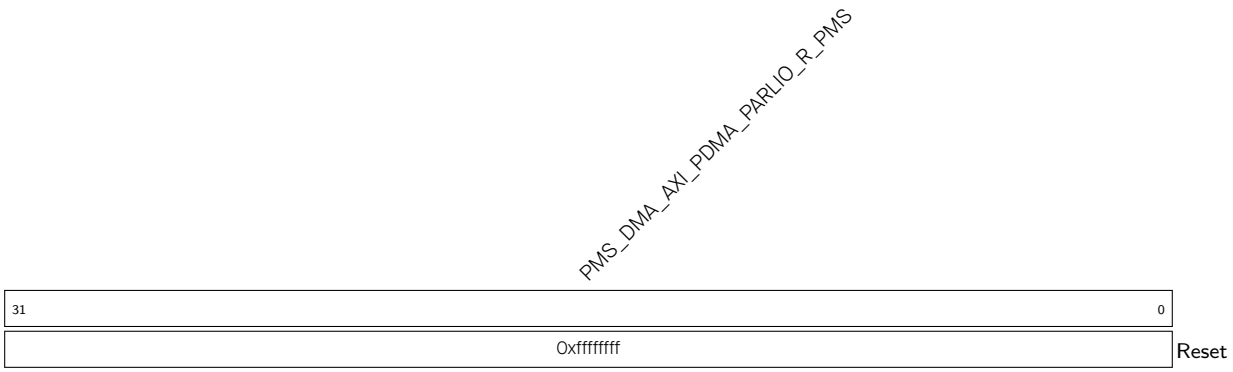
PMS_DMA_AXI_PDMA_GPSPI3_R_PMS Configures GDMA-AXI permission to read 32 address ranges requested by GP-SPI3. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.26. PMS_DMA_AXI_PDMA_GPSPI3_W_PMS_REG (0x0188)



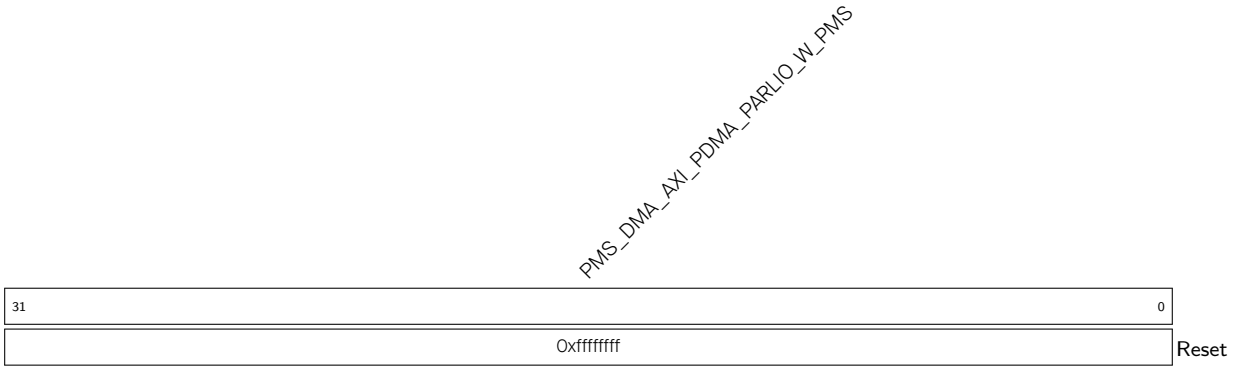
PMS_DMA_AXI_PDMA_GPSPI3_W_PMS Configures GDMA-AXI permission to write 32 address ranges requested by GP-SPI3. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.27. PMS_DMA_AXI_PDMA_PARLIO_R_PMS_REG (0x018C)



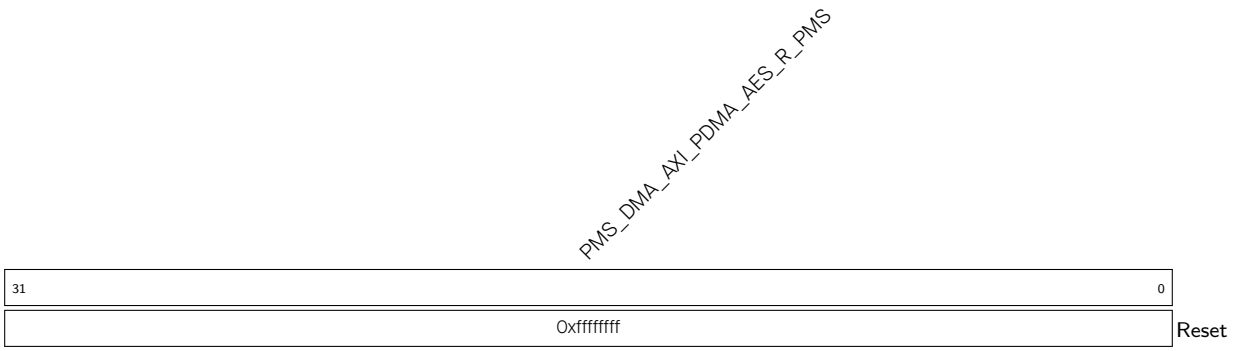
PMS_DMA_AXI_PDMA_PARLIO_R_PMS Configures GDMA-AXI permission to read 32 address ranges requested by PARLIO (Parallel IO Controller). Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.28. PMS_DMA_AXI_PDMA_PARLIO_W_PMS_REG (0x0190)



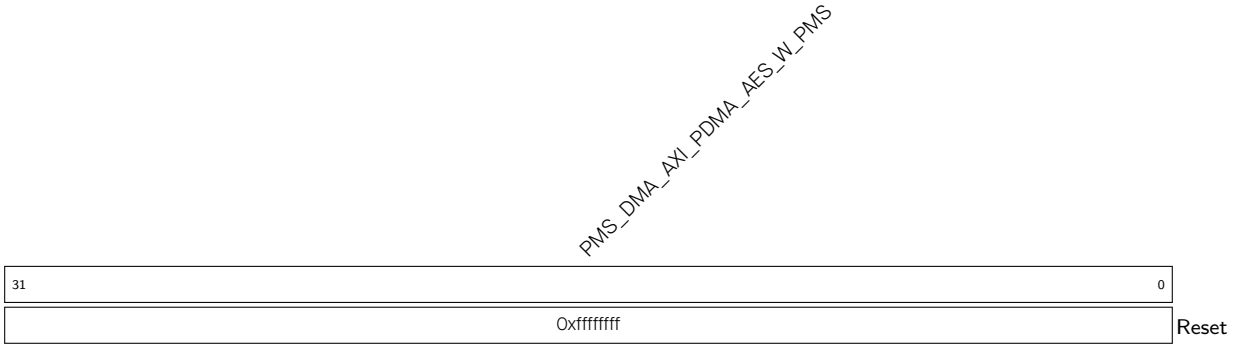
PMS_DMA_AXI_PDMA_PARLIO_W_PMS Configures GDMA-AXI permission to write 32 address ranges requested by PARLIO. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.29. PMS_DMA_AXI_PDMA_AES_R_PMS_REG (0x0194)



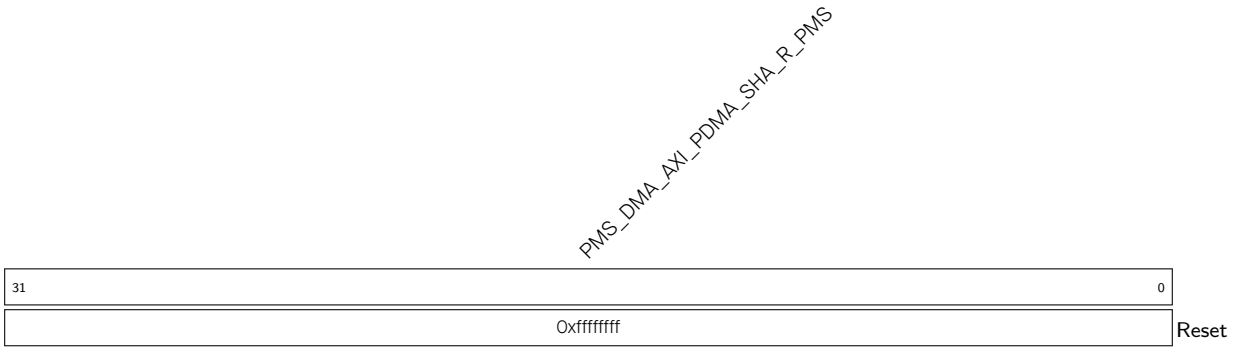
PMS_DMA_AXI_PDMA_AES_R_PMS Configures GDMA-AXI permission to read 32 address ranges requested by AES. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.30. PMS_DMA_AXI_PDMA_AES_W_PMS_REG (0x0198)



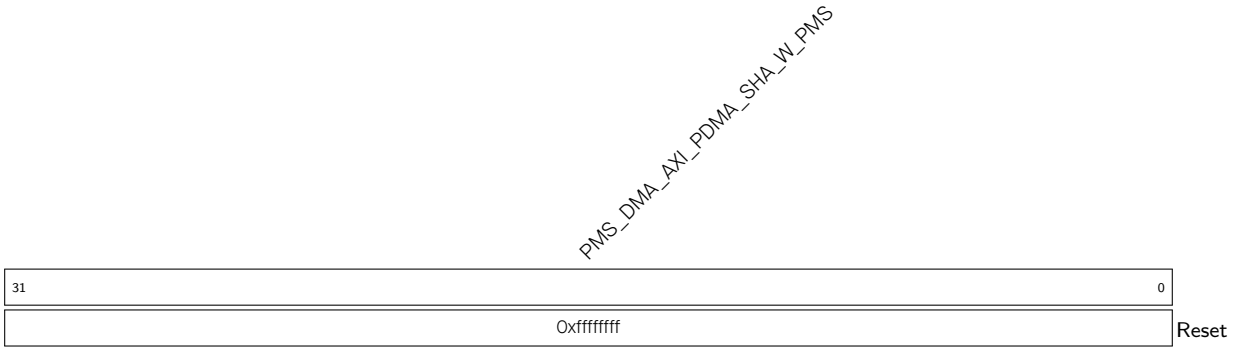
PMS_DMA_AXI_PDMA_AES_W_PMS Configures GDMA-AXI permission to write 32 address ranges requested by AES. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.31. PMS_DMA_AXI_PDMA_SHA_R_PMS_REG (0x019C)



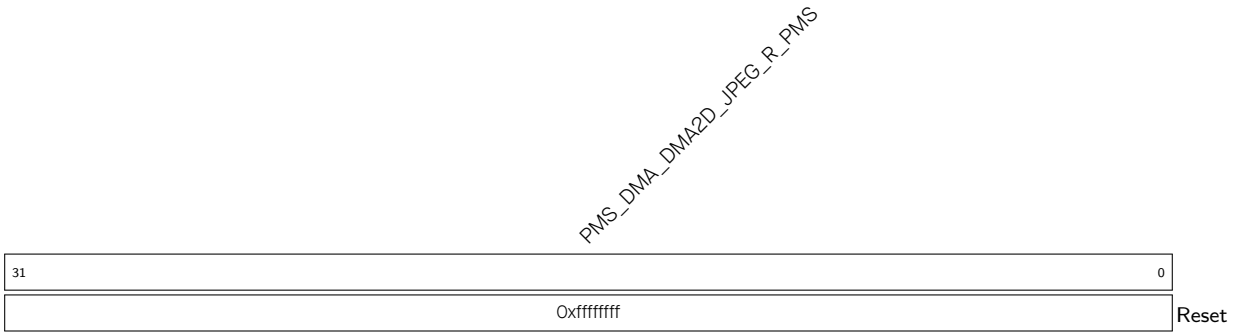
PMS_DMA_AXI_PDMA_SHA_R_PMS Configures GDMA-AXI permission to read 32 address ranges requested by SHA. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.32. PMS_DMA_AXI_PDMA_SHA_W_PMS_REG (0x01A0)



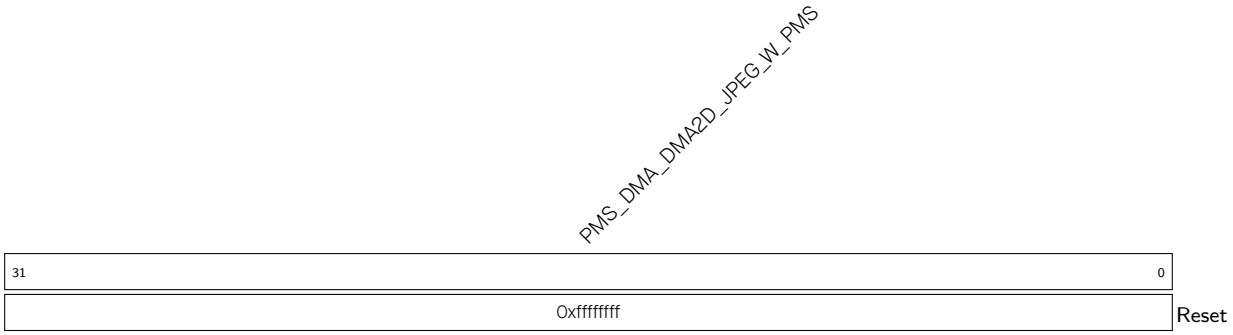
PMS_DMA_AXI_PDMA_SHA_W_PMS Configures GDMA-AXI permission to write 32 address ranges requested by SHA. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.33. PMS_DMA_DMA2D_JPEG_PMS_R_REG (0x01A4)



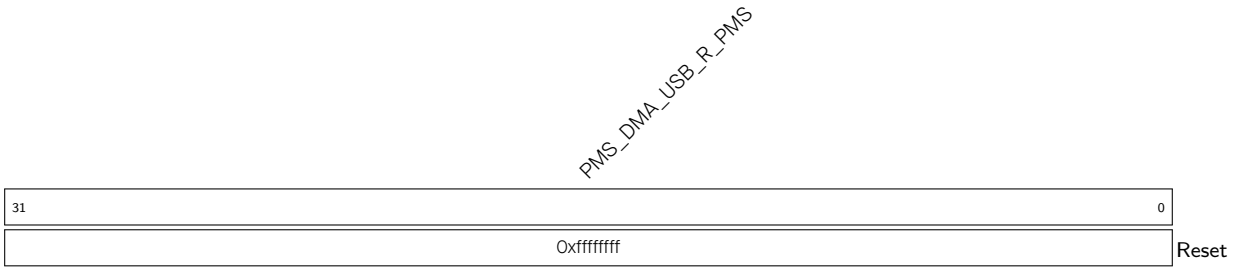
PMS_DMA_DMA2D_JPEG_R_PMS Configures 2D-DMA permission to read 32 address ranges requested by JPEG. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.34. PMS_DMA_DMA2D_JPEG_PMS_W_REG (0x01A8)



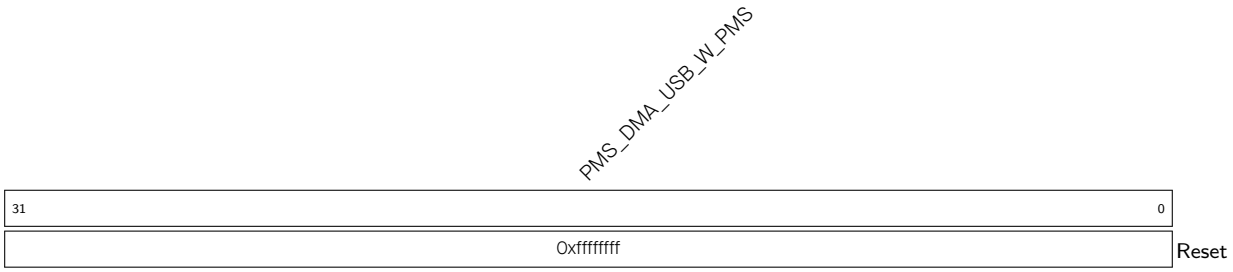
PMS_DMA_DMA2D_JPEG_W_PMS Configures 2D-DMA permission to write 32 address ranges requested by JPEG. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.35. PMS_DMA_USB_PMS_R_REG (0x01AC)



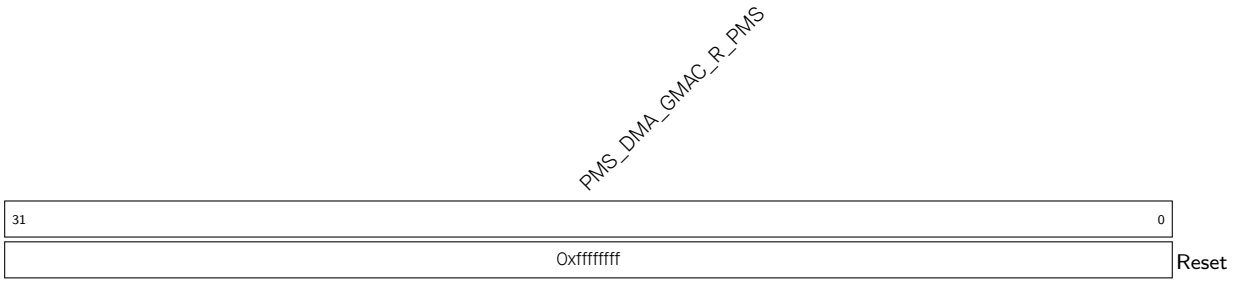
PMS_DMA_USB_R_PMS Configures read permission for USB 2.0 High-Speed OTG to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.36. PMS_DMA_USB_PMS_W_REG (0x01B0)



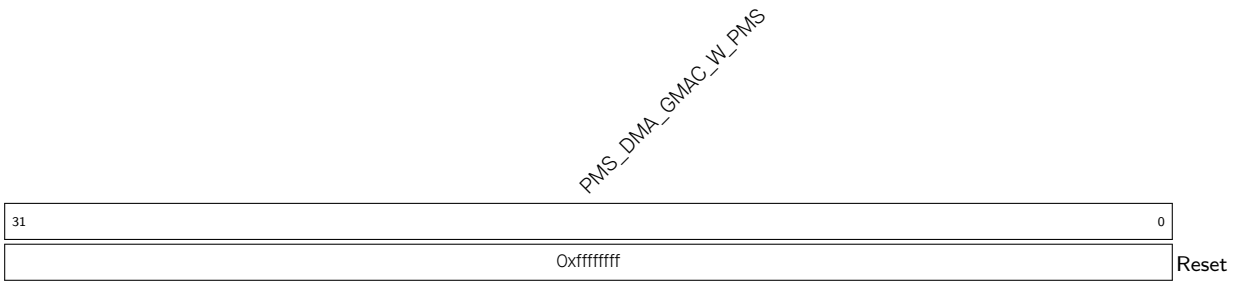
PMS_DMA_USB_W_PMS Configures write permission for USB 2.0 High-Speed OTG to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.37. PMS_DMA_GMAC_PMS_R_REG (0x01B4)



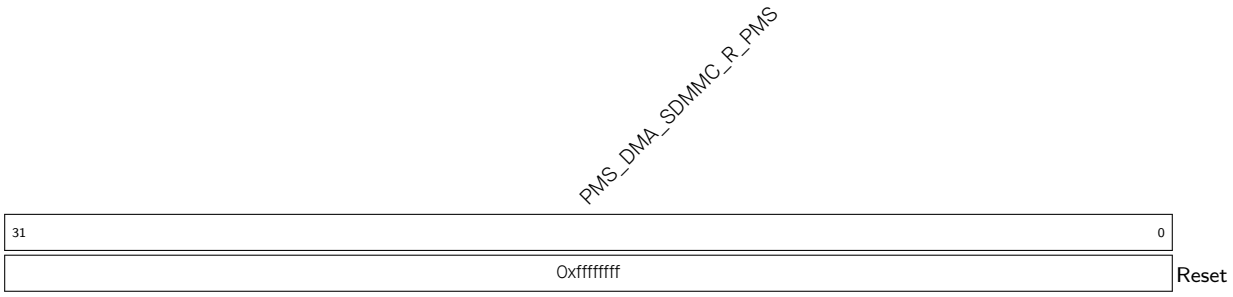
PMS_DMA_GMAC_R_PMS Configures read permission for EMAC to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.38. PMS_DMA_GMAC_PMS_W_REG (0x01B8)



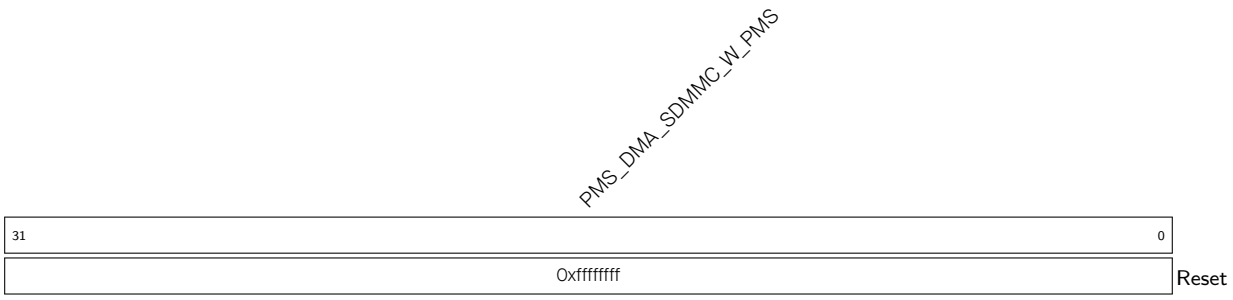
PMS_DMA_GMAC_W_PMS Configures write permission for EMAC to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.39. PMS_DMA_SDMMC_PMS_R_REG (0x01BC)



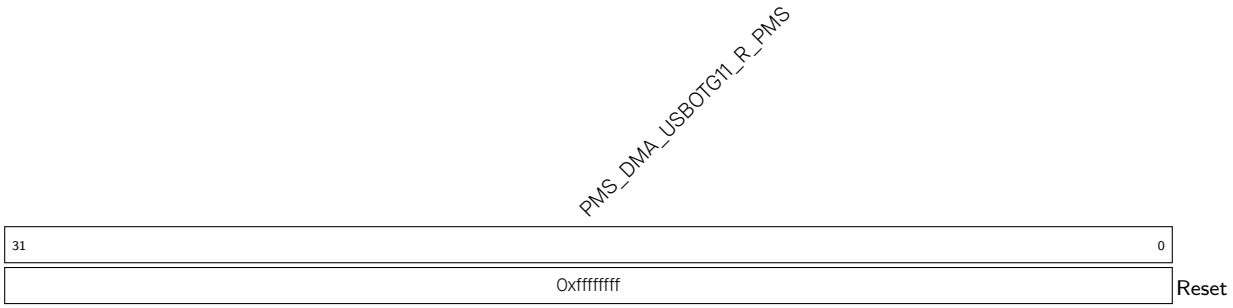
PMS_DMA_SDMMC_R_PMS Configures read permission for SDMMC to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.40. PMS_DMA_SDMMC_PMS_W_REG (0x01C0)



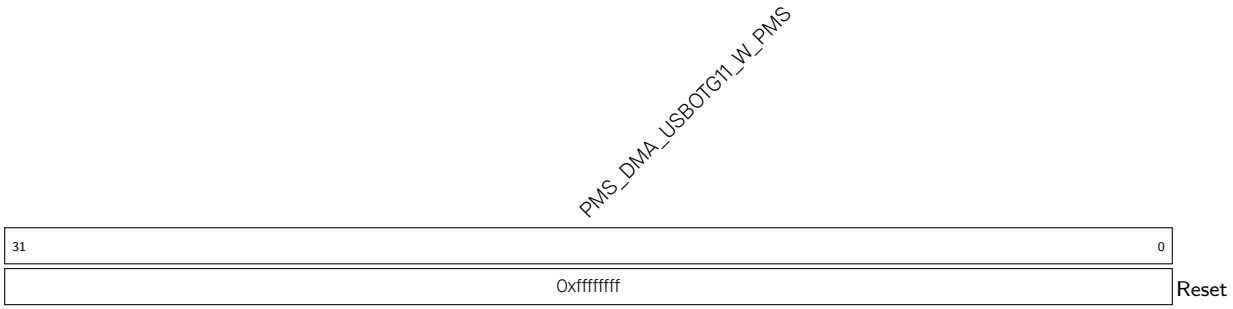
PMS_DMA_SDMMC_W_PMS Configures write permission for SDMMC to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.41. PMS_DMA_USBOTG11_PMS_R_REG (0x01C4)



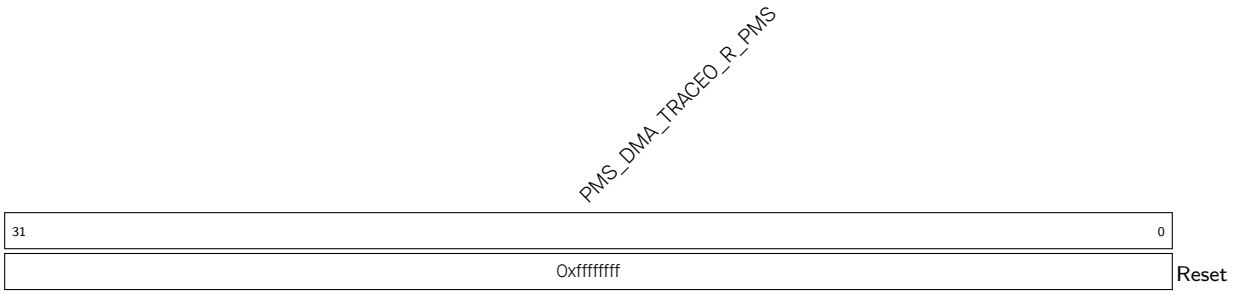
PMS_DMA_USBOTG11_R_PMS Configures read permission for USB 2.0 Full-Speed OTG to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.42. PMS_DMA_USBOTG11_PMS_W_REG (0x01C8)



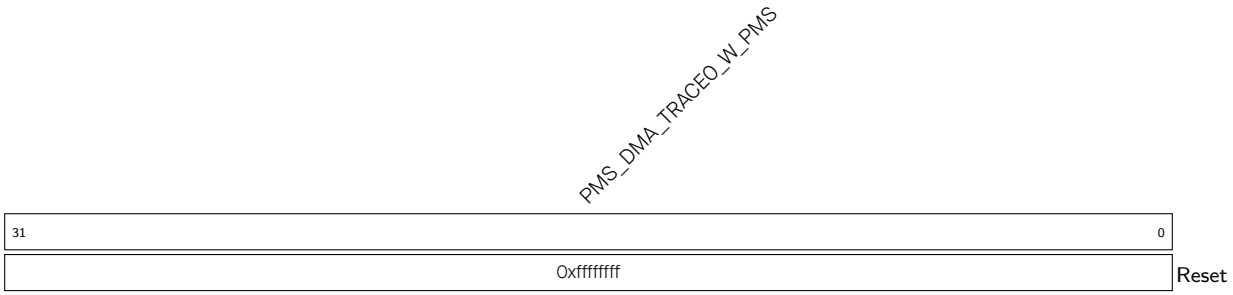
PMS_DMA_USBOTG11_W_PMS Configures write permission for USB 2.0 Full-Speed OTG to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.43. PMS_DMA_TRACE0_PMS_R_REG (0x01CC)



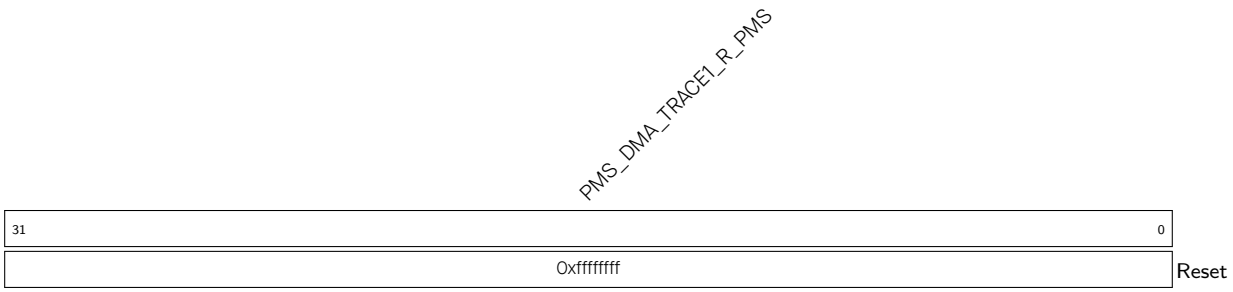
PMS_DMA_TRACE0_R_PMS Configures read permission for TRACE0 to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.44. PMS_DMA_TRACE0_PMS_W_REG (0x01D0)



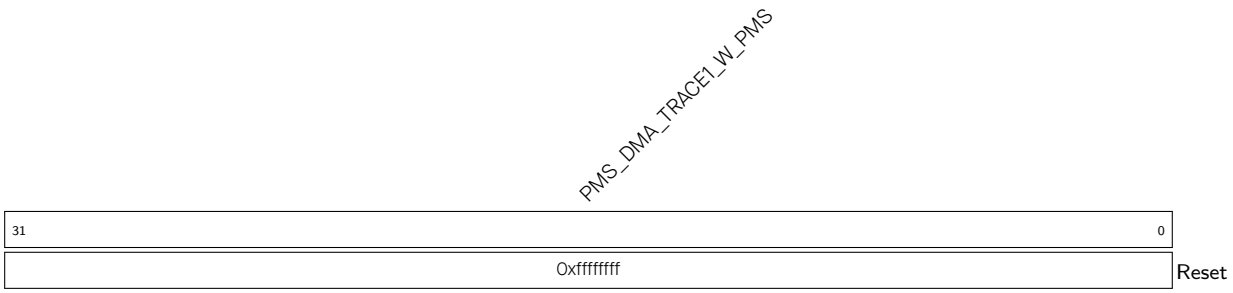
PMS_DMA_TRACE0_W_PMS Configures write permission for TRACE0 to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.45. PMS_DMA_TRACE1_PMS_R_REG (0x01D4)



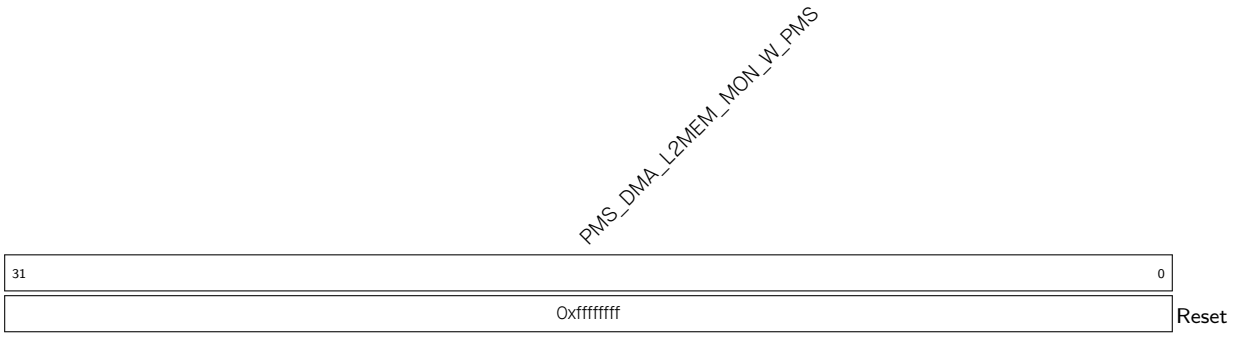
PMS_DMA_TRACE1_R_PMS Configures read permission for TRACE1 to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.46. PMS_DMA_TRACE1_PMS_W_REG (0x01D8)



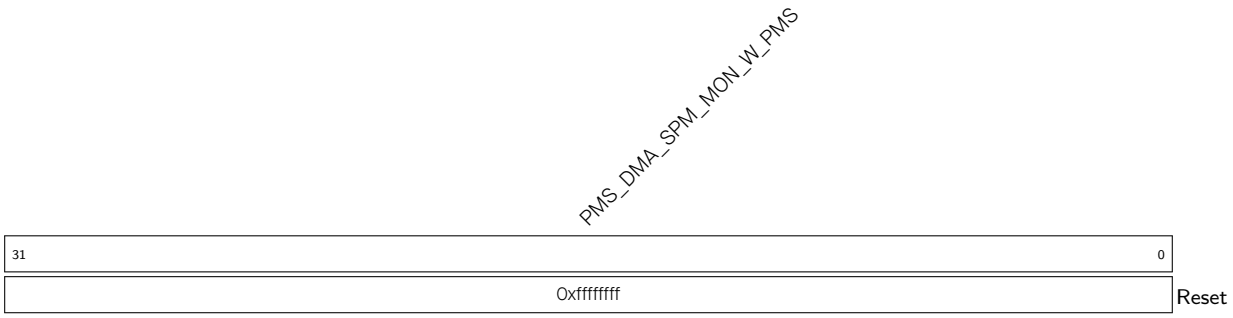
PMS_DMA_TRACE1_W_PMS Configures write permission for TRACE1 to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.47. PMS_DMA_L2MEM_MON_PMS_W_REG (0x01E0)



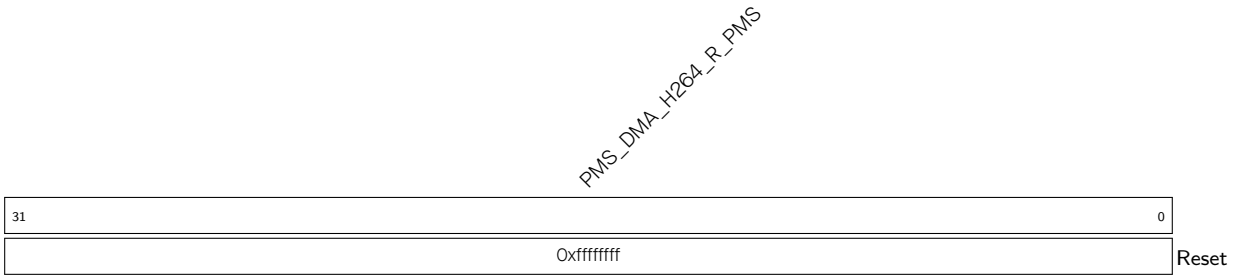
PMS_DMA_L2MEM_MON_W_PMS Configures write permission for L2MEM monitor to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.48. PMS_DMA_SPM_MON_PMS_W_REG (0x01E8)



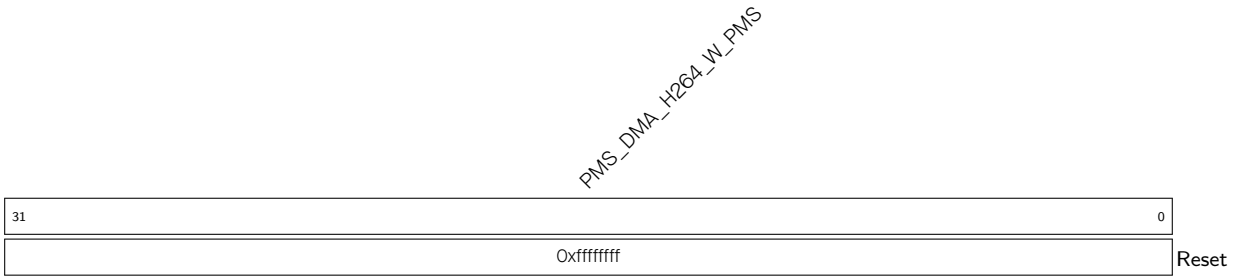
PMS_DMA_SPM_MON_W_PMS Configures write permission for SPM monitor to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.49. PMS_DMA_H264_PMS_R_REG (0x01FC)



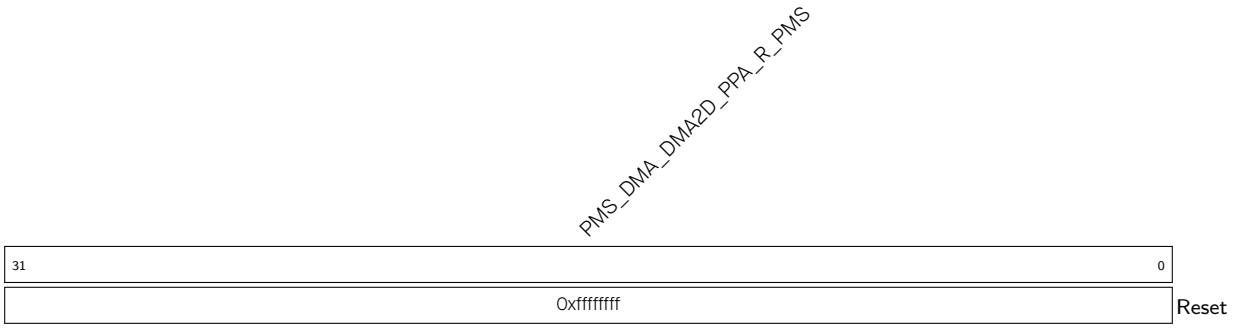
PMS_DMA_H264_R_PMS Configures read permission for H264 DMA to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.50. PMS_DMA_H264_PMS_W_REG (0x0200)



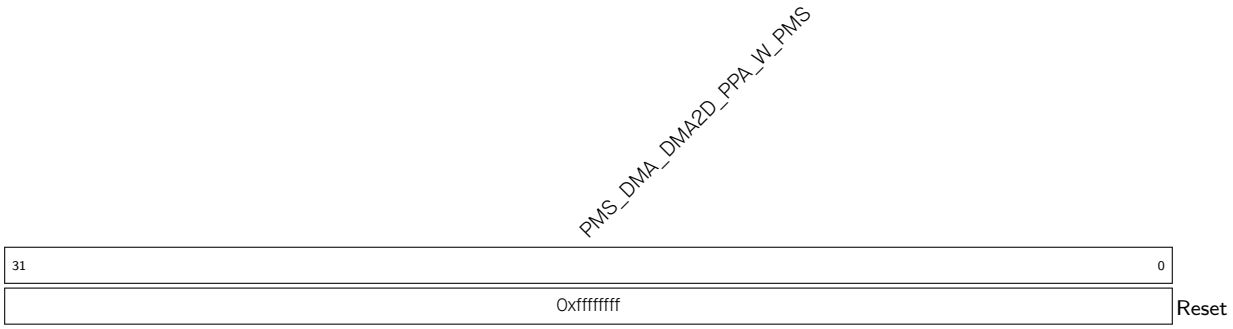
PMS_DMA_H264_W_PMS Configures write permission for H264 DMA to access 32 address ranges. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.51. PMS_DMA_DMA2D_PPA_PMS_R_REG (0x0204)



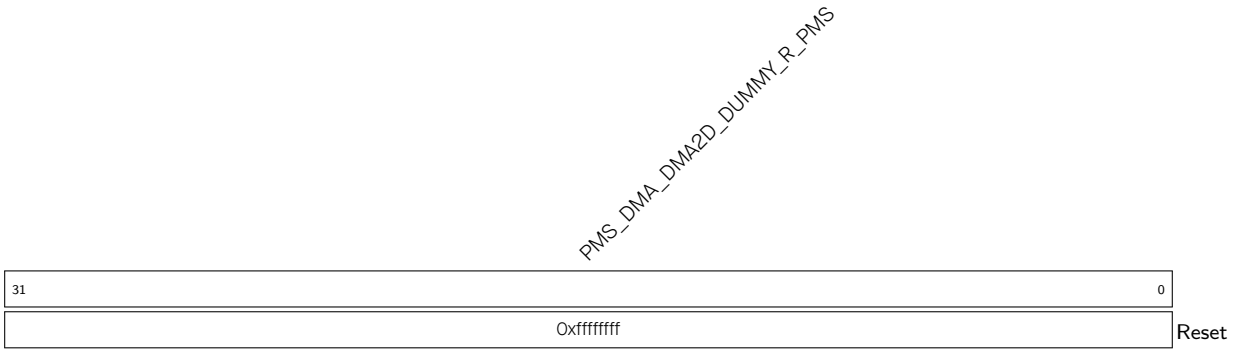
PMS_DMA_DMA2D_PPA_R_PMS Configures 2D-DMA permission to read 32 address ranges requested by PPA (Pixel-Processing Accelerator). Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.52. PMS_DMA_DMA2D_PPA_PMS_W_REG (0x0208)



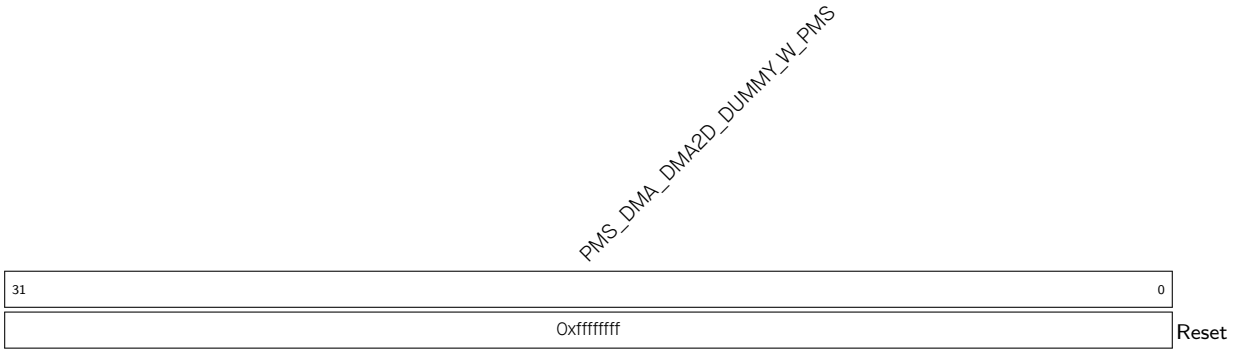
PMS_DMA_DMA2D_PPA_W_PMS Configures 2D-DMA permission to write 32 address ranges requested by PPA. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.53. PMS_DMA_DMA2D_DUMMY_PMS_R_REG (0x020C)



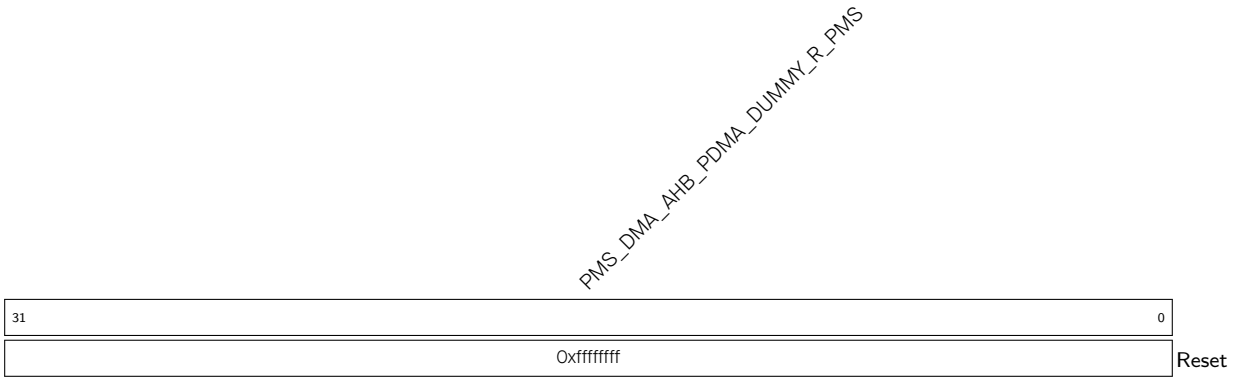
PMS_DMA_DMA2D_DUMMY_R_PMS Configures 2D-DMA permission to read 32 address ranges requested by Dummy. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.54. PMS_DMA_DMA2D_DUMMY_PMS_W_REG (0x0210)



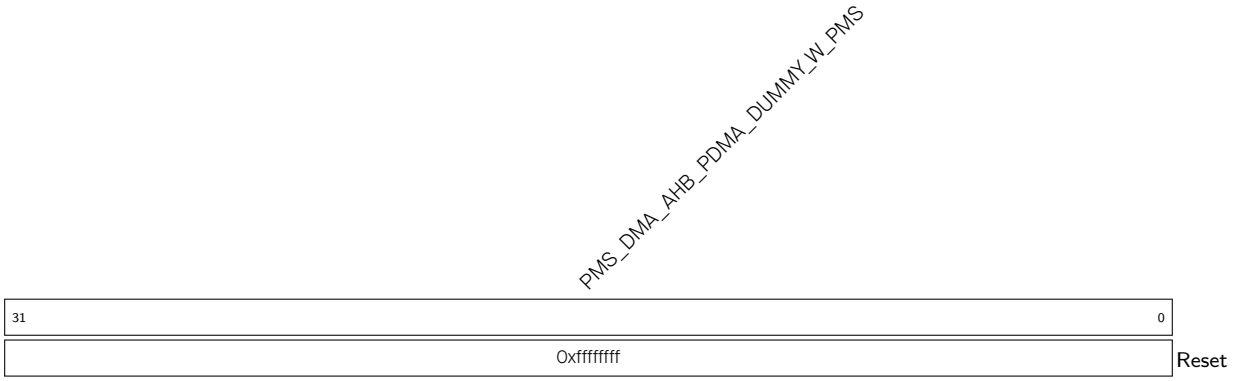
PMS_DMA_DMA2D_DUMMY_W_PMS Configures 2D-DMA permission to write 32 address ranges requested by Dummy. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.55. PMS_DMA_AHB_PDMA_DUMMY_R_PMS_REG (0x0214)



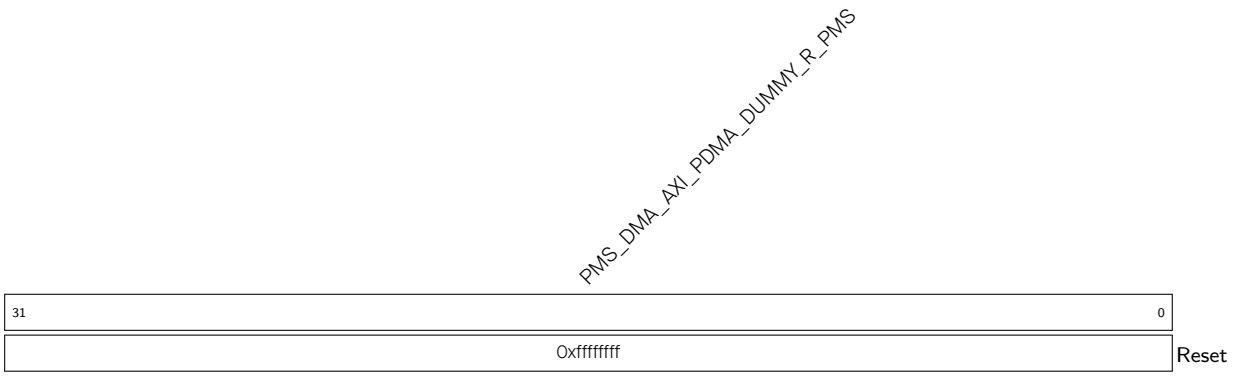
PMS_DMA_AHB_PDMA_DUMMY_R_PMS Configures GDMA-AHB permission to read 32 address ranges requested by Dummy. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

(R/W)

Register 20.56. PMS_DMA_AHB_PDMA_DUMMY_W_PMS_REG (0x0218)



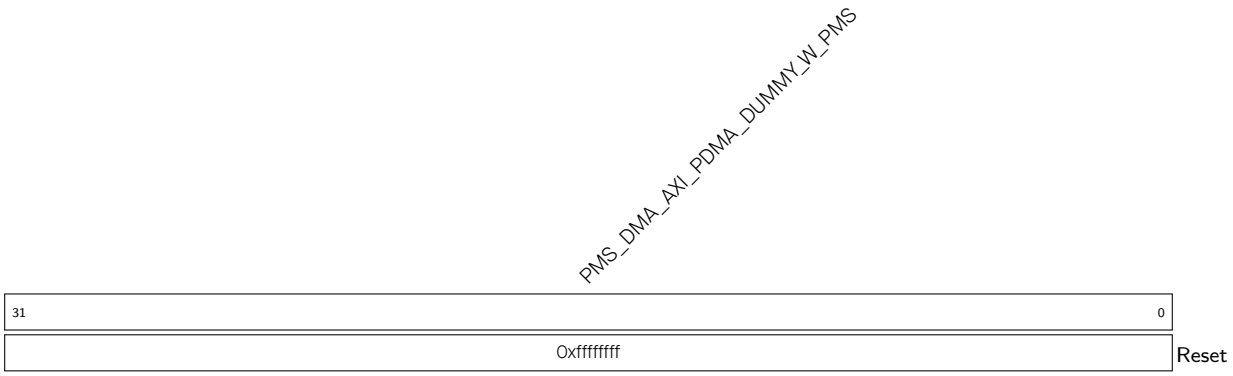
PMS_DMA_AHB_PDMA_DUMMY_W_PMS Configures GDMA-AHB permission to write 32 address ranges requested by Dummy. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

1: Enable write permission.

(R/W)

Register 20.57. PMS_DMA_AXI_PDMA_DUMMY_R_PMS_REG (0x021C)



PMS_DMA_AXI_PDMA_DUMMY_R_PMS Configures GDMA-AXI permission to read 32 address ranges requested by Dummy. Bit 0 corresponds to region0, and so on.

0: Disable read permission.

1: Enable read permission.

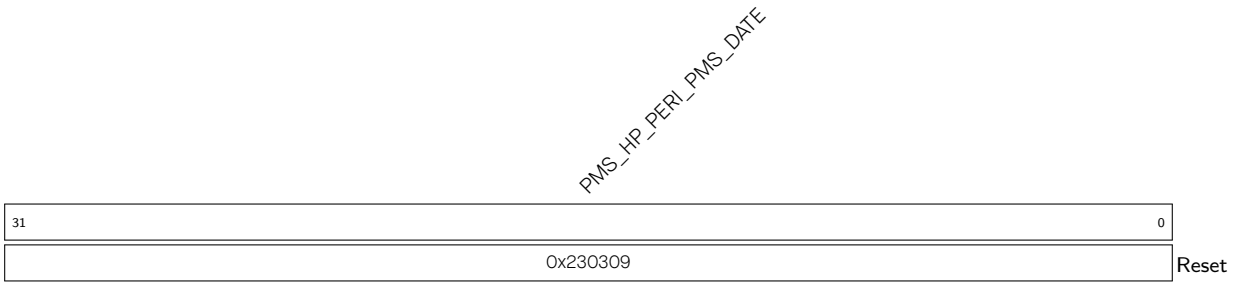
(R/W)

Register 20.58. PMS_DMA_AXI_PDMA_DUMMY_W_PMS_REG (0x0220)

PMS_DMA_AXI_PDMA_DUMMY_W_PMS Configures GDMA-AXI permission to write 32 address ranges requested by Dummy. Bit 0 corresponds to region0, and so on.

0: Disable write permission.

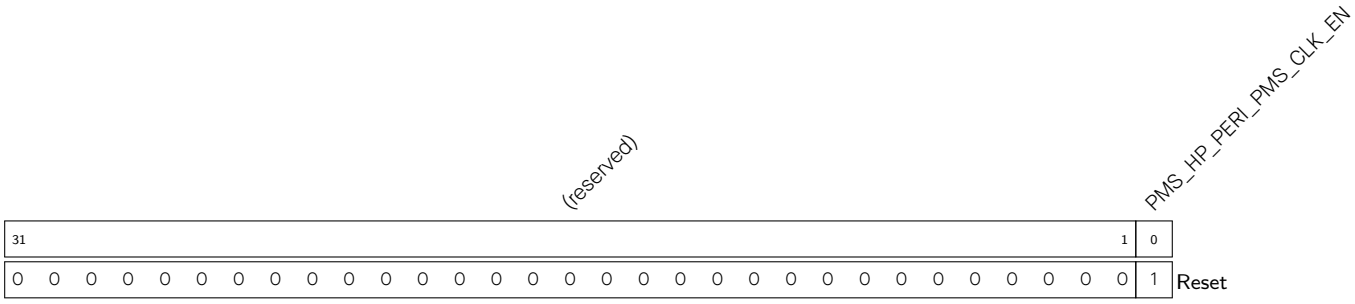
1: Enable write permission.



(R/W)

20.7.2 HP_PERI_PMS_REG

The addresses in this section are relative to the HP_PERI_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

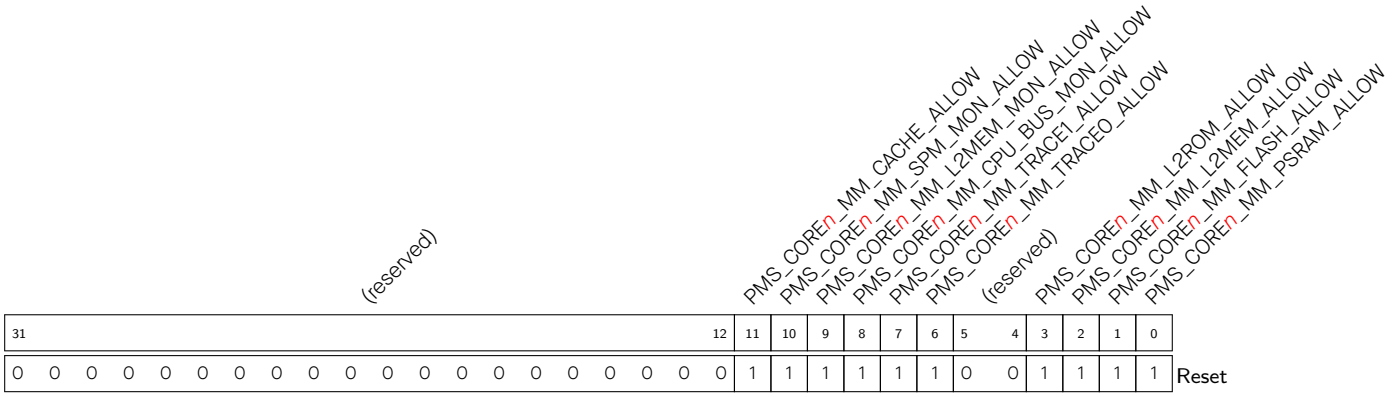


For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 20.59. PMS_HP_PERI_PMS_DATE_REG (0x0000)

PMS_HP_PERI_PMS_DATE Version control register. (R/W)

Register 20.60. PMS_HP_PERI_PMS_CLK_EN_REG (0x0004)



PMS_HP_PERI_PMS_CLK_EN Configures whether to keep the clock always on.

0: Enable automatic clock gating

1: Keep the clock always on

(R/W)

Register 20.61. PMS_CORE*n*_MM_HP_PERI_PMS_REG0_REG (*n*: 0-1) (0x0008+0x20*n)

PMS_CORE*n*_MM_PSRAM_ALLOW Configures whether HP CPU*n* in machine mode has permission to access external RAM without going through cache.

0: Not allowed

1: Allowed

(R/W)

PMS_CORE*n*_MM_FLASH_ALLOW Configures whether HP CPU*n* in machine mode has permission to access external flash without going through cache.

0: Not allowed

1: Allowed

(R/W)

PMS_CORE*n*_MM_L2MEM_ALLOW Configures whether HP CPU*n* in machine mode has permission to access HP L2MEM without going through cache.

0: Not allowed

1: Allowed

(R/W)

PMS_CORE*n*_MM_L2ROM_ALLOW Configures whether HP CPU*n* in machine mode has permission to access HP ROM without going through cache.

0: Not allowed

1: Allowed

(R/W)

PMS_CORE*n*_MM_TRACE0_ALLOW Configures whether HP CPU*n* in machine mode has permission to access TRACE0.

0: Not allowed

1: Allowed

(R/W)

PMS_CORE*n*_MM_TRACE1_ALLOW Configures whether HP CPU*n* in machine mode has permission to access TRACE1.

0: Not allowed

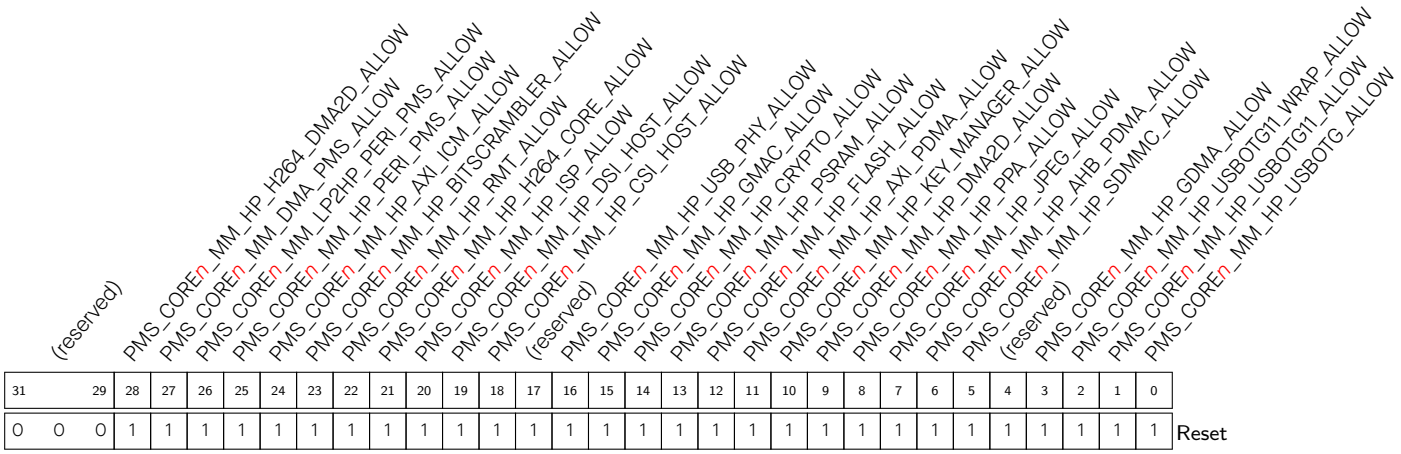
1: Allowed

(R/W)

Continued on the next page...

Register 20.61. PMS_CORE*n*_MM_HP_PERI_PMS_REG0_REG (*n*: 0-1) (0x0008+0x20**n*)

Continued from the previous page...



PMS_CORE*n*_MM_CPU_BUS_MON_ALLOW Configures whether HP CPU*n* in machine mode has permission to access CPU bus monitor.

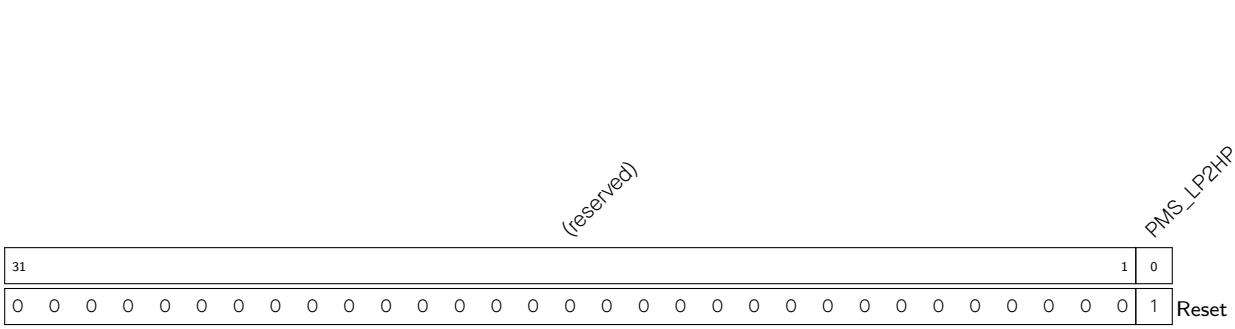
20.7.3 LP2HP_PERI_PMS_REG

The addresses in this section are relative to the LP2HP_PERI_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

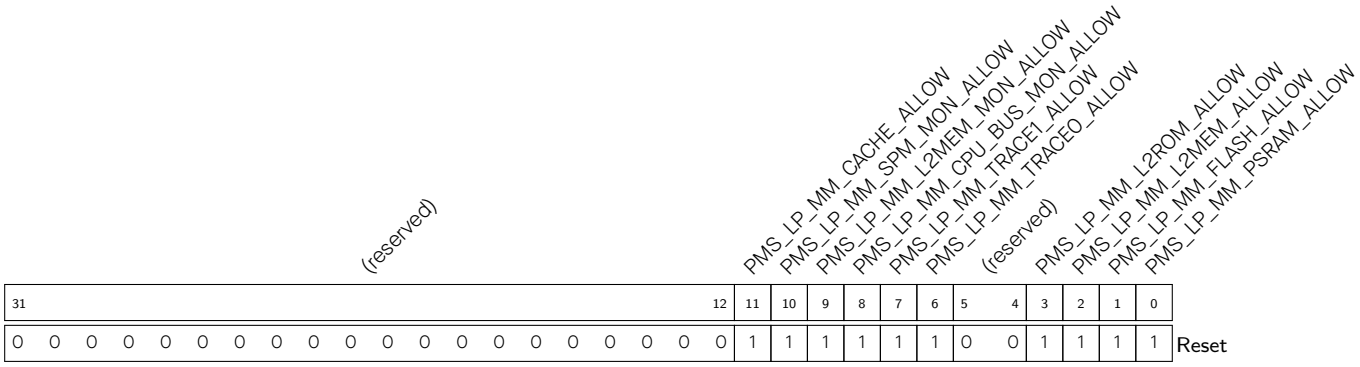


For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 20.69. PMS_LP2HP_PERI_PMS_DATE_REG (0x0000)

PMS_LP2HP_PERI_PMS_DATE Version control register. (R/W)

Register 20.70. PMS_LP2HP_PERI_PMS_CLK_EN_REG (0x0004)



PMS_LP2HP_PERI_PMS_CLK_EN Configures whether to keep the clock always on.

0: Enable automatic clock gating.

1: Keep the clock always on.

(R/W)

Register 20.71. PMS_LP_MM_PMS_REG0_REG (0x0008)

PMS_LP_MM_PSRAM_ALLOW Configures whether the LP CPU in machine mode has permission to access external RAM without going through cache.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_FLASH_ALLOW Configures whether the LP CPU in machine mode has permission to access external flash without going through cache.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_L2MEM_ALLOW Configures whether the LP CPU in machine mode has permission to access HP L2M2M without going through cache.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_L2ROM_ALLOW Configures whether the LP CPU in machine mode has permission to access HP ROM without going through cache.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_TRACE0_ALLOW Configures whether the LP CPU in machine mode has permission to access TRACE0.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_TRACE1_ALLOW Configures whether the LP CPU in machine mode has permission to access TRACE1.

0: Not allowed

1: Allowed

(R/W)

Continued on the next page...

Register 20.71. PMS_LP_MM_PMS_REG0_REG (0x0008)

PMS_LP_MM_CPU_BUS_MON_ALLOW Configures whether the LP CPU in machine mode has permission to access CPU bus monitor.
0: Not allowed
1: Allowed
(R/W)

PMS_LP_MM_L2MEM_MON_ALLOW Configures whether the LP CPU in machine mode has permission to access L2MEM monitor.
0: Not allowed
1: Allowed
(R/W)

PMS_LP_MM_SPM_MON_ALLOW Configures whether the LP CPU in machine mode has permission to access SPM monitor.
0: Not allowed
1: Allowed
(R/W)

PMS_LP_MM_CACHE_ALLOW Configures whether the LP CPU in machine mode has permission to access cache.
0: Not allowed
1: Allowed
(R/W)

Register 20.72. PMS_LP_MM_PMS_REG1_REG (0x0030)

PMS_LP_MM_HP_USBOTG_ALLOW Configures whether the LP CPU in machine mode has permission to access USB 2.0 High-Speed OTG.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_HP_USBOTG11_ALLOW Configures whether the LP CPU in machine mode has permission to access USB 2.0 Full-Speed OTG.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_HP_USBOTG11_WRAP_ALLOW Configures whether the LP CPU in machine mode has permission to access USB 2.0 Full-Speed OTG's wrap.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_HP_GDMA_ALLOW Configures whether the LP CPU in machine mode has permission to access HP VDMA.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_HP_SDMMC_ALLOW Configures whether the LP CPU in machine mode has permission to access HP SDMMC.

0: Not allowed

1: Allowed

(R/W)

PMS_LP_MM_HP_AHB_PDMA_ALLOW Configures whether the LP CPU in machine mode has permission to access GDMA-AHB.

0: Not allowed

1: Allowed

(R/W)

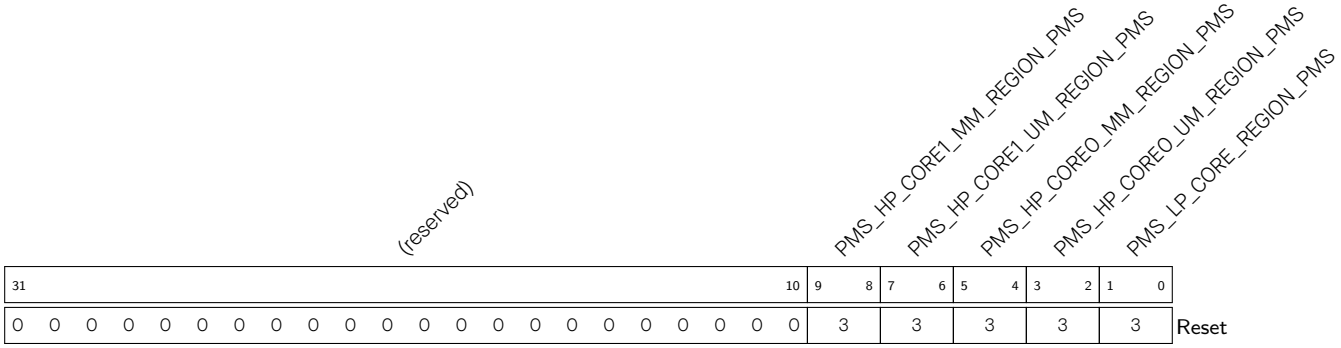
PMS_LP_MM_LP_TRNG_ALLOW Configures whether LP CPU in machine mode has permission to access LP TRNG.
0: Not allowed
1: Allowed
(R/W)

Register 20.78. PMS_PERI_REGION*n*_LOW_REG (*n*: 0-1) (0x000C+0x8**n*)



PMS_PERI_REGION*n*_LOW Configures the high 30 bits of the start address of peripheral register's region*n*. (R/W)

Register 20.79. PMS_PERI_REGION*n*_HIGH_REG (*n*: 0-1) (0x0010+0x8n*)**

PMS_PERI_REGION*n*_HIGH Configures the high 30 bits of the end address of peripheral register's region*n*. (R/W)

Register 20.80. PMS_PERI_REGION_PMS_REG (0x001C)

PMS_LP_CORE_REGION_PMS Configures whether LP core in machine mode has permission to access address region0 and address region1. Bit0 corresponds to region0 and bit1 corresponds to region1.

0: Not allowed

1: Allowed

(R/W)

PMS_HP_CORE0_UM_REGION_PMS Configures whether HP CPU0 in user mode has permission to access address region0 and address region1. Bit2 corresponds to region0 and bit3 corresponds to region1.

0: Not allowed

1: Allowed

(R/W)

PMS_HP_CORE0_MM_REGION_PMS Configures whether HP CPU0 in machine mode has permission to access address region0 and address region1. Bit4 corresponds to region0 and bit5 corresponds to region1.

0: Not allowed

1: Allowed

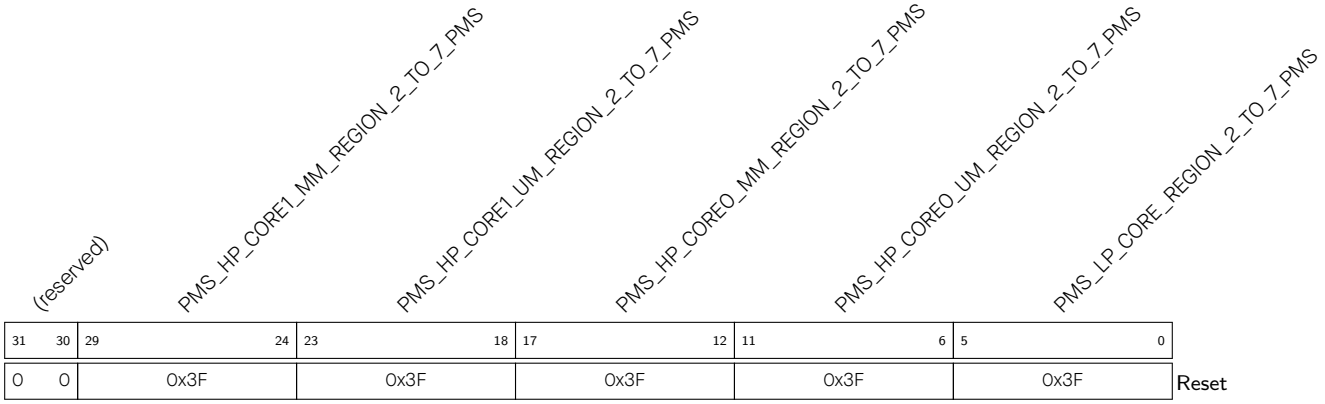
(R/W)

PMS_HP_CORE1_UM_REGION_PMS Configures whether HP CPU1 in user mode has permission to access address region0 and address region1. Bit6 corresponds to region0 and bit7 corresponds to region1.

0: Not allowed

1: Allowed

(R/W)



PMS_HP_CORE1_MM_REGION_PMS Configures whether HP CPU1 in machine mode has permission to access address region0 and address region1. Bit8 corresponds to region0 and bit9 corresponds to region1.

0: Not allowed

1: Allowed

(R/W)

Register 20.81. PMS_PERI_REGION_2_TO_7_PMS_REG (0x0020)

PMS_LP_CORE_REGION_2_TO_7_PMS Configures whether LP CPU in machine mode has permission to access address region2 to address region7. Bit0 corresponds to region2 and bit5 corresponds to region7.

0: Not allowed

1: Allowed

(R/W)

PMS_HP_CORE0_UM_REGION_2_TO_7_PMS Configures whether HP CPU0 in user mode has permission to access address region2 to address region7. Bit0 corresponds to region2 and bit5 corresponds to region7.

0: Not allowed

1: Allowed

(R/W)

PMS_HP_CORE0_MM_REGION_2_TO_7_PMS Configures whether HP CPU0 in machine mode has permission to access address region2 to address region7. Bit0 corresponds to region2 and bit5 corresponds to region7.

0: Not allowed

1: Allowed

(R/W)

PMS_HP_CORE1_UM_REGION_2_TO_7_PMS Configures whether HP CPU1 in user mode has permission to access address region2 to address region7. Bit0 corresponds to region2 and bit5 corresponds to region7.

0: Not allowed

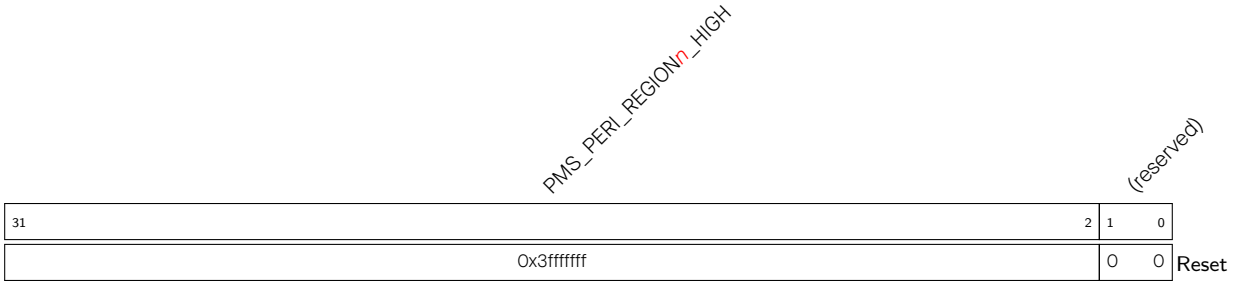
1: Allowed

(R/W)

PMS_HP_CORE1_MM_REGION_2_TO_7_PMS Configures whether HP CPU0 in machine mode has permission to access address region2 to address region7. Bit0 corresponds to region2 and bit5 corresponds to region7.

0: Not allowed

1: Allowed

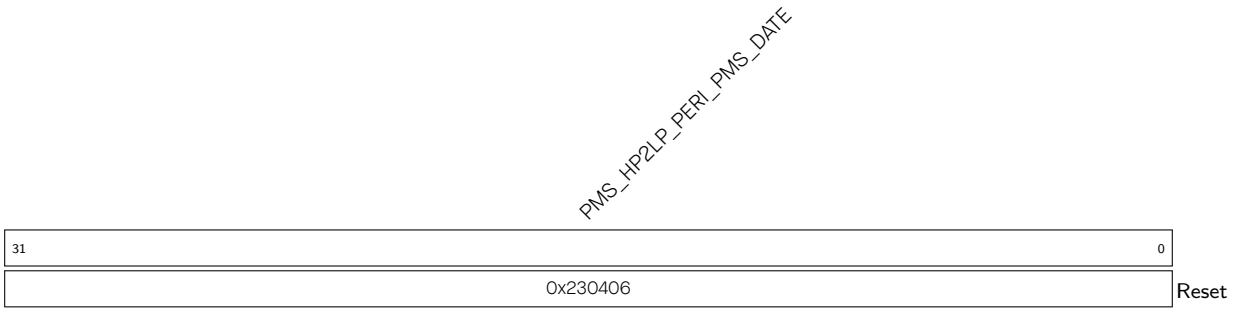


(R/W)

Register 20.82. PMS_PERI_REGION*m*_LOW_REG (*m*: 2-7) (0x0024+0x8*(*m*-2))

PMS_PERI_REGION*m*_LOW Configures the high 30 bits of the start address of peripheral register's region*m*. (R/W)

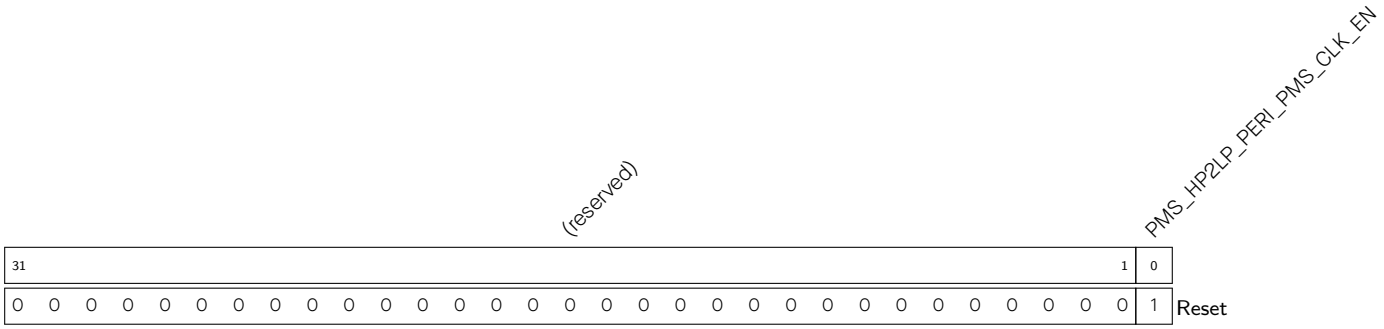
Register 20.83. PMS_PERI_REGION*m*_HIGH_REG (*m*: 2-7) (0x0028+0x8*(*m*-2))



PMS_PERI_REGION*m*_HIGH Configures the high 30 bits of the end address of peripheral register's region*m*. (R/W)

20.7.5 HP2LP_PERI_PMS_REG

The addresses in this section are relative to the H2LP_PERI_PMS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

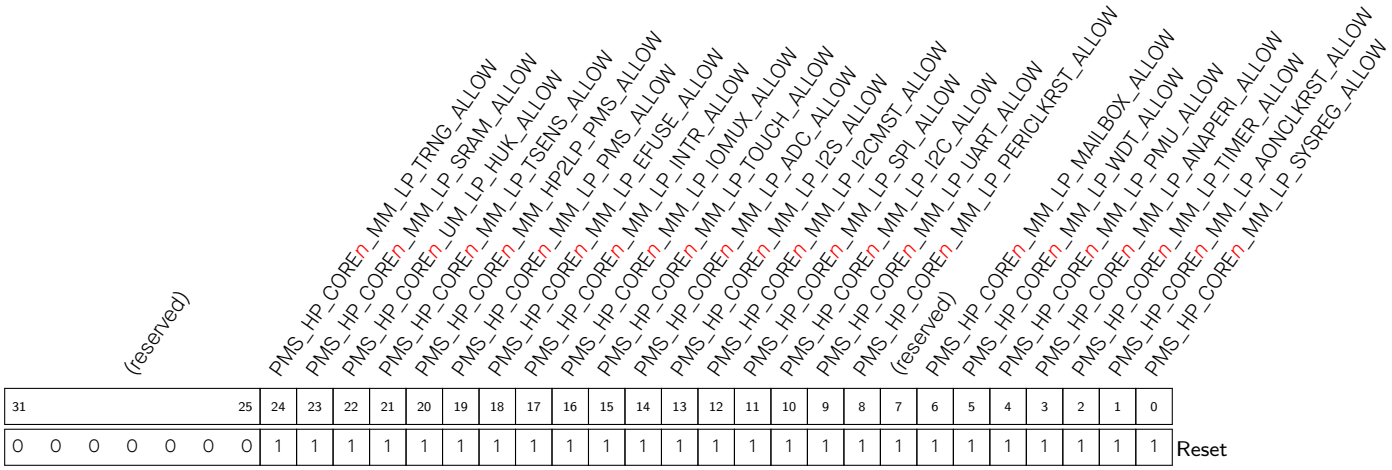


For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 20.84. PMS_HP2LP_PERI_PMS_DATE_REG (0x0000)

PMS_HP2LP_PERI_PMS_DATE Version control register (R/W)

Register 20.85. PMS_HP2LP_PERI_PMS_CLK_EN_REG (0x0004)



PMS_HP2LP_PERI_PMS_CLK_EN Configures whether to keep the clock always on.

0: Enable automatic clock gating

1: Keep the clock always on

(R/W)

Register 20.86. PMS_HP_CORE*n*_MM_PMS_REG0_REG (*n*: 0-1) (0x0008+0x8**n*)

PMS_HP_CORE*n*_MM_LP_SYSREG_ALLOW Configures whether HP CPU*n* in machine mode has permission to access LP System Registers.

0: Not allowed

1: Allowed

(R/W)

PMS_HP_CORE*n*_MM_LP_AONCLKRST_ALLOW Configures whether HP CPU*n* in machine mode has permission to access LP_AONCLKRST.

Chapter 21

System Registers (SYSREG)

21.1 Overview

ESP32-P4 includes various features that can be configured through dedicated registers. This chapter mainly enumerates such registers. For detailed introduction about a specific feature, please go to respective chapters.

21.2 Function Description

21.2.1 HP System Registers

21.2.1.1 External Memory Encryption/Decryption Configuration

Register HP_SYSTEM_CRYPTO_CTRL_REG configures encryption and decryption options of the external memory (external Flash and RAM). For details, please refer to Chapter 34 *External Memory Encryption and Decryption (XTS_AES)*.

21.2.1.2 HP Peripherals Clock Configuration and Power Control

The following registers are used to control the power signals of memory in corresponding peripherals.

- RSA: HP_SYSTEM_HP_RSA_PD_CTRL_REG
- ECC: HP_SYSTEM_HP_ECC_PD_CTRL_REG
- RSA: HP_SYSTEM_HP_UART_PD_CTRL_REG

The following fields in register HP_SYSTEM_HP_PERI_MEM_CLK_FORCE_ON_REG control the clock gating signals of memory in corresponding peripherals.

- GDMA: HP_SYSTEM_GDMA_MEM_CLK_FORCE_ON
- BitScrambler
  - TX memory: HP_SYSTEM_BITSCRAMBLER_TX_MEM_CLK_FORCE_ON
  - RX memory: HP_SYSTEM_BITSCRAMBLER_RX_MEM_CLK_FORCE_ON
- RMT: HP_SYSTEM_RMT_MEM_CLK_FORCE_ON

21.2.1.3 HP Cache Clock and Reset Configuration

ESP32-P4 allows software to directly control the clock and reset signals of HP cache.

The following fields in register HP_SYSTEM_HP_CACHE_CLK_CONFIG_REG control the clock signals of different HP cache. Writing 1 to respective fields enables the clock for respective cache.

- L1 ichache 0: HP_SYSTEM_L1_I0_CACHE_CLK_ON
- L1 ichache 1: HP_SYSTEM_L1_I1_CACHE_CLK_ON
- L1 dcache: HP_SYSTEM_L1_D_CACHE_CLK_ON
- L2 cache: HP_SYSTEM_L2_CACHE_CLK_ON

The following fields in register HP_SYSTEM_CACHE_RESET_CONFIG_REG control the reset signals of different HP cache. Writing 1 and then 0 to respective fields resets respective cache.

- L1 ichache 0: HP_SYSTEM_L1_I0_CACHE_RESET
- L1 ichache 1: HP_SYSTEM_L1_I1_CACHE_RESET
- L1 dcache: HP_SYSTEM_L1_D_CACHE_RESET

21.2.1.4 HP SPM and HP L2MEM Clock Configuration

The following register fields control the clock signals of HP SPM (Scratchpad Memory) and HP L2MEM. Writing 1 to respective register fields forcibly enable the clock of respective memory.

- HP SPM: HP_SYSTEM_HP_SPM_CLK_FORCE_ON
- L2MEM: HP_SYSTEM_L2_MEM_CLK_FORCE_ON
- L2ROM: HP_SYSTEM_L2_ROM_CLK_FORCE_ON

21.2.1.5 HP SPM Parity Check Configuration

ESP32-P4's has implemented Parity Check in HP SPM to detect one-bit memory flip error.

This feature can be configured and controlled via the following registers:

- HP_SYSTEM_HP_SPM_PARITY_CHECK_CTRL_REG: write 1 to enable the parity check in HP SPM.
- HP_SYSTEM_HP_SPM_INIT_REG: configures the initialization of HP SPM before enabling the parity check.
- Interrupt (HP_SPM_PARITY_ERR_INT) related registers:
  - HP_SYSTEM_HP_SPM_INT_RAW_REG: the raw interrupt status of HP_SPM_PARITY_ERR_INT
  - HP_SYSTEM_HP_SPM_INT_ST_REG: the masked interrupt status of HP_SPM_PARITY_ERR_INT
  - HP_SYSTEM_HP_SPM_INT_ENA_REG: write 1 to enable HP_SPM_PARITY_ERR_INT
  - HP_SYSTEM_HP_SPM_INT_CLR_REG: write 1 to clear HP_SPM_PARITY_ERR_INT
- HP_SYSTEM_HP_SPM_PARITY_INT_RECORD_REG: records the address when HP_SPM_PARITY_ERR_INT occurs.
- HP_SYSTEM_HP_SPM_ERR_RESP_CTRL_REG: write 1 so HP SPM reports parity error to the HP CPU and triggers exception.

For detailed configuration steps, please refer to Chapter 9 *System and Memory*.

21.2.1.6 HP L2MEM ECC Check Configuration

ESP32-P4's has implemented the Error Correction Code (ECC) check in HP L2MEM (including L2RAM and cache) to correct one-bit memory flip error.

This feature can be configured and controlled via the following registers:

- HP_SYSTEM_L2_MEM_L2_RAM_ECC_REG and HP_SYSTEM_L2_MEM_L2_CACHE_ECC_REG: write 1 to enable the ECC check for L2MEM and cache respectively.
- HP_SYSTEM_L2_MEM_REFRESH_REG: configures the initialization of HP L2MEM before enabling the ECC check.
- Interrupt (L2_MEM_ECC_ERR_INT) related registers:
  - HP_SYSTEM_L2_MEM_INT_RAW_REG: the raw interrupt status of L2_MEM_ECC_ERR_INT
  - HP_SYSTEM_L2_MEM_INT_ST_REG: the masked interrupt status of L2_MEM_ECC_ERR_INT
  - HP_SYSTEM_L2_MEM_INT_ENA_REG: write 1 to enable L2_MEM_ECC_ERR_INT
  - HP_SYSTEM_L2_MEM_INT_CLR_REG: write 1 to clear L2_MEM_ECC_ERR_INT
- HP_SYSTEM_L2_MEM_INT_RECORD1_REG: records information when L2_MEM_ECC_ERR_INT occurs.
- HP_SYSTEM_L2_MEM_ERR_RESP_CTRL_REG: write 1 so HP L2MEM reports ECC error to HP CPU and triggers exception.

For detailed configuration steps, please refer to Chapter 9 *System and Memory*.

21.2.1.7 BitScrambler Configuration

ESP32-P4 has some peripherals that support DMA. These peripherals sometimes need BitScramblers to change the format of data before communicating with DMA.

Configure HP_SYSTEM_BITSCRAMBLER_PERI_SEL_REG to attach such a peripheral to the RX and TX channels of bitscamblers respectively.

For detailed configuration steps, please refer to Chapter 62 *BitScrambler*.

For a list of DMA-capable peripherals, please refer to Chapter 11 *Reset and Clock*.

21.2.1.8 Ethernet MAC Control

ESP32-P4 can send and receive data via Ethernet MAC (Media Access Controller) according to the IEEE 802.3 standard.

The control and configuration registers are:

- HP_SYSTEM_GMAC_CTRL0_REG
- HP_SYSTEM_GMAC_CTRL1_REG
- HP_SYSTEM_GMAC_CTRL2_REG

For details, please refer to Chapter 55 *Ethernet Media Access Controller (EMAC)*.

21.2.1.9 USB 2.0 High-Speed OTG Control

ESP32-P4 features a USB 2.0 High-Speed OTG peripheral (OTG_HS). To control it, use HP_SYSTEM_USBOTG20_CTRL_REG.

Register HP_SYSTEM_USB_OTGHS_PHY_ST_REG represents the USB OTGHS PHY status.

For details, please refer to Chapter *52 USB 2.0 High-Speed OTG*.

21.2.1.10 CPU Control and Record

ESP32-P4 configures CPU debug features and stores its status information via the following system registers.

- HP_SYSTEM_CPU_CORESTALLED_ST_REG: records the core stalled status of CPU0 and CPU1.
- HP_SYSTEM_CORE_DEBUG_RUNSTALL_CONF_REG: write 1 to enable debug runstall feature between HP CPU and LP CPU.
- HP_SYSTEM_HP_CORE_DMACTIVE_LPCORE_REG: represents the dmactive value of LP CPU's debug module.
- HP_SYSTEM_HP_CPU_WAKEUP_EVENT_REG: write 1 to wake up HP CPU0 or HP CPU1.

21.2.1.11 HP to LP Interrupt and Wakeup Control

HP system registers provide grouped control for routing peripheral interrupts and wakeup events from the HP domain to the LP CPU and PMU.

- Interrupt enable: HP_SYSTEM_HP2LP_INTR_GROUP0_EN_REG ~ HP_SYSTEM_HP2LP_INTR_GROUP3_EN_REG
- Interrupt status: HP_SYSTEM_HP2LP_INTR_GROUP0_ST_REG ~ HP_SYSTEM_HP2LP_INTR_GROUP3_ST_REG
- Wakeup enable: HP_SYSTEM_HP2LP_WAKEUP_GROUP0_EN_REG ~ HP_SYSTEM_HP2LP_WAKEUP_GROUP3_EN_REG

For details, please refer to Chapter *2 High-Performance CPU*.

21.2.1.12 HP GPIO Hold Control

Each GPIO pin of ESP32-P4 has an individual hold function that is controlled by the following registers:

- HP_SYSTEM_GPIO_O_HOLD_CTRL0_REG: controls the hold signal of HP GPIO16 ~ HP GPIO47
- HP_SYSTEM_GPIO_O_HOLD_CTRL1_REG: controls the hold signal of GPIO48 ~ HP GPIO56
- HP_SYSTEM_GPIO_DED_HOLD_CTRL_REG: the lower 6 bits control the hold signal of flash pads, and the higher 20 bits control the hold signal of 16 line PSRAM pad

For details, please refer to Chapter *10 GPIO Matrix and IO MUX*.

21.2.1.13 HP GPIO Output Control

Each GPIO pin of ESP32-P4 can be configured to directly output the desired value via the following registers (hysteresis):

- HP_SYSTEM_GPIO_O_HYS_CTRL0_REG: configures whether to enable the hysteresis feature of HP GPIO16 ~ HP GPIO47.
- HP_SYSTEM_GPIO_O_HYS_CTRL1_REG: configures whether to enable the hysteresis feature of HP GPIO48 ~ HP GPIO56.

For details, please refer to Section 10.10 in Chapter 10 *GPIO Matrix and IO MUX*.

21.2.1.14 Illegal Access and Unauthorized Access

ESP32-P4's buses return error response and record transfer address, transfer direction, and master id when illegal access and unauthorized access occur.

- Illegal access: access to unmapped address space
- Unauthorized access: access to mapped address space without permission

Such information will be logged in the following registers:

- HP CPU and other AHB masters (ICM_CPU_ADDRHOLE_INT)
  - HP_SYSTEM_ICM_CPU_ADDRHOLE_ADDR_REG
  - HP_SYSTEM_ICM_CPU_ADDRHOLE_INFO_REG
- AXI masters (ICM_SYS_ADDRHOLE_INT)
  - HP_SYSTEM_ICM_SYS_ADDRHOLE_ADDR_REG
  - HP_SYSTEM_ICM_SYS_ADDRHOLE_INFO_REG

For detailed information on address space mapping, please refer to Chapter 9 *System and Memory*.

For detailed information on access permission management, please refer to Chapter 20 *Permission Control (PMS)*.

21.2.1.15 HP CPU Bus Timeout Protection

ESP32-P4 supports Timeout Protection on HP CPU's IBUS, DBUS and AHB bus.

When a transfer is initiated, the counter inside the Timeout Protection module increments by one on each clock cycle.

- If the accumulated value remains below the timeout threshold and the slave device responds to the transfer, the internal counter is cleared.
- If the accumulated value exceeds the timeout threshold and the slave device has not responded, the Timeout Protection module takes control of the bus to return an error response to the HP CPU. At the same time, an interrupt is generated.

Related control and configuration registers are described below.

HP CPU IBUS Timeout Protection

Configure HP_SYSTEM_HP_CORE_IBUS_TIMEOUT_REG to enable timeout protection and set the timeout threshold for HP CPU accessing HP SPM, L2MEM and EXT MEM by IBUS.

When a timeout occurs, the HP_CORE*x*_IBUS_TIMEOUT_INT interrupt will be asserted.

HP CPU DBUS Timeout Protection

Configure HP_SYSTEM_HP_CORE_DBUS_TIMEOUT_REG to enable timeout protection and set the timeout threshold for HP CPU accessing HP SPM, L2MEM and EXT MEM by DBUS.

When a timeout occurs, the HP_CORE*x*_DBUS_TIMOUT_INT interrupt will be asserted.

HP CPU AHB BUS Timeout Protection

Configure HP_SYSTEM_HP_CORE_AHB_TIMEOUT_REG to enable timeout protection and set the timeout threshold for HP CPU accessing LP peripherals, HP peripherals registers by AHB bus.

When a timeout occurs, the HP_CORE*x*_AHB_TIMEOUT_INT interrupt will be asserted.

21.2.1.16 AXI Matrix

ESP32-P4's AXI Matrix connects multiple AXI-compliant master and slave devices, enabling efficient communication.

- Masters such as all AHB masters (master port1 through AHB2AXI bridge), HP CPU cache (master port2), DW GDMA_0 (master port6), DW GDMA_1 (master port7), AXI GDMA (master port9), 2DDMA (master port11), H264_0 (master port12), and H264_1 (master port13)
- Slaves such as L2MEM (slave port2), Flash (slave port3), PSRAM (slave port4), DSI Host (slave port6) and CSI Host(slave port7).

All AXI master ports except master port 2 in the AXI matrix support the QoS (Quality of Service) bandwidth regulator. The AXI matrix also includes a deadlock timeout protection mechanism, slave arbiter priority configuration for slave ports, and QoS arbiter priority configuration for master ports.

Deadlock Timeout Protection

ESP32-P4's Deadlock Timeout Protection is always enabled. Configure the timeout threshold for all AXI masters in the AXI matrix that access AXI Slaves such as Flash, PSRAM, DSI HOST, and CSI HOST via HP_SYSTEM_ICM_DLOCK_TIMEOUT_REG.

When a timeout occurs, AXI Matrix will record transfer direction, AXI ID, master ID and slave ID in HP_SYSTEM_ICM_DLOCK_STATUS_REG, and assert ICM_DLOCK_INTR interrupt at the same time.

Slave Arbiter Priority

Configure the arbitration priority for slaves in the AXI Matrix to arbitrate reading data and responses via HP_SYSTEM_ICM_SLV_ARB_PRIORITY_REG.

The higher the value, the higher the priority.

Master QoS Arbiter Priority

Configure the QoS (Quality of Service) values for masters in the AXI matrix to arbitrate the read address channel and write address channel via HP_SYSTEM_ICM_MST_ARQOS_REG0_REG and HP_SYSTEM_ICM_MST_AWQOS_REG0_REG, respectively.

A higher QoS value indicates a higher priority during arbitration.

21.2.1.17 Post Write

The following registers controls the Post Write mode of different components to speed up the write access.

- HP_SYSTEM_PERI1_APB_POSTW_EN_REG: enables the Post Write mode for APB2APB bridge between peripherals.
- HP_SYSTEM_APB_SYNC_POSTW_EN_REG: enables the Post Write mode for APB2APB bridge in DSI, CSI and ISP.
- HP_SYSTEM_CPU_ICM_H2X_POST_WR_EN: enables the Post Write mode for AHB2AXI bridge from AHB masters to AXI slaves.

21.2.2 LP System Registers

21.2.2.1 LP Timer Stall Control

The LP_SYSTEM_SYSTIMER_STALL_SEL field allows selection of the systimer_stall signal source for the LP timer, choosing between HP CPU0 and HP CPU1:

- 0: from CPU0
- 1: from CPU1

21.2.2.2 Focused Ion Beam (FIB) Control

The LP_SYSTEM_LP_FIB_SEL field allows selection of the control source for the brownout detector and the super watchdog, choosing between the analog system or software register.

- Bit-1: selects the control source for the brownout detector.
  - 0: controlled by software register
  - 1: controlled by the analog system.
- Bit-2: selects the control source for the super watchdog.
  - 0: controlled by software register
  - 1: controlled by the analog system.

Configure LP_SYSTEM_DIG_FIB to enable the brownout detector or the super watchdog via software register.

- Bit-1: write 1 to enable the brownout detector.
- Bit-2: write 1 to enable the super watchdog.

Read LP_SYSTEM_ANA_FIB to check the FIB state of brownout detector or the super watchdog via analog system (FIB state).

- Bit-1: brownout detector
- Bit-2: super watchdog

21.2.2.3 Boot Mode

Configure LP_SYSTEM_FORCE_DOWNLOAD_BOOT to forcibly switch the chip from SPI Boot mode to Joint Download Boot mode.

21.2.2.4 LP CPU Control

Configure the LP CPU via LP_SYSTEM_SYS_CTRL_REG. In particular:

- LP_SYSTEM_LP_CPU_BOOT_ADDR: configures the boot address of the LP CPU.
- LP_SYSTEM_LP_CPU_EXC_PC_REG: represents the exception PC address of the LP CPU.
- LP_SYSTEM_LP_CPU_DBG_PC_REG: represents the current PC address of the LP CPU.
- LP_SYSTEM_LP_CORE_ERR_RESP_DIS: configures whether or not to disable error response for respective LP CPU buses.

  - Bit-0: IBUS
  - Bit-1: DBUS
  - Bit-2: AHB bus

- LP_SYSTEM_LP_CORE_ETM_WAKEUP_FLAG: indicates the status of an ETM task triggered by a wakeup event of the LP CPU.
- LP_SYSTEM_LP_CORE_ETM_WAKEUP_FLAG_CLR: write 1 to clear LP_SYSTEM_LP_CORE_ETM_WAKEUP_FLAG.

21.2.2.5 Reset Control

ESP32-P4 supports for types of resets that occur at different levels. Such reset can be controlled by some system registers introduced in the following sections.

For a full list of all the reset types and reset sources, please refer to Chapter 11 *Reset and Clock*.

Analog and System Reset Source Bypass Control

LP_SYSTEM_ANA_RST_BYPASS: configures whether to bypass the following reset sources:

- Brown-out detector
- Super watchdog
- Power glitch detector

LP_SYSTEM_SYS_RST_BYPASS: configures whether to bypass the following reset sources:

- Software
- HP Watchdog timer
- LP Watchdog timer
- eFuse

Power-On Reset Bypass Control

LP_SYSTEM_HP_PO_RSTN_BYPASS_CTRL: configures whether or not to bypass the following reset sources for the HP power domain during the Power-On reset.

- Bit-0: eFuse
- Bit-1: LP watchdog timer
- Bit-2: USB (JTAG)
- Bit-3: USB (UART)
- Bit-4: Unused
- Bit-5: Unused
- Bit-6: HP watchdog timer
- Bit-7: Software

LP_SYSTEM_HP_PO_CNNT_RSTN_BYPASS_CTRL: configures whether or not to bypass the following reset sources for the HP CNNT power domain during the Power-On reset.

- Bit-0: eFuse
- Bit-1: LP watchdog timer
- Bit-2: USB (JTAG)
- Bit-3: USB (UART)
- Bit-4: Unused
- Bit-5: Unused
- Bit-6: HP watchdog timer
- Bit-7: Software

For details about ESP32-P4's power domains, please refer to Chapter 15 *Low-Power Management*.

Software System Reset

Configure LP_SYSTEM_SYS_SW_RST to trigger a software system reset.

IOMUX Reset

Configure LP_SYSTEM_IO_MUX_RESET_DISABLE to disable the HP IOMUX reset.

21.2.2.6 Wakeup Control

These registers control the behavior of some PMU wakeup sources.

LP_SYSTEM_USBOTG20_IN_SUSPEND: configures whether or not to enable wakeup signals from USB OTG2.0.

LP_SYSTEM_USBOTG20_WAKEUP_CLR: write 1 to clear wakeup signals from USB OTG2.0 to PMU.

LP_SYSTEM_USBOTG20_LS_MODE: configures whether USB OTG2.0 operates in low-speed mode.

Register LP_SYSTEM_HP_USB_OTGHS_PHY_CTRL_REG controls the USB OTGHS PHY pull-up and pull-down signals.

21.2.2.7 Pad Hold Control

The following registers control pad hold during sleep or reset:

- LP_SYSTEM_PAD_RTC_HOLD_CTRL0_REG: controls pad 0 ~ pad 31
- LP_SYSTEM_PAD_RTC_HOLD_CTRL1_REG: controls pad 32 ~ pad 56
- LP_SYSTEM_DED_PAD_RTC_HOLD_CTRL_REG: controls flash and PSRAM pads

21.2.2.8 Power Discharge Control

Register LP_SYSTEM_DISCHARGE_REG controls discharge of LDO flash and LP PUF memory.

21.2.2.9 LPROM and LP SPM Clock Control

LP_SYSTEM_LP_SPM_ROM_CLK_FORCE_ON: set to force on LP SPM_ROM clock if LP CPU clock is on.

LP_SYSTEM_LP_SPM_RAM_CLK_FORCE_ON: set to force on LP SPM_RAM clock.

21.2.2.10 Analog Voltage Comparator

Analog voltage comparator*x* (*x* = 0, 1) are configured by the following register fields:

- LP_SYSTEM_XPD_COMP*x* (*x* = 0, 1): configures whether or not to enable analog voltage comparator*x*.
- LP_SYSTEM_MODE_COMP*x* (*x* = 0, 1): configures the comparison mode:
  - 0: comparing the main voltage with the external reference voltage
  - 1: comparing the main voltage with the internal reference voltage
- LP_SYSTEM_DREF_COMP*x* (*x* = 0, 1): configures the internal reference voltage.
  - The adjustable voltage range is 0 to (0.7 * VDDPST_6) V.
  - The adjystable step is 0.1 * VDDPST_6 V.

For details, please refer to Chapter 66 *Analog Voltage Comparator*.

21.2.2.11 Illegal Access and Unauthorized Access

ESP32-P4's buses return error response and record transfer address, transfer direction, and master id when illegal access and unauthorized access occur.

- Illegal access: access to unmapped address space
- Unauthorized access: access to mapped address space without permission

Such information will be logged in the following registers:

- For LP CPU's access by IBUS and DBUS (IDBUS_ADDRHOLE_INTR)
  - LP_SYSTEM_IDBUS_ADDRHOLE_ADDR_REG
  - LP_SYSTEM_IDBUS_ADDRHOLE_INFO_REG
- For LP CPU's access by AHB or an access from HP CPU (LP_ADDRHOLE_INTR):
  - LP_SYSTEM_LP_ADDRHOLE_ADDR_REG
  - LP_SYSTEM_LP_ADDRHOLE_INFO_REG

For detailed information on address space mapping, please refer to Chapter 9 *System and Memory*.

For detailed information on access permission management, please refer to Chapter 20 *Permission Control (PMS)*.

21.2.2.12 LP Bus Timeout Protection

ESP32-P4 supports Timeout Protection on LP CPU's IBUS, DBUS and AHB bus.

When a transfer is initiated, the counter inside the Timeout Protection module increments by one on each clock cycle.

- If the accumulated value remains below the timeout threshold and the slave device responds to the transfer, the internal counter is cleared.
- If the accumulated value exceeds the timeout threshold and the slave device has not responded, the Timeout Protection module takes control of the bus to return an error response to the LP CPU. At the same time, an interrupt is generated.

Related control and configuration registers are described below.

LP CPU IBUS Timeout Protection

Configure LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_REG to enable timeout protection and set the timeout threshold for LP CPU accessing LPROM and LP SPM by IBUS. When a timeout occurs, the LP_CORE_IBUS_TIMEOUT_INTR interrupt will be asserted.

LP CPU DBUS Timeout Protection

Configure LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_REG to enable timeout protection and set the timeout threshold for LP CPU accessing LPROM and LP SPM by DBUS.

When a timeout occurs, the LP_CORE_DBUS_TIMEOUT_INTR interrupt will be asserted.

LP CPU AHB Bus Timeout Protection

Configure LP_SYSTEM_LP_CORE_AHB_TIMEOUT_REG to enable timeout protection and set the timeout threshold for LP CPU accessing LP peripherals, HP peripherals and CPU peripherals by AHB bus.

When a timeout occurs, the LP_CORE_AHB_TIMEOUT_INTR interrupt will be asserted.

21.2.2.13 RNG Control

Registers LP_SYSTEM_RNG_DATA_REG and LP_SYSTEM_RNG_CFG_REG are used to configure and control the random number generator.

21.3 Interrupt

ESP32-P4's System Registers can generate the following interrupt signal(s) that will be sent to the Interrupt Matrix.

- HP_SYSREG_INTR
- SYS_ICM_INTR
- LP_SYSREG_INTR

There are several internal interrupt sources from System Registers that can generate the above interrupt signal(s). The interrupt sources from System Registers are listed with their trigger conditions and the resulted interrupt signal(s) in Table 21.3-1.

Table 21.3-1. System Registers Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal

CPU_INT_FROM_CPU0	Software interrupt. Triggered by writing 1 to HP_SYSTEM_HP_CPU_INT_FROM_CPU_0_REG	HP_SYSREG_INTR
CPU_INT_FROM_CPU1	Software interrupt. Triggered by writing 1 to HP_SYSTEM_HP_CPU_INT_FROM_CPU_1_REG	
CPU_INT_FROM_CPU2	Software interrupt. Triggered by writing 1 to HP_SYSTEM_HP_CPU_INT_FROM_CPU_2_REG	
CPU_INT_FROM_CPU3	Software interrupt. Triggered by writing 1 to HP_SYSTEM_HP_CPU_INT_FROM_CPU_3_REG	
L2_MEM_ERR_RESP_INT	Triggered when an error response occurs in L2MEM	
L2_MEM_EXCEED_ADDR_INT	Triggered when L2MEM exceeds its address range	
L2_MEM_ECC_ERR_INT	Triggered when a one-bit flip error is detected and corrected by ECC in L2MEM	
HP_SPM_PARITY_ERR_INT	Triggered when a parity error occurs in HP SPM	
CPU_ICM_H2X_BRESP_ERR_INT	Triggered when a BRESP error occurs in Post Write mode in AHB2AXI	
HP_CORE1_DBUS_TIMEOUT_INT	Triggered upon HP CPU1 DBUS timeout	
HP_CORE0_DBUS_TIMEOUT_INT	Triggered upon HP CPU0 DBUS timeout	
HP_CORE1_IBUS_TIMEOUT_INT	Triggered upon HP CPU1 IBUS timeout	
HP_CORE0_IBUS_TIMEOUT_INT	Triggered upon HP CPU0 IBUS timeout	
HP_CORE1_AHB_TIMEOUT_INT	Triggered upon HP CPU1 AHB bus timeout	
HP_CORE0_AHB_TIMEOUT_INT	Triggered upon HP CPU0 AHB bus timeout	
ICM_CPU_ADDRHOLE_INT	Triggered when illegal/unauthorized access occurs in HP CPU and AHB matrix	SYS_ICM_INTR
ICM_SYS_ADDRHOLE_INT	Triggered when illegal/unauthorized access occurs in HP AXI matrix	
ICM_DLOCK_INT	Triggered when any AXI transfer in the AXI matrix times out	LP_SYSREG_INTR
SLOW_CLK_TICK_INT	ETM tick event interrupt. The interrupt source is periodically triggered at the frequency of LP_SLOW_CLK when the LP CPU is not sleeping. This event source can be disabled via the LP_CLKRST_ETM_EVENT_TICK_EN.	
ETM_TASK_ULP_INT	From ULP_TASK_INT_CPU. Ref to 14 *Event Task Matrix (ETM)* for details	
LP_CORE_DBUS_TIMEOUT_INT	Triggered upon LP CPU DBUS timeout	
LP_CORE_IBUS_TIMEOUT_INT	Triggered upon LP CPU IBUS timeout	
LP_CORE_AHB_TIMEOUT_INT	Triggered upon LP CPU AHB timeout	
IDBUS_ADDRHOLE_INT	Triggered when illegal/unauthorized access occurs on LP CPU IBUS or DBUS	
LP_ADDRHOLE_INT	Triggered when illegal/unauthorized access occurs in LP AHB matrix	

Note:

For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

21.4 Register Summary

21.4.1 HP Register Summary

The addresses in this section are relative to HP System Registers base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section Access Types for Registers.

Name	Description	Address	Access
Version Register			
HP_SYSTEM_VER_DATE_REG	Version control	0x0000	R/W
HP_SYSTEM_CLK_EN_REG	Clock gating control	0x0004	R/W
Interrupt Register			
HP_SYSTEM_HP_CPU_INT_FROM_CPU_0_REG	Software interrupt 0	0x0010	R/W
HP_SYSTEM_HP_CPU_INT_FROM_CPU_1_REG	Software interrupt 1	0x0014	R/W
HP_SYSTEM_HP_CPU_INT_FROM_CPU_2_REG	Software interrupt 2	0x0018	R/W
HP_SYSTEM_HP_CPU_INT_FROM_CPU_3_REG	Software interrupt 3	0x001C	R/W
HP_SYSTEM_HP_SPM_INT_RAW_REG	HP SPM interrupt raw	0x00FC	R/WTC /SS
HP_SYSTEM_HP_SPM_INT_ST_REG	Masked HP SPM interrupt status	0x0100	RO
HP_SYSTEM_HP_SPM_INT_ENA_REG	HP SPM interrupt enable	0x0104	R/W
HP_SYSTEM_HP_SPM_INT_CLR_REG	HP SPM interrupt clear	0x0108	WT
HP_SYSTEM_HP_CORE_TIMEOUT_INT_RAW_REG	HP CPU timeout interrupt raw	0x01A8	R/WTC /SS
HP_SYSTEM_HP_CORE_TIMEOUT_INT_ST_REG	HP CPU timeout masked interrupt	0x01AC	RO
HP_SYSTEM_HP_CORE_TIMEOUT_INT_ENA_REG	HP CPU timeout interrupt enable	0x01B0	R/W
HP_SYSTEM_HP_CORE_TIMEOUT_INT_CLR_REG	HP CPU timeout interrupt clear	0x01B4	WT
HP_SYSTEM_HP_CACHE_CLK_CONFIG_REG	Cache clock configuration	0x0020	R/W
HP_SYSTEM_CACHE_RESET_CONFIG_REG	Cache reset configuration	0x0024	R/W
HP_SYSTEM_HP_SPM_RAM_PWR_CTRL0_REG	HP SPM clock force on	0x003C	R/W
HP_SYSTEM_L2_ROM_PWR_CTRL0_REG	L2ROM clock force on	0x0040	R/W
HP_SYSTEM_HP_L2_MEM_RAM_PWR_CTRL0_REG	L2MEM clock force on	0x0060	R/W
HP_SYSTEM_CPU_CORESTALLED_ST_REG	HP CPU stall status	0x0064	RO
HP_SYSTEM_CRYPTO_CTRL_REG	Encryption control	0x0070	R/W
HP_SYSTEM_GPIO_0_HOLD_CTRL0_REG	HP GPIO hold control 0	0x0074	R/W
HP_SYSTEM_GPIO_0_HOLD_CTRL1_REG	HP GPIO hold control 1	0x0078	R/W
HP_SYSTEM_L2_MEM_INT_RAW_REG	HP L2MEM interrupt raw	0x009C	R/WTC /SS
HP_SYSTEM_L2_MEM_INT_ST_REG	Masked HP L2MEM interrupt status	0x00A0	RO
HP_SYSTEM_L2_MEM_INT_ENA_REG	HP L2MEM interrupt enable	0x00A4	R/W
HP_SYSTEM_L2_MEM_INT_CLR_REG	HP L2MEM interrupt clear	0x00A8	WT
HP_SYSTEM_AHB2AXI_BRESP_ERR_INT_RAW_REG	AHB to AXI BRESP error interrupt raw	0x0188	R/WTC /SS
HP_SYSTEM_AHB2AXI_BRESP_ERR_INT_ST_REG	AHB to AXI BRESP error interrupt status	0x018C	RO

Name	Description	Address	Access
HP_SYSTEM_AHB2AXI_BRESP_ERR_INT_ENA_REG	AHB to AXI BRESP error interrupt enable	0x0190	R/W
HP_SYSTEM_AHB2AXI_BRESP_ERR_INT_CLR_REG	AHB to AXI BRESP error interrupt clear	0x0194	WT
HP_SYSTEM_L2_MEM_L2_RAM_ECC_REG	HP L2MEM ECC enable	0x00AC	R/W
HP_SYSTEM_L2_MEM_INT_RECORD0_REG	HP L2MEM interrupt record 0	0x00B0	RO
HP_SYSTEM_L2_MEM_INT_RECORD1_REG	HP L2MEM interrupt record 1	0x00B4	RO
HP_SYSTEM_L2_MEM_L2_CACHE_ECC_REG	L2 cache ECC enable	0x00C4	R/W
HP_SYSTEM_HP_L1CACHE_BUS0_ID_REG	L1 cache bus 0 ID	0x00C8	R/W
HP_SYSTEM_HP_L1CACHE_BUS1_ID_REG	L1 cache bus 1 ID	0x00CC	R/W
HP_SYSTEM_GPIO_DED_HOLD_CTRL_REG	HP GPIO hold control	0x00F0	R/W
HP_SYSTEM_HP_USB20OTG_MEM_CTRL_REG	MEM in USB OTG FS clock force on	0x00F8	R/W
HP_SYSTEM_HP_SPM_PARITY_INT_RECORD_REG	HP SPM parity interrupt status	0x010C	RO
HP_SYSTEM_HP_L1_CACHE_PWR_CTRL_REG	HP L1 cache memory force on	0x0110	R/W
HP_SYSTEM_HP_L2_CACHE_PWR_CTRL_REG	HP L2 cache memory force on	0x0114	R/W
HP_SYSTEM_HP_CPU_WAITI_CONF_REG	CPU_WAITI configuration	0x0118	R/W
HP_SYSTEM_CORE_DEBUG_RUNSTALL_CONF_REG	CPU debug runstall configuration	0x011C	R/W
HP_SYSTEM_HP_CORE_AHB_TIMEOUT_REG	HP CPU AHB bus timeout	0x0120	R/W
HP_SYSTEM_HP_CORE_IBUS_TIMEOUT_REG	HP CPU IBUS timeout	0x0124	R/W
HP_SYSTEM_HP_CORE_DBUS_TIMEOUT_REG	HP CPU DBUS timeout	0x0128	R/W
HP_SYSTEM_HP_ICM_CPU_H2X_CFG_REG	AHB to AXI bridge configuration	0x0138	varies
HP_SYSTEM_PERI1_APB_POSTW_EN_REG	HP PERI1 APB post write enable	0x013C	R/W
HP_SYSTEM_BITSCRAMBLER_PERI_SEL_REG	BitScrambler peripherals select	0x0140	R/W
HP_SYSTEM_APB_SYNC_POSTW_EN_REG	HP PERI0 APB post write enable	0x0144	R/W
HP_SYSTEM_HP_RSA_PD_CTRL_REG	RSA memory PD control	0x01D0	R/W
HP_SYSTEM_HP_ECC_PD_CTRL_REG	ECC memory PD control	0x01D4	R/W
HP_SYSTEM_HP_RNG_CFG_REG	RNG configuration	0x01D8	R/W
HP_SYSTEM_HP_UART_PD_CTRL_REG	Memory PD control	0x01DC	R/W
HP_SYSTEM_HP_PERI_MEM_CLK_FORCE_ON_REG	HP PERI memory clock force on	0x01E0	R/W
HP_SYSTEM_HP_CPU_WAKEUP_EVENT_REG	CPU wakeup event control	0x01EC	R/W
HP_SYSTEM_HP2LP_INTR_GROUP0_EN_REG	HP to LP interrupt enable group 0	0x01F0	R/W
HP_SYSTEM_HP2LP_INTR_GROUP1_EN_REG	HP to LP interrupt enable group 1	0x01F4	R/W
HP_SYSTEM_HP2LP_INTR_GROUP2_EN_REG	HP to LP interrupt enable group 2	0x01F8	R/W
HP_SYSTEM_HP2LP_INTR_GROUP3_EN_REG	HP to LP interrupt enable group 3	0x01FC	R/W
HP_SYSTEM_HP2LP_WAKEUP_GROUP0_EN_REG	HP to LP wakeup enable group 0	0x0210	R/W
HP_SYSTEM_HP2LP_WAKEUP_GROUP1_EN_REG	HP to LP wakeup enable group 1	0x0214	R/W
HP_SYSTEM_HP2LP_WAKEUP_GROUP2_EN_REG	HP to LP wakeup enable group 2	0x0218	R/W
HP_SYSTEM_HP2LP_WAKEUP_GROUP3_EN_REG	HP to LP wakeup enable group 3	0x021C	R/W
HP_SYSTEM_GDMA_CTRL_REG	DW-GDMA control	0x0148	R/W
HP_SYSTEM_GMAC_CTRL0_REG	GMAC control 0	0x014C	varies
HP_SYSTEM_GMAC_CTRL1_REG	GMAC control 1	0x0150	RO
HP_SYSTEM_GMAC_CTRL2_REG	GMAC control 2	0x0154	RO
HP_SYSTEM_USBOTG20_CTRL_REG	USB OTGHS control	0x015C	varies
HP_SYSTEM_HP_SPM_ERR_RESP_CTRL_REG	HP SPM error response enable	0x0160	R/W

Name	Description	Address	Access
HP_SYSTEM_L2_MEM_REFRESH_REG	HP SPM refresh	0x0164	varies
HP_SYSTEM_HP_SPM_INIT_REG	HP SPM initialization	0x0168	varies
HP_SYSTEM_HP_SPM_PARITY_CHECK_CTRL_REG	HP SPM parity check enable	0x016C	R/W
HP_SYSTEM_L2_MEM_ERR_RESP_CTRL_REG	HP L2MEM error response	0x0198	R/W
HP_SYSTEM_L2_MEM_AHB_BUFFER_CTRL_REG	HP L2MEM AHB buffer enable	0x019C	R/W
HP_SYSTEM_HP_CORE_DMACTIVE_LPCORE_REG	HP CPU debug module active	0x01A0	RO
Control Registers			
HP_SYSTEM_HP_CORE_ERR_RESP_DIS_REG	HP CPU error response masked	0x01A4	R/W
HP_SYSTEM_GPIO_O_HYS_CTRL0_REG	HP GPIO hysteresis control 0	0x01C0	R/W
HP_SYSTEM_GPIO_O_HYS_CTRL1_REG	HP GPIO hysteresis control 1	0x01C4	R/W
Status Registers			
HP_SYSTEM_USB_OTGHS_PHY_ST_REG	USB OTGHS PHY status	0x01E8	RO
HP_SYSTEM_HP2LP_INTR_GROUP0_ST_REG	HP to LP interrupt status group 0	0x0200	RO
HP_SYSTEM_HP2LP_INTR_GROUP1_ST_REG	HP to LP interrupt status group 1	0x0204	RO
HP_SYSTEM_HP2LP_INTR_GROUP2_ST_REG	HP to LP interrupt status group 2	0x0208	RO
HP_SYSTEM_HP2LP_INTR_GROUP3_ST_REG	HP to LP interrupt status group 3	0x020C	RO

21.4.2 ICM Register Summary

The addresses in this section are relative to relative to AXI ICM base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section Access Types for Registers.

Name	Description	Address	Access
Version Register			
HP_SYSTEM_ICM_VER_DATE_REG	ICM version control	0x0000	R/W
Clock Gating Register			
HP_SYSTEM_ICM_CLK_EN_REG	Clock gating control	0x0004	R/W
Status Register			
HP_SYSTEM_ICM_DLOCK_STATUS_REG	ICM deadlock status	0x0008	RO
HP_SYSTEM_ICM_SYS_ADDRHOLE_ADDR_REG	System address hole address	0x0038	RO
HP_SYSTEM_ICM_SYS_ADDRHOLE_INFO_REG	System address hole information	0x003C	RO
HP_SYSTEM_ICM_CPU_ADDRHOLE_ADDR_REG	CPU address hole address	0x0040	RO
HP_SYSTEM_ICM_CPU_ADDRHOLE_INFO_REG	CPU address hole information	0x0044	RO
Interrupt Register			
HP_SYSTEM_ICM_INT_RAW_REG	ICM interrupt raw status	0x000C	R/WTC/SS
HP_SYSTEM_ICM_INT_ST_REG	ICM masked interrupt status	0x0010	RO
HP_SYSTEM_ICM_INT_ENA_REG	ICM interrupt enable	0x0014	R/W
HP_SYSTEM_ICM_INT_CLR_REG	ICM interrupt clear	0x0018	WT
Configuration Register			
HP_SYSTEM_ICM_SLV_ARB_PRIORITY_REG	Slave arbitration priority configuration	0x0024	R/W
HP_SYSTEM_ICM_MST_ARQOS_REG0_REG	ARQoS configuration	0x0028	R/W

Name	Description	Address	Access
HP_SYSTEM_ICM_MST_AWQOS_REG0_REG	AWQoS configuration	0x0030	R/W
HP_SYSTEM_ICM_DLOCK_TIMEOUT_REG	ICM deadlock timeout	0x0048	R/W

21.4.3 LP Register Summary

The addresses in this section are relative to LP System Registers base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section Access Types for Registers.

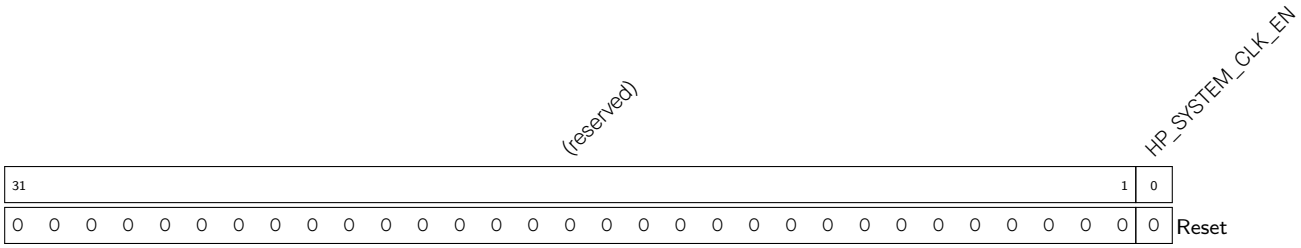
Name	Description	Address	Access
Configuration & Control Registers			
LP_SYSTEM_LP_SYS_VER_DATE_REG	Version control	0x0000	R/W
LP_SYSTEM_SYS_CTRL_REG	System control	0x0008	varies
LP_SYSTEM_LP_CLK_CTRL_REG	Clock control	0x000C	R/W
LP_SYSTEM_LP_RST_CTRL_REG	Reset control	0x0010	R/W
LP_SYSTEM_LP_CORE_BOOT_ADDR_REG	LP CPU boot address	0x0018	R/W
LP_SYSTEM_LP_SPM_PWR_CTRL_REG	LPROM and LP SPM clock control	0x0024	R/W
LP_SYSTEM_USB_CTRL_REG	USB control	0x0100	varies
LP_SYSTEM_PAD_COMP0_REG	Pad compensation 0	0x0148	R/W
LP_SYSTEM_PAD_COMP1_REG	Pad compensation 1	0x014C	R/W
LP_SYSTEM_HP_MEM_AUX_CTRL_REG	High-performance memory auxiliary control	0x0180	R/W
LP_SYSTEM_LP_MEM_AUX_CTRL_REG	Low-power memory auxiliary control	0x0184	R/W
LP_SYSTEM_HP_ROM_AUX_CTRL_REG	High-performance ROM auxiliary control	0x0188	R/W
LP_SYSTEM_LP_ROM_AUX_CTRL_REG	Low-power ROM auxiliary control	0x018C	R/W
LP_SYSTEM_HP_POR_RST_BYPASS_CTRL_REG	Power-on reset control	0x01A0	R/W
LP_SYSTEM_LP_CORE_AHB_TIMEOUT_REG	CPU AHB bus timeout	0x01B0	R/W
LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_REG	CPU IBUS timeout	0x01B4	R/W
LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_REG	CPU DBUS timeout	0x01B8	R/W
LP_SYSTEM_LP_CORE_ERR_RESP_DIS_REG	CPU error response control	0x01BC	R/W
LP_SYSTEM_RNG_CFG_REG	RNG configuration	0x01C0	varies
LP_SYSTEM_PAD_RTC_HOLD_CTRL0_REG	Pad hold control 0	0x01C4	R/W
LP_SYSTEM_PAD_RTC_HOLD_CTRL1_REG	Pad hold control 1	0x01C8	R/W
LP_SYSTEM_DED_PAD_RTC_HOLD_CTRL_REG	Dedicated pad hold control	0x01CC	R/W
LP_SYSTEM_DISCHARGE_REG	PUF memory and LDO flash discharge control	0x0200	R/W
LP_SYSTEM_HP_USB_OTGHS_PHY_CTRL_REG	USB OTGHS PHY control	0x0204	R/W
Status Registers			
LP_SYSTEM_LP_ADDRHOLE_ADDR_REG	AHB bus address hole address	0x0168	RO
LP_SYSTEM_LP_ADDRHOLE_INFO_REG	AHB bus address hole information	0x016C	RO
LP_SYSTEM_LP_CPU_DBG_PC_REG	LP CPU debug PC	0x0190	RO
LP_SYSTEM_LP_CPU_EXC_PC_REG	LP CPU exception PC	0x0194	RO

Name	Description	Address	Access
LP_SYSTEM_IDBUS_ADDRHOLE_ADDR_REG	CPU IBUS and DBUS address hole address	0x0198	RO
LP_SYSTEM_IDBUS_ADDRHOLE_INFO_REG	CPU IBUS and DBUS address hole information	0x019C	RO
LP_SYSTEM_RNG_DATA_REG	RNG data	0x01A4	RO
Interrupt Registers			
LP_SYSTEM_INT_RAW_REG	Raw interrupt status	0x0170	R/SS /WTC
LP_SYSTEM_INT_ST_REG	Masked interrupt status	0x0174	RO
LP_SYSTEM_INT_ENA_REG	Interrupt enable	0x0178	R/W
LP_SYSTEM_INT_CLR_REG	Interrupt clear	0x017C	WT

21.5 Registers

21.5.1 HP Registers

The addresses in this section are relative to HP System Registers base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

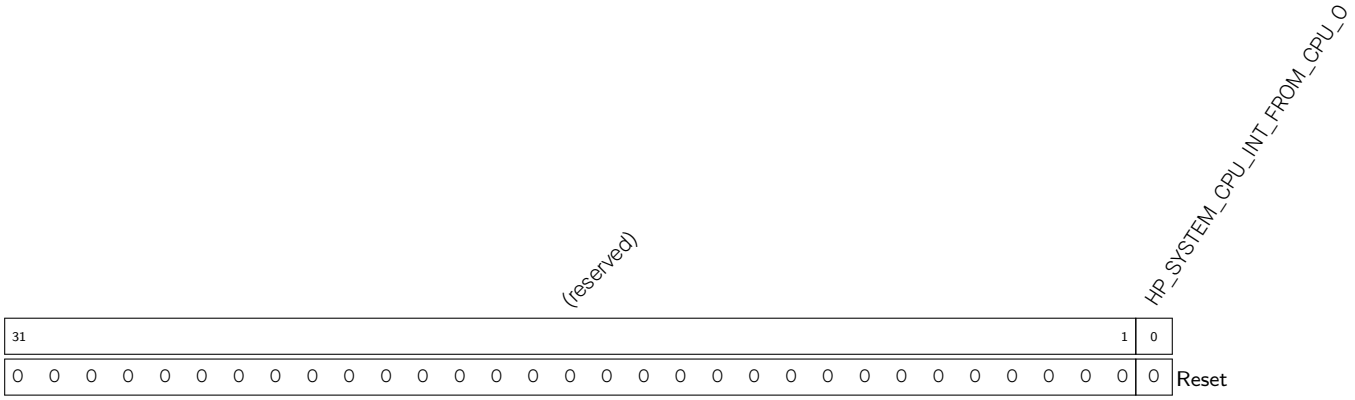


For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 21.1. HP_SYSTEM_VER_DATE_REG (0x0000)

HP_SYSTEM_REG_VER_DATE Version control register. (R/W)

Register 21.2. HP_SYSTEM_CLK_EN_REG (0x0004)



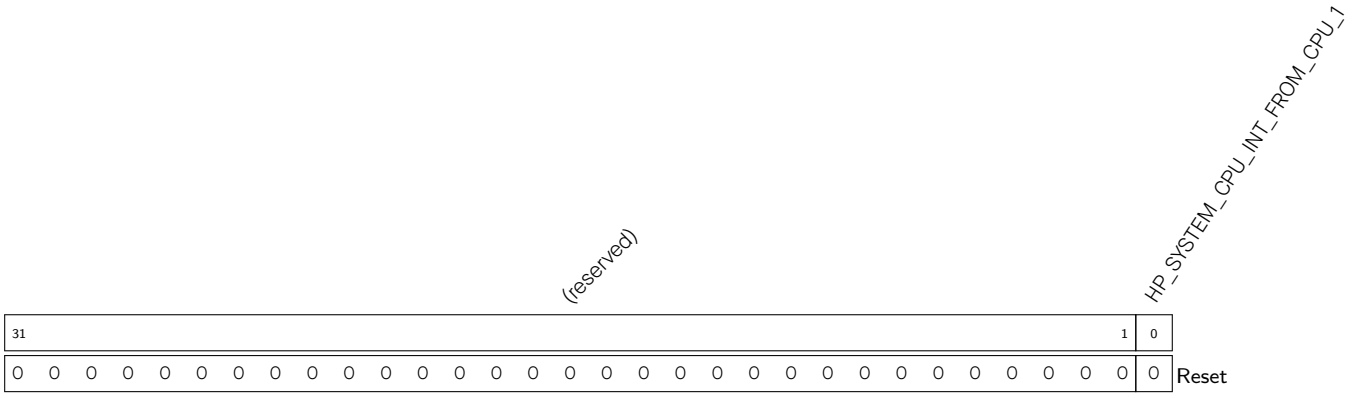
HP_SYSTEM_CLK_EN Configures whether to enable system clock.

0: Disable

1: Enable

(R/W)

Register 21.3. HP_SYSTEM_HP_CPU_INT_FROM_CPU_0_REG (0x0010)



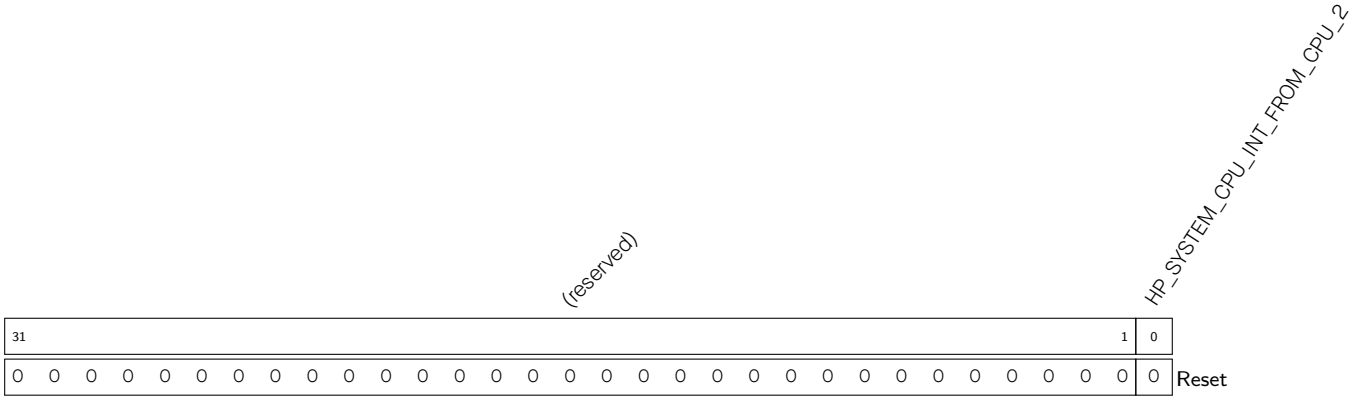
HP_SYSTEM_CPU_INT_FROM_CPU_0 Configures whether to generate CPU_INT_FROM_CPU0.

0: No effect

1: Generate

(R/W)

Register 21.4. HP_SYSTEM_HP_CPU_INT_FROM_CPU_1_REG (0x0014)



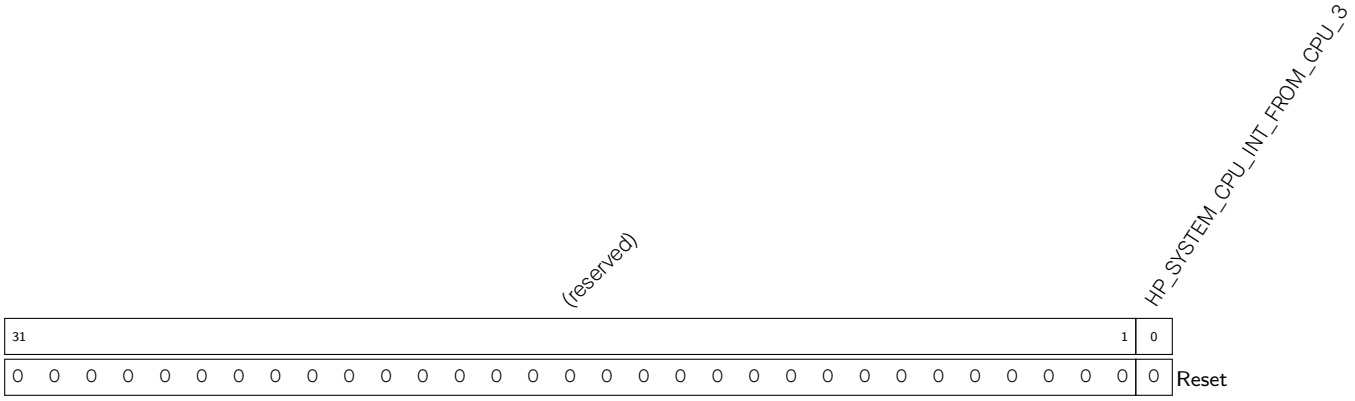
HP_SYSTEM_CPU_INT_FROM_CPU_1 Configures whether to generate CPU_INT_FROM_CPU1.

0: No effect

1: Generate

(R/W)

Register 21.5. HP_SYSTEM_HP_CPU_INT_FROM_CPU_2_REG (0x0018)



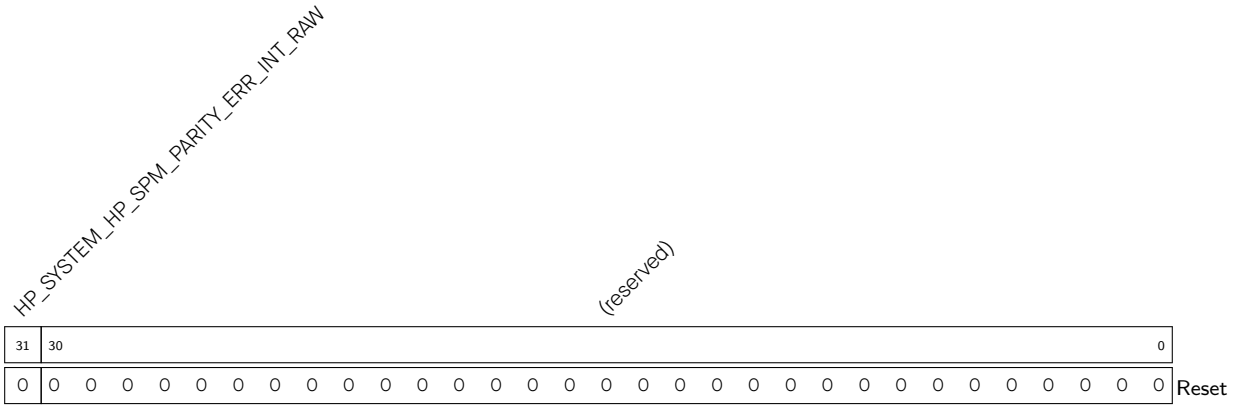
HP_SYSTEM_CPU_INT_FROM_CPU_2 Configures whether to generate CPU_INT_FROM_CPU2.

0: No effect

1: Generate

(R/W)

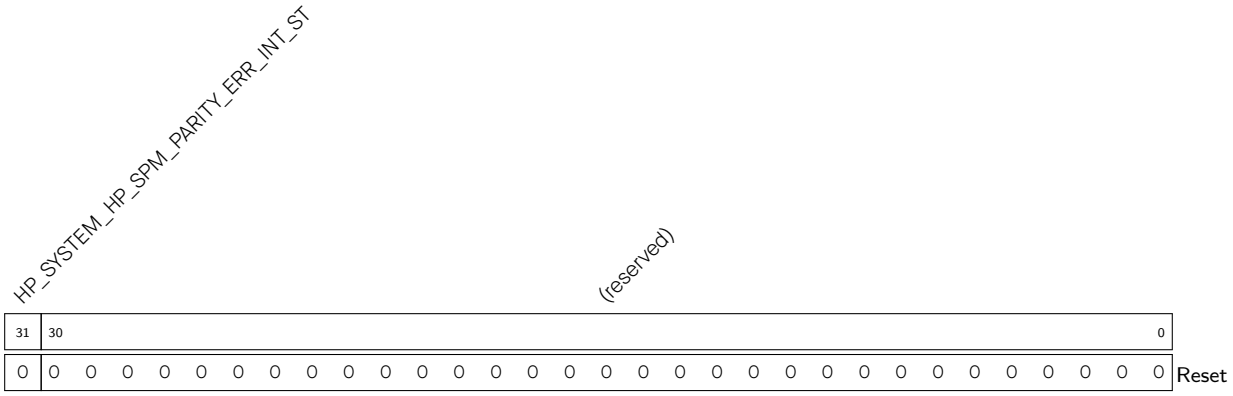
Register 21.6. HP_SYSTEM_HP_CPU_INT_FROM_CPU_3_REG (0x001C)



HP_SYSTEM_CPU_INT_FROM_CPU_3 Configures whether to generate CPU_INT_FROM_CPU3.

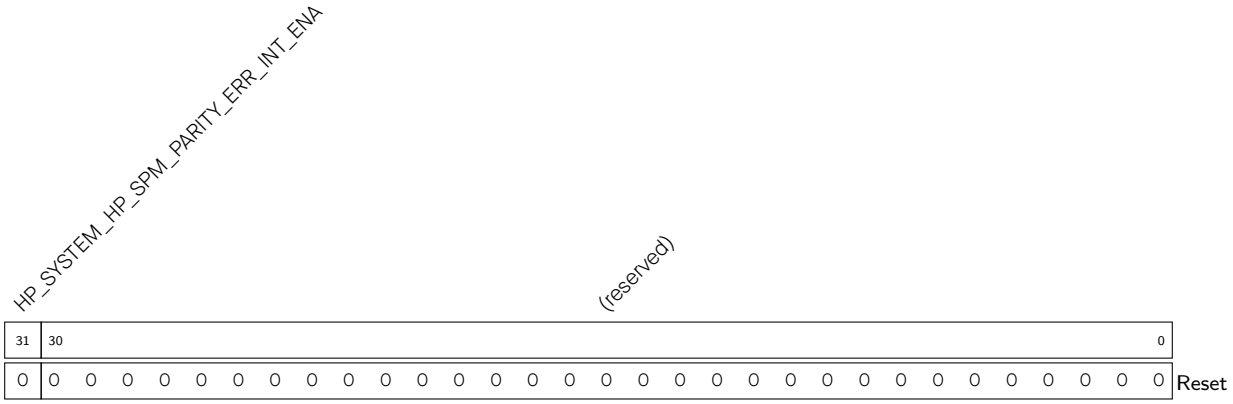
0: No effect

1: Generate



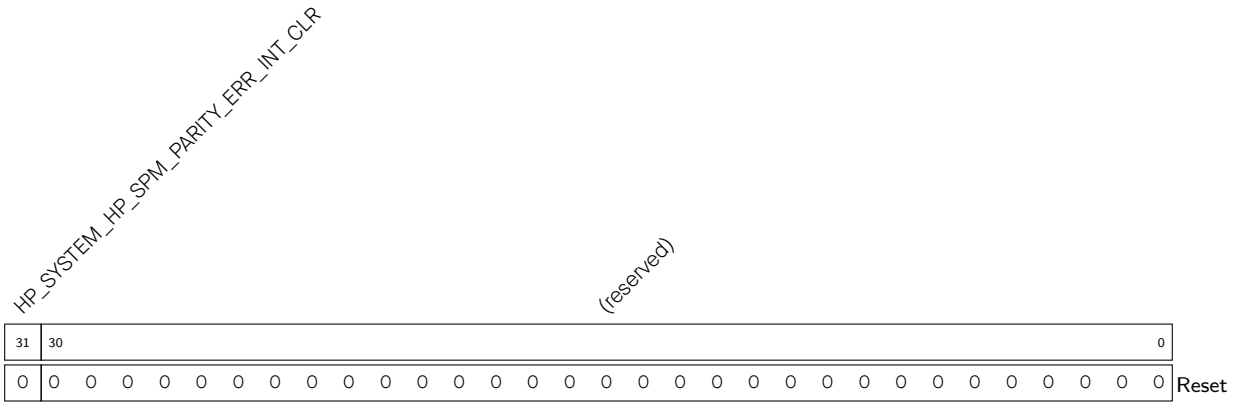
(R/W)

Register 21.7. HP_SYSTEM_HP_SPM_INT_RAW_REG (0x00FC)



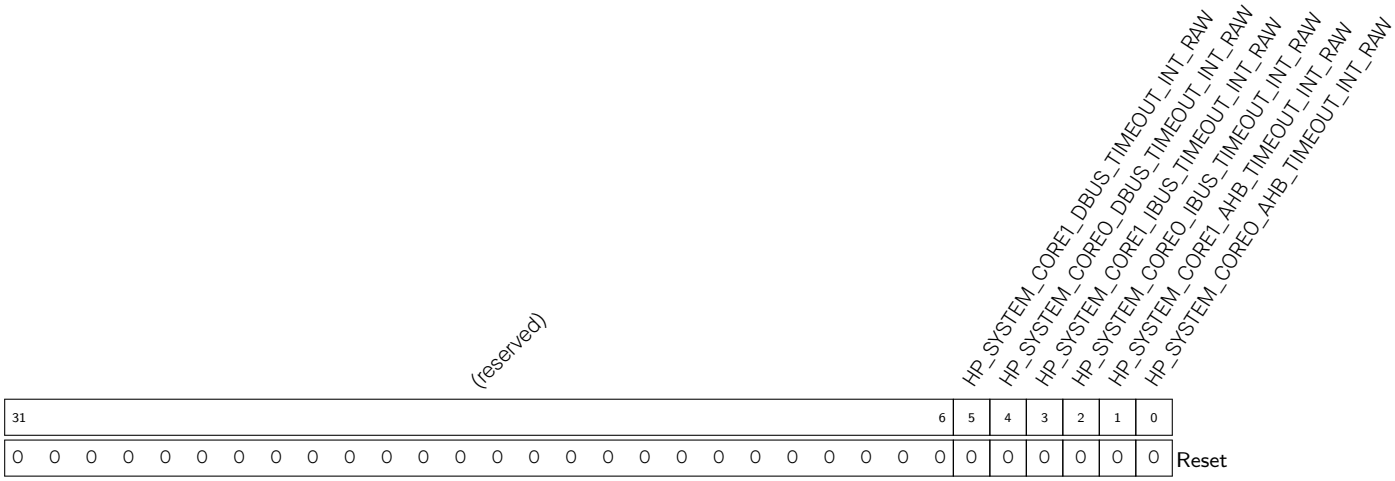
HP_SYSTEM_HP_SPM_PARITY_ERR_INT_RAW The raw interrupt status of HP_SPM_PARITY_ERR_INT, triggered when a parity error occurs. (R/WTC/SS)

Register 21.8. HP_SYSTEM_HP_SPM_INT_ST_REG (0x0100)



HP_SYSTEM_HP_SPM_PARITY_ERR_INT_ST The masked interrupt status of HP_SPM_PARITY_ERR_INT. (RO)

Register 21.9. HP_SYSTEM_HP_SPM_INT_ENA_REG (0x0104)



HP_SYSTEM_HP_SPM_PARITY_ERR_INT_ENA Write 1 to enable HP_SPM_PARITY_ERR_INT. (R/W)

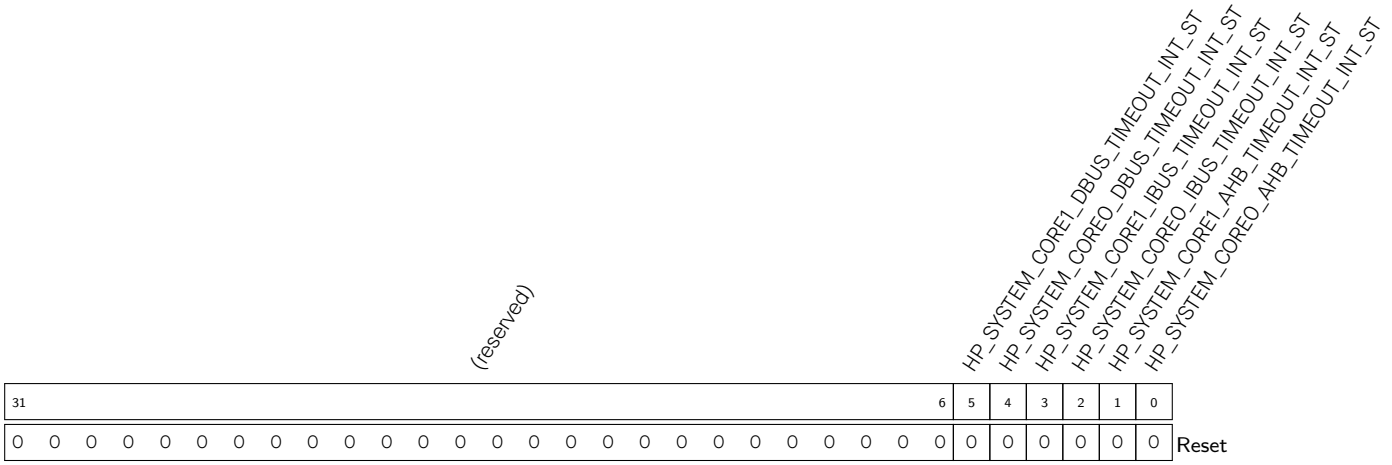
Register 21.10. HP_SYSTEM_HP_SPM_INT_CLR_REG (0x0108)

HP_SYSTEM_HP_SPM_PARITY_ERR_INT_CLR Write 1 to clear HP_SPM_PARITY_ERR_INT. (WT)

Register 21.11. HP_SYSTEM_HP_CORE_TIMEOUT_INT_RAW_REG (0x01A8)

HP_SYSTEM_COREO_AHB_TIMEOUT_INT_RAW The raw interrupt status of HP_COREO_AHB_TIMEOUT_INT. (R/WTC/SS)

HP_SYSTEM_CORE1_AHB_TIMEOUT_INT_RAW The raw interrupt status of HP_CORE1_AHB_TIMEOUT_INT. (R/WTC/SS)



HP_SYSTEM_COREO_IBUS_TIMEOUT_INT_RAW The raw interrupt status of HP_COREO_IBUS_TIMEOUT_INT. (R/WTC/SS)

HP_SYSTEM_CORE1_IBUS_TIMEOUT_INT_RAW The raw interrupt status of HP_CORE1_IBUS_TIMEOUT_INT. (R/WTC/SS)

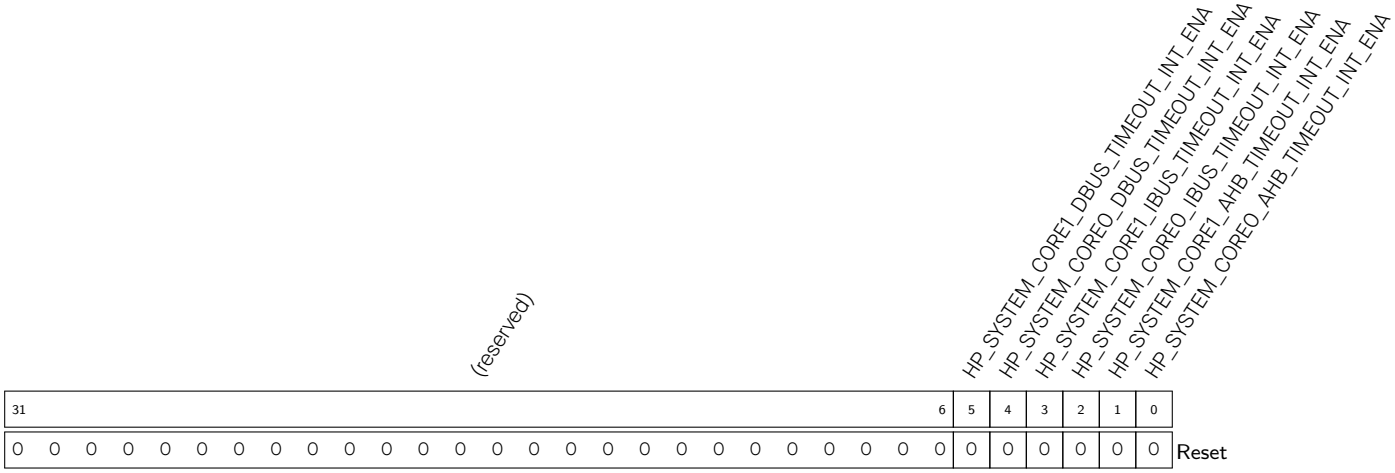
HP_SYSTEM_COREO_DBUS_TIMEOUT_INT_RAW The raw interrupt status of HP_COREO_DBUS_TIMEOUT_INT. (R/WTC/SS)

HP_SYSTEM_CORE1_DBUS_TIMEOUT_INT_RAW The raw interrupt status of HP_CORE1_DBUS_TIMEOUT_INT. (R/WTC/SS)

Register 21.12. HP_SYSTEM_HP_CORE_TIMEOUT_INT_ST_REG (0x01AC)

HP_SYSTEM_COREO_AHB_TIMEOUT_INT_ST The masked interrupt status of HP_COREO_AHB_TIMEOUT_INT. (RO)

HP_SYSTEM_CORE1_AHB_TIMEOUT_INT_ST The masked interrupt status of HP_CORE1_AHB_TIMEOUT_INT. (RO)



HP_SYSTEM_COREO_IBUS_TIMEOUT_INT_ST The masked interrupt status of HP_COREO_IBUS_TIMEOUT_INT. (RO)

HP_SYSTEM_CORE1_IBUS_TIMEOUT_INT_ST The masked interrupt status of HP_CORE1_IBUS_TIMEOUT_INT. (RO)

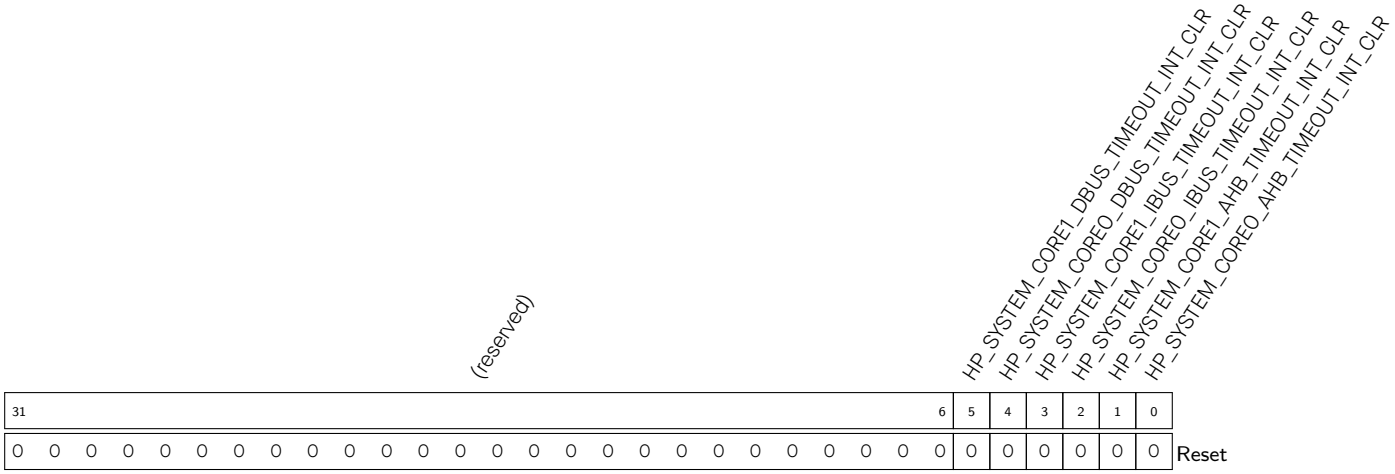
HP_SYSTEM_COREO_DBUS_TIMEOUT_INT_ST The masked interrupt status of HP_COREO_DBUS_TIMEOUT_INT. (RO)

HP_SYSTEM_CORE1_DBUS_TIMEOUT_INT_ST The masked interrupt status of HP_CORE1_DBUS_TIMEOUT_INT. (RO)

Register 21.13. HP_SYSTEM_HP_CORE_TIMEOUT_INT_ENA_REG (0x01B0)

HP_SYSTEM_CORE0_AHB_TIMEOUT_INT_ENA Write 1 to enable HP_CORE0_AHB_TIMEOUT_INT. (R/W)

HP_SYSTEM_CORE1_AHB_TIMEOUT_INT_ENA Write 1 to enable HP_CORE1_AHB_TIMEOUT_INT. (R/W)



HP_SYSTEM_CORE0_IBUS_TIMEOUT_INT_ENA Write 1 to enable HP_CORE0_IBUS_TIMEOUT_INT. (R/W)

HP_SYSTEM_CORE1_IBUS_TIMEOUT_INT_ENA Write 1 to enable HP_CORE1_IBUS_TIMEOUT_INT. (R/W)

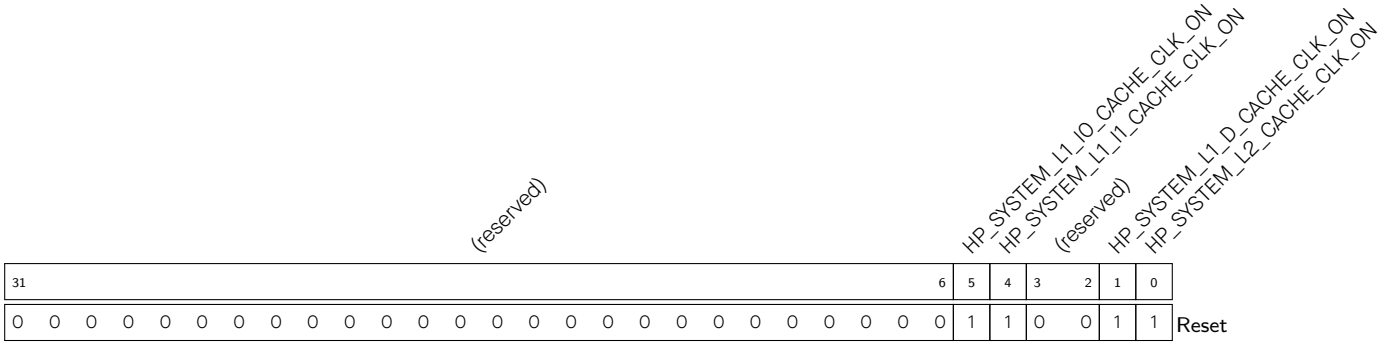
HP_SYSTEM_CORE0_DBUS_TIMEOUT_INT_ENA Write 1 to enable HP_CORE0_DBUS_TIMEOUT_INT. (R/W)

HP_SYSTEM_CORE1_DBUS_TIMEOUT_INT_ENA Write 1 to enable HP_CORE1_DBUS_TIMEOUT_INT. (R/W)

Register 21.14. HP_SYSTEM_HP_CORE_TIMEOUT_INT_CLR_REG (0x01B4)

HP_SYSTEM_CORE0_AHB_TIMEOUT_INT_CLR Write 1 to clear HP_CORE0_AHB_TIMEOUT_INT. (WT)

HP_SYSTEM_CORE1_AHB_TIMEOUT_INT_CLR Write 1 to clear HP_CORE1_AHB_TIMEOUT_INT. (WT)



HP_SYSTEM_CORE0_IBUS_TIMEOUT_INT_CLR Write 1 to clear HP_CORE0_IBUS_TIMEOUT_INT. (WT)

HP_SYSTEM_CORE1_IBUS_TIMEOUT_INT_CLR Write 1 to clear HP_CORE1_IBUS_TIMEOUT_INT. (WT)

HP_SYSTEM_CORE0_DBUS_TIMEOUT_INT_CLR Write 1 to clear HP_CORE0_DBUS_TIMEOUT_INT. (WT)

HP_SYSTEM_CORE1_DBUS_TIMEOUT_INT_CLR Write 1 to clear HP_CORE1_DBUS_TIMEOUT_INT. (WT)

Register 21.15. HP_SYSTEM_HP_CACHE_CLK_CONFIG_REG (0x0020)

HP_SYSTEM_L2_CACHE_CLK_ON Configures whether to enable L2 cache clock.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_L1_D_CACHE_CLK_ON Configures whether to enable L1 dcache clock.

0: Disable

1: Enable

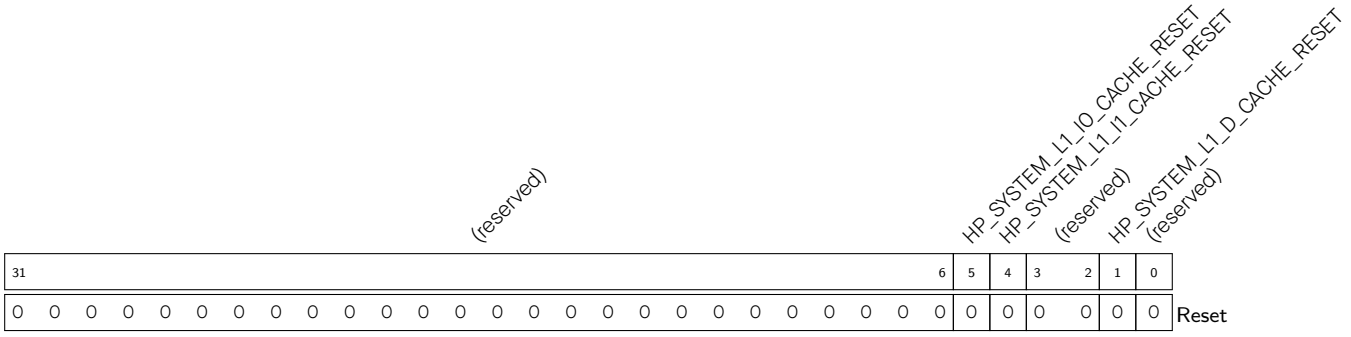
(R/W)

HP_SYSTEM_L1_I1_CACHE_CLK_ON Configures whether to enable L1 ichache 1 clock.

0: Disable

1: Enable

(R/W)



HP_SYSTEM_L1_I0_CACHE_CLK_ON Configures whether to enable L1 ichache 0 clock.

0: Disable

1: Enable

(R/W)

Register 21.16. HP_SYSTEM_CACHE_RESET_CONFIG_REG (0x0024)

HP_SYSTEM_L1_D_CACHE_RESET Configures whether to reset L1 dcache.

0: No effect

1: Reset

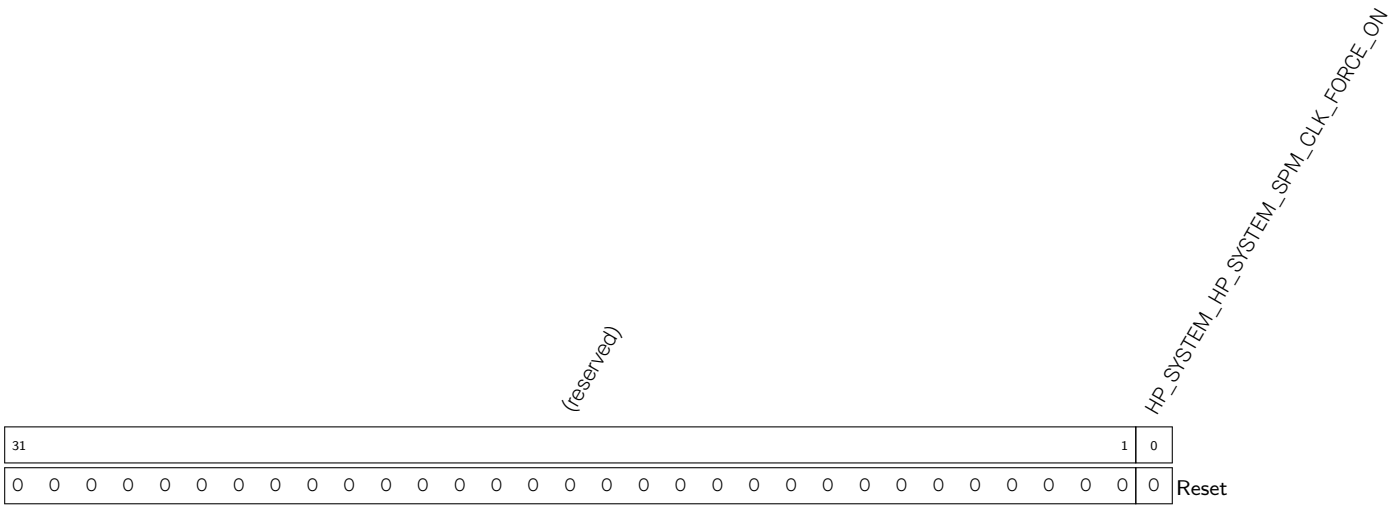
(R/W)

HP_SYSTEM_L1_I1_CACHE_RESET Configures whether to reset L1 ichache 1.

0: No effect

1: Reset

(R/W)



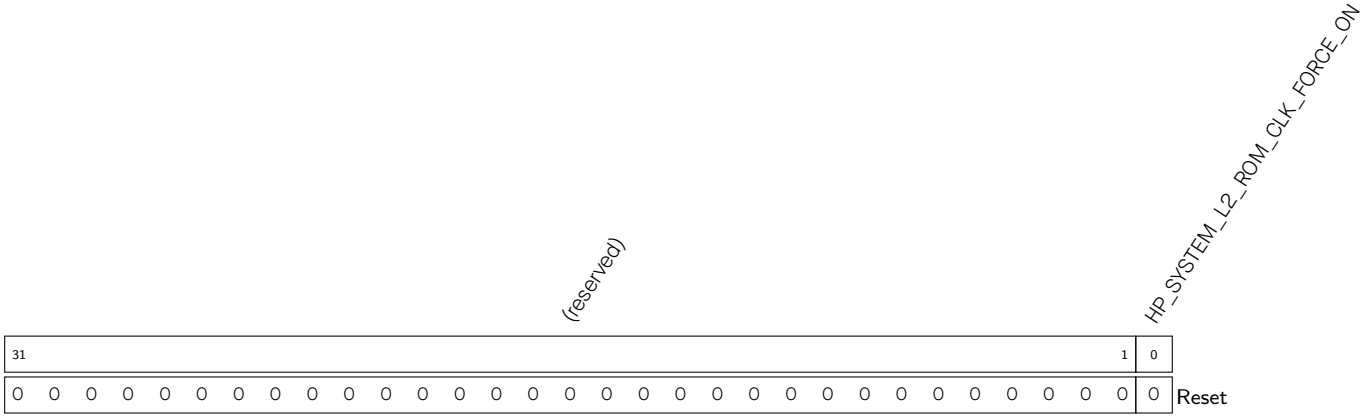
HP_SYSTEM_L1_IO_CACHE_RESET Configures whether to reset L1 ichache 0.

0: No effect

1: Reset

(R/W)

Register 21.17. HP_SYSTEM_HP_SPM_RAM_PWR_CTRL0_REG (0x003C)



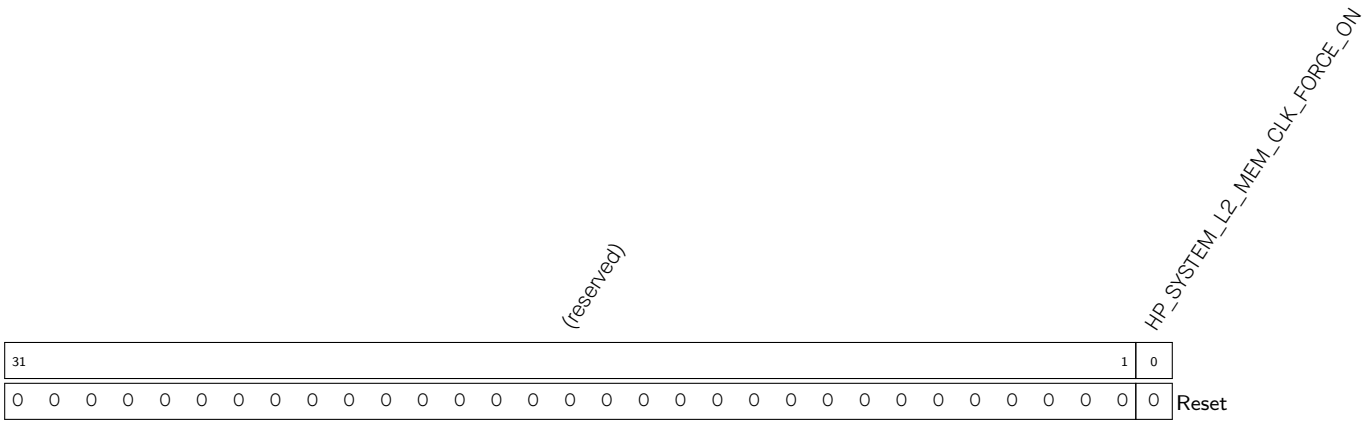
HP_SYSTEM_HP_SPM_CLK_FORCE_ON Configures whether to force on HP SPM clock.

0: No effect

1: Force on

(R/W)

Register 21.18. HP_SYSTEM_L2_ROM_PWR_CTRL0_REG (0x0040)



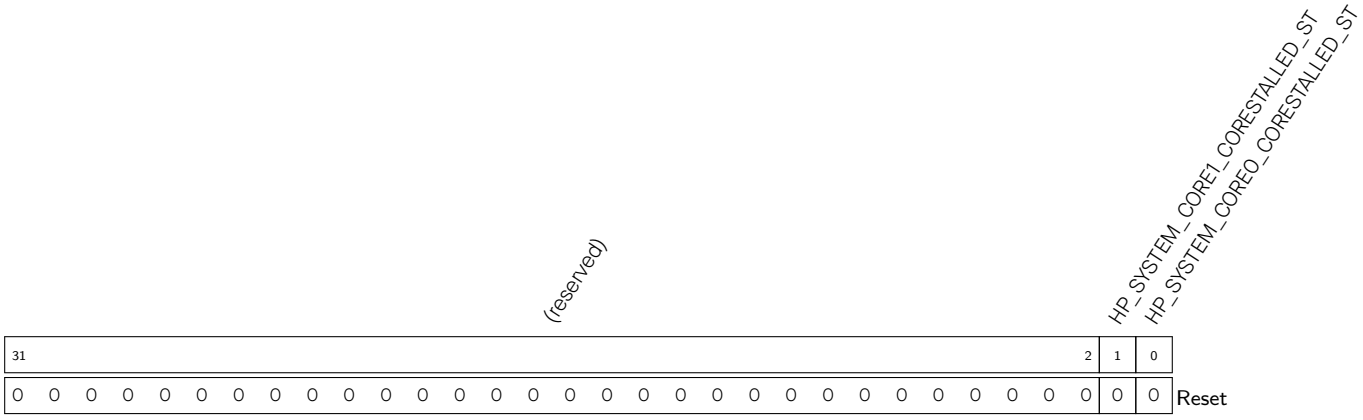
HP_SYSTEM_L2_ROM_CLK_FORCE_ON Configures whether to force on L2ROM clock.

0: No effect

1: Force on

(R/W)

Register 21.19. HP_SYSTEM_HP_SYSTEM_L2_MEM_RAM_PWR_CTRL0_REG (0x0060)

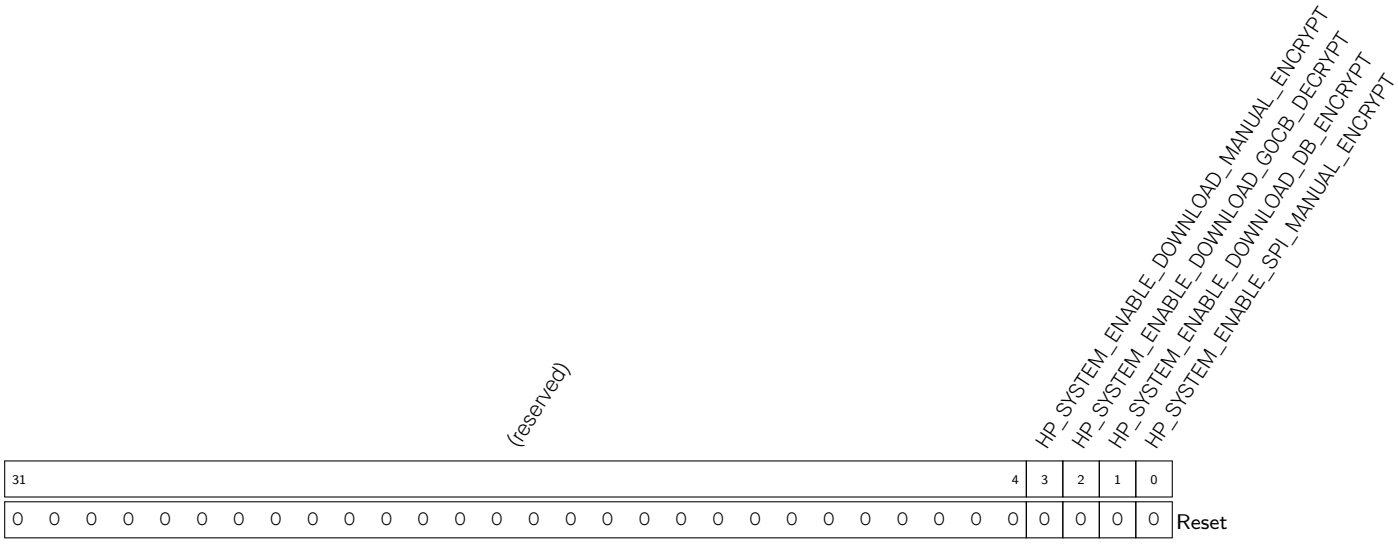


HP_SYSTEM_L2_MEM_CLK_FORCE_ON Configures whether to force on L2MEM clock.

0: No effect

1: Force on

(R/W)



Register 21.20. HP_SYSTEM_CPU_CORESTALLED_ST_REG (0x0064)

HP_SYSTEM_CORE0_CORESTALLED_ST Represents the CPU stall status of HP CPU0. (RO)

HP_SYSTEM_CORE1_CORESTALLED_ST Represents the CPU stall status of HP CPU1. (RO)

Register 21.21. HP_SYSTEM_CRYPTO_CTRL_REG (0x0070)

HP_SYSTEM_ENABLE_SPI_MANUAL_ENCRYPT Configures whether to enable Manual Encryption in SPI Boot mode.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_ENABLE_DOWNLOAD_DB_ENCRYPT Configures whether to enable Auto Encryption in Joint Download Boot mode.

0: Disable

1: Enable

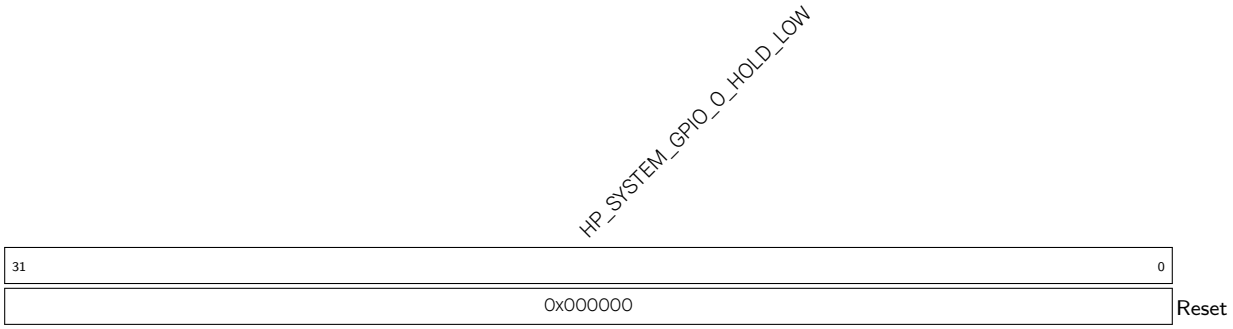
(R/W)

HP_SYSTEM_ENABLE_DOWNLOAD_GOCB_DECRYPT Configures whether to enable Auto Decryption in Joint Download Boot mode.

0: Disable

1: Enable

(R/W)



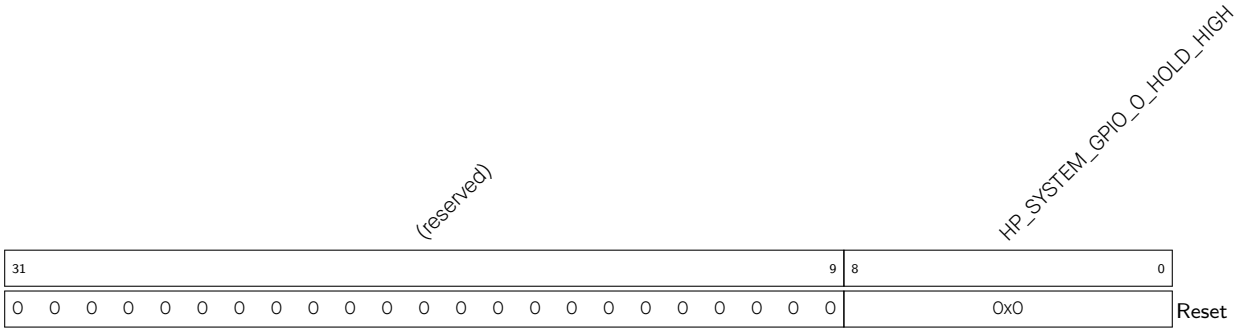
HP_SYSTEM_ENABLE_DOWNLOAD_MANUAL_ENCRYPT Configures whether to enable Manual Encryption in Joint Download Boot mode.

0: Disable

1: Enable

(R/W)

Register 21.22. HP_SYSTEM_GPIO_O_HOLD_CTRL0_REG (0x0074)



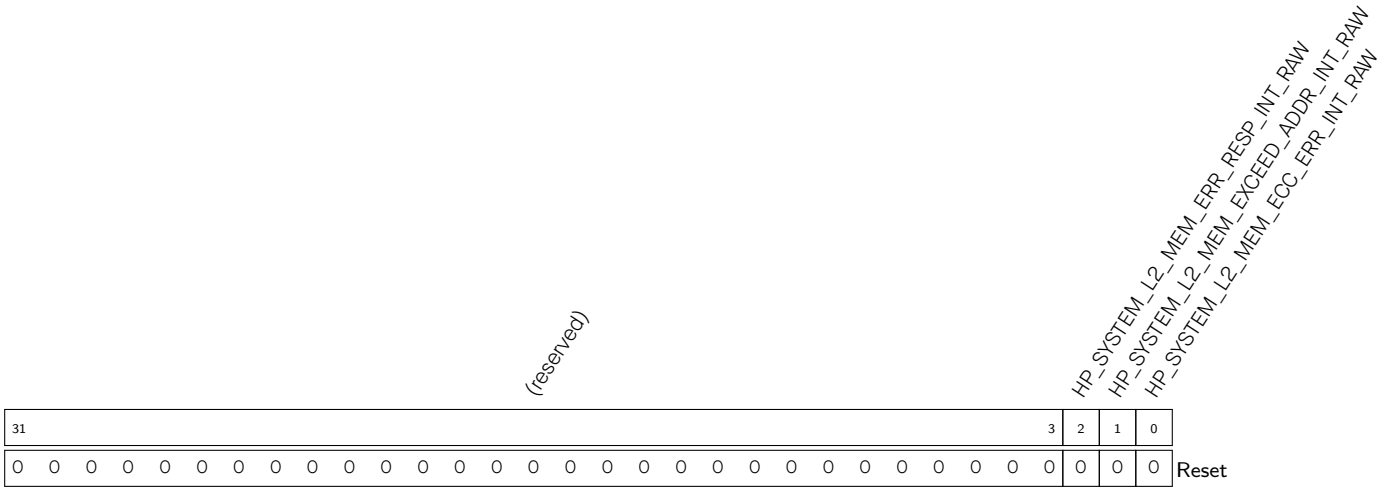
HP_SYSTEM_GPIO_O_HOLD_LOW Configures whether to hold HP GPIO16 ~ HP GPIO47.

0: No effect

1: Hold

(R/W)

Register 21.23. HP_SYSTEM_GPIO_O_HOLD_CTRL1_REG (0x0078)



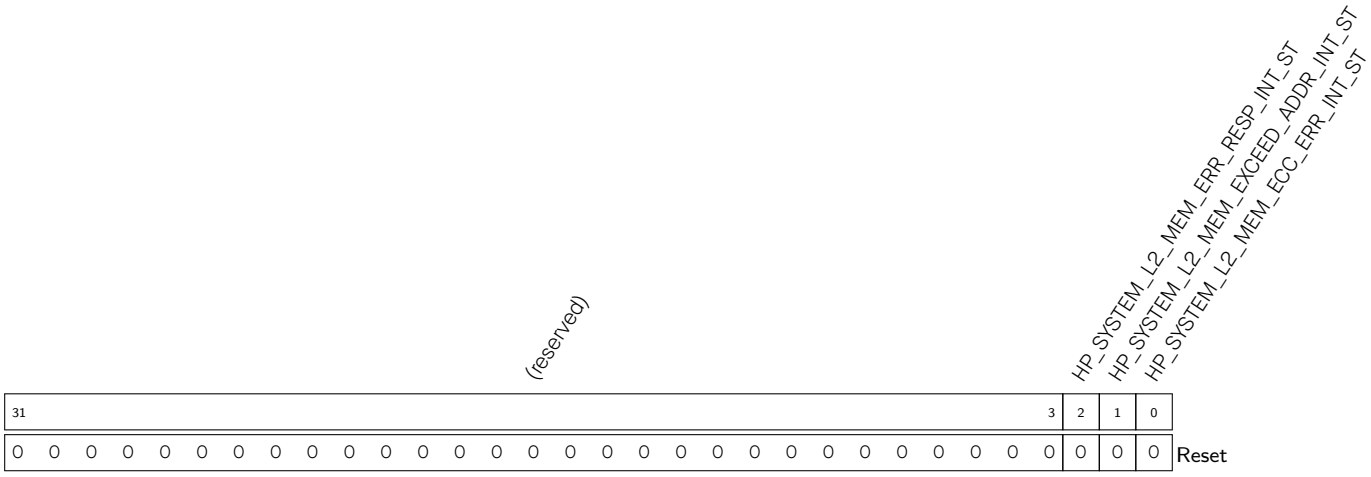
HP_SYSTEM_GPIO_O_HOLD_HIGH Configures whether to hold HP GPIO48 ~ HP GPIO56.

0: No effect

1: Hold

(R/W)

Register 21.24. HP_SYSTEM_L2_MEM_INT_RAW_REG (0x009C)

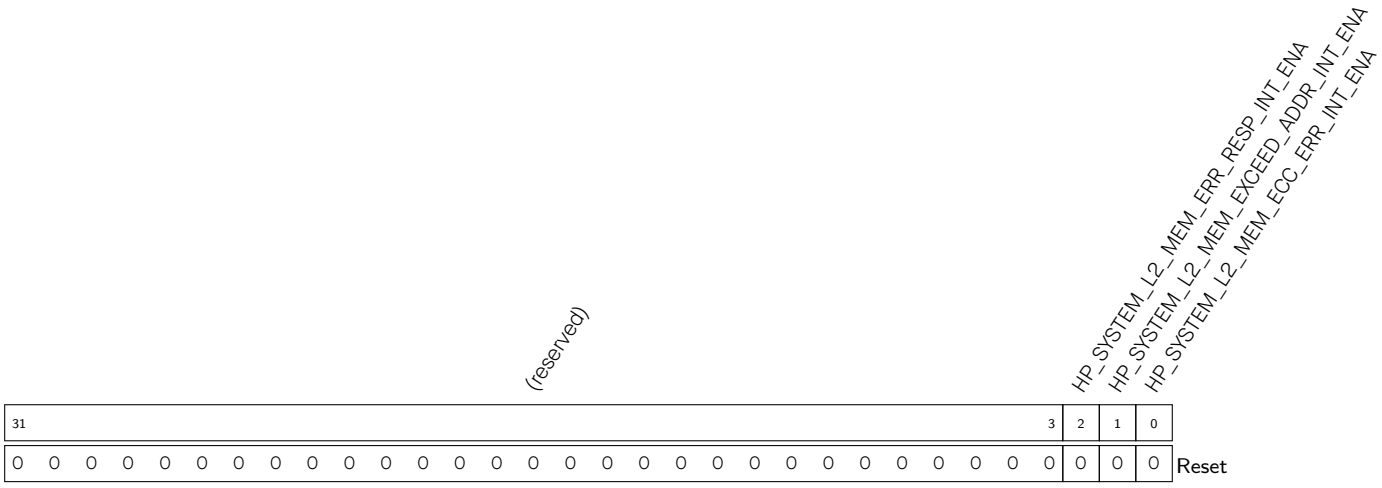


HP_SYSTEM_L2_MEM_ECC_ERR_INT_RAW The raw interrupt status of L2_MEM_ECC_ERR_INT, triggered when a one-bit flip error is detected and corrected by ECC. (R/WTC/SS)

HP_SYSTEM_L2_MEM_EXCEED_ADDR_INT_RAW The raw interrupt status of L2_MEM_EXCEED_ADDR_INT, triggered when access address exceeds limits in different modes.
Bypass mode: 0xff9ffff
L2 cache 128 KB mode: 0xff80000
L2 cache 256 KB mode: 0xff60000
(R/WTC/SS)

HP_SYSTEM_L2_MEM_ERR_RESP_INT_RAW The raw interrupt status of L2_MEM_ERR_RESP_INT, triggered when an error response occurs. (R/WTC/SS)

Register 21.25. HP_SYSTEM_L2_MEM_INT_ST_REG (0x00A0)

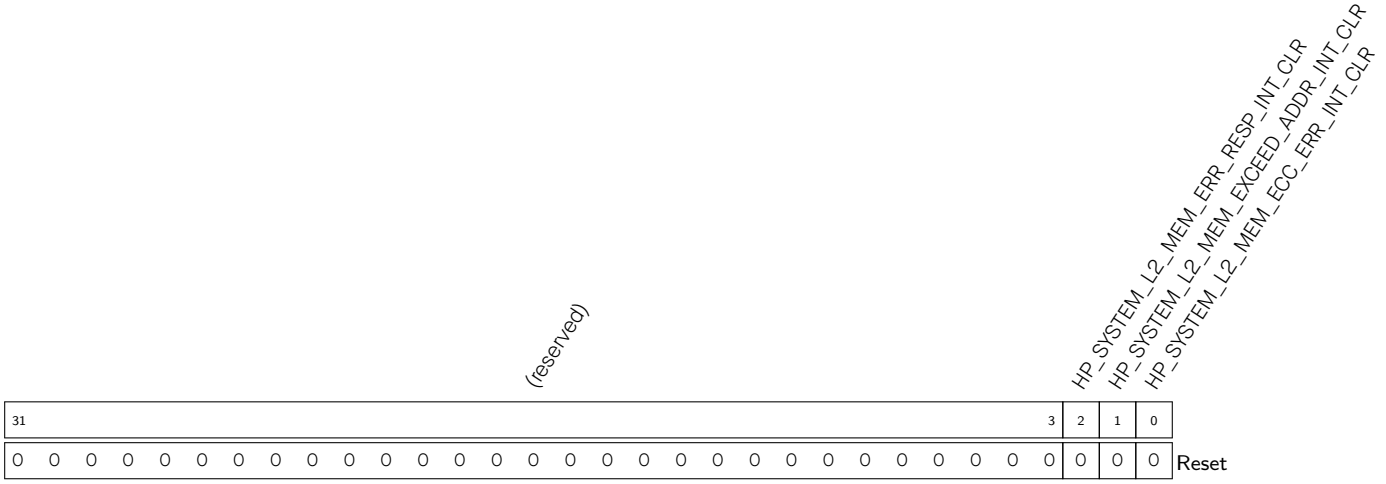


HP_SYSTEM_L2_MEM_ECC_ERR_INT_ST The masked interrupt status of L2_MEM_ECC_ERR_INT. (RO)

HP_SYSTEM_L2_MEM_EXCEED_ADDR_INT_ST The masked interrupt status of L2_MEM_EXCEED_ADDR_INT. (RO)

HP_SYSTEM_L2_MEM_ERR_RESP_INT_ST The masked interrupt status of L2_MEM_ERR_RESP_INT. (RO)

Register 21.26. HP_SYSTEM_L2_MEM_INT_ENA_REG (0x00A4)

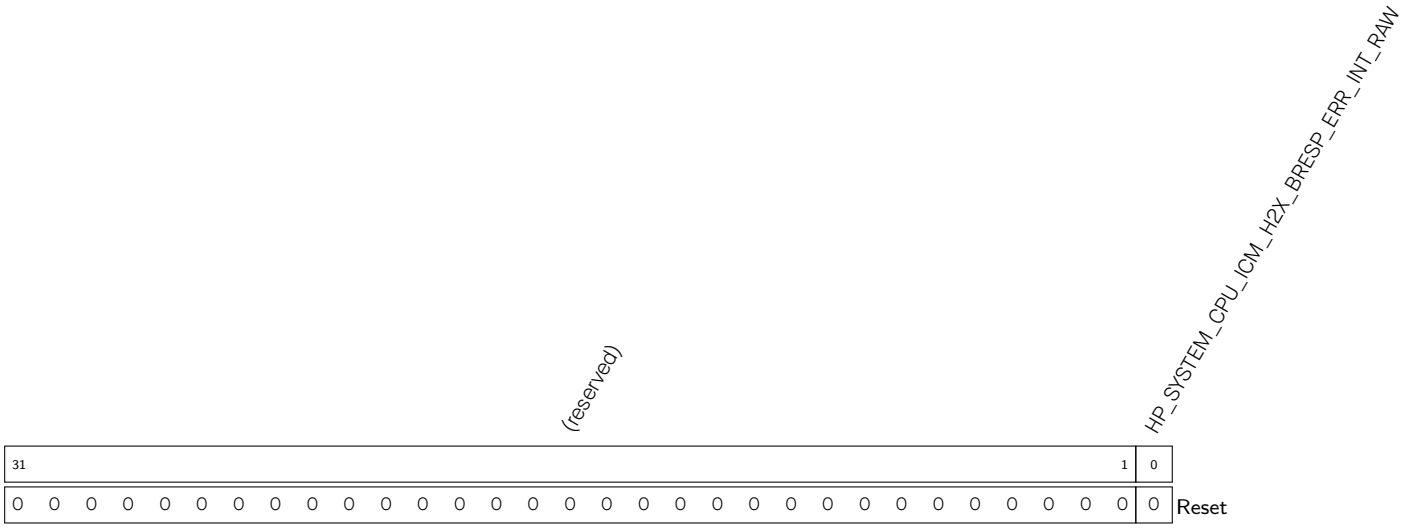


HP_SYSTEM_L2_MEM_ECC_ERR_INT_ENA Write 1 to enable L2_MEM_ECC_ERR_INT. (R/W)

HP_SYSTEM_L2_MEM_EXCEED_ADDR_INT_ENA Write 1 to enable L2_MEM_EXCEED_ADDR_INT. (R/W)

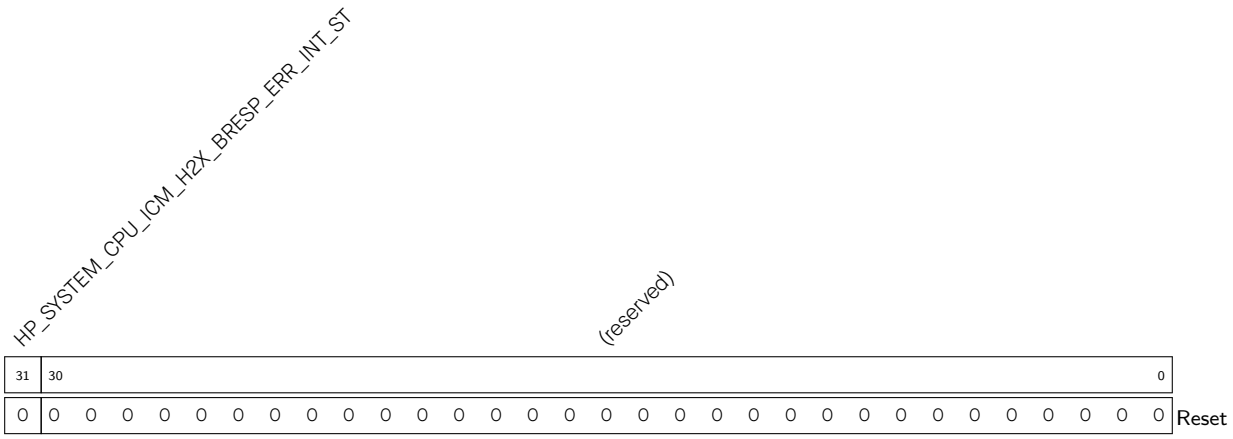
HP_SYSTEM_L2_MEM_ERR_RESP_INT_ENA Write 1 to enable L2_MEM_ERR_RESP_INT. (R/W)

Register 21.27. HP_SYSTEM_L2_MEM_INT_CLR_REG (0x00A8)



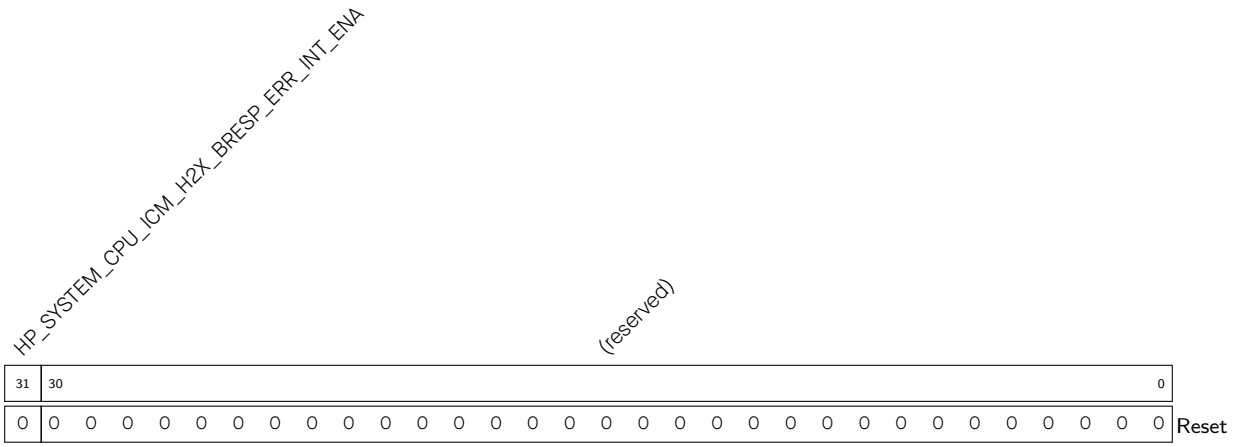
HP_SYSTEM_L2_MEM_ECC_ERR_INT_CLR Write 1 to clear L2_MEM_ECC_ERR_INT. (WT)

HP_SYSTEM_L2_MEM_EXCEED_ADDR_INT_CLR Write 1 to clear L2_MEM_EXCEED_ADDR_INT. (WT)



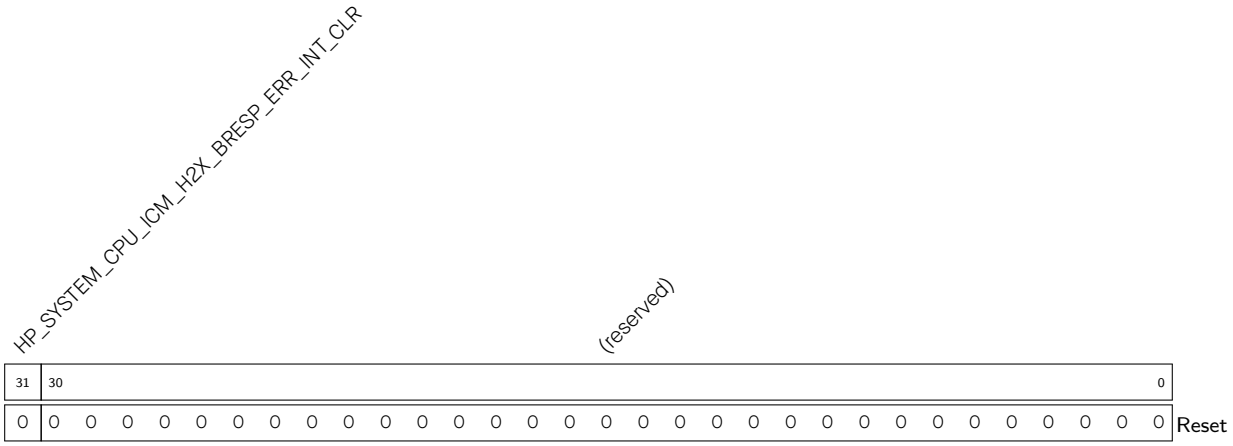
HP_SYSTEM_L2_MEM_ERR_RESP_INT_CLR Write 1 to clear L2_MEM_ERR_RESP_INT. (WT)

Register 21.28. HP_SYSTEM_AHB2AXI_BRESP_ERR_INT_RAW_REG (0x0188)



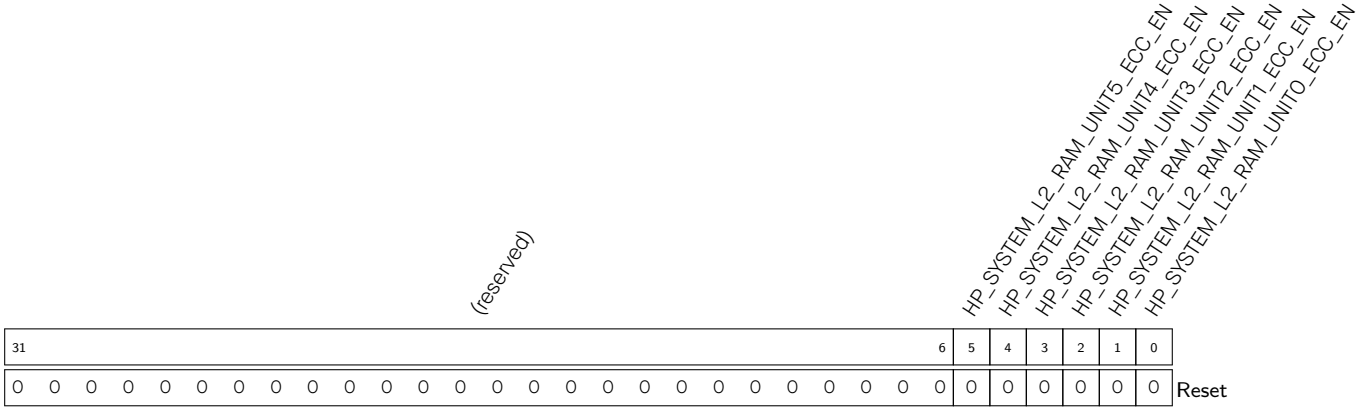
HP_SYSTEM_CPU_ICM_H2X_BRESP_ERR_INT_RAW The raw interrupt status of CPU_ICM_H2X_BRESP_ERR_INT. (R/WTC/SS)

Register 21.29. HP_SYSTEM_AHB2AXI_BRESP_ERR_INT_ST_REG (0x018C)



HP_SYSTEM_CPU_ICM_H2X_BRESP_ERR_INT_ST The masked interrupt status of CPU_ICM_H2X_BRESP_ERR_INT. (RO)

Register 21.30. HP_SYSTEM_AHB2AXI_BRESP_ERR_INT_ENA_REG (0x0190)



HP_SYSTEM_CPU_ICM_H2X_BRESP_ERR_INT_ENA Write 1 to enable CPU_ICM_H2X_BRESP_ERR_INT. (R/W)

Register 21.31. HP_SYSTEM_AHB2AXI_BRESP_ERR_INT_CLR_REG (0x0194)

HP_SYSTEM_CPU_ICM_H2X_BRESP_ERR_INT_CLR Write 1 to clear CPU_ICM_H2X_BRESP_ERR_INT. (WT)

Register 21.32. HP_SYSTEM_L2_MEM_L2_RAM_ECC_REG (0x00AC)

HP_SYSTEM_L2_RAM_UNIT0_ECC_EN Configures whether to enable the ECC check for L2MEM unit0.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_L2_RAM_UNIT1_ECC_EN Configures whether to enable the ECC check for L2MEM unit1.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_L2_RAM_UNIT2_ECC_EN Configures whether to enable the ECC check for L2MEM unit2.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_L2_RAM_UNIT3_ECC_EN Configures whether to enable the ECC check for L2MEM unit3.

0: Disable

1: Enable

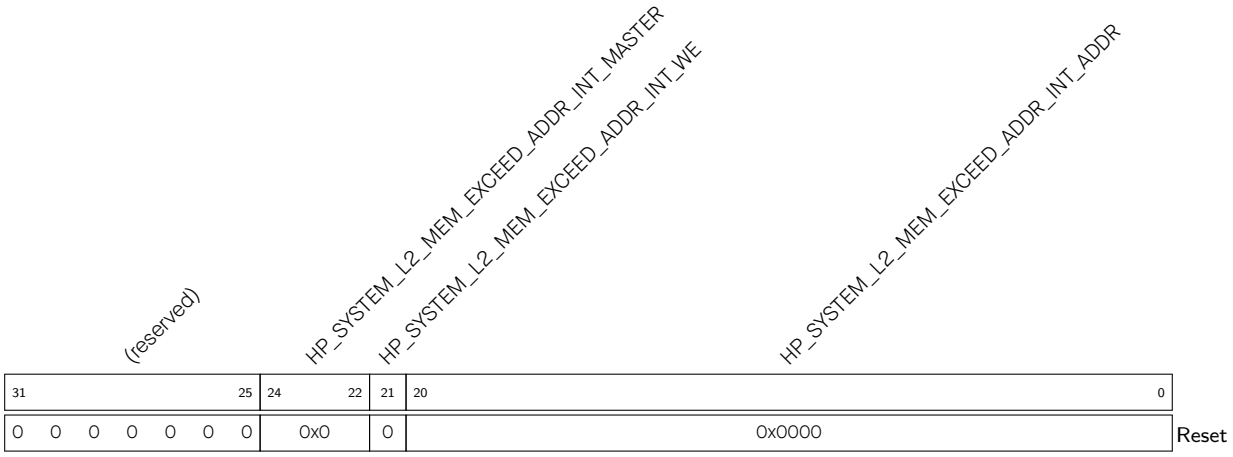
(R/W)

HP_SYSTEM_L2_RAM_UNIT4_ECC_EN Configures whether to enable the ECC check for L2MEM unit4.

0: Disable

1: Enable

(R/W)



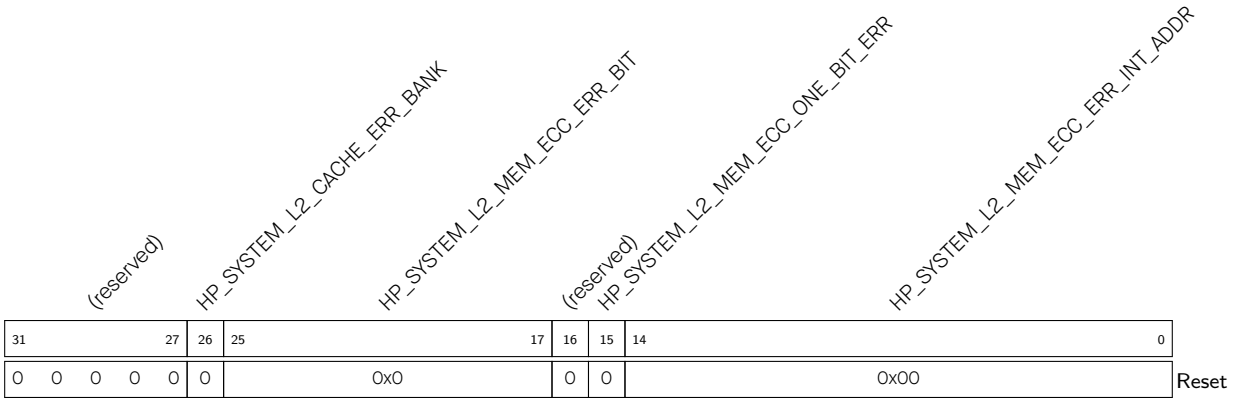
HP_SYSTEM_L2_RAM_UNIT5_ECC_EN Configures whether to enable the ECC check for L2MEM unit5.

0: Disable

1: Enable

(R/W)

Register 21.33. HP_SYSTEM_L2_MEM_INT_RECORD0_REG (0x00B0)



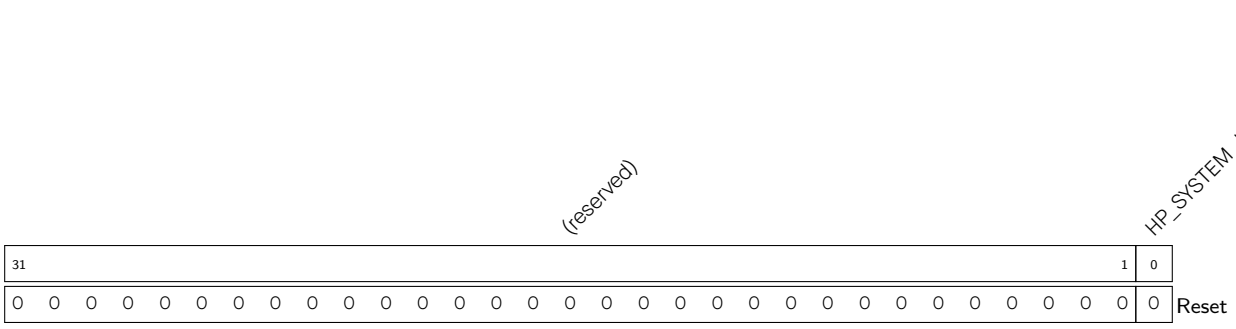
HP_SYSTEM_L2_MEM_EXCEED_ADDR_INT_ADDR Records the address when L2_MEM_EXCEED_ADDR_INT occurs. (RO)

HP_SYSTEM_L2_MEM_EXCEED_ADDR_INT_WE Records the operation (write/read) when L2_MEM_EXCEED_ADDR_INT occurs. (RO)

HP_SYSTEM_L2_MEM_EXCEED_ADDR_INT_MASTER Records source that triggered L2_MEM_EXCEED_ADDR_INT.

0: Invalid. No effect
1: cachebus0
2: cachebus1
3: dma_axi
4: Invalid. No effect
5: Invalid. No effect
6: ahb
7: Invalid. No effect
(RO)

Register 21.34. HP_SYSTEM_L2_MEM_INT_RECORD1_REG (0x00B4)



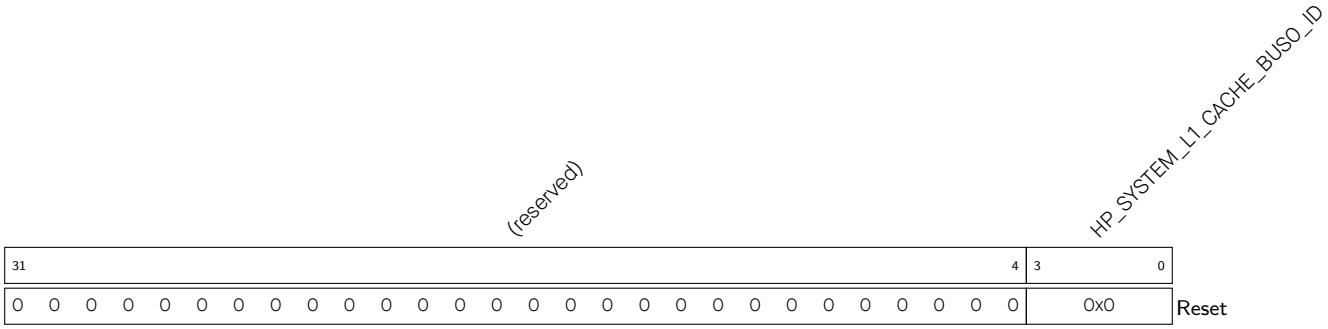
HP_SYSTEM_L2_MEM_ECC_ERR_INT_ADDR Records the address when L2_MEM_ECC_ERR_INT occurs. (RO)

HP_SYSTEM_L2_MEM_ECC_ONE_BIT_ERR Records the error when L2_MEM_ECC_ERR_INT occurs. (RO)

HP_SYSTEM_L2_MEM_ECC_ERR_BIT Records the flipped bit that triggered L2_MEM_ECC_ERR_INT. (RO)

HP_SYSTEM_L2_CACHE_ERR_BANK Records the bank number of L2 cache ECC error. (RO)

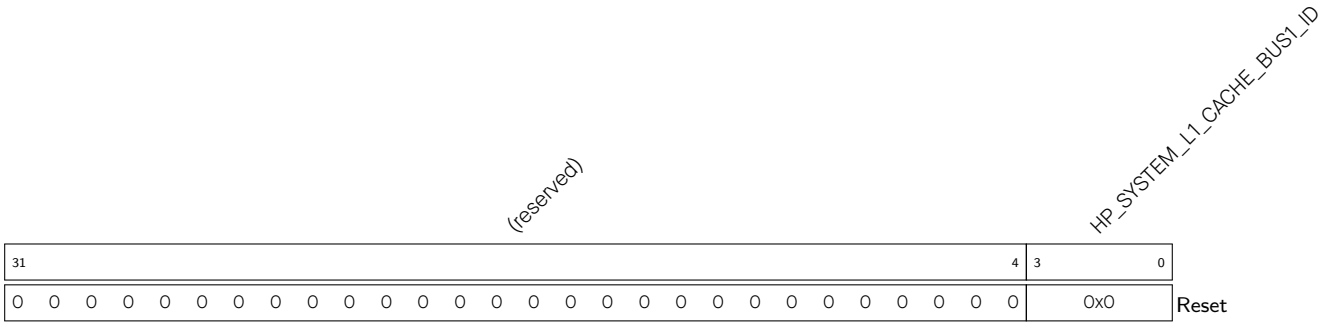
Register 21.35. HP_SYSTEM_L2_MEM_L2_CACHE_ECC_REG (0x00C4)



HP_SYSTEM_L2_CACHE_ECC_EN Configures whether to enable the ECC check for L2 cache.

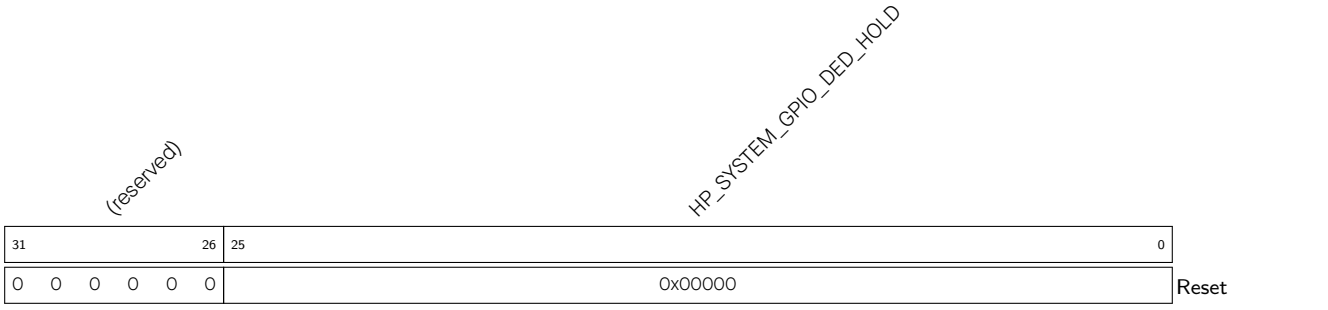
0: Disable

1: Enable



(R/W)

Register 21.36. HP_SYSTEM_HP_L1CACHE_BUS0_ID_REG (0x00C8)

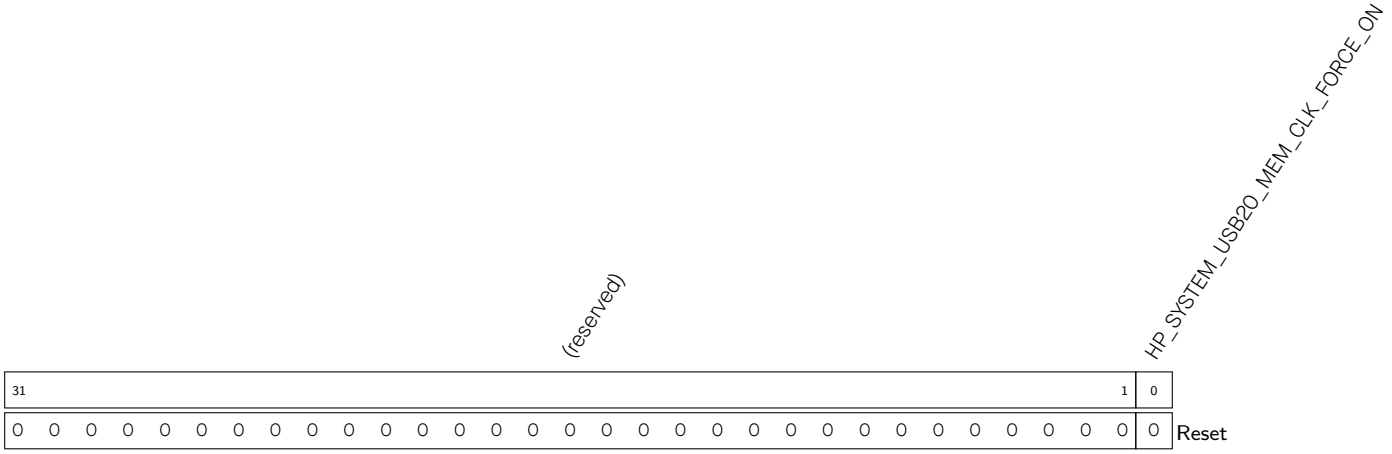


HP_SYSTEM_L1_CACHE_BUS0_ID Configures the L1 cache bus0 UID. (R/W)

Register 21.37. HP_SYSTEM_HP_L1CACHE_BUS1_ID_REG (0x00CC)

HP_SYSTEM_L1_CACHE_BUS1_ID Configures the L1 cache bus1 UID. (R/W)

Register 21.38. HP_SYSTEM_GPIO_DED_HOLD_CTRL_REG (0x00F0)



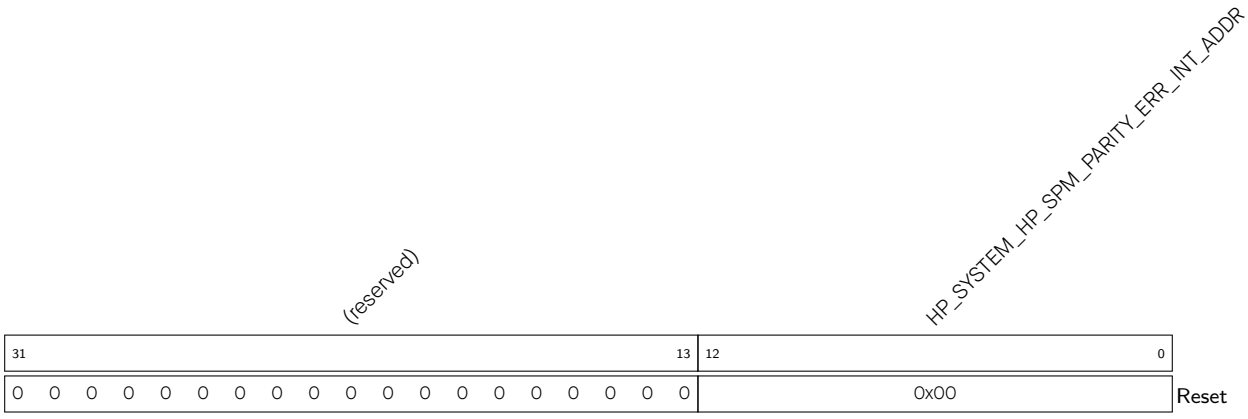
HP_SYSTEM_GPIO_DED_HOLD Configures whether to hold the pin status.

Bit[25:6]: 16 line PSRAM pins

Bit[5:0]: flash pins

(R/W)

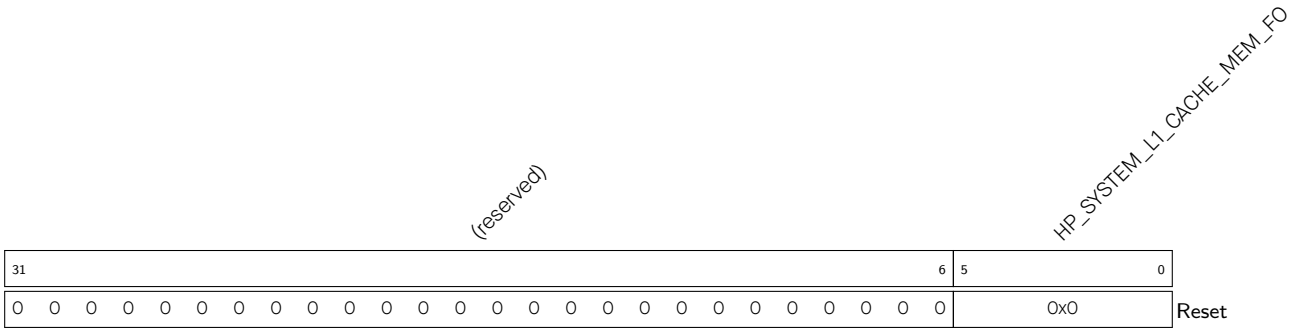
Register 21.39. HP_SYSTEM_HP_USB20OTG_MEM_CTRL_REG (0x00F8)



HP_SYSTEM_USB20_MEM_CLK_FORCE_ON Configures whether to force on the memory clock in USB OTGHS.

0: Disable

1: Enable

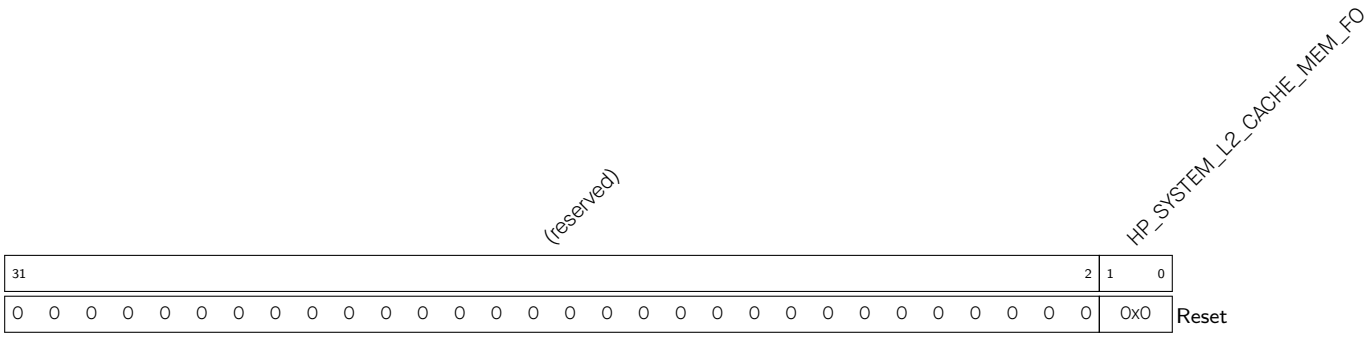


(R/W)

Register 21.40. HP_SYSTEM_HP_SPM_PARITY_INT_RECORD_REG (0x010C)

HP_SYSTEM_HP_SPM_PARITY_ERR_INT_ADDR Records the address when HP_SPM_PARITY_ERR_INT occurs. (RO)

Register 21.41. HP_SYSTEM_HP_L1_CACHE_PWR_CTRL_REG (0x0110)



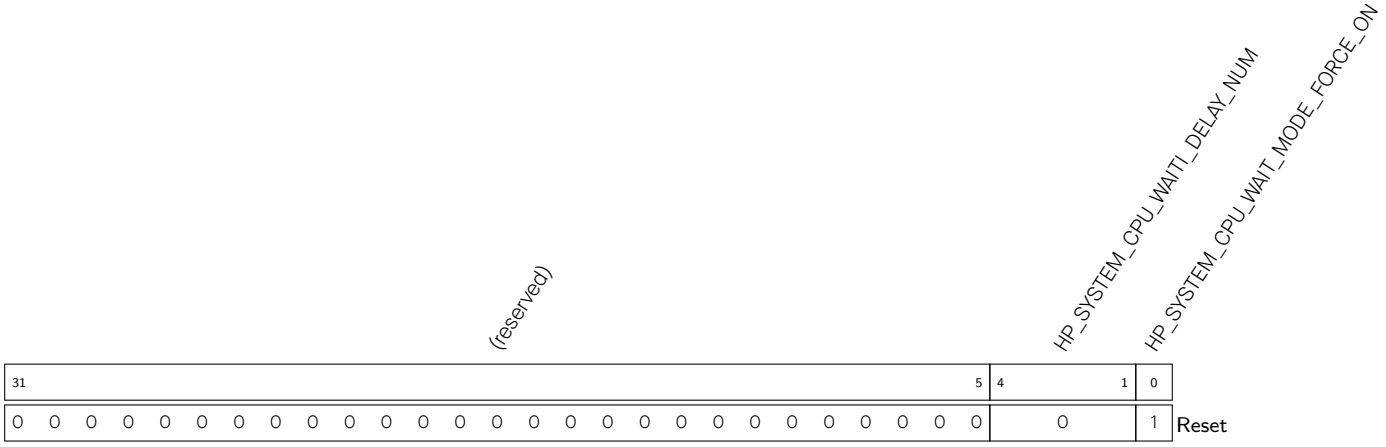
HP_SYSTEM_L1_CACHE_MEM_FO Configures whether to force L1 cache on.

0: Disable

1: Enable

(R/W)

Register 21.42. HP_SYSTEM_HP_L2_CACHE_PWR_CTRL_REG (0x0114)

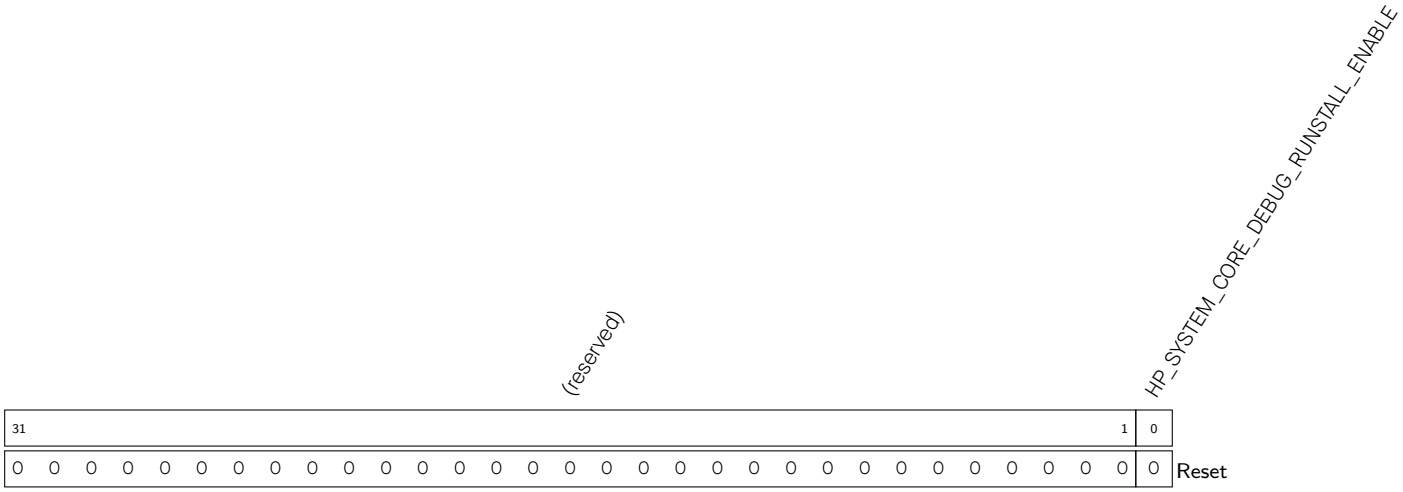


HP_SYSTEM_L2_CACHE_MEM_FO Configures whether to force L2 cache on.

0: Disable

1: Enable

(R/W)

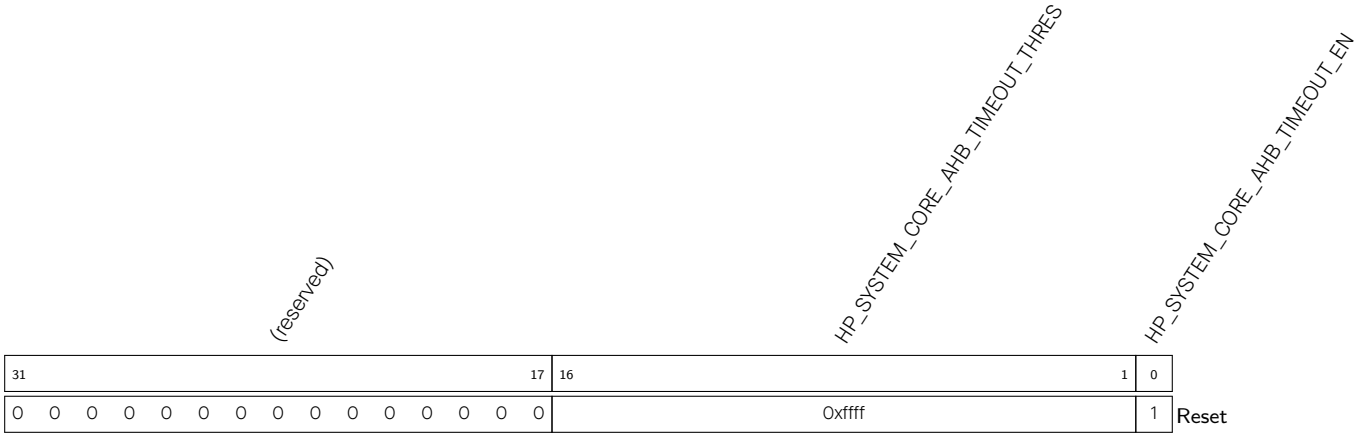


Register 21.43. HP_SYSTEM_HP_CPU_WAITI_CONF_REG (0x0118)

HP_SYSTEM_CPU_WAIT_MODE_FORCE_ON Configures whether to force on cpu_waiti_clk. (R/W)

HP_SYSTEM_CPU_WAITI_DELAY_NUM Configures the delay cycles when CPU enters wait mode. After the configured delay, cpu_waiti_clk turns off. (R/W)

Register 21.44. HP_SYSTEM_CORE_DEBUG_RUNSTALL_CONF_REG (0x011C)

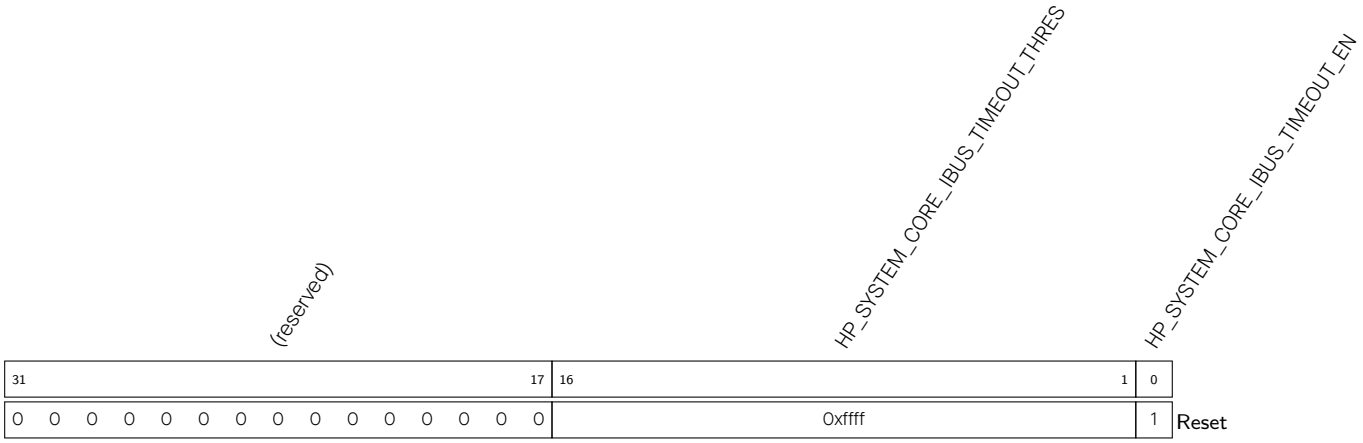


HP_SYSTEM_CORE_DEBUG_RUNSTALL_ENABLE Configures whether to enable debug runstall feature between HP CPU and LP CPU.

0: Disable

1: Enable

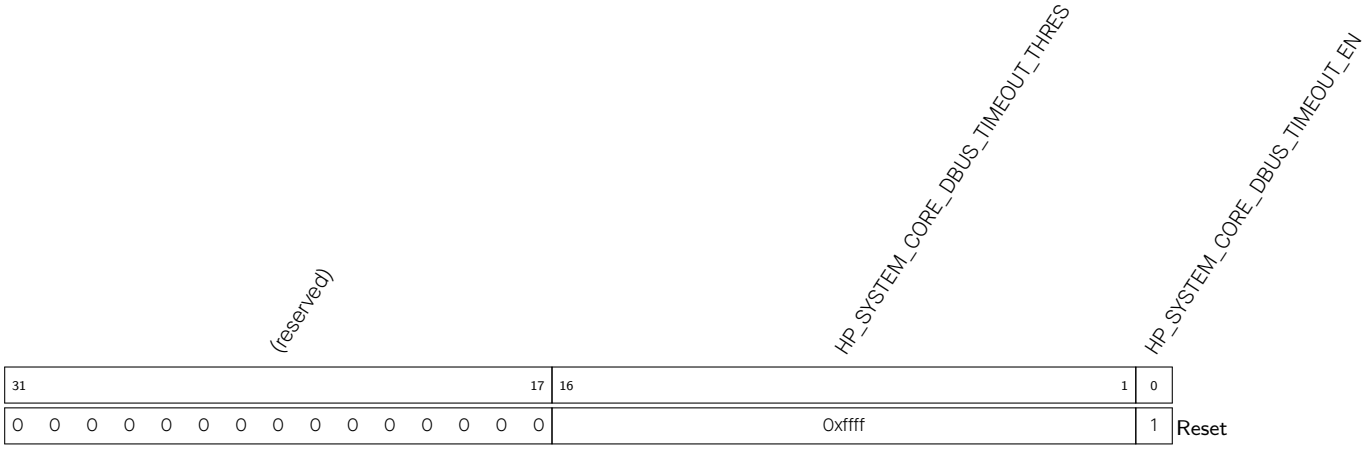
(R/W)



Register 21.45. HP_SYSTEM_HP_CORE_AHB_TIMEOUT_REG (0x0120)

HP_SYSTEM_CORE_AHB_TIMEOUT_EN Configures whether to enable timeout protection on HP CPU0/1 AHB bus. (R/W)

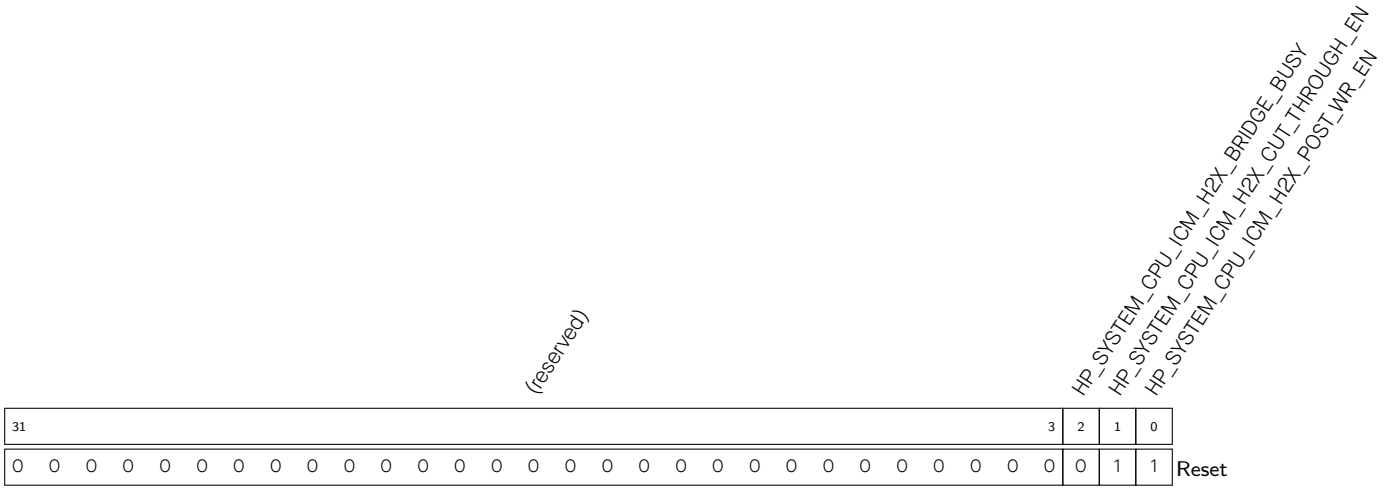
HP_SYSTEM_CORE_AHB_TIMEOUT_THRES Configures HP CPU0/1 AHB bus timeout threshold. (R/W)



Register 21.46. HP_SYSTEM_HP_CORE_IBUS_TIMEOUT_REG (0x0124)

HP_SYSTEM_CORE_IBUS_TIMEOUT_EN Configures whether to enable timeout protection on HP CPU0/1 IBUS. (R/W)

HP_SYSTEM_CORE_IBUS_TIMEOUT_THRES Configures HP CPU0/1 IBUS timeout threshold. (R/W)

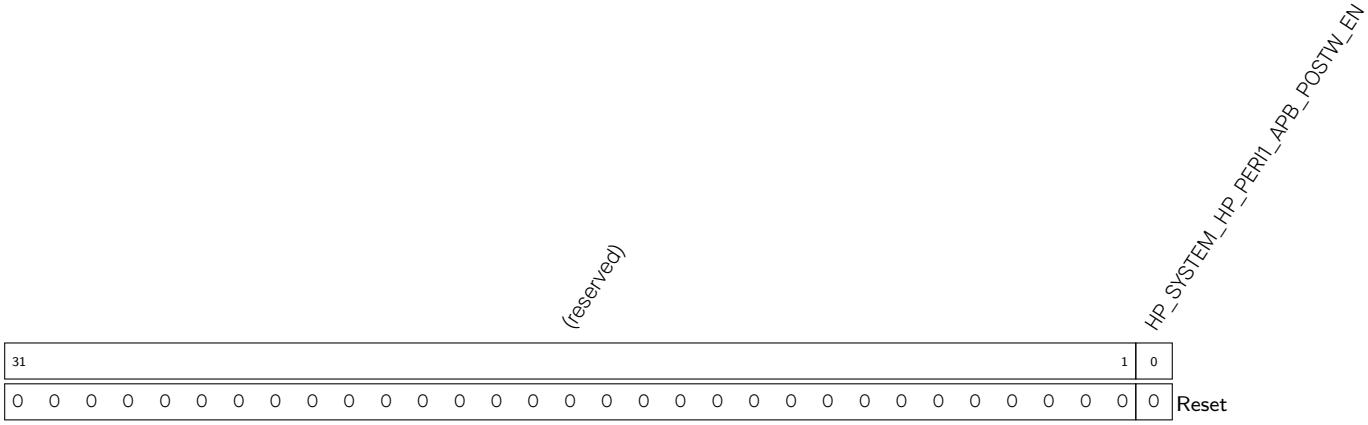


Register 21.47. HP_SYSTEM_HP_CORE_DBUS_TIMEOUT_REG (0x0128)

HP_SYSTEM_CORE_DBUS_TIMEOUT_EN Configures whether to enable timeout protection on HP CPU0/1 DBUS. (R/W)

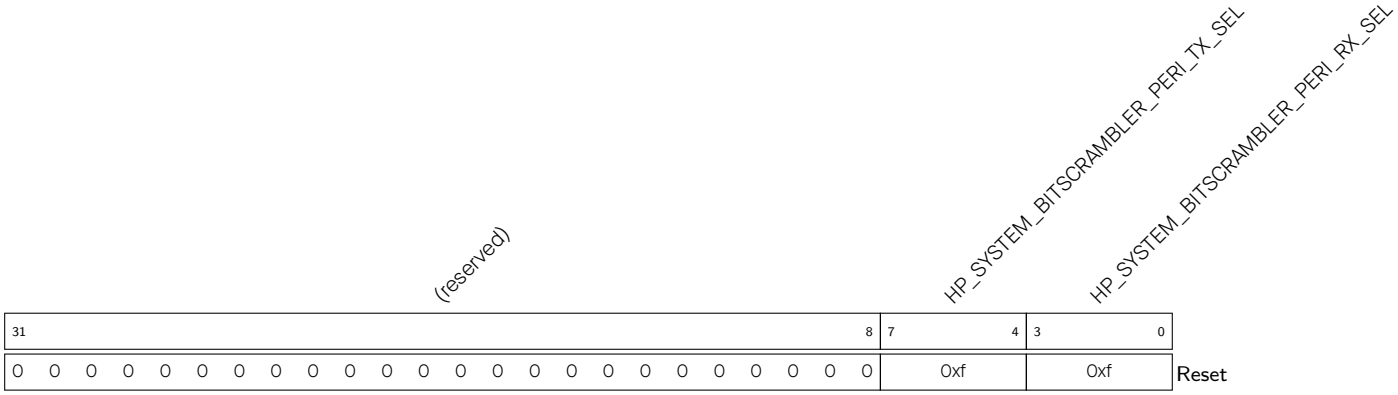
HP_SYSTEM_CORE_DBUS_TIMEOUT_THRES Configures HP CPU0/1 DBUS timeout threshold. (R/W)

Register 21.48. HP_SYSTEM_HP_ICM_CPU_H2X_CFG_REG (0x0138)



HP_SYSTEM_CPU_ICM_H2X_POST_WR_EN Configures whether to enable Post Write mode in AHB2AXI bridge for improved write performance. (R/W)

HP_SYSTEM_CPU_ICM_H2X_CUT_THROUGH_EN Configures whether to enable CUT Through mode in AHB2AXI bridge for improved write performance. (R/W)



HP_SYSTEM_CPU_ICM_H2X_BRIDGE_BUSY Indicates when AHB2AXI bridge is busy. (RO)

Register 21.49. HP_SYSTEM_PERI1_APB_POSTW_EN_REG (0x013C)

HP_SYSTEM_HP_PERI1_APB_POSTW_EN Configures whether to enable Post Write mode for peripherals' APB2APB bridge, which accelerates write operations but requires time to update register values. (R/W)

Register 21.50. HP_SYSTEM_BITSCRAMBLER_PERI_SEL_REG (0x0140)

HP_SYSTEM_BITSCRAMBLER_PERI_RX_SEL Configures the DMA-capable peripheral for BitScrambler's Rx channel.

0: LCD_CAM

1: GPSPI2

2: GPSPI3

3: PARL_IO

4: AES

5: SHA

6: ADC

14: Invalid. No effect
15: Invalid. No effect
(R/W)

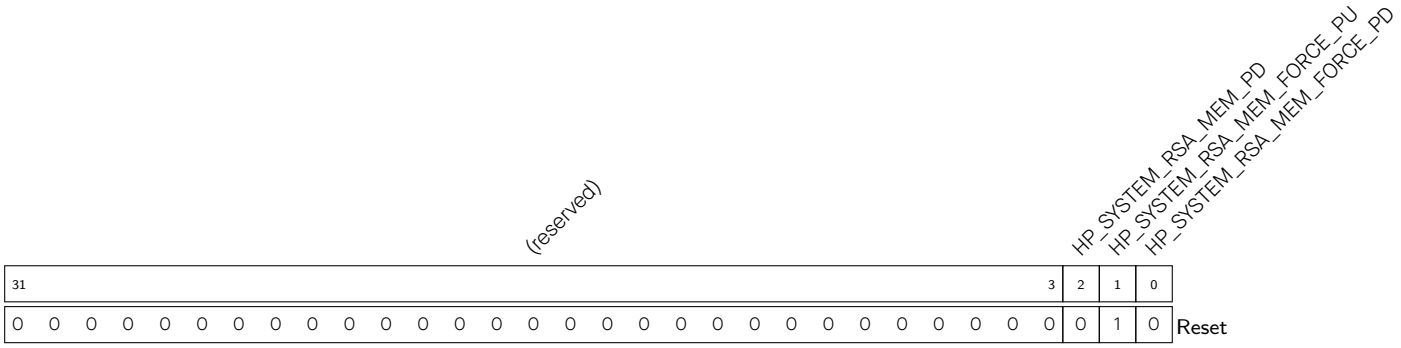
Register 21.51. HP_SYSTEM_APB_SYNC_POSTW_EN_REG (0x0144)



HP_SYSTEM_SYS_GMAC_APB_POSTW_EN Configures whether to enable Post Write mode for synchronous APB2APB bridge in GMAC, which accelerates write operations but requires time to update register values. (R/W)

HP_SYSTEM_SYS_DSI_HOST_APB_POSTW_EN Configures whether to enable Post Write mode for synchronous APB2APB bridge in DSI Host, which accelerates write operations but requires time to update register values. (R/W)

HP_SYSTEM_SYS_CSI_HOST_APB_SYNC_POSTW_EN Configures whether to enable Post Write mode for synchronous APB2APB bridge in CSI Host, which accelerates write operations but requires time to update register values. (R/W)

HP_SYSTEM_SYS_CSI_HOST_APB_ASYNC_POSTW_EN Configures whether to enable Post Write mode for asynchronous APB2APB bridge in CSI Host, which accelerates write operations but requires time to update register values. (R/W)

Register 21.52. HP_SYSTEM_HP_RSA_PD_CTRL_REG (0x01D0)

HP_SYSTEM_RSA_MEM_FORCE_PD Configures whether to force power down RSA internal memory. This setting has a lower priority than HP_SYSTEM_RSA_MEM_FORCE_PU.

0: No effect

1: Power down

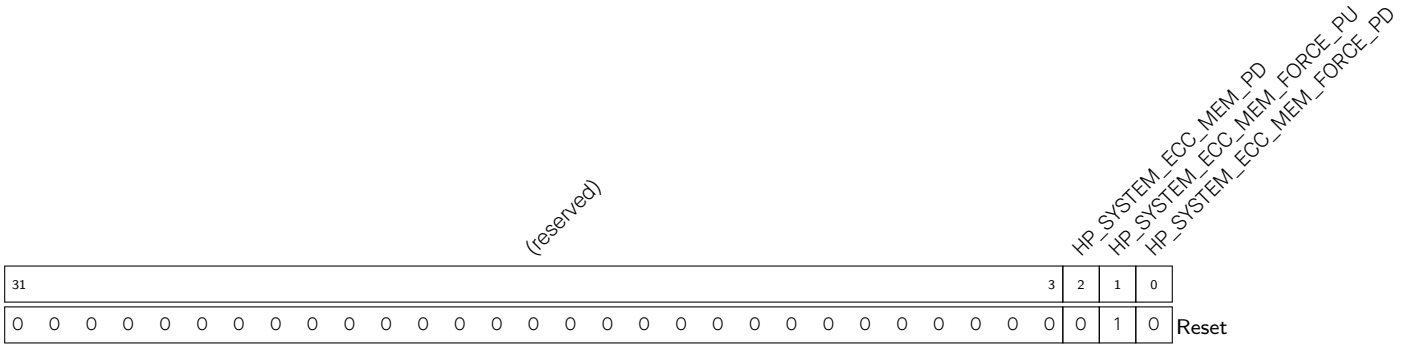
(R/W)

HP_SYSTEM_RSA_MEM_FORCE_PU Configures whether to force power up RSA internal memory.

0: No effect

1: Power up

(R/W)



HP_SYSTEM_RSA_MEM_PD Configures whether to power down RSA internal memory.

0: No effect

1: Power down

(R/W)

Register 21.53. HP_SYSTEM_HP_ECC_PD_CTRL_REG (0x01D4)

HP_SYSTEM_ECC_MEM_FORCE_PD Configures whether to force power down ECC internal memory. This setting has a lower priority than HP_SYSTEM_ECC_MEM_FORCE_PU.

0: No effect

1: Power down

(R/W)

HP_SYSTEM_ECC_MEM_FORCE_PU Configures whether to force power up ECC internal memory.

0: No effect

1: Power up

(R/W)

HP_SYSTEM_ECC_MEM_PD Configures whether to power down ECC internal memory.

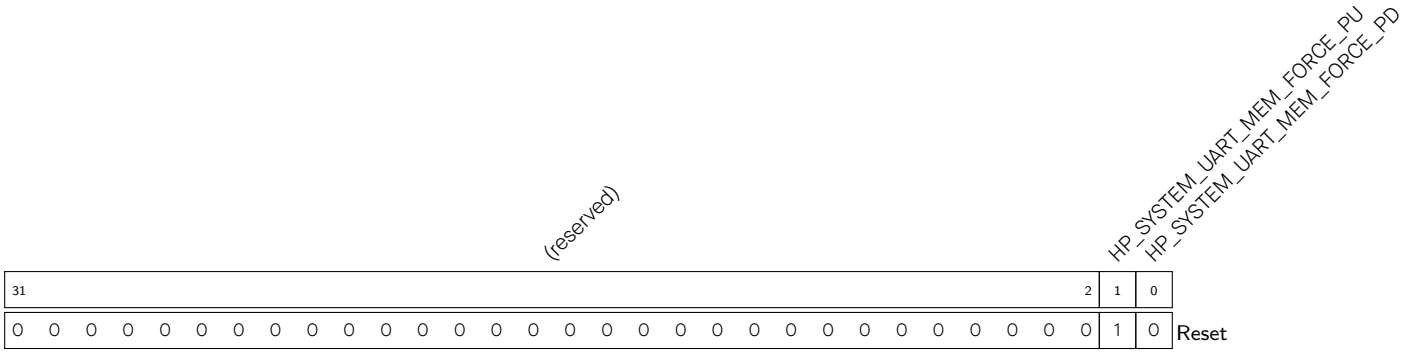
0: No effect

1: Power down

(R/W)

Register 21.54. HP_SYSTEM_HP_RNG_CFG_REG (0x01D8)

HP_SYSTEM_RNG_SAMPLE_ENABLE Configures whether to enable the RNG sample chain.



0: Disable

1: Enable

(R/W)

HP_SYSTEM_RNG_CHAIN_CLK_DIV_NUM Configures the chain clock division number for debugging. (R/W)

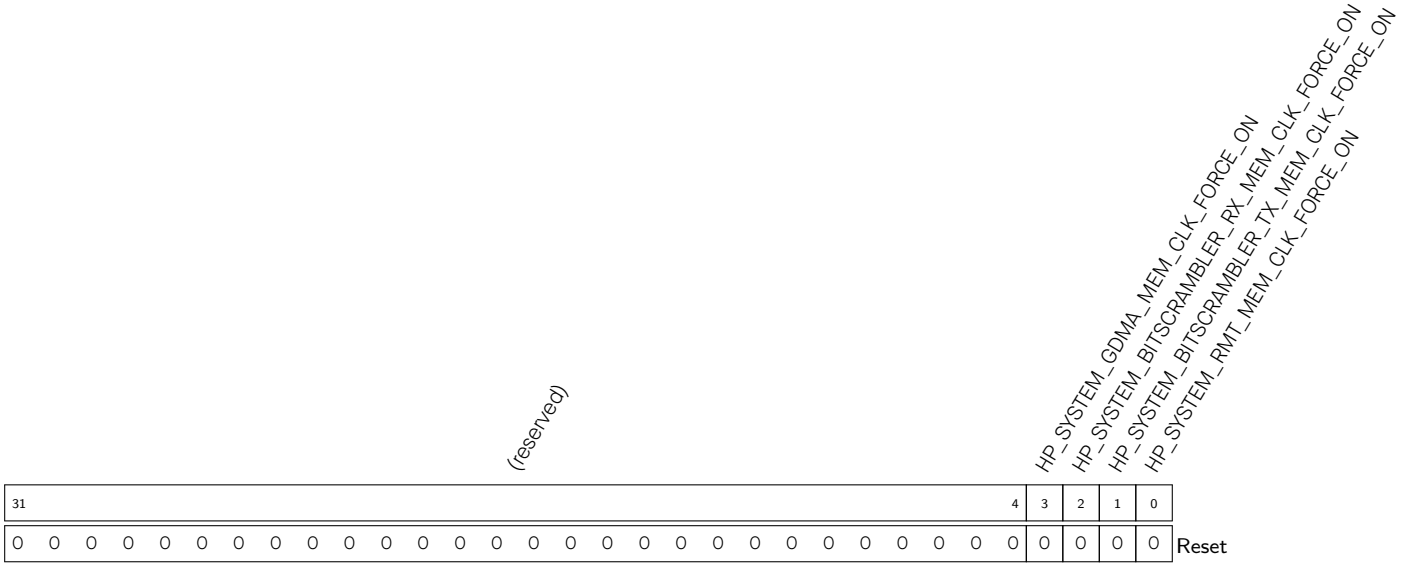
Register 21.55. HP_SYSTEM_HP_UART_PD_CTRL_REG (0x01DC)

HP_SYSTEM_UART_MEM_FORCE_PD Configures whether to force power down HP UART internal memory.

0: No effect

1: Power down

(R/W)



HP_SYSTEM_UART_MEM_FORCE_PU Configures whether to force power up HP UART internal memory.

0: No effect

1: Power up

(R/W)

Register 21.56. HP_SYSTEM_HP_PERI_MEM_CLK_FORCE_ON_REG (0x01E0)

HP_SYSTEM_RMT_MEM_CLK_FORCE_ON Configures whether to force enable the clock gating of the memory clock in RMT.

0: No effect

1: Force on

(R/W)

HP_SYSTEM_BITSCRAMBLER_TX_MEM_CLK_FORCE_ON Configures whether to force enable the clock gating of the TX memory clock in BitScrambler.

0: No effect

1: Force on

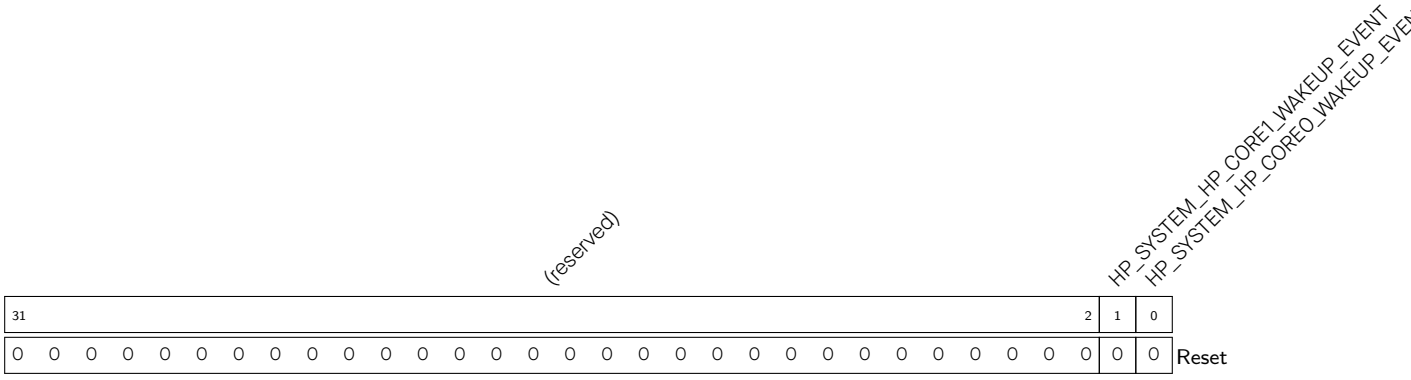
(R/W)

HP_SYSTEM_BITSCRAMBLER_RX_MEM_CLK_FORCE_ON Configures whether to force enable the clock gating of the RX memory clock in BitScrambler.

0: No effect

1: Force on

(R/W)



HP_SYSTEM_GDMA_MEM_CLK_FORCE_ON Configures whether to force enable the clock gating of the memory clock in GDMA.

0: No effect

1: Force on

(R/W)

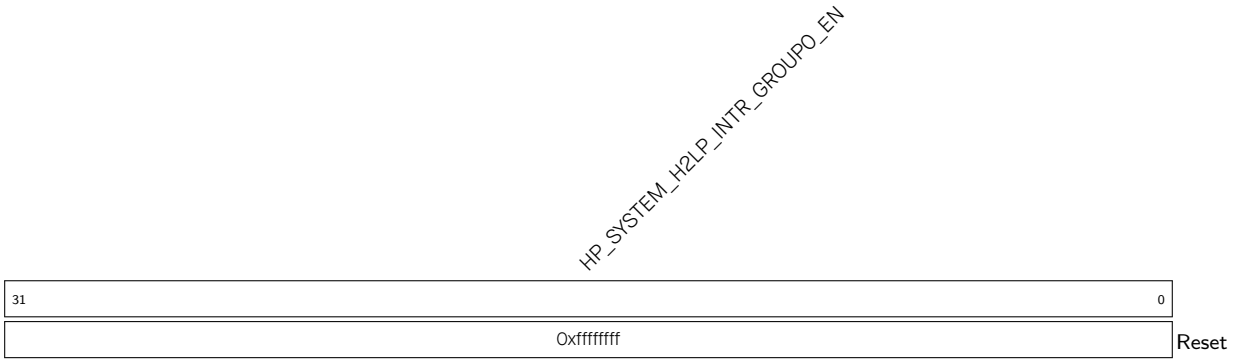
Register 21.57. HP_SYSTEM_HP_CPU_WAKEUP_EVENT_REG (0x01EC)

HP_SYSTEM_HP_CORE0_WAKEUP_EVENT Configures whether to wake up HP CPU0.

0: No effect

1: Wake up

(R/W)



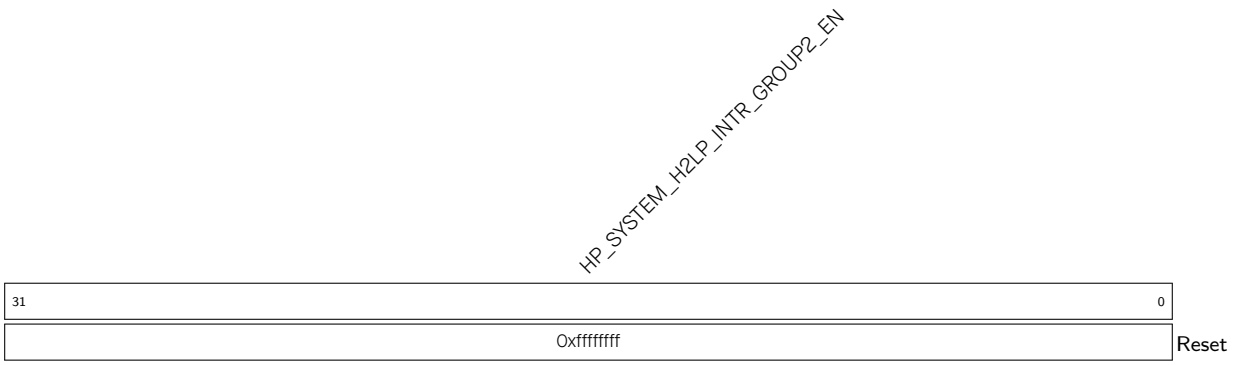
HP_SYSTEM_HP_CORE1_WAKEUP_EVENT Configures whether to wake up HP CPU1.

0: No effect

1: Wake up

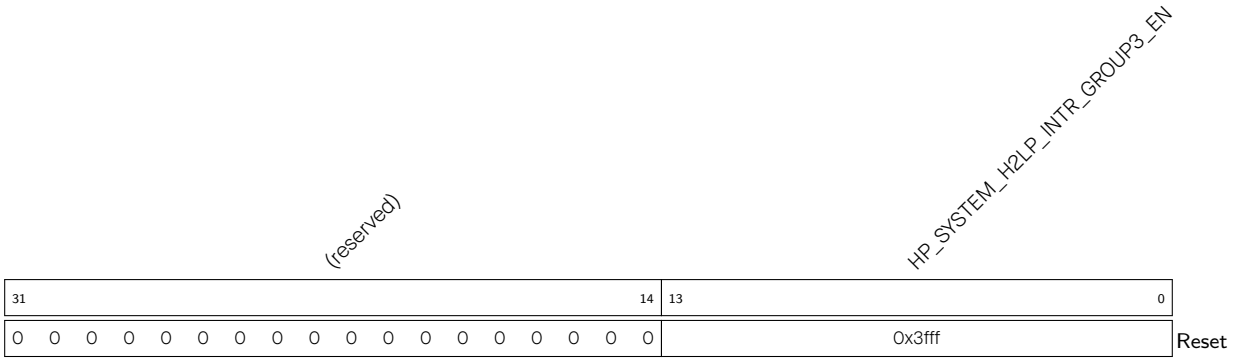
(R/W)

Register 21.58. HP_SYSTEM_HP2LP_INTR_GROUP0_EN_REG (0x01F0)



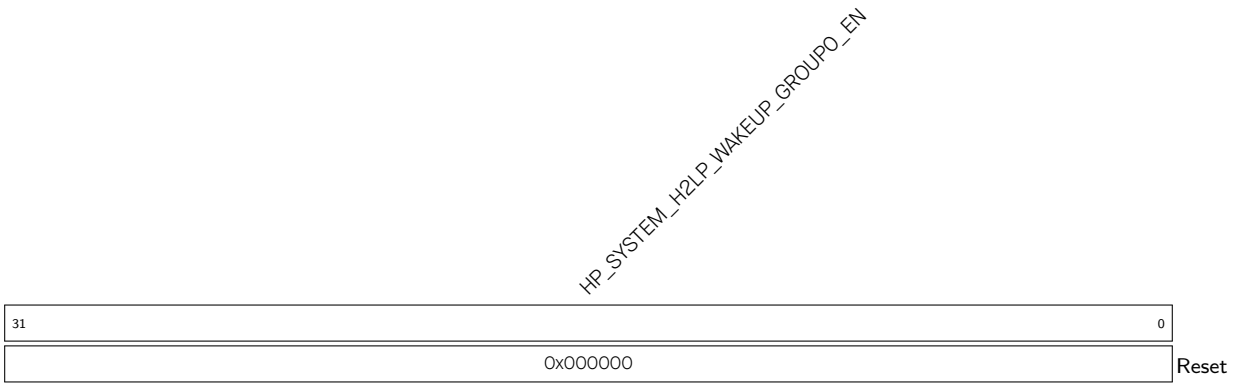
HP_SYSTEM_H2LP_INTR_GROUP0_EN Write 1 to enable the corresponding peripheral interrupt to LP CPU. (R/W)

Register 21.59. HP_SYSTEM_HP2LP_INTR_GROUP1_EN_REG (0x01F4)



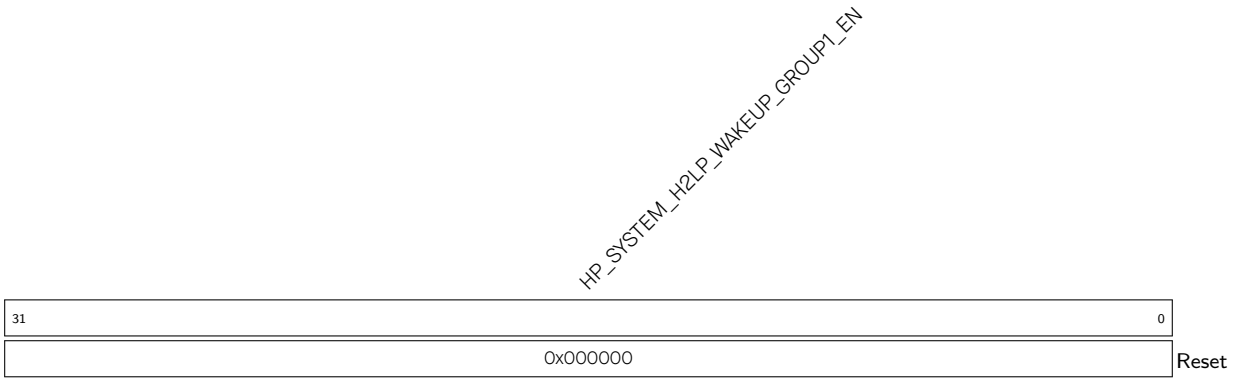
HP_SYSTEM_H2LP_INTR_GROUP1_EN Write 1 to enable the corresponding peripheral interrupt to LP CPU. (R/W)

Register 21.60. HP_SYSTEM_HP2LP_INTR_GROUP2_EN_REG (0x01F8)



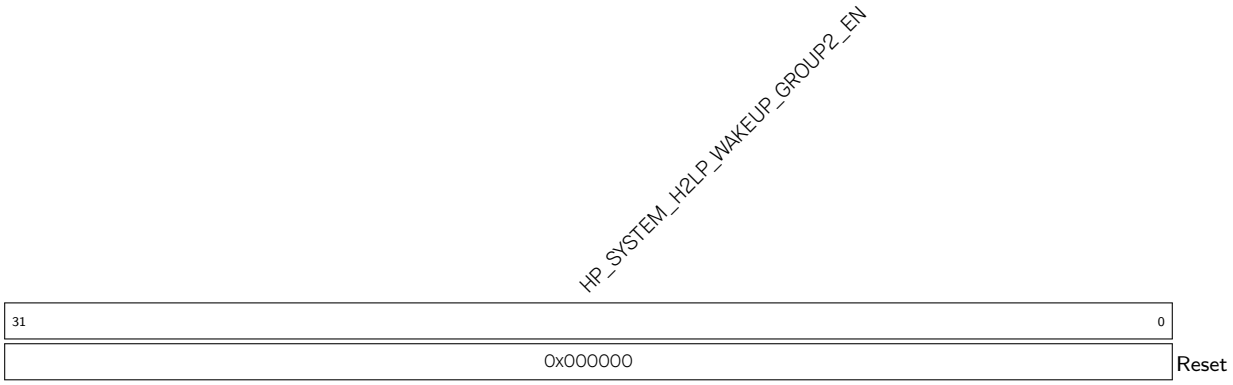
HP_SYSTEM_H2LP_INTR_GROUP2_EN Write 1 to enable the corresponding peripheral interrupt to LP CPU. (R/W)

Register 21.61. HP_SYSTEM_HP2LP_INTR_GROUP3_EN_REG (0x01FC)



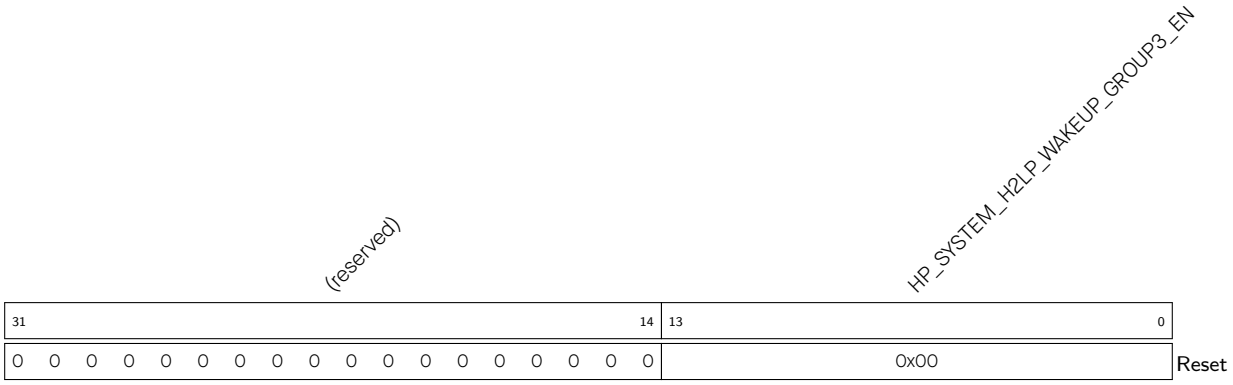
HP_SYSTEM_H2LP_INTR_GROUP3_EN Write 1 to enable the corresponding peripheral interrupt to LP CPU. (R/W)

Register 21.62. HP_SYSTEM_HP2LP_WAKEUP_GROUP0_EN_REG (0x0210)



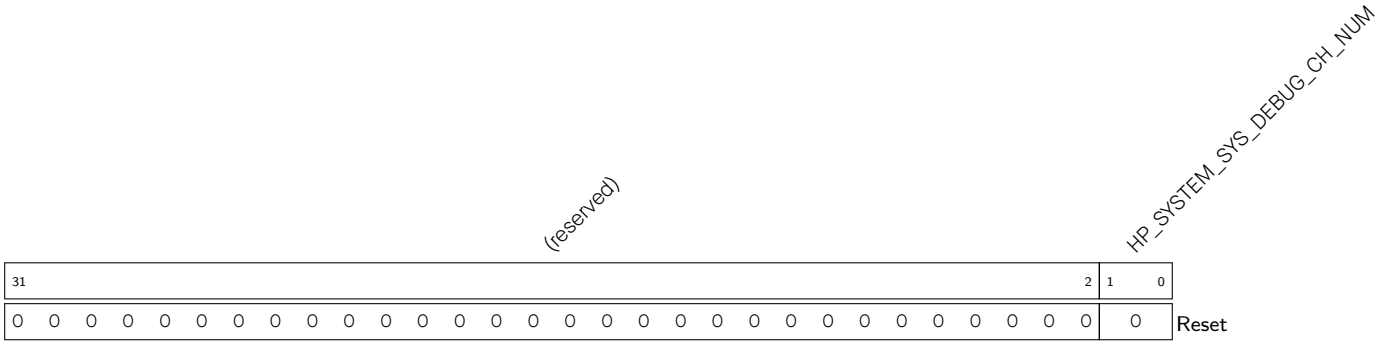
HP_SYSTEM_H2LP_WAKEUP_GROUP0_EN Write 1 to enable the corresponding peripheral wakeup to PMU. (R/W)

Register 21.63. HP_SYSTEM_HP2LP_WAKEUP_GROUP1_EN_REG (0x0214)



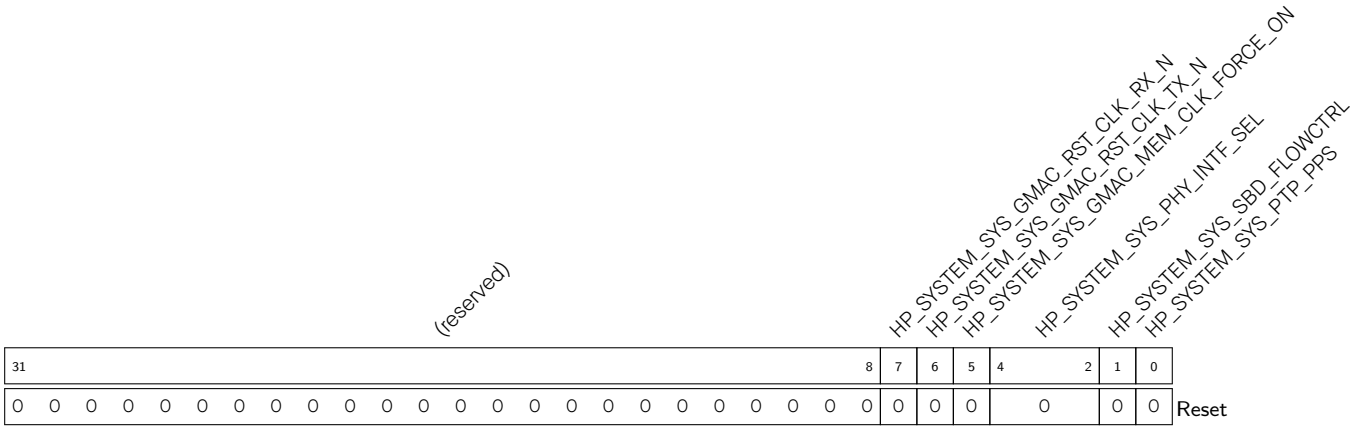
HP_SYSTEM_H2LP_WAKEUP_GROUP1_EN Write 1 to enable the corresponding peripheral wakeup to PMU. (R/W)

Register 21.64. HP_SYSTEM_HP2LP_WAKEUP_GROUP2_EN_REG (0x0218)



HP_SYSTEM_H2LP_WAKEUP_GROUP2_EN Write 1 to enable the corresponding peripheral wakeup to PMU. (R/W)

Register 21.65. HP_SYSTEM_HP2LP_WAKEUP_GROUP3_EN_REG (0x021C)



HP_SYSTEM_H2LP_WAKEUP_GROUP3_EN Write 1 to enable the corresponding peripheral wakeup to PMU. (R/W)

Register 21.66. HP_SYSTEM_GDMA_CTRL_REG (0x0148)

HP_SYSTEM_SYS_DEBUG_CH_NUM Configures the number of GDMA debug channels. (R/W)

Register 21.67. HP_SYSTEM_GMAC_CTRL0_REG (0x014C)

HP_SYSTEM_SYS_PTP_PPS Represents pulse per second output from Ethernet MAC. (RO)

HP_SYSTEM_SYS_SBD_FLOWCTRL Configures sideband flow control signal.

0: No effect

1: Instruct Ethernet MAC to transmit Pause frames in Full-duplex mode and enable back-pressure in half-duplex mode.

(R/W)

HP_SYSTEM_SYS_PHY_INTF_SEL Configures Ethernet PHY interface.

0: MII

1: Invalid. No effect

2: Invalid. No effect

3: Invalid. No effect

4: RMII

5: Invalid. No effect

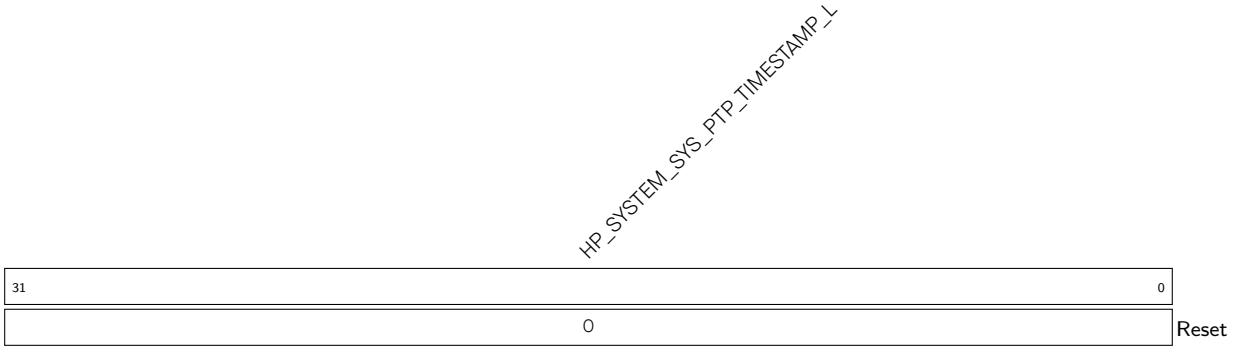
6: Invalid. No effect

7: Invalid. No effect

(R/W)

HP_SYSTEM_SYS_GMAC_MEM_CLK_FORCE_ON Configures whether to force enable the memory clock of GMAC memory.

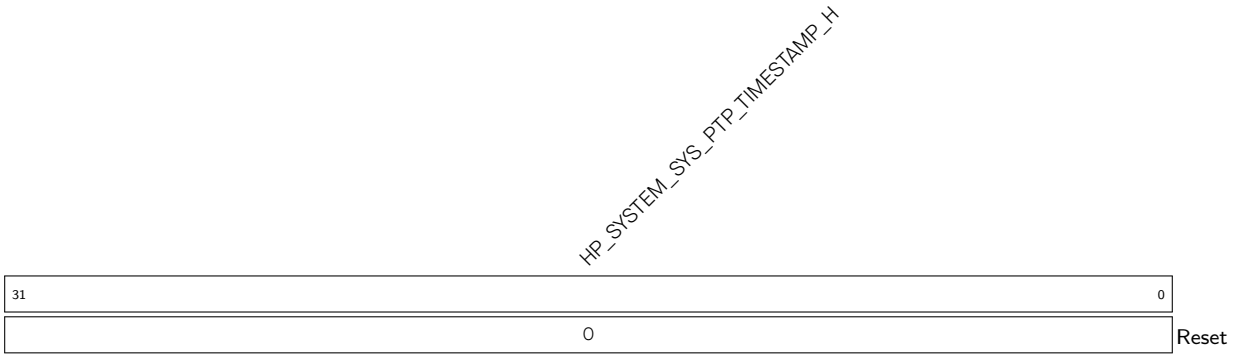
0: No effect



1: Force on

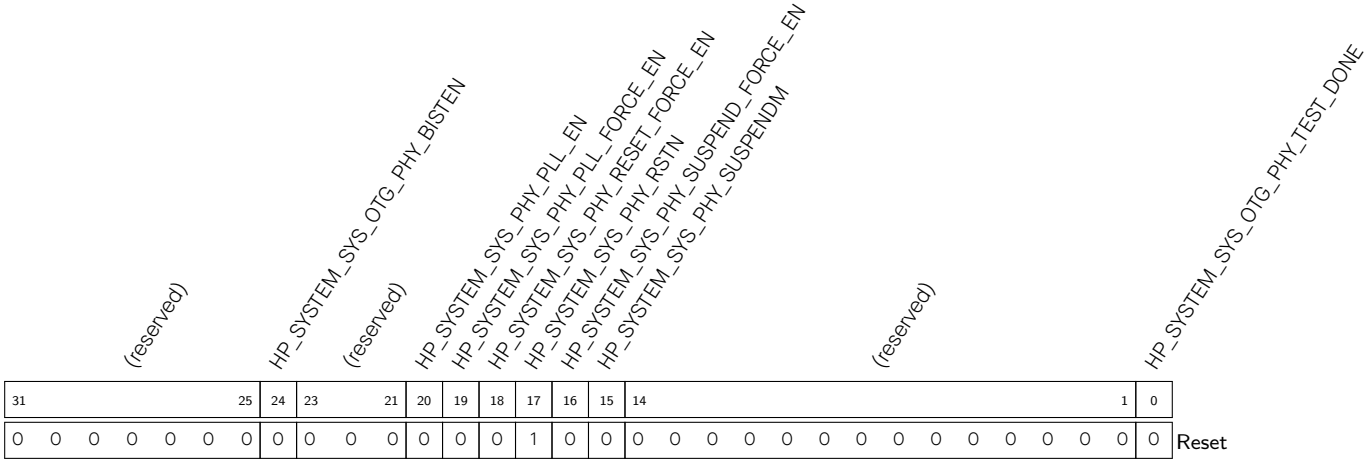
(R/W)

HP_SYSTEM_SYS_GMAC_RST_CLK_TX_N Represents an active-low reset signal synchronized to the Ethernet MAC Tx clock. (RO)



HP_SYSTEM_SYS_GMAC_RST_CLK_RX_N Represents an active-low reset signal synchronized to the Ethernet MAC Rx clock. (RO)

Register 21.68. HP_SYSTEM_GMAC_CTRL1_REG (0x0150)



HP_SYSTEM_SYS_PTP_TIMESTAMP_L Represents the lower 32 bits of timestamp output from Ethernet MAC synchronized to clk_ptp_ref clock. (RO)

Register 21.69. HP_SYSTEM_GMAC_CTRL2_REG (0x0154)

HP_SYSTEM_SYS_PTP_TIMESTAMP_H Represents the upper 32 bits of timestamp output from Ethernet MAC synchronized to clk_ptp_ref clock. (RO)

Register 21.70. HP_SYSTEM_USBOTG20_CTRL_REG (0x015C)

HP_SYSTEM_SYS_OTG_PHY_TEST_DONE Indicates the status of USB OTG_HS PHY BIST test.

0: Fail

1: Pass

(RO)

HP_SYSTEM_SYS_PHY_SUSPENDM Configures whether to drive USB OTG_HS PHY into Suspend mode. This setting is only valid when HP_SYSTEM_PHY_SUSPEND_FORCE_EN is set to 1.

0: No effect

1: In Suspend mode

(R/W)

HP_SYSTEM_SYS_PHY_SUSPEND_FORCE_EN Configures whether to allow forcing USB OTG_HS PHY into Suspend mode by setting HP_SYSTEM_PHY_SUSPENDM.

0: No effect

1: Force in Suspend mode

(R/W)

HP_SYSTEM_SYS_PHY_RSTN Configures whether to reset USB OTG_HS PHY. This setting is only valid when HP_SYSTEM_PHY_RESET_FORCE_EN is set to 1.

0: Reset

1: No effect

(R/W)

HP_SYSTEM_SYS_PHY_RESET_FORCE_EN Configures whether to allow forcibly resetting USB OTG_HS PHY by clearing HP_SYSTEM_PHY_RSTN.

0: No effect

1: Force reset

(R/W)

Continued on the next page...

Register 21.70. HP_SYSTEM_USBOTG20_CTRL_REG (0x015C)

Continued from the previous page...

HP_SYSTEM_SYS_PHY_PLL_FORCE_EN Configures whether to allow forcibly enabling USB OTG_HS PHY PLL by setting HP_SYSTEM_PHY_PLL_EN.

0: No effect

1: Force enable

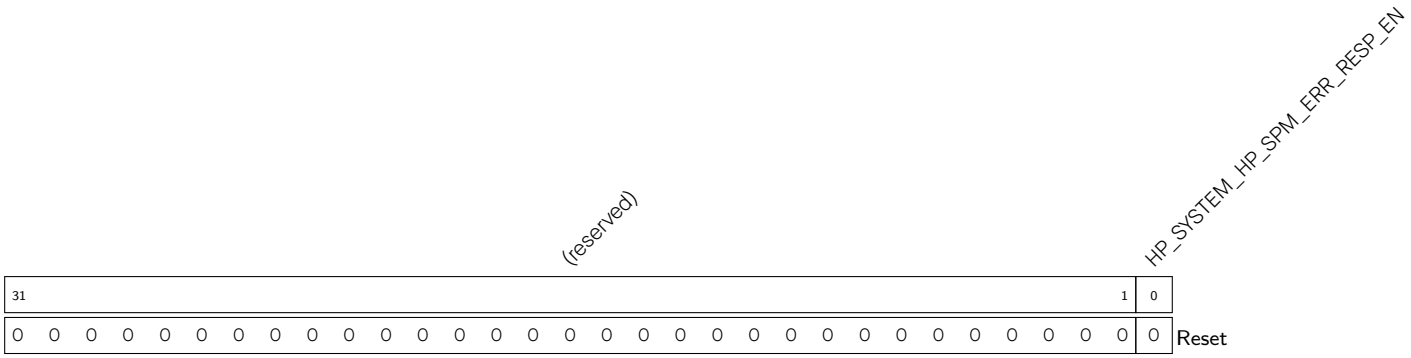
(R/W)

HP_SYSTEM_SYS_PHY_PLL_EN Configures whether to enable USB OTG_HS PHY PLL. This setting is only valid when HP_SYSTEM_PHY_PLL_FORCE_EN is set.

0: No effect

1: Enable

(R/W)



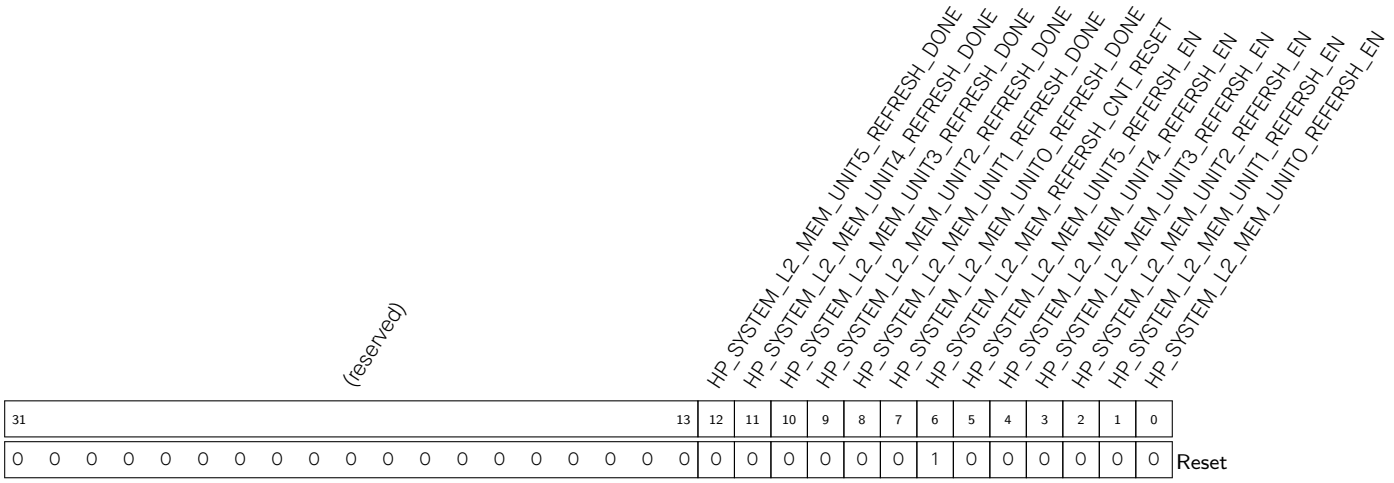
HP_SYSTEM_SYS_OTG_PHY_BISTEN Configures whether to drive USB OTG_HS PHY into BIST mode and perform self-test.

0: No effect

1: In BIST mode

(R/W)

Register 21.71. HP_SYSTEM_HP_SPM_ERR_RESP_CTRL_REG (0x0160)



HP_SYSTEM_HP_SPM_ERR_RESP_EN Configures whether to report parity error to the HP CPU and trigger exception.

0: Disable

1: Enable

(R/W)

Register 21.72. HP_SYSTEM_L2_MEM_REFRESH_REG (0x0164)

HP_SYSTEM_L2_MEM_UNIT0_REFERSH_EN Configures whether to refresh the ECC bit of L2MEM unit0.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_L2_MEM_UNIT1_REFERSH_EN Configures whether to refresh the ECC bit of L2MEM unit1.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_L2_MEM_UNIT2_REFERSH_EN Configures whether to refresh the ECC bit of L2MEM unit2.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_L2_MEM_UNIT3_REFERSH_EN Configures whether to refresh the ECC bit of L2MEM unit3.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_L2_MEM_UNIT4_REFERSH_EN Configures whether to refresh the ECC bit of L2MEM unit4.

0: Disable

1: Enable

(R/W)

Continued on the next page...

Register 21.72. HP_SYSTEM_L2_MEM_REFRESH_REG (0x0164)

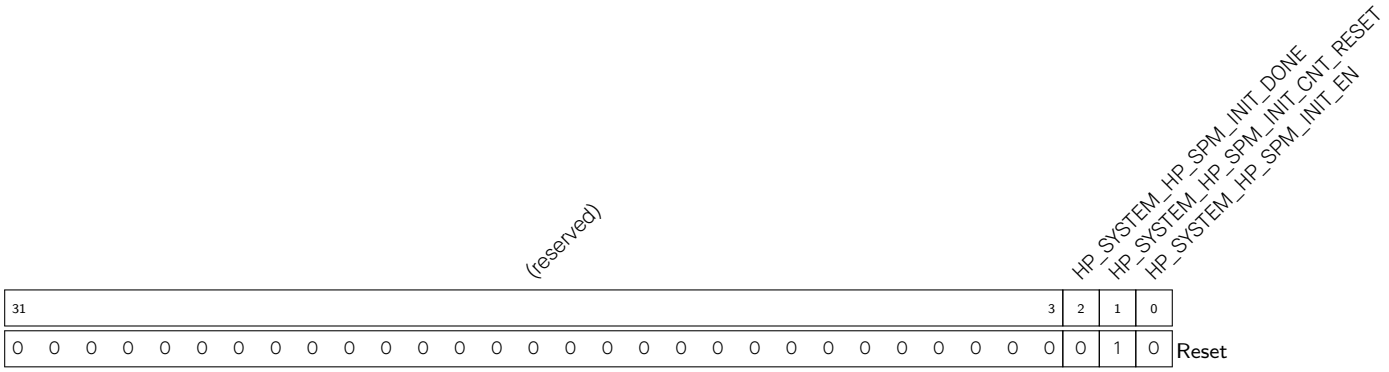
Continued from the previous page...

HP_SYSTEM_L2_MEM_UNIT5_REFERSH_EN Configures whether to refresh the ECC bit of L2MEM unit5.
0: Disable
1: Enable
(R/W)

HP_SYSTEM_L2_MEM_REFERSH_CNT_RESET Configures whether to reset L2MEM refresh count.
0: No effect
1: Reset
(R/W)

HP_SYSTEM_L2_MEM_UNIT0_REFRESH_DONE Represents the refresh status of L2MEM unit0 ECC bit. (RO)

HP_SYSTEM_L2_MEM_UNIT1_REFRESH_DONE Represents the refresh status of L2MEM unit1 ECC bit. (RO)



HP_SYSTEM_L2_MEM_UNIT2_REFRESH_DONE Represents the refresh status of L2MEM unit2 ECC bit. (RO)

HP_SYSTEM_L2_MEM_UNIT3_REFRESH_DONE Represents the refresh status of L2MEM unit3 ECC bit. (RO)

HP_SYSTEM_L2_MEM_UNIT4_REFRESH_DONE Represents the refresh status of L2MEM unit4 ECC bit. (RO)

HP_SYSTEM_L2_MEM_UNIT5_REFRESH_DONE Represents the refresh status of L2MEM unit5 ECC bit. (RO)

Register 21.73. HP_SYSTEM_HP_SPM_INIT_REG (0x0168)

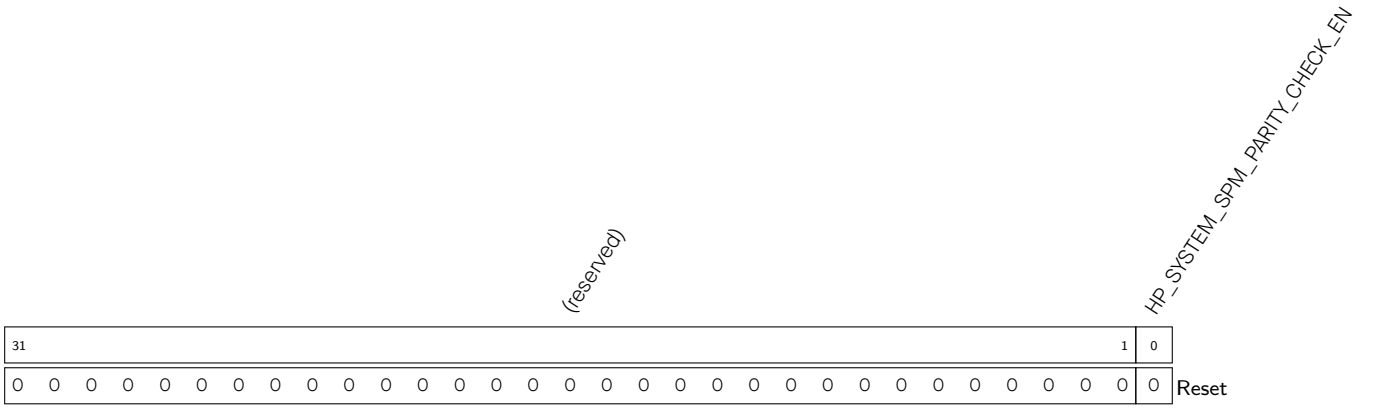
HP_SYSTEM_HP_SPM_INIT_EN Configures whether to enable HP SPM parity bit initialization.

0: Disable

1: Enable

(R/W)

HP_SYSTEM_HP_SPM_INIT_CNT_RESET Configures whether to reset SPM initialization count.



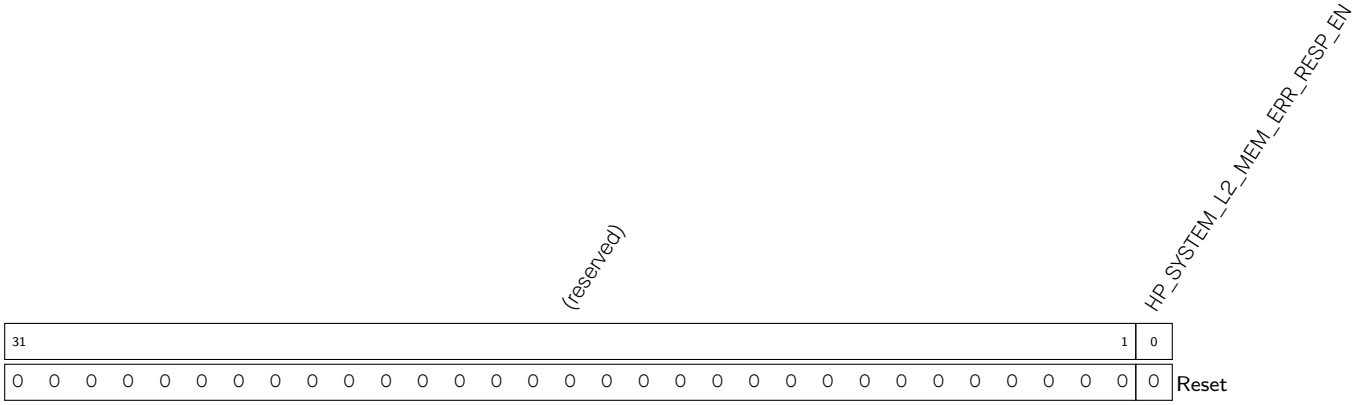
0: No effect

1: Reset

(R/W)

HP_SYSTEM_HP_SPM_INIT_DONE Represents the initialization status of HP SPM parity bits. (RO)

Register 21.74. HP_SYSTEM_HP_SPM_PARITY_CHECK_CTRL_REG (0x016C)



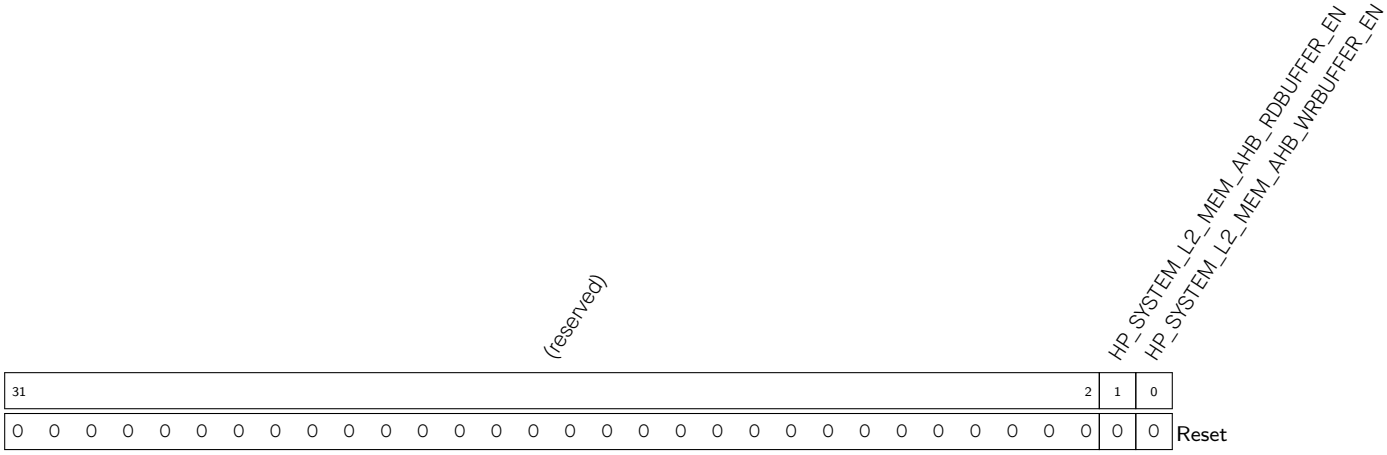
HP_SYSTEM_HP_SPM_PARITY_CHECK_EN Configures whether to enable parity error check in HP SPM.

0: Disable

1: Enable

(R/W)

Register 21.75. HP_SYSTEM_L2_MEM_ERR_RESP_CTRL_REG (0x0198)



HP_SYSTEM_L2_MEM_ERR_RESP_EN Configures whether to report ECC error to the HP CPU and trigger exception.

0: Disable

1: Enable

(R/W)

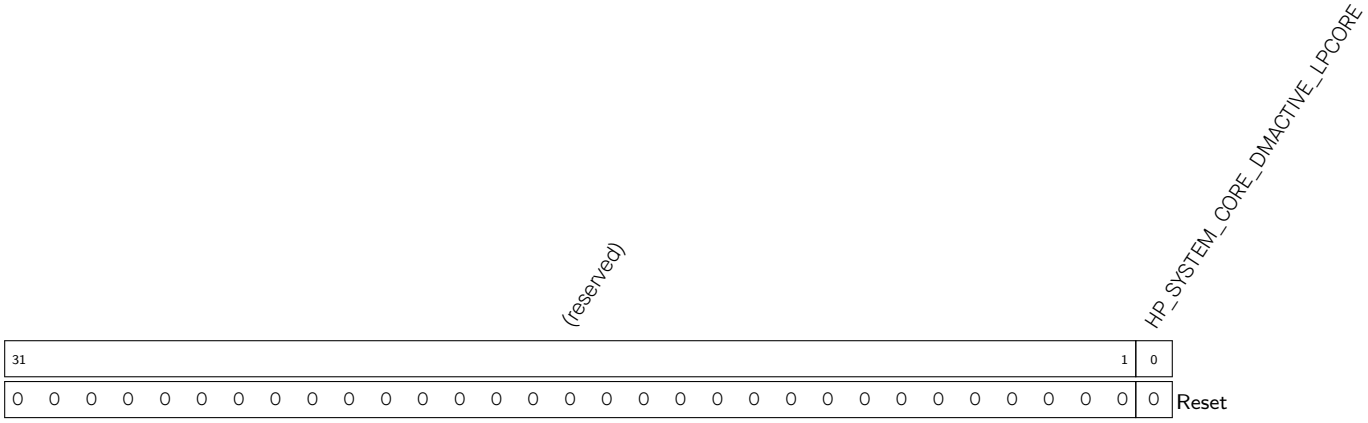
Register 21.76. HP_SYSTEM_L2_MEM_AHB_BUFFER_CTRL_REG (0x019C)

HP_SYSTEM_L2_MEM_AHB_WRBUFFER_EN Configures whether to enable L2MEM AHB write buffer.

0: Disable

1: Enable

(R/W)



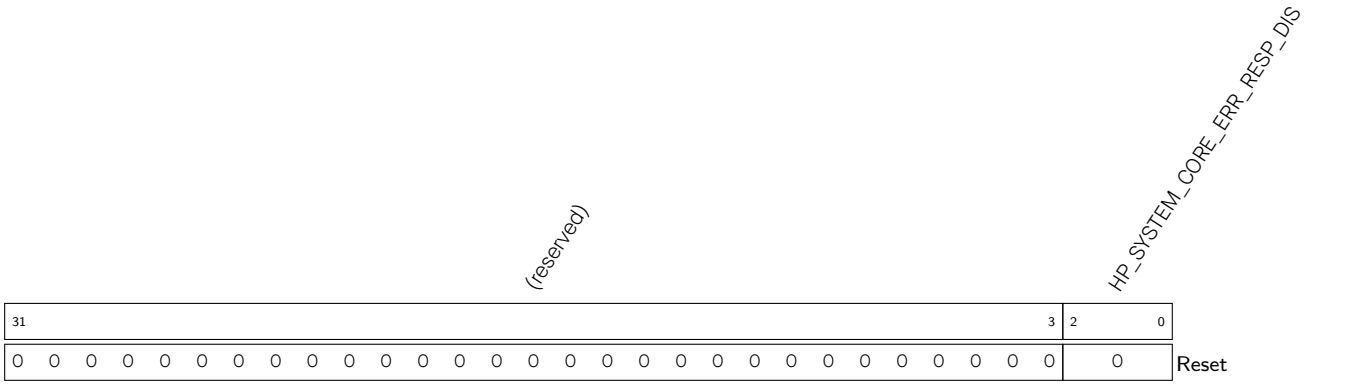
HP_SYSTEM_L2_MEM_AHB_RDBUFFER_EN Configures whether to enable L2MEM AHB read buffer.

0: Disable

1: Enable

(R/W)

Register 21.77. HP_SYSTEM_HP_CORE_DMACTIVE_LPCORE_REG (0x01A0)



HP_SYSTEM_CORE_DMACTIVE_LPCORE Represents the dmactive value of LP CPU's debug module.

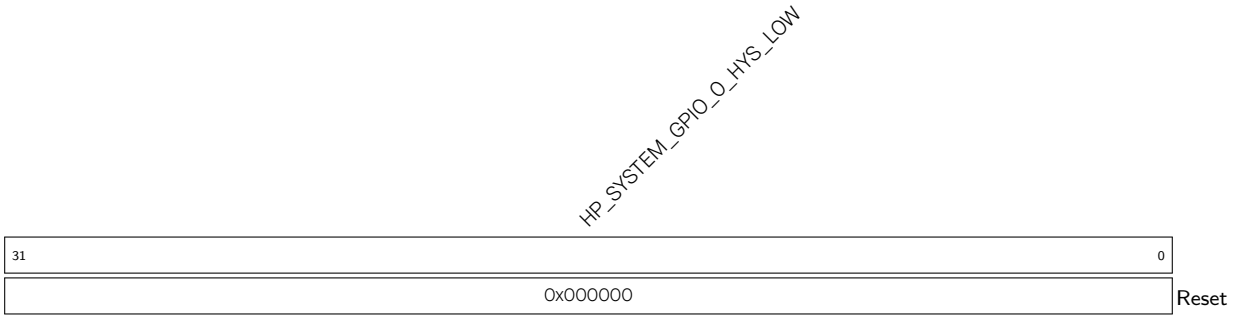
0: Indicates that the LP CPU is not connected to the JTAG interface, or is not in debug mode.

1: Indicates that the LP CPU is connected to the JTAG interface and is in debug mode.

(RO)

Register 21.78. HP_SYSTEM_HP_CORE_ERR_RESP_DIS_REG (0x01A4)

HP_SYSTEM_CORE_ERR_RESP_DIS Configures whether to disable the error response on different buses.



Bit[2]: AHB bus

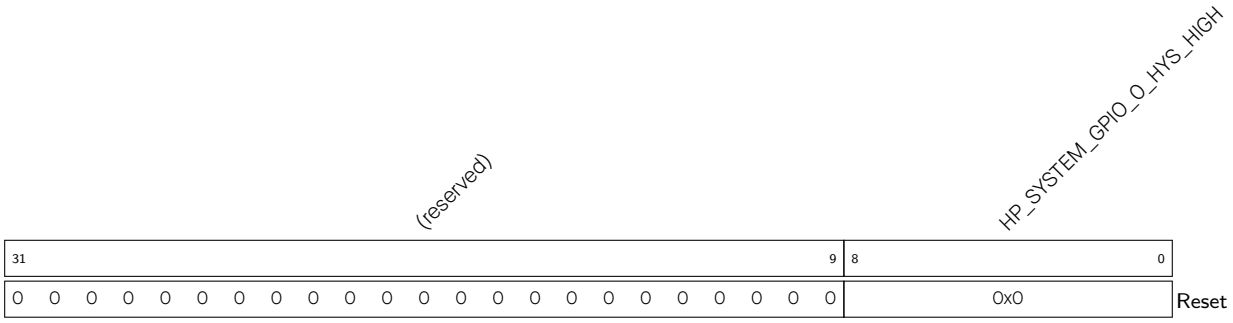
Bit[1]: DBUS

Bit[0]: IBUS

(R/W)

Register 21.79. HP_SYSTEM_GPIO_O_HYS_CTRL0_REG (0x01C0)

HP_SYSTEM_GPIO_O_HYS_LOW Configures whether to enable the hysteresis feature of HP GPIO16 ~ HP GPIO47.



0: No effect

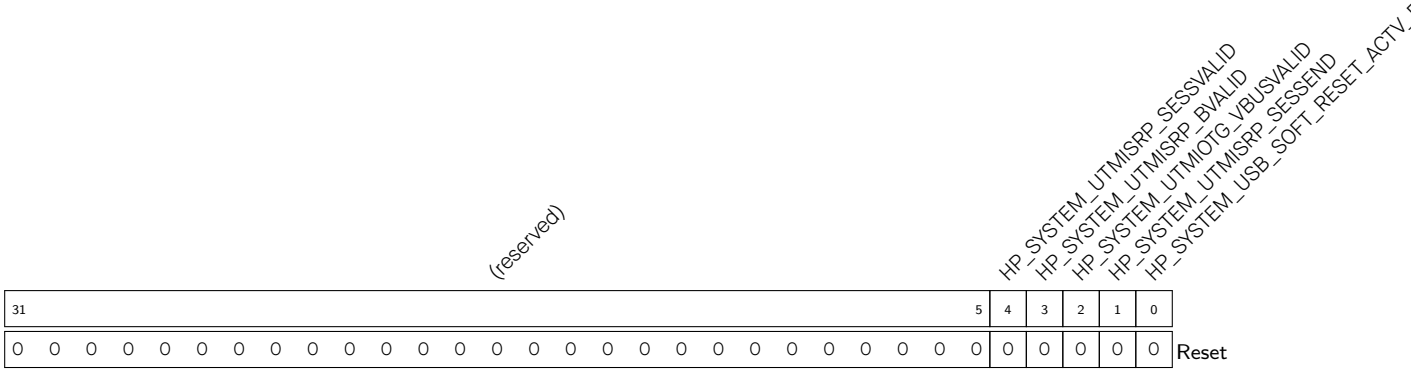
1: Enable

See detailed information in Section 10.10 of Chapter 10 *GPIO Matrix and IO MUX*.

(R/W)

Register 21.80. HP_SYSTEM_GPIO_O_HYS_CTRL1_REG (0x01C4)

HP_SYSTEM_GPIO_O_HYS_HIGH Configures whether to enable the hysteresis feature of HP GPIO48 ~ HP GPIO56.



0: No effect

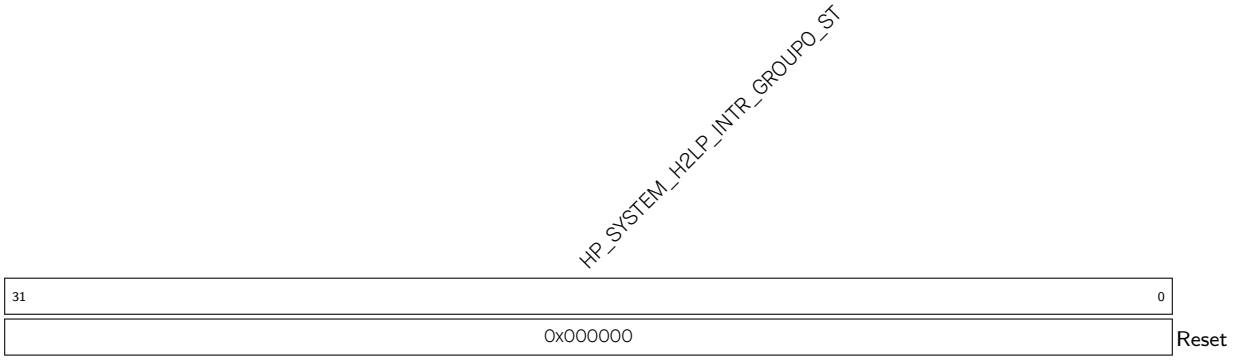
1: Enable

See detailed information in Section 10.10 of Chapter 10 *GPIO Matrix and IO MUX*.

(R/W)

Register 21.81. HP_SYSTEM_USB_OTGHS_PHY_ST_REG (0x01E8)

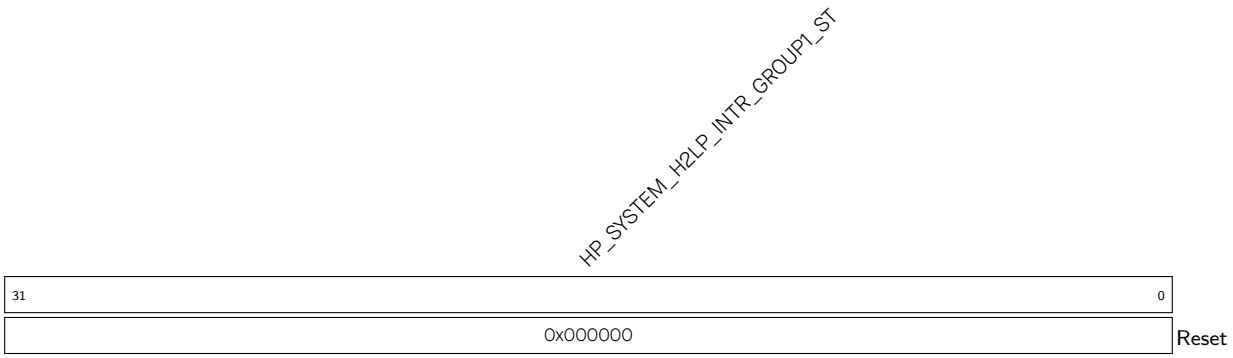
HP_SYSTEM_USB_SOFT_RESET_ACTV_PDOMAIN Represents the USB soft reset active status in the power domain. (RO)



HP_SYSTEM_UTMISRP_SESSEND Represents the USB OTG2.0 session end status. (RO)

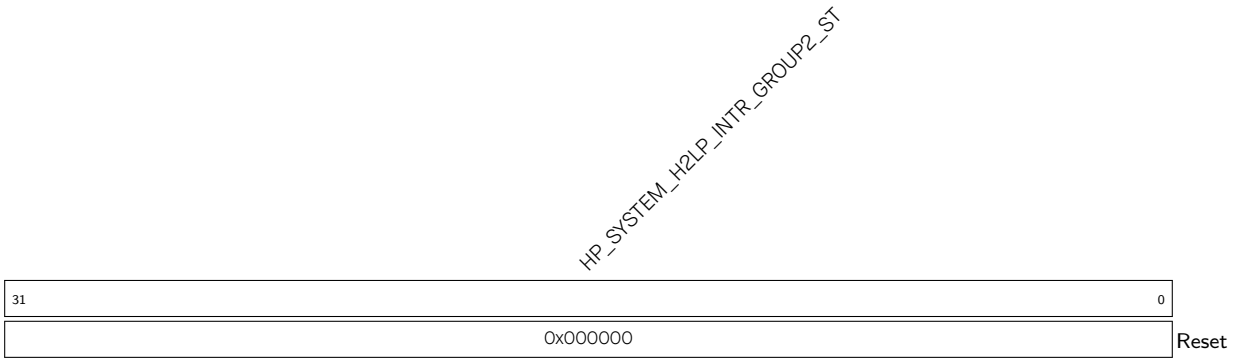
HP_SYSTEM_UTMIOTG_VBUSVALID Represents the USB OTG2.0 VBUS valid status. (RO)

HP_SYSTEM_UTMISRP_BVALID Represents the USB OTG2.0 B-valid status. (RO)



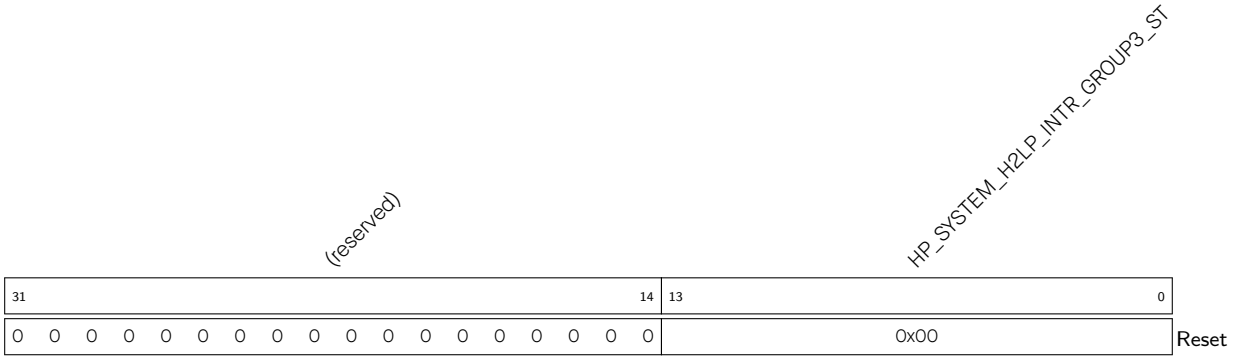
HP_SYSTEM_UTMISRP_SESSVALID Represents the USB OTG2.0 session valid status. (RO)

Register 21.82. HP_SYSTEM_HP2LP_INTR_GROUP0_ST_REG (0x0200)



HP_SYSTEM_H2LP_INTR_GROUP0_ST Each bit represents the status of the corresponding peripheral interrupt to LP CPU. (RO)

Register 21.83. HP_SYSTEM_HP2LP_INTR_GROUP1_ST_REG (0x0204)

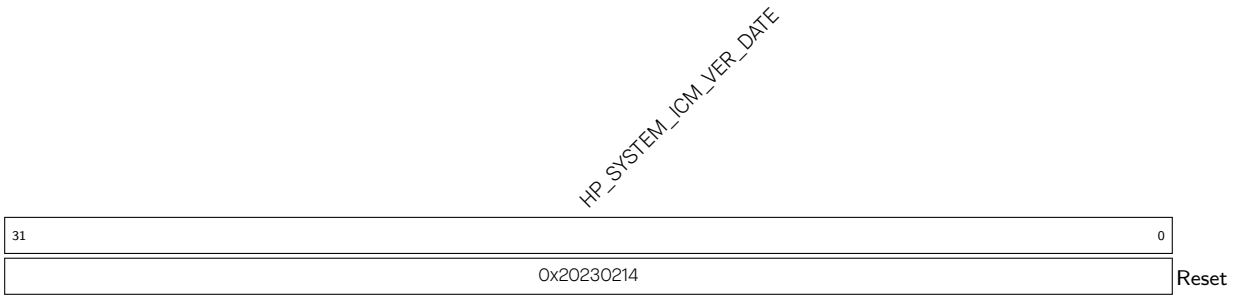


HP_SYSTEM_H2LP_INTR_GROUP1_ST Each bit represents the status of the corresponding peripheral interrupt to LP CPU. (RO)

Register 21.84. HP_SYSTEM_HP2LP_INTR_GROUP2_ST_REG (0x0208)

HP_SYSTEM_H2LP_INTR_GROUP2_ST Each bit represents the status of the corresponding peripheral interrupt to LP CPU. (RO)

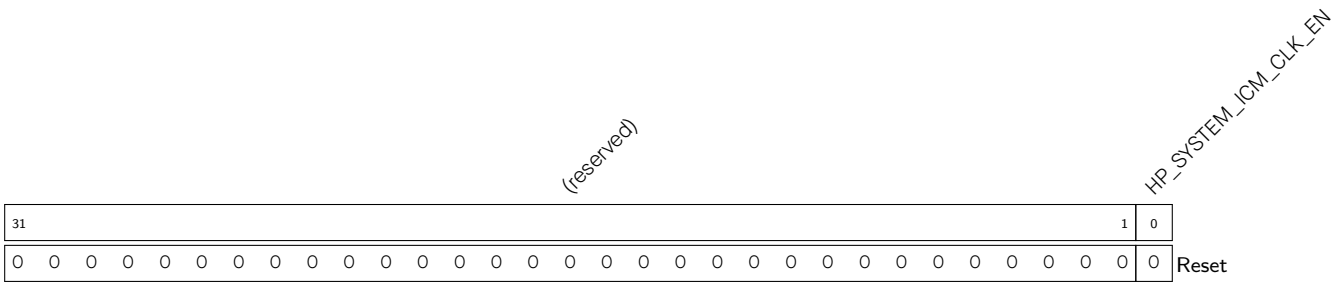
Register 21.85. HP_SYSTEM_HP2LP_INTR_GROUP3_ST_REG (0x020C)



HP_SYSTEM_H2LP_INTR_GROUP3_ST Each bit represents the status of the corresponding peripheral interrupt to LP CPU. (RO)

21.5.2 ICM Register

The addresses in this section are relative to AXI ICM base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

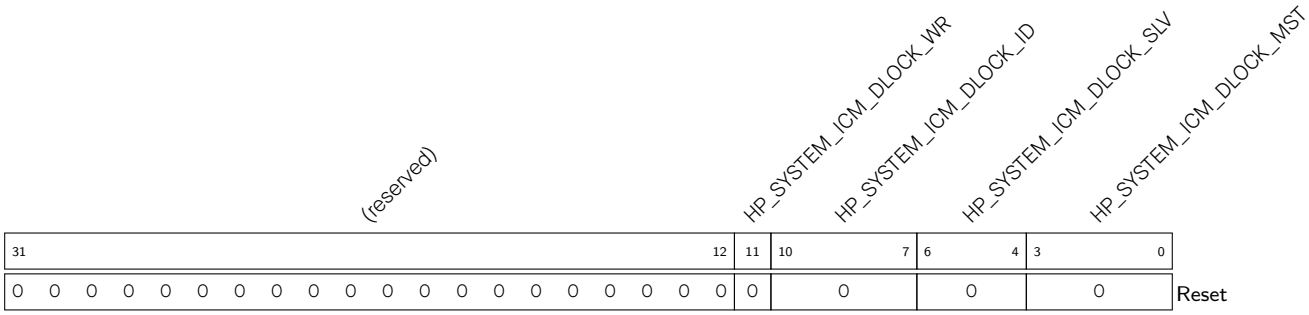


For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 21.86. HP_SYSTEM_ICM_VER_DATE_REG (0x0000)

HP_SYSTEM_ICM_VER_DATE Version control register. (R/W)

Register 21.87. HP_SYSTEM_ICM_CLK_EN_REG (0x0004)



HP_SYSTEM_ICM_CLK_EN Configures whether to force the register clock on.

0: The clock is enabled only during register access

1: Force clock on for the register

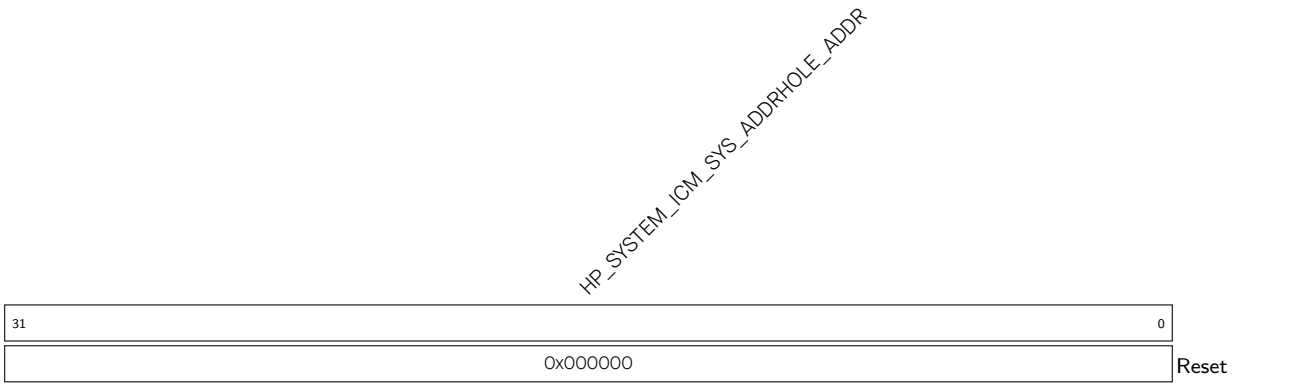
(R/W)

Register 21.88. HP_SYSTEM_ICM_DLOCK_STATUS_REG (0x0008)

HP_SYSTEM_ICM_DLOCK_MST Represents the lowest numbered master involved in a deadlock. (RO)

HP_SYSTEM_ICM_DLOCK_SLV Represents the slave with which the deadlock has occurred. (RO)

HP_SYSTEM_ICM_DLOCK_ID Represents the AXI ID of the transaction that is deadlocked. (RO)



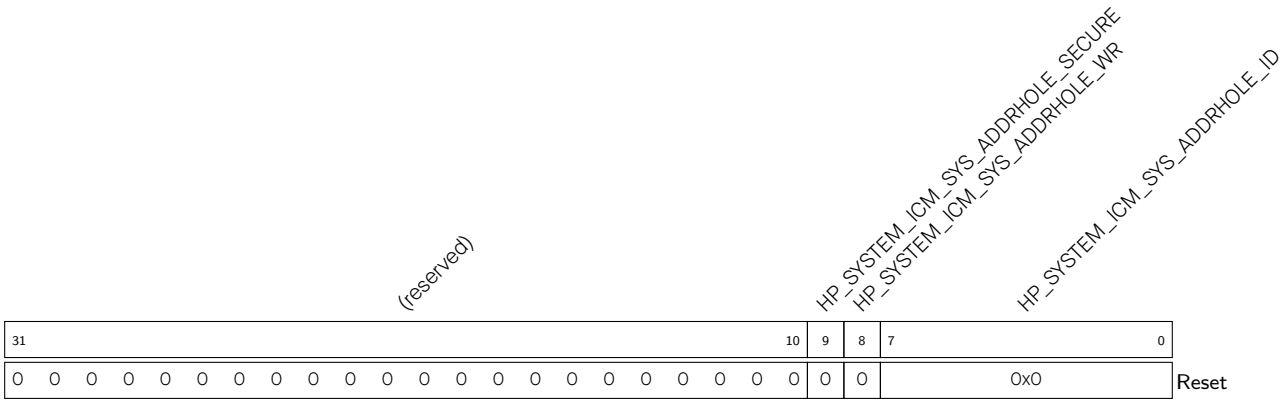
HP_SYSTEM_ICM_DLOCK_WR Represents whether the deadlocked transaction is a write operation.

0: Not a write operation

1: Write operation

(RO)

Register 21.89. HP_SYSTEM_ICM_SYS_ADDRHOLE_ADDR_REG (0x0038)



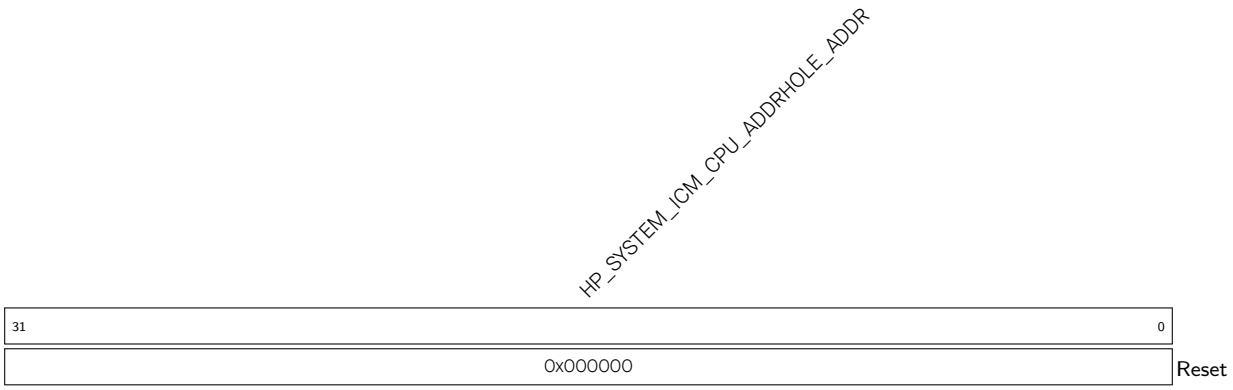
HP_SYSTEM_ICM_SYS_ADDRHOLE_ADDR Represents the address when ICM_SYS_ADDRHOLE_INT occurs.

If HP_SYSTEM_ICM_SYS_ADDRHOLE_SECURE is 0, the address is an unauthorized access address.

If HP_SYSTEM_ICM_SYS_ADDRHOLE_SECURE is 1, the address is an illegal access address.

(RO)

Register 21.90. HP_SYSTEM_ICM_SYS_ADDRHOLE_INFO_REG (0x003C)

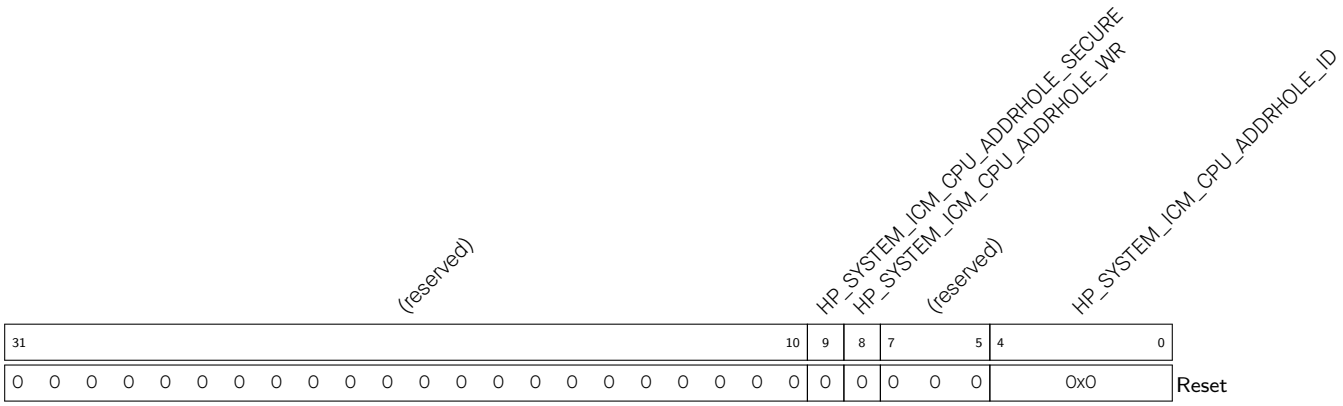


HP_SYSTEM_ICM_SYS_ADDRHOLE_ID Represents the master ID when ICM_SYS_ADDRHOLE_INT occurs. This ID consists of a 4-bit CID and a 4-bit UID (refer to the related IP for details). The CID is used for master verification in ICM. CID values correspond to the following masters:
1: CACHE
5: GDMA MST1
6: GDMA MST2
8: AXI GDMA
10: DMA2D
11: H264 MST1
12: H264 MST2
(RO)

HP_SYSTEM_ICM_SYS_ADDRHOLE_WR Represents the type of transfer when ICM_SYS_ADDRHOLE_INT occurs.
0: Read transfer
1: Write transfer
(RO)

HP_SYSTEM_ICM_SYS_ADDRHOLE_SECURE Represents the type of access error when ICM_SYS_ADDRHOLE_INT occurs.
0: Unauthorized access
1: Illegal access
(RO)

Register 21.91. HP_SYSTEM_ICM_CPU_ADDRHOLE_ADDR_REG (0x0040)



HP_SYSTEM_ICM_CPU_ADDRHOLE_ADDR Represents the address when ICM_CPU_ADDRHOLE_INT occurs.

If HP_SYSTEM_ICM_CPU_ADDRHOLE_SECURE is 0, the address is an unauthorized access address.

If HP_SYSTEM_ICM_CPU_ADDRHOLE_SECURE is 1, the address is an illegal access address. (RO)

Register 21.92. HP_SYSTEM_ICM_CPU_ADDRHOLE_INFO_REG (0x0044)

HP_SYSTEM_ICM_CPU_ADDRHOLE_ID Represents the master ID when ICM_CPU_ADDRHOLE_INT occurs.

0: HP CPU0

1: HP CPU1

2: LP CPU

3: USBOTGFS

5: GMAC

6: SDMMC

7: USBOTGHS

8: TRACE0

9: TRACE1

10: SPM Monitor

11: L2MEM Monitor

16-31: AHB GDMA

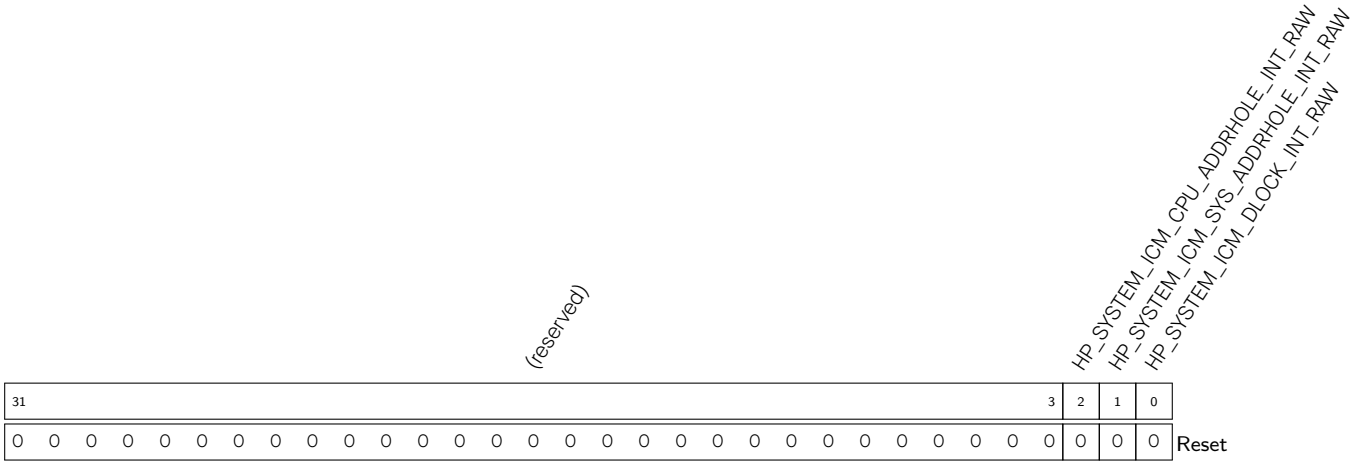
(RO)

HP_SYSTEM_ICM_CPU_ADDRHOLE_WR Represents the type of transfer when ICM_CPU_ADDRHOLE_INT occurs.

0: Read transfer

1: Write transfer

(RO)



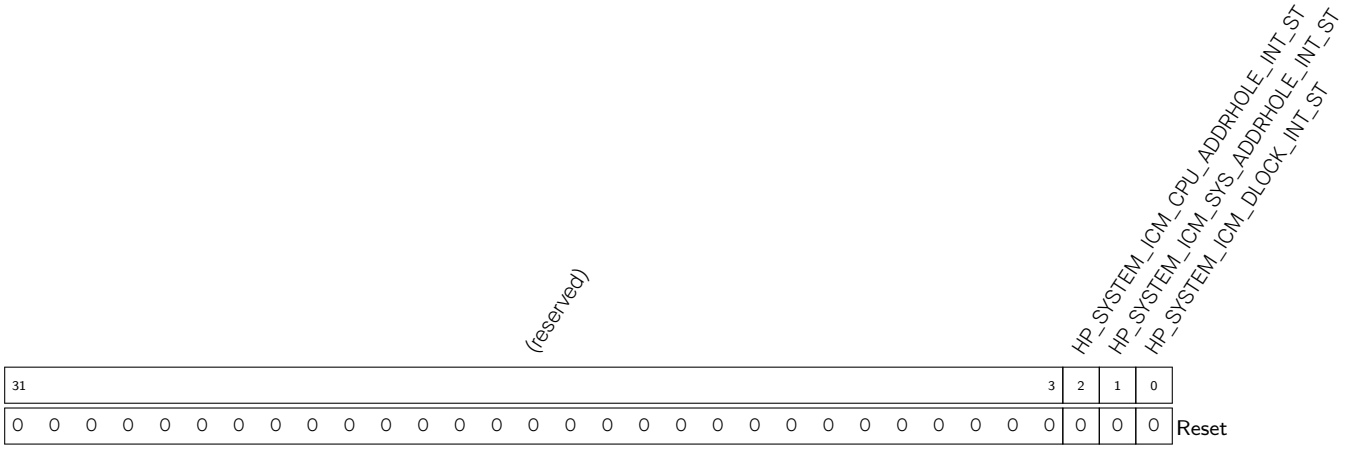
HP_SYSTEM_ICM_CPU_ADDRHOLE_SECURE Represents the type of access error when ICM_CPU_ADDRHOLE_INT occurs.

0: Unauthorized access

1: Illegal access

(RO)

Register 21.93. HP_SYSTEM_ICM_INT_RAW_REG (0x000C)

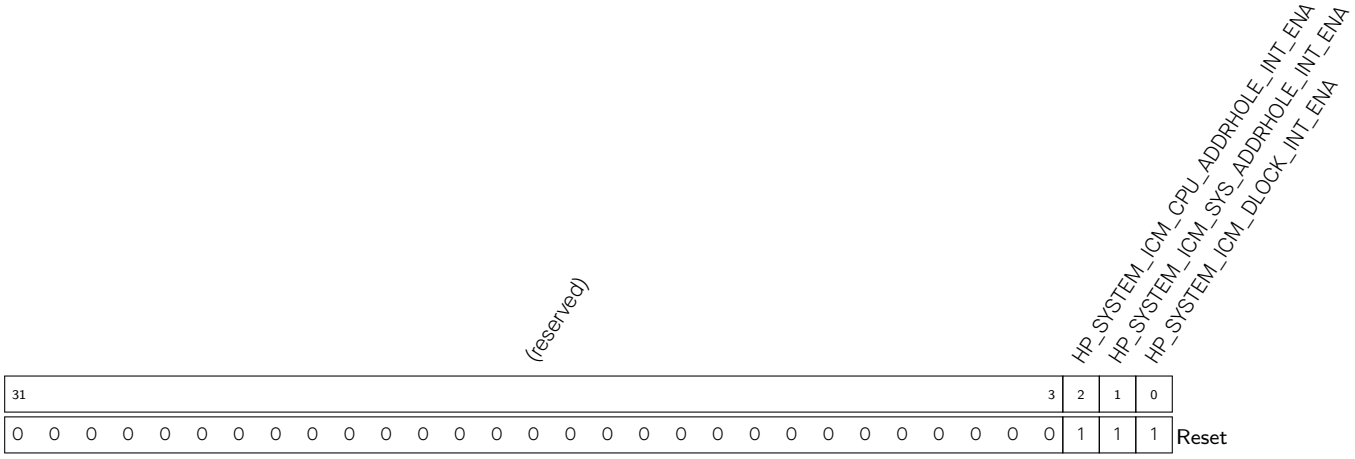


HP_SYSTEM_ICM_DLOCK_INT_RAW The raw interrupt status of ICM_DLOCK_INT. (R/WTC/SS)

HP_SYSTEM_ICM_SYS_ADDRHOLE_INT_RAW The raw interrupt status of ICM_SYS_ADDRHOLE_INT. (R/WTC/SS)

HP_SYSTEM_ICM_CPU_ADDRHOLE_INT_RAW The raw interrupt status of ICM_CPU_ADDRHOLE_INT. (R/WTC/SS)

Register 21.94. HP_SYSTEM_ICM_INT_ST_REG (0x0010)

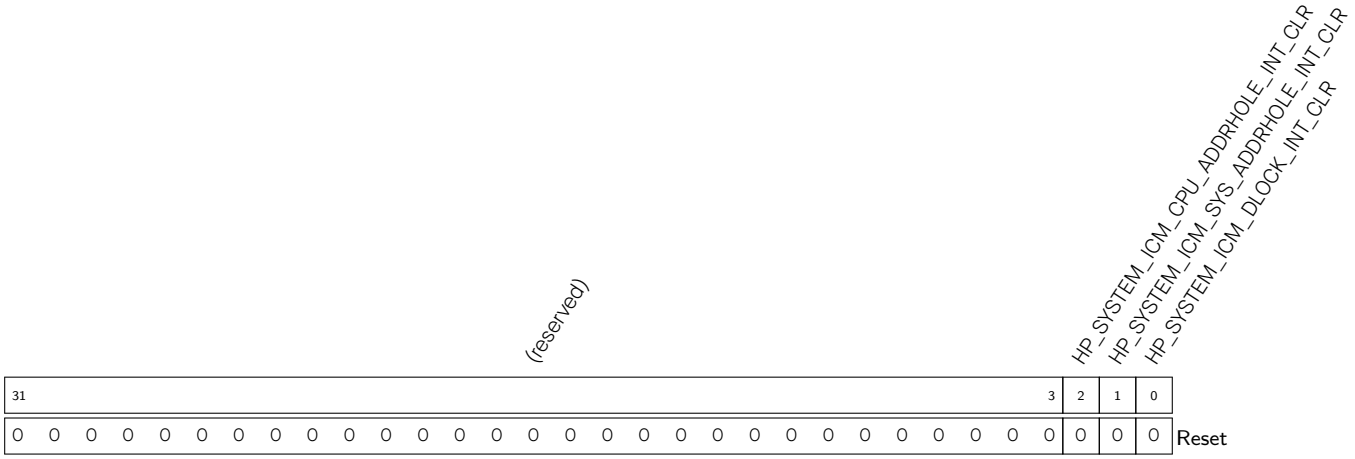


HP_SYSTEM_ICM_DLOCK_INT_ST The masked interrupt status of DLOCK_INT. (RO)

HP_SYSTEM_ICM_SYS_ADDRHOLE_INT_ST The masked interrupt status of ICM_SYS_ADDRHOLE_INT. (RO)

HP_SYSTEM_ICM_CPU_ADDRHOLE_INT_ST The masked interrupt status of ICM_CPU_ADDRHOLE_INT. (RO)

Register 21.95. HP_SYSTEM_ICM_INT_ENA_REG (0x0014)

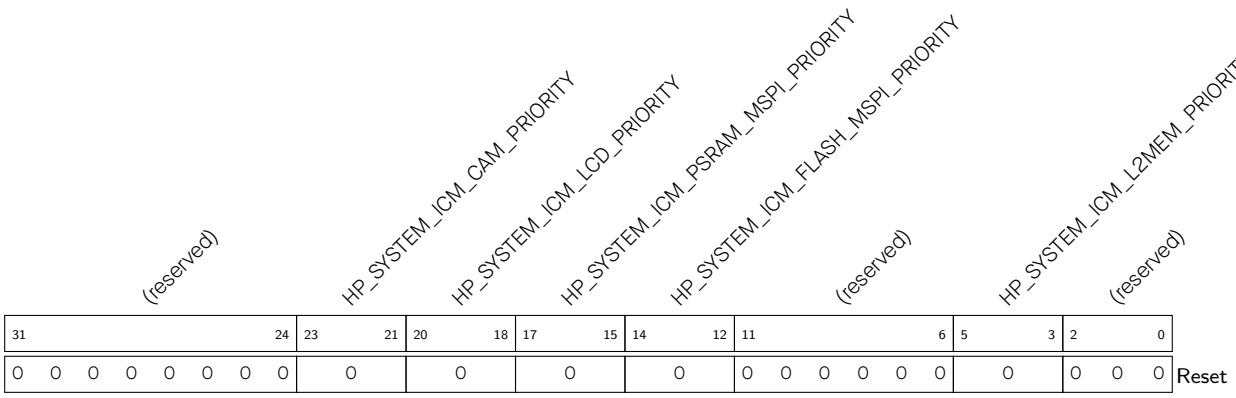


HP_SYSTEM_ICM_DLOCK_INT_ENA Write 1 to enable DLOCK_INT. (R/W)

HP_SYSTEM_ICM_SYS_ADDRHOLE_INT_ENA Write 1 to enable ICM_SYS_ADDRHOLE_INT. (R/W)

HP_SYSTEM_ICM_CPU_ADDRHOLE_INT_ENA Write 1 to enable ICM_CPU_ADDRHOLE_INT. (R/W)

Register 21.96. HP_SYSTEM_ICM_INT_CLR_REG (0x0018)



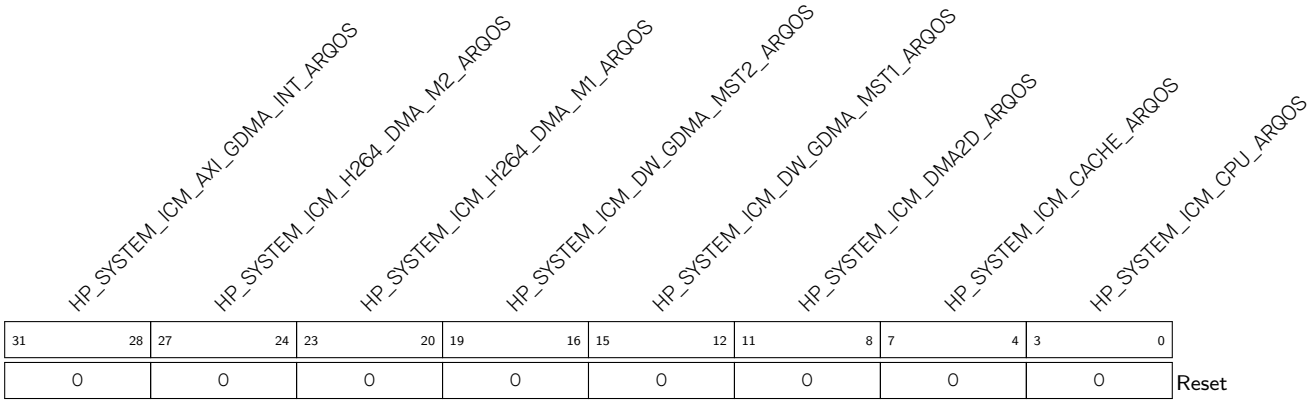
HP_SYSTEM_ICM_DLOCK_INT_CLR Write 1 to clear DLOCK_INT. (WT)

HP_SYSTEM_ICM_SYS_ADDRHOLE_INT_CLR Write 1 to clear ICM_SYS_ADDRHOLE_INT. (WT)

HP_SYSTEM_ICM_CPU_ADDRHOLE_INT_CLR Write 1 to clear ICM_CPU_ADDRHOLE_INT. (WT)

Register 21.97. HP_SYSTEM_ICM_SLV_ARB_PRIORITY_REG (0x0024)

HP_SYSTEM_ICM_L2MEM_PRIORITY Configures the arbitration priority of L2MEM for response channels among slaves connected to SYS ICM. (R/W)



HP_SYSTEM_ICM_FLASH_MSPI_PRIORITY Configures the arbitration priority of FLASH MSPI for response channels among slaves connected to SYS ICM. (R/W)

HP_SYSTEM_ICM_PSRAM_MSPI_PRIORITY Configures the arbitration priority of PSRAM MSPI for response channels among slaves connected to SYS ICM. (R/W)

HP_SYSTEM_ICM_LCD_PRIORITY Configures the arbitration priority of MIPI_LCD registers for response channels among slaves connected to SYS ICM. (R/W)

HP_SYSTEM_ICM_CAM_PRIORITY Configures the arbitration priority of MIPI_CAM registers for response channels among slaves connected to SYS ICM. (R/W)

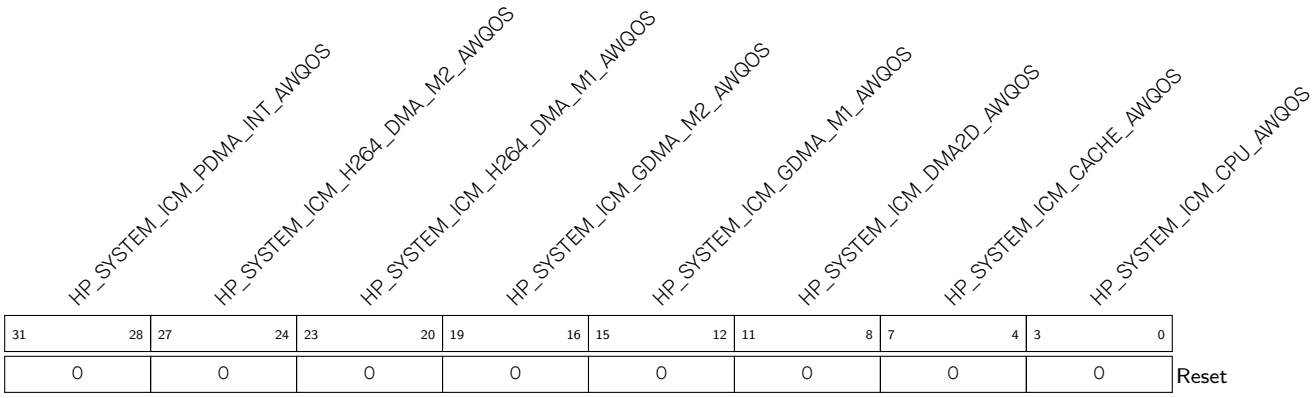
Register 21.98. HP_SYSTEM_ICM_MST_ARQOS_REG0_REG (0x0028)

HP_SYSTEM_ICM_CPU_ARQOS Configures the ARQoS value for CPU ICM. (R/W)

HP_SYSTEM_ICM_CACHE_ARQOS Configures the ARQoS value for CACHE. (R/W)

HP_SYSTEM_ICM_DMA2D_ARQOS Configures the ARQoS value for DMA2D. (R/W)

HP_SYSTEM_ICM_DW_GDMA_MST1_ARQOS Configures the ARQoS value for DW-GDMA MST1. (R/W)



HP_SYSTEM_ICM_DW_GDMA_MST2_ARQOS Configures the ARQoS value for DW-GDMA MST2. (R/W)

HP_SYSTEM_ICM_H264_DMA_M1_ARQOS Configures the ARQoS value for H264 DMAMST1. (R/W)

HP_SYSTEM_ICM_H264_DMA_M2_ARQOS Configures the ARQoS value for H264 DMAMST2. (R/W)

HP_SYSTEM_ICM_AXI_GDMA_INT_ARQOS Configures the ARQoS value for AXI GDMA. (R/W)

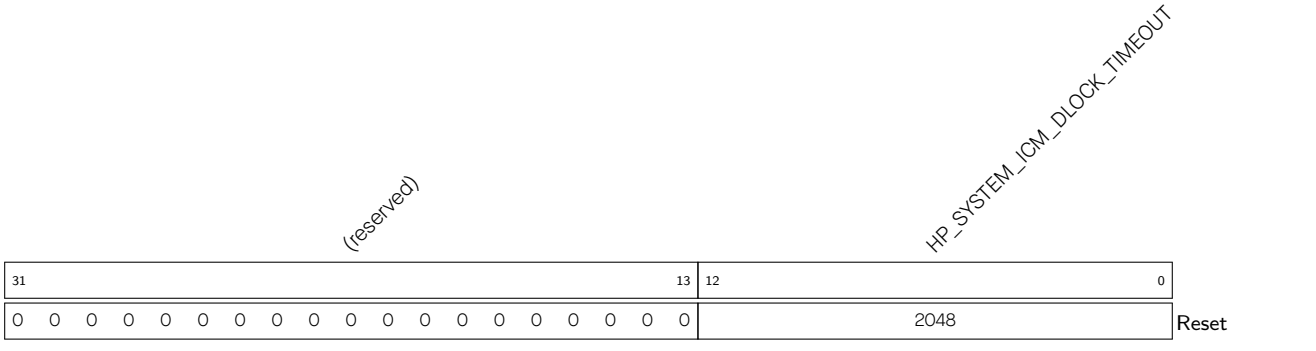
Register 21.99. HP_SYSTEM_ICM_MST_AWQOS_REG0_REG (0x0030)

HP_SYSTEM_ICM_CPU_AWQOS Configures the AWQoS value for the CPU ICM. (R/W)

HP_SYSTEM_ICM_CACHE_AWQOS Configures the AWQoS value for the CACHE. (R/W)

HP_SYSTEM_ICM_DMA2D_AWQOS Configures the AWQoS value for the DMA2D. (R/W)

HP_SYSTEM_ICM_GDMA_M1_AWQOS Configures the AWQoS value for the DW-GDMA MST1. (R/W)



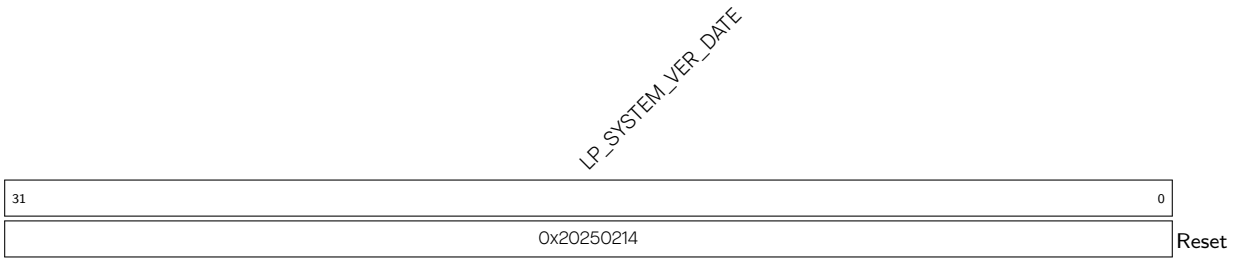
HP_SYSTEM_ICM_GDMA_M2_AWQOS Configures the AWQoS value for the DW-GDMA MST2. (R/W)

HP_SYSTEM_ICM_H264_DMA_M1_AWQOS Configures the AWQoS value for the H264 DMA MST1. (R/W)

HP_SYSTEM_ICM_H264_DMA_M2_AWQOS Configures the AWQoS value for the H264 DMA MST2. (R/W)

HP_SYSTEM_ICM_PDMA_INT_AWQOS Configures the AWQoS value for the AXI GDMA. (R/W)

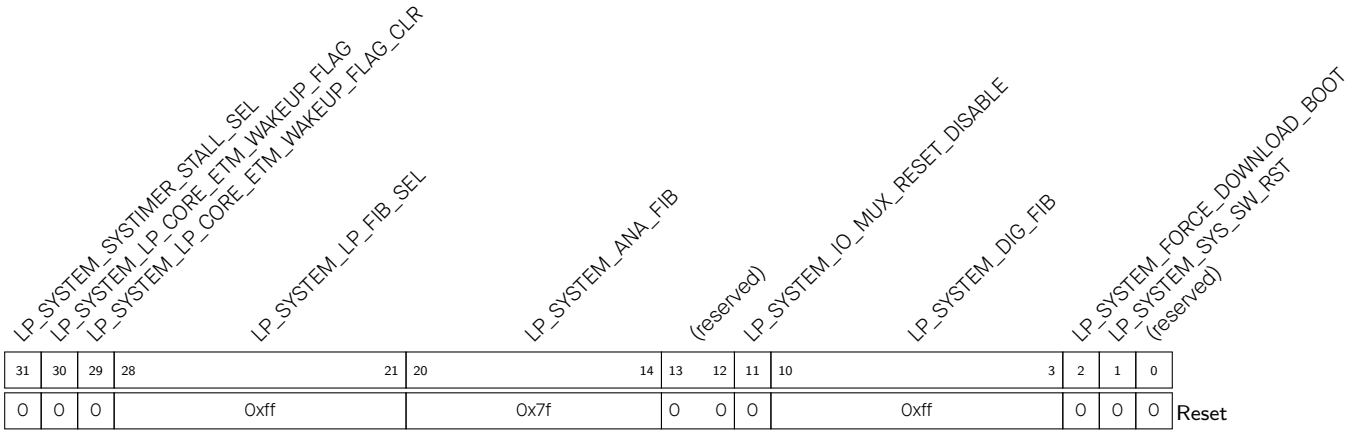
Register 21.100. HP_SYSTEM_ICM_DLOCK_TIMEOUT_REG (0x0048)



HP_SYSTEM_ICM_DLOCK_TIMEOUT Configures the deadlock timeout threshold value. Deadlock will occur if there is no response within the configured threshold.
(R/W)

21.5.3 LP Registers

The addresses in this section are relative to LP System Registers base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 21.101. LP_SYSTEM_LP_SYS_VER_DATE_REG (0x0000)

LP_SYSTEM_VER_DATE Version control register. (R/W)

Register 21.102. LP_SYSTEM_SYS_CTRL_REG (0x0008)

LP_SYSTEM_SYS_SW_RST Configures whether to trigger a software system reset. (WT)

LP_SYSTEM_FORCE_DOWNLOAD_BOOT Configures whether to forcibly enter Joint Download Boot mode when the pad boot mode is set to SPI Boot mode.

0: Not forcibly enter in Joint Download Boot mode

1: Forcibly enter in Joint Download Boot mode

(R/W)

LP_SYSTEM_DIG_FIB Configures software FIB.

Bit[0]: Unused

Bit[1]: Software BOD enable

Bit[2]: Software SWD enable

Bit[3]: Unused

Bit[4]: Software DCDC switch

Bit[5]: Software DCDC VSET enable

Bit[6]: Unused

Bit[7]: Unused

(R/W)

LP_SYSTEM_IO_MUX_RESET_DISABLE Configures whether to disable the HP IOMUX reset.

0: Enable IOMUX reset

1: Disable IOMUX reset

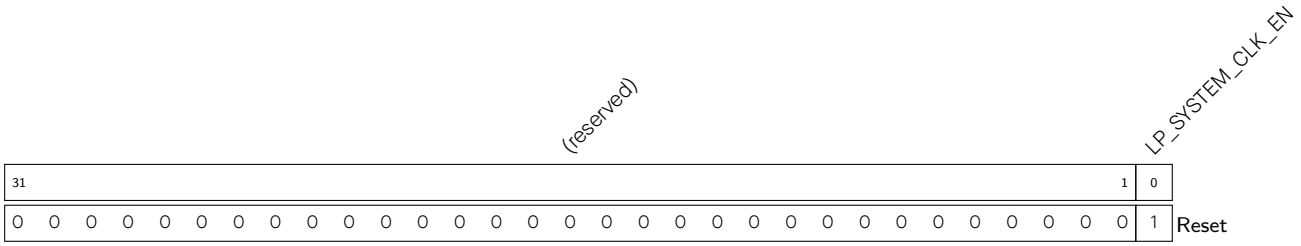
(R/W)

Continued on the next page...

Register 21.102. LP_SYSTEM_SYS_CTRL_REG (0x0008)

Continued from the previous page...

LP_SYSTEM_ANA_FIB Represents analog FIB state.
Bit[0]: Unused
Bit[1]: Analog BOD enable
Bit[2]: Analog SWD enable
Bit[3]: Unused
Bit[4]: Unused
Bit[5]: Unused
Bit[6]: Unused
Bit[7]: Unused
(RO)



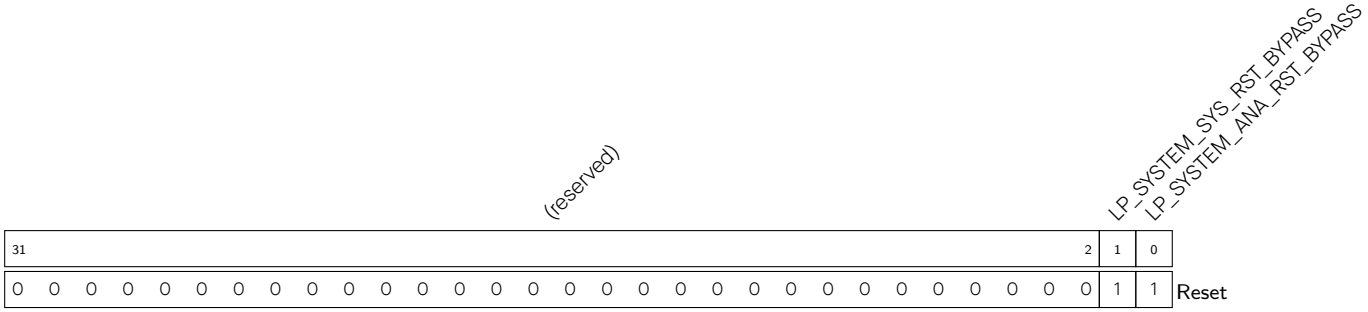
LP_SYSTEM_LP_FIB_SEL Configures FIB control source select.
Bit[0]: Unused
Bit[1]: Configures BOD enable control select
0: Controlled by software
1: Controlled by analog
Bit[2]: Configures SWD enable control select
0: Controlled by software
1: Controlled by analog
Bit[3]: Unused
Bit[4]: Unused
Bit[5]: Unused
Bit[6]: Unused
Bit[7]: Unused
(R/W)

LP_SYSTEM_LP_CORE_ETM_WAKEUP_FLAG_CLR Write 1 to clear LP_SYSTEM_LP_CORE_ETM_WAKEUP_FLAG. (WT)

LP_SYSTEM_LP_CORE_ETM_WAKEUP_FLAG Represents ETM task of ULP wakeup. (R/WTC/SS)

LP_SYSTEM_SYSTIMER_STALL_SEL Configures whether the LP systimer_stall signal is from HP CPU0 or HP CPU1.
0: From HP CPU0
1: From HP CPU1
(R/W)

Register 21.103. LP_SYSTEM_LP_CLK_CTRL_REG (0x000C)



LP_SYSTEM_CLK_EN Configures whether the register clock is always on.

0: The clock is enabled only during register access

1: The clock is always on

(R/W)

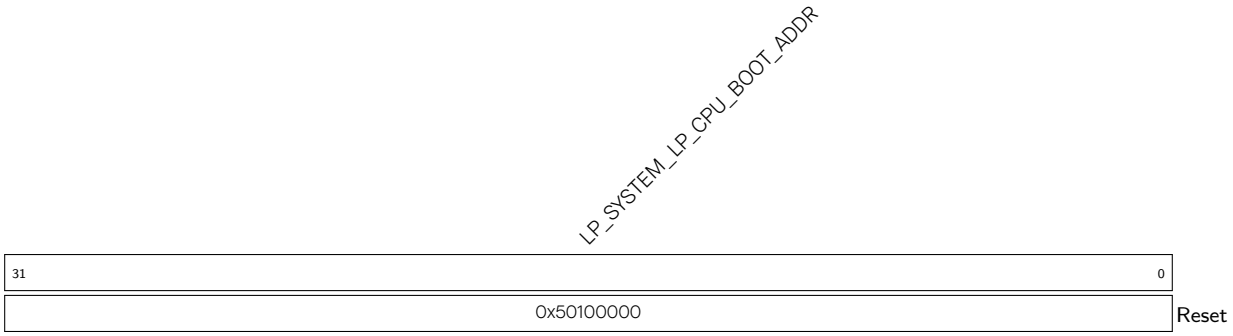
Register 21.104. LP_SYSTEM_LP_RST_CTRL_REG (0x0010)

LP_SYSTEM_ANA_RST_BYPASS Configures whether to bypass these analog reset sources: brown-out detector, super WDT and power glitch detector.

0: Not bypass

1: Bypass

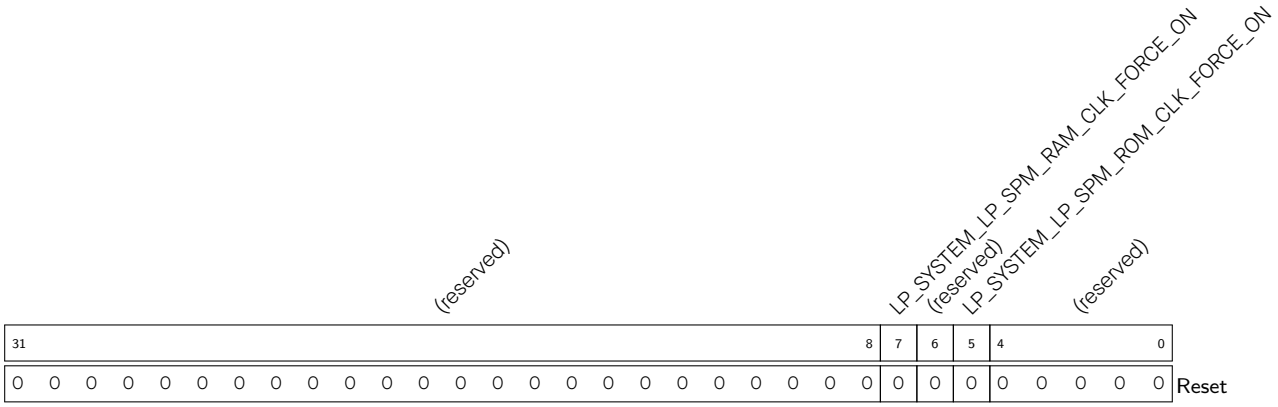
(R/W)



LP_SYSTEM_SYS_RST_BYPASS Configures whether to bypass these digital reset sources: software, HP watchdog timer, LP watchdog timer and eFuse.

0: Not bypass

1: Bypass



(R/W)

Register 21.105. LP_SYSTEM_LP_CORE_BOOT_ADDR_REG (0x0018)

LP_SYSTEM_LP_CPU_BOOT_ADDR Configures the LP CPU boot address. (R/W)

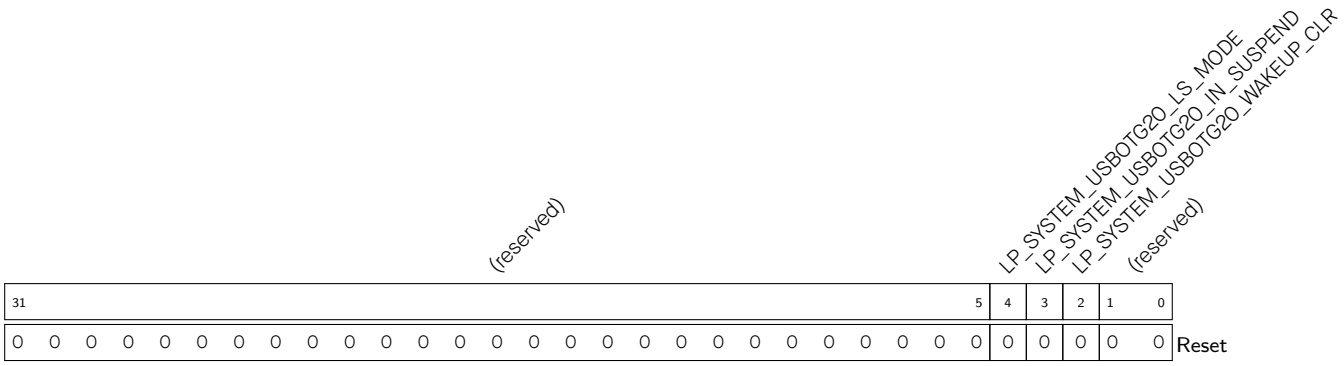
Register 21.106. LP_SYSTEM_LP_SPM_PWR_CTRL_REG (0x0024)

LP_SYSTEM_LP_SPM_ROM_CLK_FORCE_ON Configures whether to force on LP SPM_ROM clock when LP CPU clock is on.

0: Not force on

1: Force on

(R/W)



LP_SYSTEM_LP_SPM_RAM_CLK_FORCE_ON Configures whether to force on LP SPM_RAM clock.

0: Not force on

1: Force on

(R/W)

Register 21.107. LP_SYSTEM_USB_CTRL_REG (0x0100)

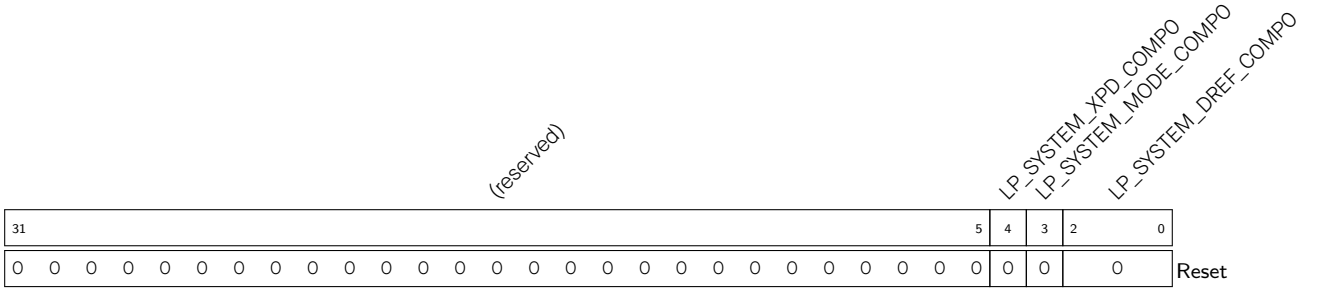
LP_SYSTEM_USBOTG20_WAKEUP_CLR Write 1 to clear wakeup signals from USB OTG2.0 to PMU. (WT)

LP_SYSTEM_USBOTG20_IN_SUSPEND Configures whether to enable wakeup signals from USB OTG2.0.

0: Disable

1: Enable

(R/W)



LP_SYSTEM_USBOTG20_LS_MODE Configures whether USB OTG2.0 operates in low-speed mode.

0: Not low-speed mode

1: Low-speed mode

(R/W)

Register 21.108. LP_SYSTEM_PAD_COMP0_REG (0x0148)

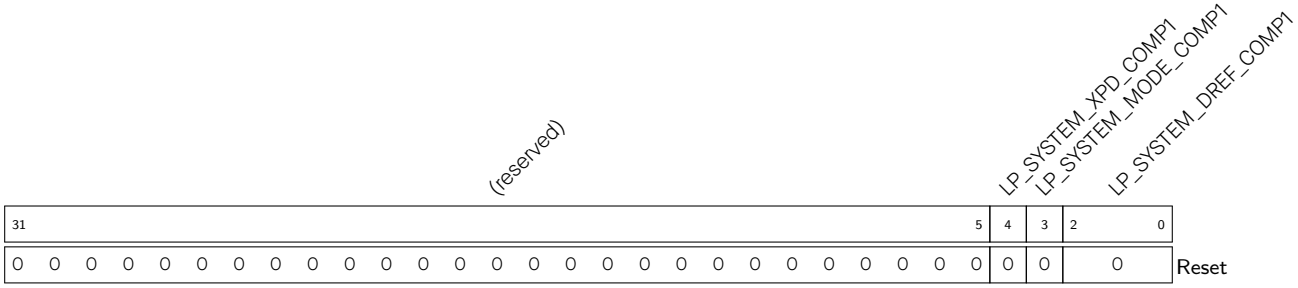
LP_SYSTEM_DREF_COMP0 Configures the internal reference voltage of pad comparator0. (R/W)

LP_SYSTEM_MODE_COMP0 Configures the comparison mode for pad comparator0.

0: Comparing the main voltage with the external reference voltage

1: Comparing the main voltage with the internal reference voltage

(R/W)



LP_SYSTEM_XPD_COMP0 Configures whether to enable pad comparator0.

0: Disable

1: Enable

(R/W)

Register 21.109. LP_SYSTEM_PAD_COMP1_REG (0x014C)

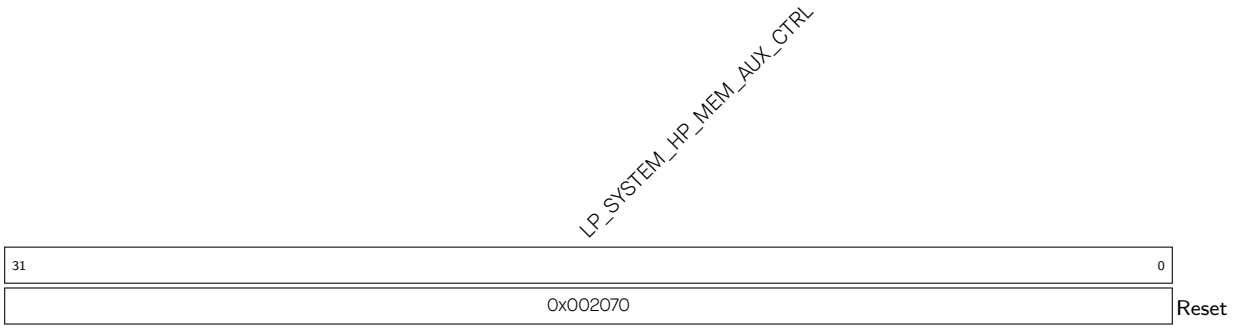
LP_SYSTEM_DREF_COMP1 Configures the internal reference voltage of pad comparator1. (R/W)

LP_SYSTEM_MODE_COMP1 Configures the comparison mode for pad comparator1.

0: Comparing the main voltage with the external reference voltage

1: Comparing the main voltage with the internal reference voltage

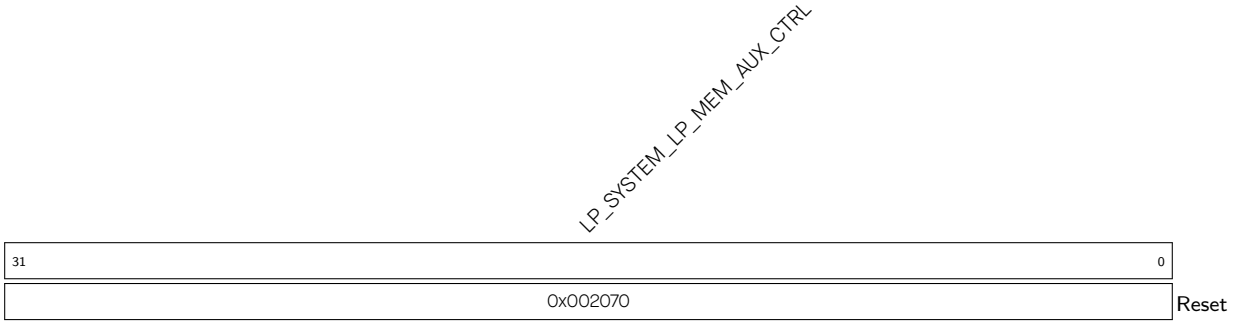
(R/W)



LP_SYSTEM_XPD_COMP1 Configures whether to enable pad comparator1.

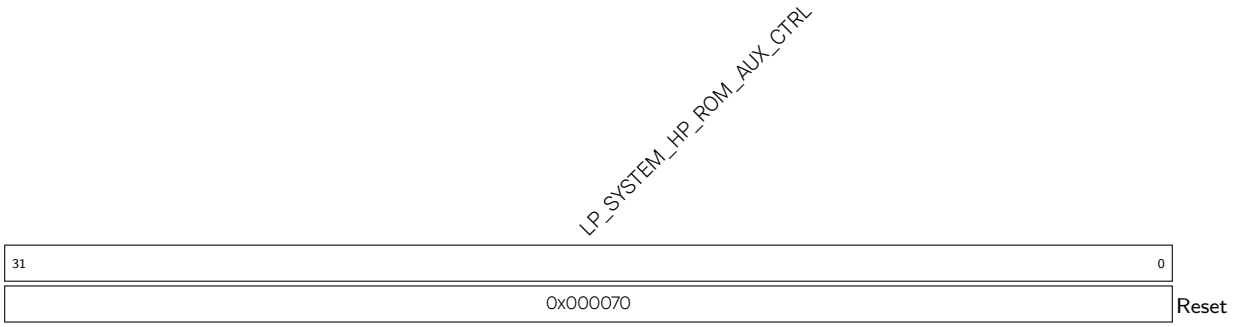
0: Disable

1: Enable



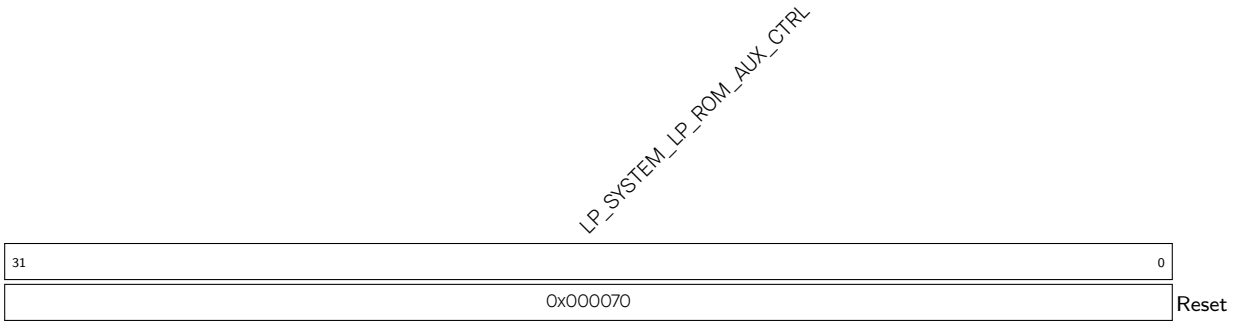
(R/W)

Register 21.110. LP_SYSTEM_HP_MEM_AUX_CTRL_REG (0x0180)



LP_SYSTEM_HP_MEM_AUX_CTRL Configures HP system memory aux control value. (R/W)

Register 21.111. LP_SYSTEM_LP_MEM_AUX_CTRL_REG (0x0184)



LP_SYSTEM_LP_MEM_AUX_CTRL Configures LP system memory aux control value. (R/W)

Register 21.112. LP_SYSTEM_HP_ROM_AUX_CTRL_REG (0x0188)

LP_SYSTEM_HP_ROM_AUX_CTRL Configures L2ROM aux control value. (R/W)

Register 21.113. LP_SYSTEM_LP_ROM_AUX_CTRL_REG (0x018C)

LP_SYSTEM_LP_ROM_AUX_CTRL Configures LPROM aux control value. (R/W)

Register 21.114. LP_SYSTEM_HP_POR_RST_BYPASS_CTRL_REG (0x01A0)

LP_SYSTEM_HP_PO_CNNT_RSTN_BYPASS_CTRL Configures whether to bypass reset sources for the HP_CNNT power domain during the Power-On reset.

Bit[0]: Configures whether to bypass eFuse reset

0: No effect

1: Bypass

Bit[1]: Configures whether to bypass LP watchdog timer reset

0: No effect

1: Bypass

Bit[2]: Configures whether to bypass USB (JTAG) reset

0: No effect

1: Bypass

Bit[3]: Configures whether to bypass USB (UART) reset

0: No effect

1: Bypass

Bit[4]: Unused

Bit[5]: Unused

Bit[6]: Configures whether to bypass HP watchdog timer reset

0: No effect

1: Bypass

Bit[7]: Configures whether to bypass software reset

0: No effect

1: Bypass

(R/W)

Continued on the next page...

Register 21.114. LP_SYSTEM_HP_POR_RST_BYPASS_CTRL_REG (0x01A0)

Continued from the previous page...

LP_SYSTEM_HP_PO_RSTN_BYPASS_CTRL Configures whether to bypass reset sources for the HP power domain during the Power-On reset.

Bit[0]: Configures whether to bypass eFuse reset

0: No effect

1: Bypass

Bit[1]: Configures whether to bypass LP watchdog timer reset

0: No effect

1: Bypass

Bit[2]: Configures whether to bypass USB (JTAG) reset

0: No effect

1: Bypass

Bit[3]: Configures whether to bypass USB (UART) reset

0: No effect

1: Bypass

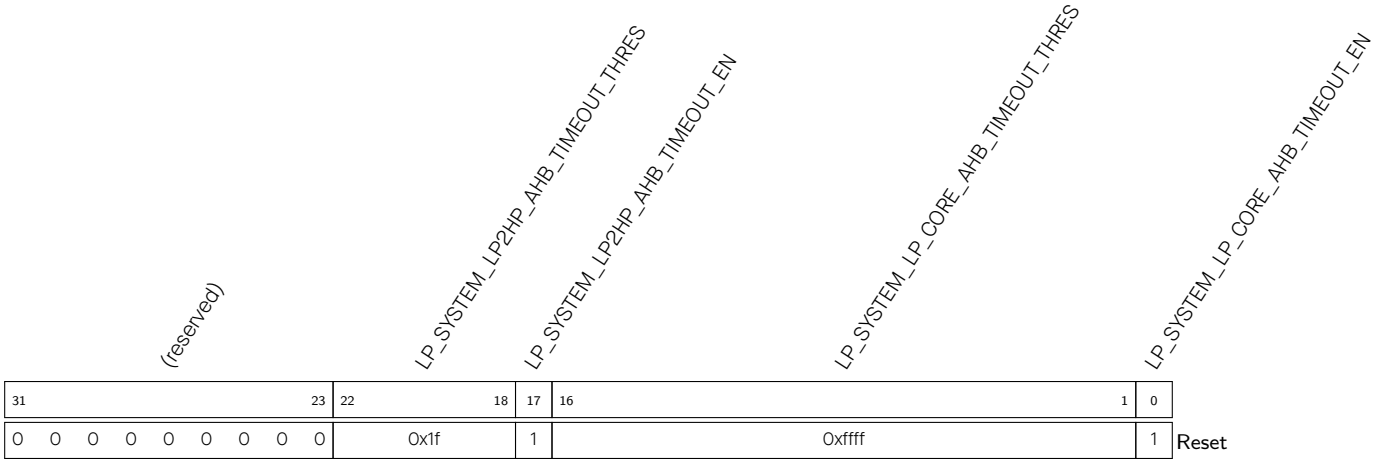
Bit[4]: Unused

Bit[5]: Unused

Bit[6]: Configures whether to bypass HP watchdog timer reset

0: No effect

1: Bypass



Bit[7]: Configures whether to bypass software reset

0: No effect

1: Bypass

(R/W)

Register 21.115. LP_SYSTEM_LP_CORE_AHB_TIMEOUT_REG (0x01B0)

LP_SYSTEM_LP_CORE_AHB_TIMEOUT_EN Configures whether to enable timeout protection on LP AHB bus.

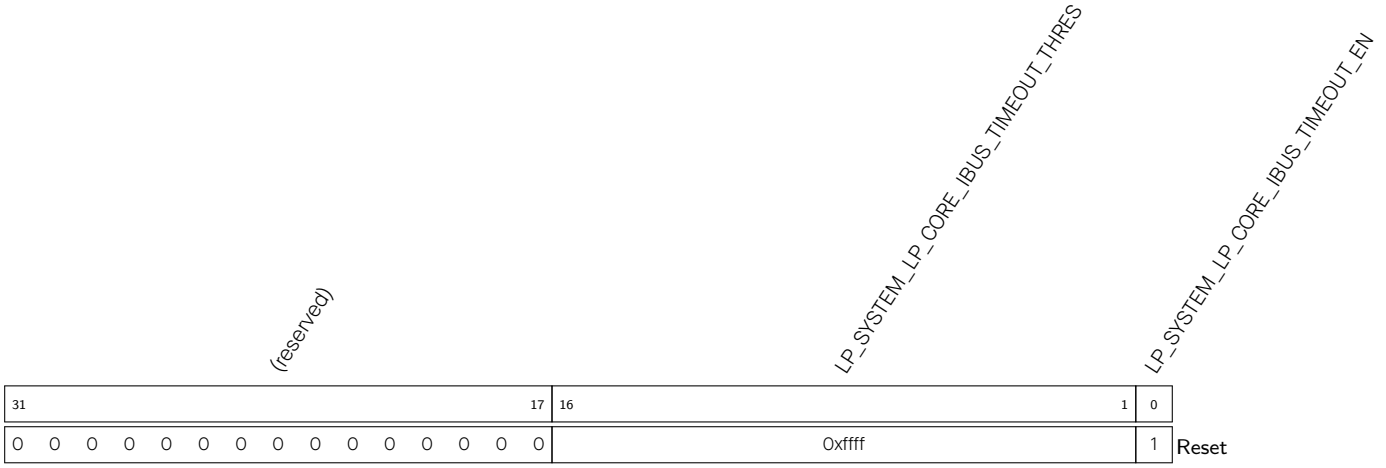
0: Disable

1: Enable

(R/W)

LP_SYSTEM_LP_CORE_AHB_TIMEOUT_THRES Configures LP_CORE_AHB_TIMEOUT_INT threshold. (R/W)

LP_SYSTEM_LP2HP_AHB_TIMEOUT_EN Configures whether to enable timeout protection on LP2HP AHB bus.



0: Disable

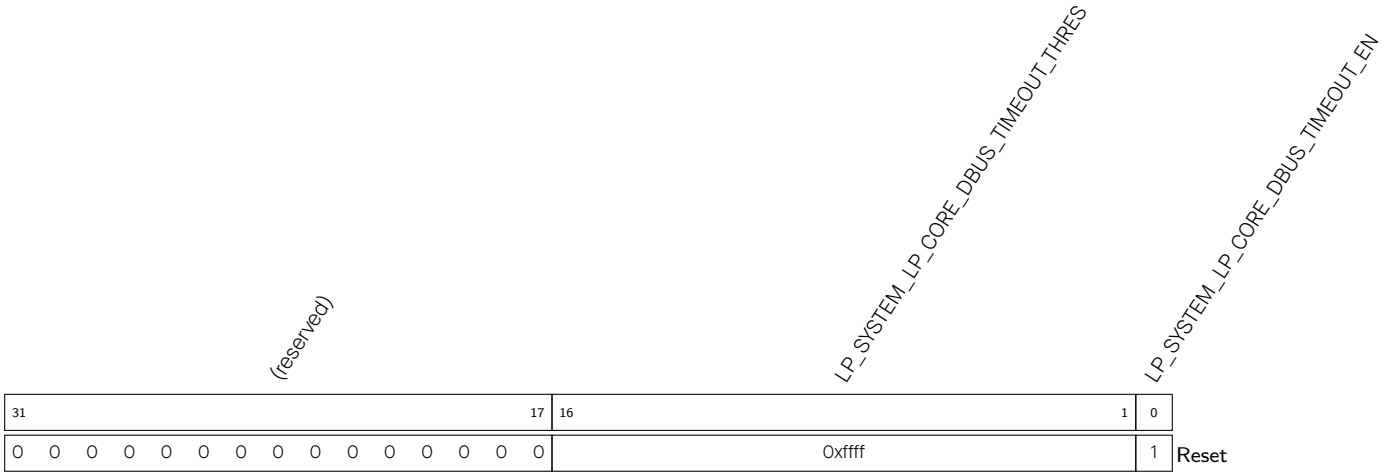
1: Enable

(R/W)

LP_SYSTEM_LP2HP_AHB_TIMEOUT_THRES Configures LP_CORE_AHB_TIMEOUT_INT threshold. (R/W)

Register 21.116. LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_REG (0x01B4)

LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_EN Configures whether to enable timeout protection on LP CPU IBUS.



0: Disable

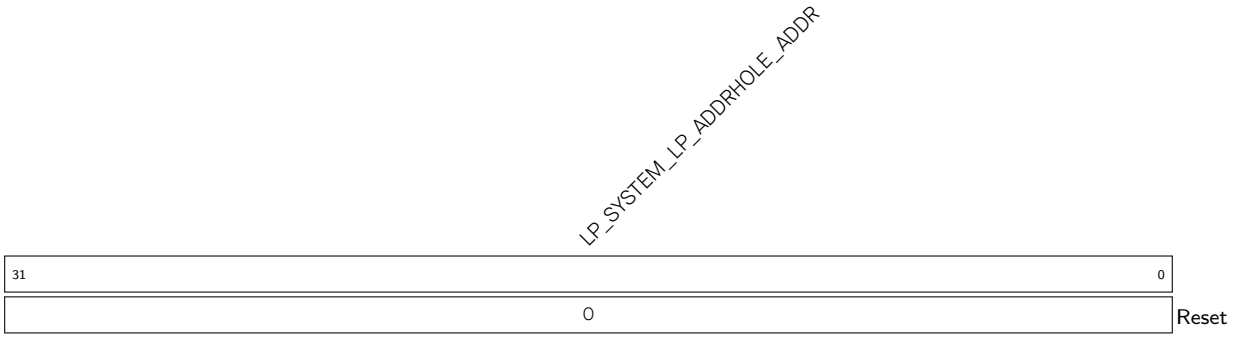
1: Enable

(R/W)

LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_THRES Configures LP_CORE_IBUS_TIMEOUT_INT threshold. (R/W)

Register 21.117. LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_REG (0x01B8)

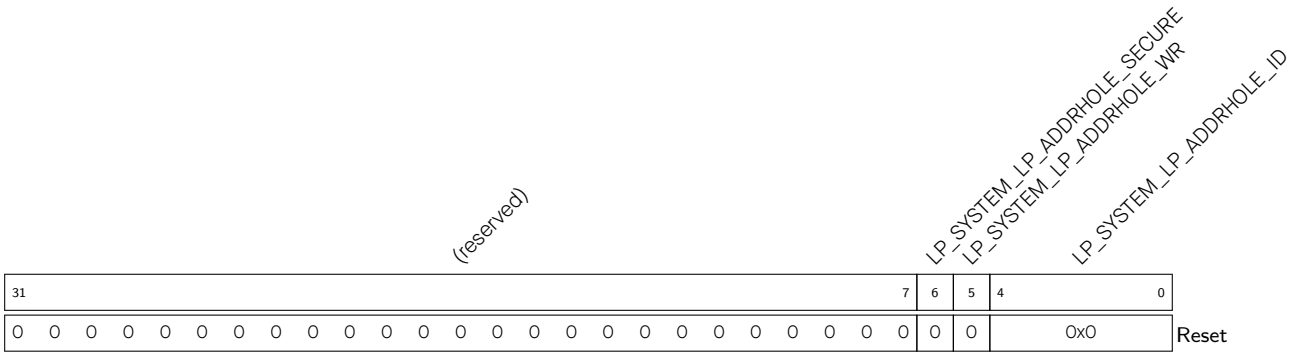
LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_EN Configures whether to enable timeout protection on LP CPU DBUS.



0: Disable

1: Enable

(R/W)



LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_THRES Configures LP_CORE_DBUS_TIMEOUT_INT threshold. (R/W)

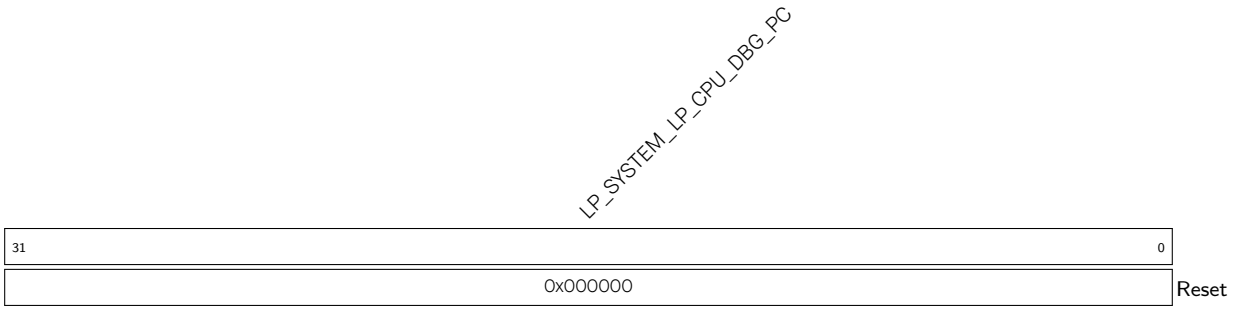
Register 21.118. LP_SYSTEM_LP_ADDRHOLE_ADDR_REG (0x0168)

LP_SYSTEM_LP_ADDRHOLE_ADDR Represents the address of transfer when LP_ADDRHOLE_INT occurs. (RO)

Register 21.119. LP_SYSTEM_LP_ADDRHOLE_INFO_REG (0x016C)

LP_SYSTEM_LP_ADDRHOLE_ID Represents the master ID when LP_ADDRHOLE_INT occurs.

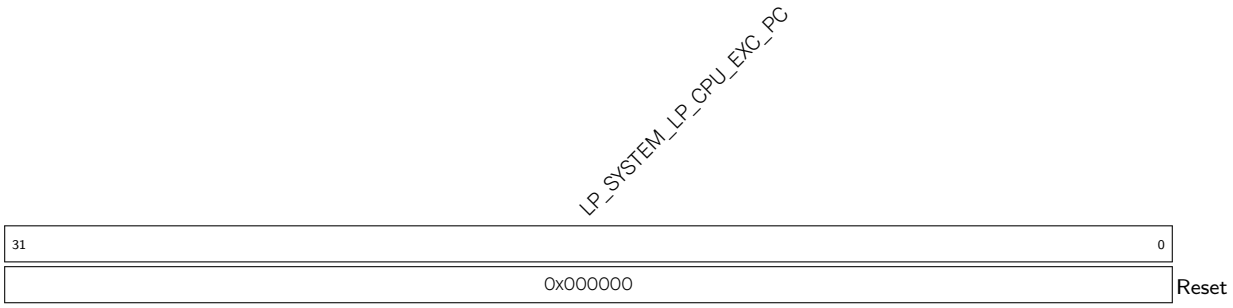
0: LP CPU0
1: LP CPU1
2: LP CPU
3: USB OTG11
4: Reserved
5: GMAC
6: SDMMC
7: USBOTG20
8: TRACE0
9: TRACE1
10: SPM monitor
11: L2MEM monitor
16~31: AHB PDMA
(RO)



LP_SYSTEM_LP_ADDRHOLE_WR Represents the direction of transfer when LP_ADDRHOLE_INT occurs.

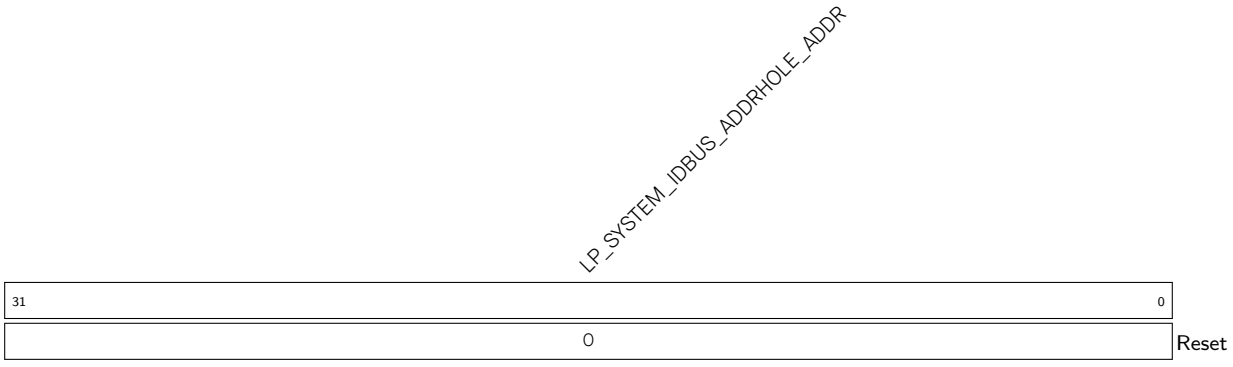
0: Read transfer
1: Write transfer
(RO)

LP_SYSTEM_LP_ADDRHOLE_SECURE Represents the address hole type when LP_ADDRHOLE_INT occurs.



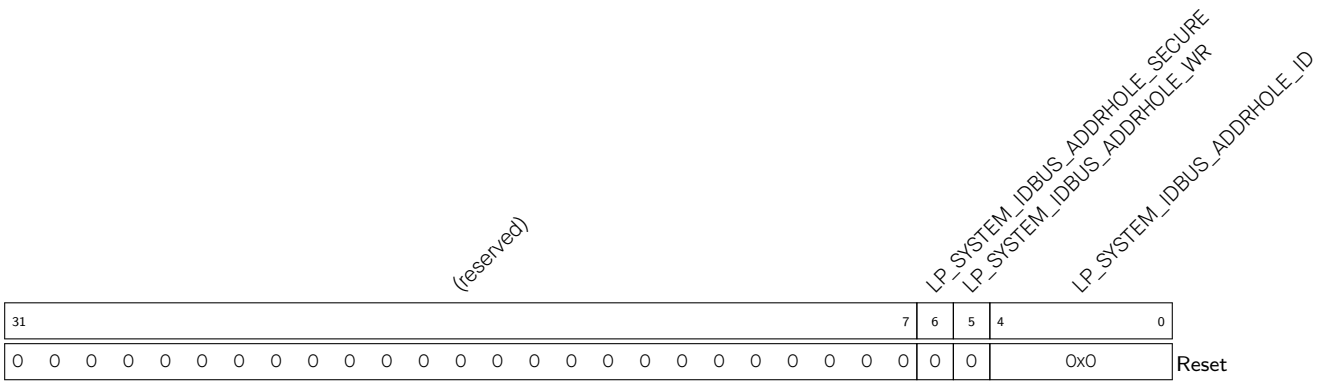
0: Access without permission
1: Illegal address access
(RO)

Register 21.120. LP_SYSTEM_LP_CPU_DBG_PC_REG (0x0190)



LP_SYSTEM_LP_CPU_DBG_PC Represents LP CPU current PC address. (RO)

Register 21.121. LP_SYSTEM_LP_CPU_EXC_PC_REG (0x0194)



LP_SYSTEM_LP_CPU_EXC_PC Represents LP CPU exception PC address. (RO)

Register 21.122. LP_SYSTEM_IDBUS_ADDRHOLE_ADDR_REG (0x0198)

LP_SYSTEM_IDBUS_ADDRHOLE_ADDR Represents the address of transfer when IDBUS_ADDRHOLE_INT occurs. (RO)

Register 21.123. LP_SYSTEM_IDBUS_ADDRHOLE_INFO_REG (0x019C)

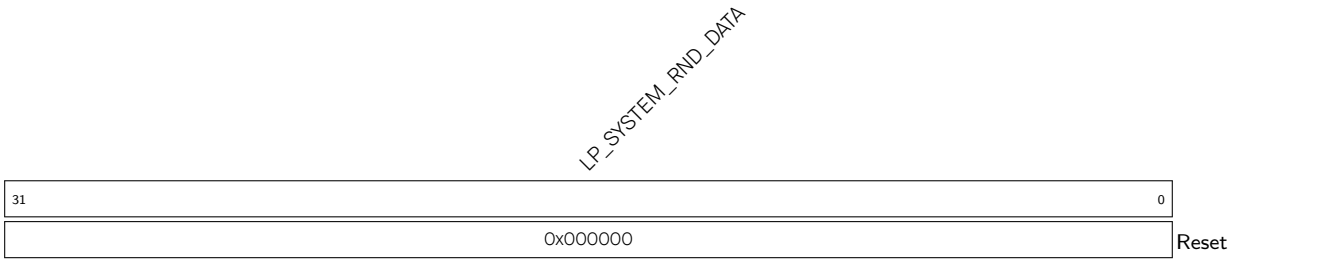
LP_SYSTEM_IDBUS_ADDRHOLE_ID Represents the LP CPU's ID value (00010) when IDBUS_ADDRHOLE_INT occurs. (RO)

LP_SYSTEM_IDBUS_ADDRHOLE_WR Represents the direction of transfer when IDBUS_ADDRHOLE_INT occurs.

0: Read transfer

1: Write transfer

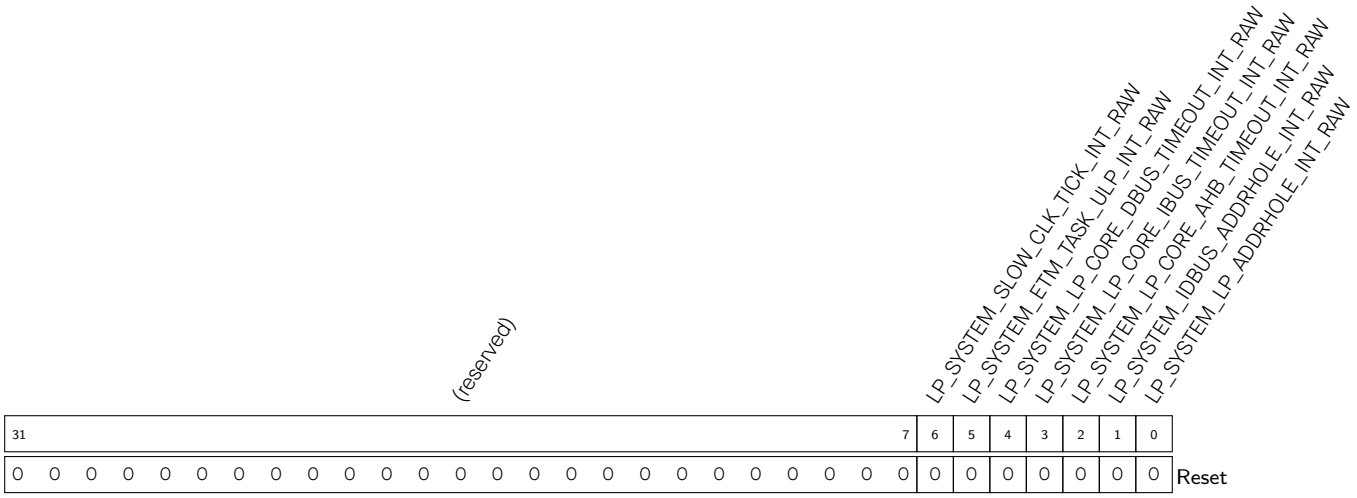
(RO)



LP_SYSTEM_IDBUS_ADDRHOLE_SECURE Represents the address hole type when IDBUS_ADDRHOLE_INT occurs.

0: Access without permission

1: Illegal address access



(RO)

Register 21.124. LP_SYSTEM_RNG_DATA_REG (0x01A4)

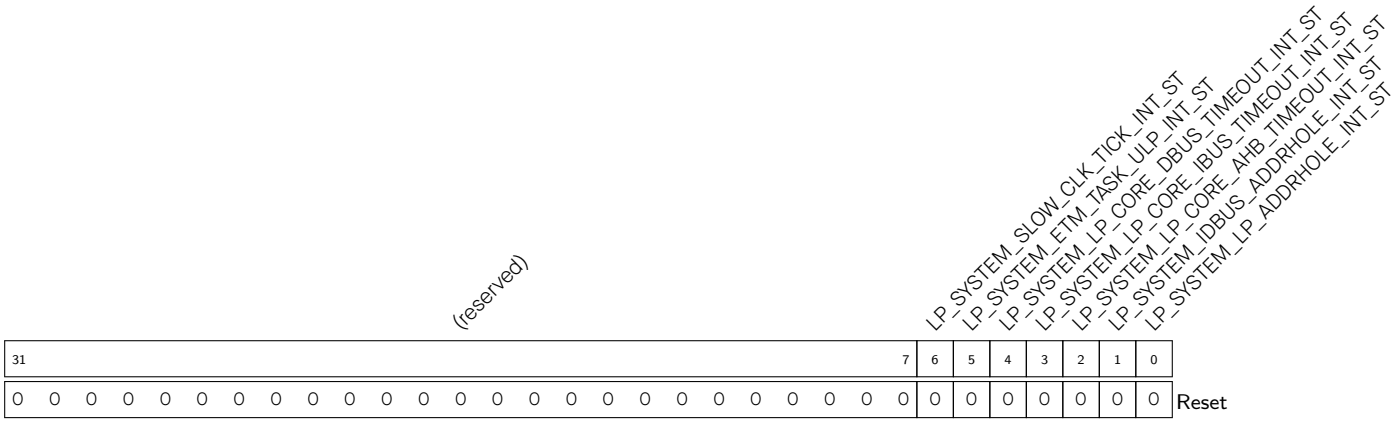
LP_SYSTEM_RND_DATA Represents the RNG-generated random numbers. (RO)

Register 21.125. LP_SYSTEM_INT_RAW_REG (0x0170)

LP_SYSTEM_LP_ADDRHOLE_INT_RAW The raw interrupt status of LP_ADDRHOLE_INT. (R/SS/WTC)

LP_SYSTEM_IDBUS_ADDRHOLE_INT_RAW The raw interrupt status of IDBUS_ADDRHOLE_INT. (R/SS/WTC)

LP_SYSTEM_LP_CORE_AHB_TIMEOUT_INT_RAW The raw interrupt status of LP_CORE_AHB_TIMEOUT_INT. (R/SS/WTC)



LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_INT_RAW The raw interrupt status of LP_CORE_IBUS_TIMEOUT_INT. (R/SS/WTC)

LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_INT_RAW The raw interrupt status of LP_CORE_DBUS_TIMEOUT_INT. (R/SS/WTC)

LP_SYSTEM_ETM_TASK_ULP_INT_RAW The raw interrupt status of ETM_TASK_ULP_INT. (R/SS/WTC)

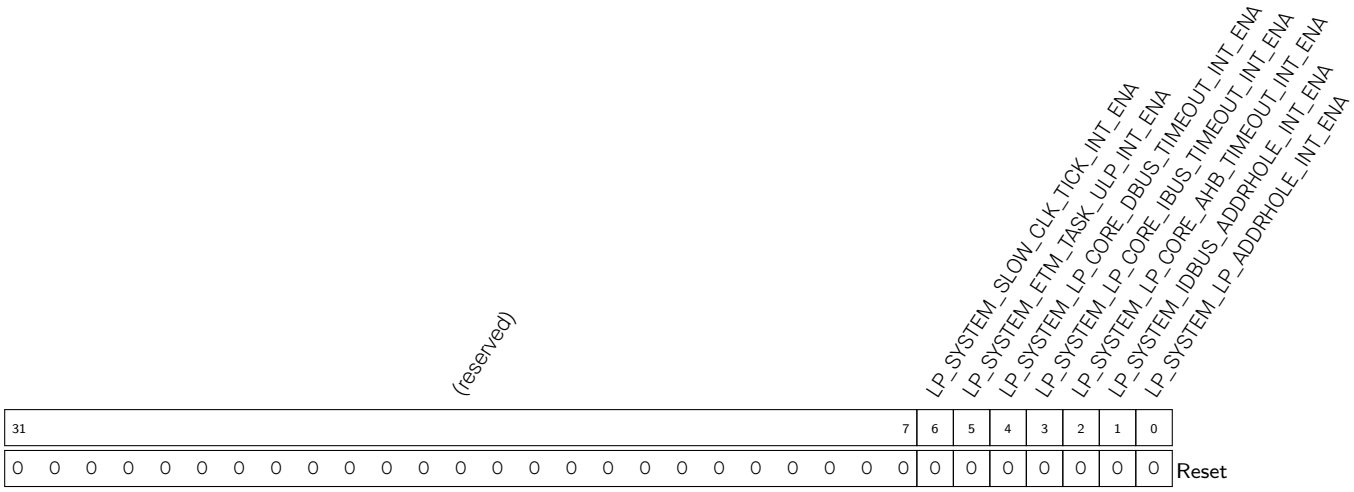
LP_SYSTEM_SLOW_CLK_TICK_INT_RAW The raw interrupt status of SLOW_CLK_TICK_INT. (R/SS/WTC)

Register 21.126. LP_SYSTEM_INT_ST_REG (0x0174)

LP_SYSTEM_LP_ADDRHOLE_INT_ST The masked interrupt status of LP_ADDRHOLE_INT. (RO)

LP_SYSTEM_IDBUS_ADDRHOLE_INT_ST The masked interrupt status of IDBUS_ADDRHOLE_INT. (RO)

LP_SYSTEM_LP_CORE_AHB_TIMEOUT_INT_ST The masked interrupt status of LP_CORE_AHB_TIMEOUT_INT. (RO)



LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_INT_ST The masked interrupt status of LP_CORE_IBUS_TIMEOUT_INT. (RO)

LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_INT_ST The masked interrupt status of LP_CORE_DBUS_TIMEOUT_INT. (RO)

LP_SYSTEM_ETM_TASK_ULP_INT_ST The masked interrupt status of ETM_TASK_ULP_INT. (RO)

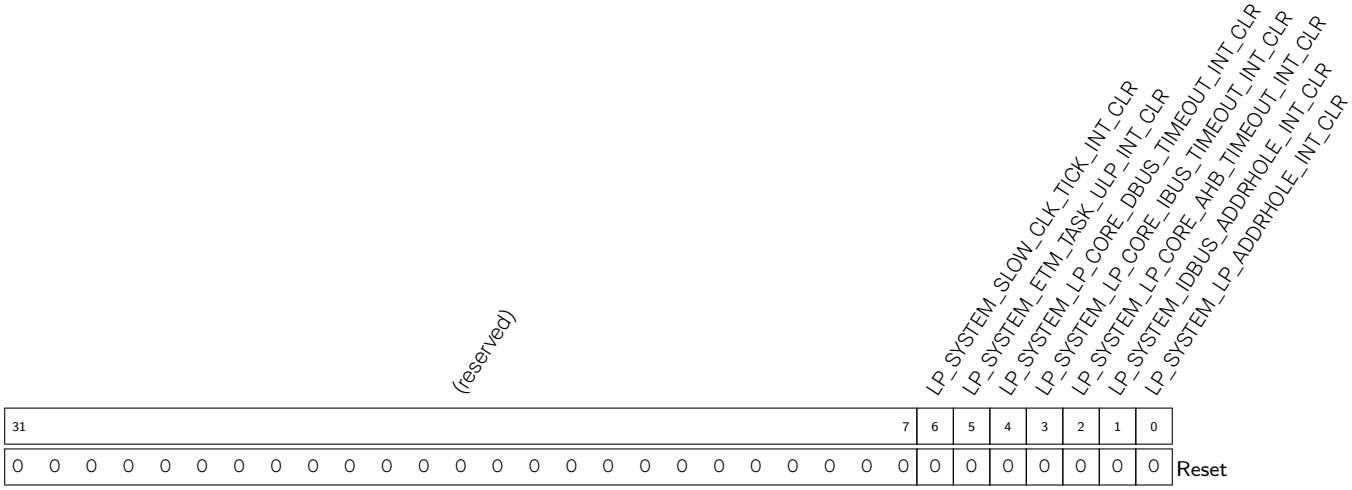
LP_SYSTEM_SLOW_CLK_TICK_INT_ST The masked interrupt status of SLOW_CLK_TICK_INT. (RO)

Register 21.127. LP_SYSTEM_INT_ENA_REG (0x0178)

LP_SYSTEM_LP_ADDRHOLE_INT_ENA Write 1 to enable LP_ADDRHOLE_INT. (R/W)

LP_SYSTEM_IDBUS_ADDRHOLE_INT_ENA Write 1 to enable IDBUS_ADDRHOLE_INT. (R/W)

LP_SYSTEM_LP_CORE_AHB_TIMEOUT_INT_ENA Write 1 to enable LP_CORE_AHB_TIMEOUT_INT. (R/W)



LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_INT_ENA Write 1 to enable LP_CORE_IBUS_TIMEOUT_INT. (R/W)

LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_INT_ENA Write 1 to enable LP_CORE_DBUS_TIMEOUT_INT. (R/W)

LP_SYSTEM_ETM_TASK_ULP_INT_ENA Write 1 to enable ETM_TASK_ULP_INT. (R/W)

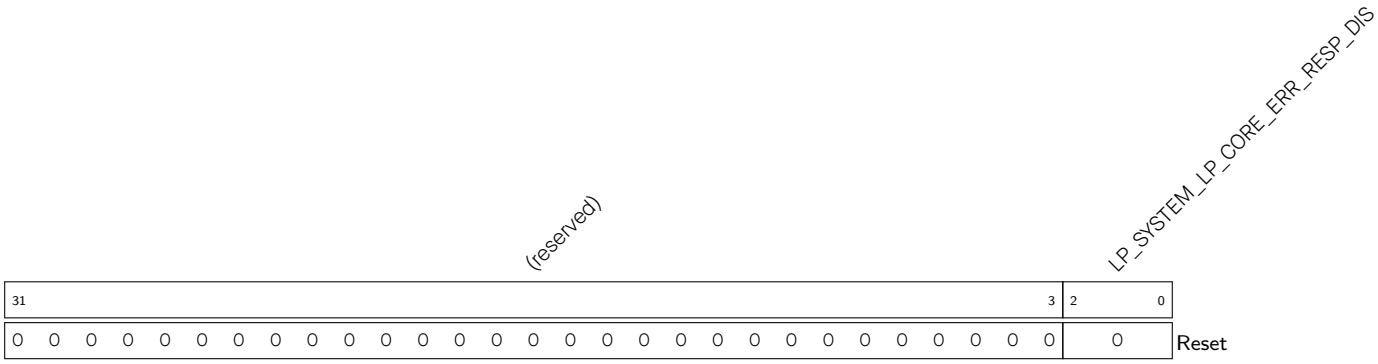
LP_SYSTEM_SLOW_CLK_TICK_INT_ENA Write 1 to enable SLOW_CLK_TICK_INT. (R/W)

Register 21.128. LP_SYSTEM_INT_CLR_REG (0x017C)

LP_SYSTEM_LP_ADDRHOLE_INT_CLR Write 1 to clear LP_ADDRHOLE_INT. (WT)

LP_SYSTEM_IDBUS_ADDRHOLE_INT_CLR Write 1 to clear IDBUS_ADDRHOLE_INT. (WT)

LP_SYSTEM_LP_CORE_AHB_TIMEOUT_INT_CLR Write 1 to clear LP_CORE_AHB_TIMEOUT_INT. (WT)



LP_SYSTEM_LP_CORE_IBUS_TIMEOUT_INT_CLR Write 1 to clear LP_CORE_IBUS_TIMEOUT_INT. (WT)

LP_SYSTEM_LP_CORE_DBUS_TIMEOUT_INT_CLR Write 1 to clear LP_CORE_DBUS_TIMEOUT_INT. (WT)

LP_SYSTEM_ETM_TASK_ULP_INT_CLR Write 1 to clear ETM_TASK_ULP_INT. (WT)

LP_SYSTEM_SLOW_CLK_TICK_INT_CLR Write 1 to clear SLOW_CLK_TICK_INT. (WT)

Register 21.129. LP_SYSTEM_LP_CORE_ERR_RESP_DIS_REG (0x01BC)

LP_SYSTEM_LP_CORE_ERR_RESP_DIS Configures whether to disable error response for LP CPU buses.

Bit[0]: Configures whether to disable error response for IBUS

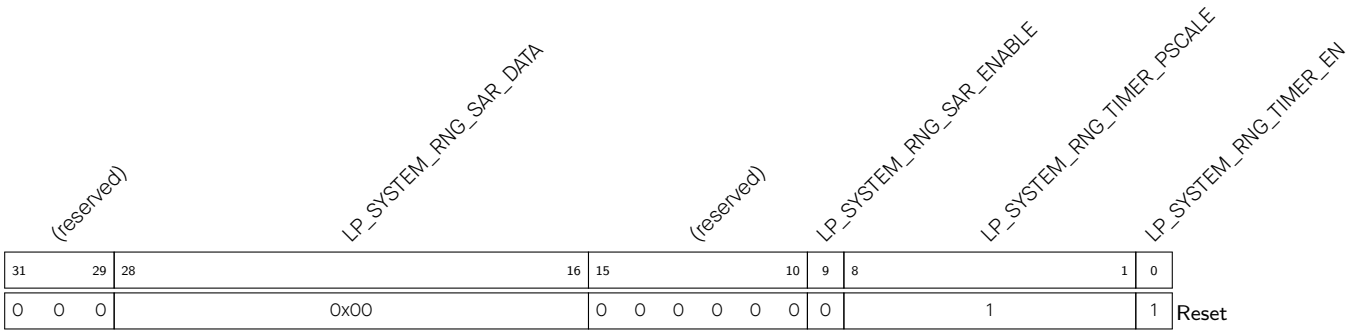
0: Enable error response

1: Disable error response

Bit[1]: Configures whether to disable error response for DBUS

0: Enable error response

1: Disable error response



Bit[2]: Configures whether to disable error response for AHB bus

0: Enable error response

1: Disable error response

(R/W)

Register 21.130. LP_SYSTEM_RNG_CFG_REG (0x01C0)

LP_SYSTEM_RNG_TIMER_EN Configures whether to enable RNG timer.

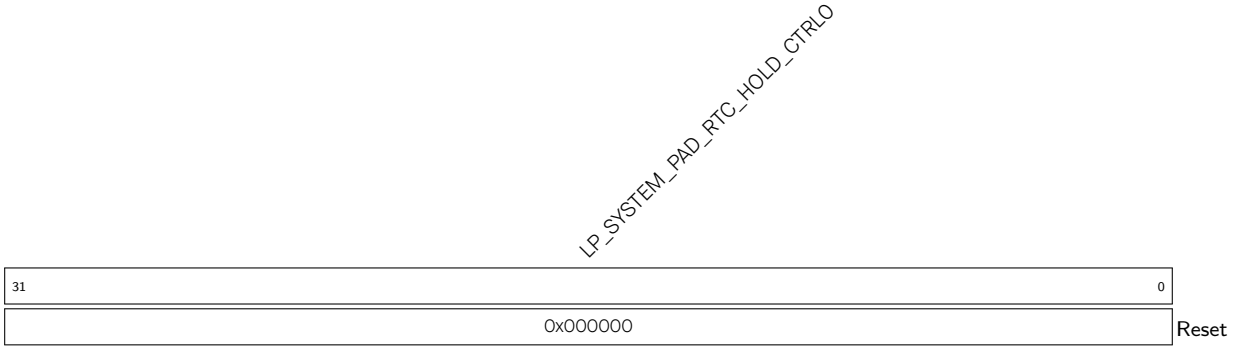
0: Disable

1: Enable

(R/W)

LP_SYSTEM_RNG_TIMER_PSCALE Configures the clock division factor for the RNG timer. (R/W)

LP_SYSTEM_RNG_SAR_ENABLE Configures whether to enable RNG_SARADC.



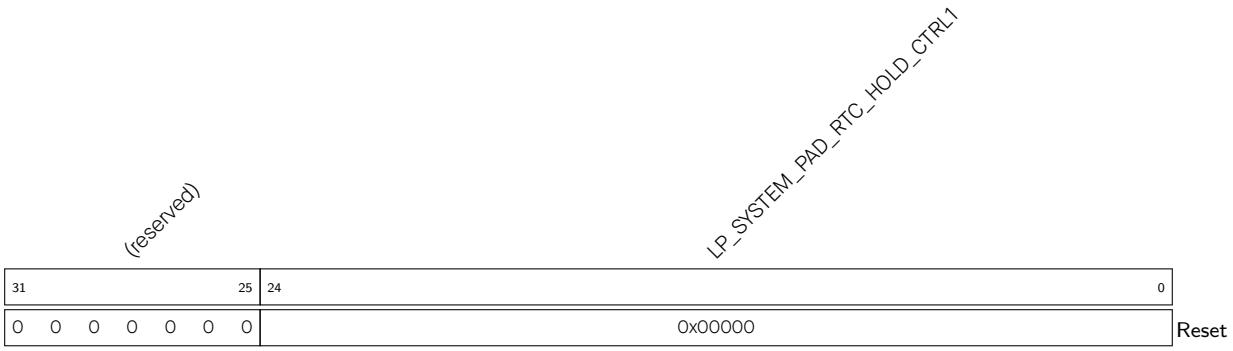
0: Disable

1: Enable

(R/W)

LP_SYSTEM_RNG_SAR_DATA Represents the analog SAR3_CAP value, which is used for debugging RNG_SARADC sample count. (RO)

Register 21.131. LP_SYSTEM_PAD_RTC_HOLD_CTRL0_REG (0x01C4)



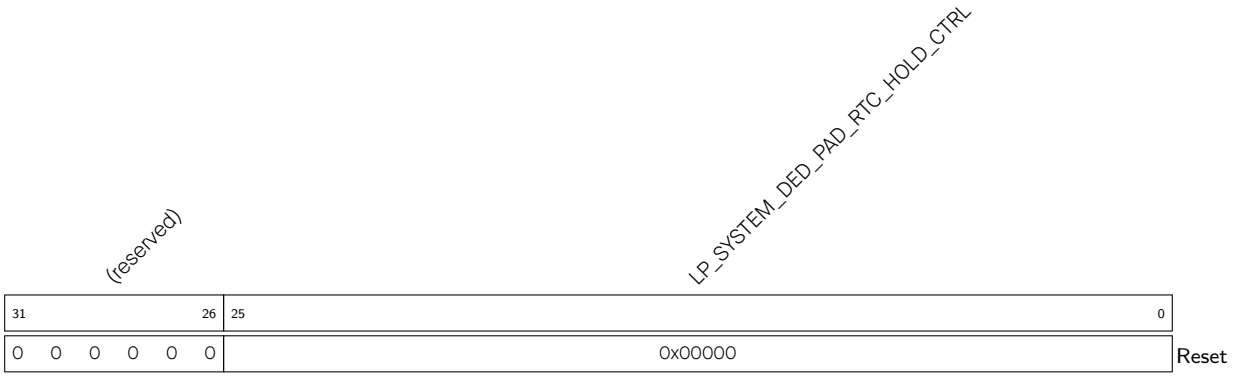
LP_SYSTEM_PAD_RTC_HOLD_CTRL0 Configures whether to hold the status of pad 0 ~ pad 31.

0: Not hold

1: Hold

(R/W)

Register 21.132. LP_SYSTEM_PAD_RTC_HOLD_CTRL1_REG (0x01C8)



LP_SYSTEM_PAD_RTC_HOLD_CTRL1 Configures whether to hold the status of pad 32 ~ pad 56.

0: Not hold

1: Hold

(R/W)

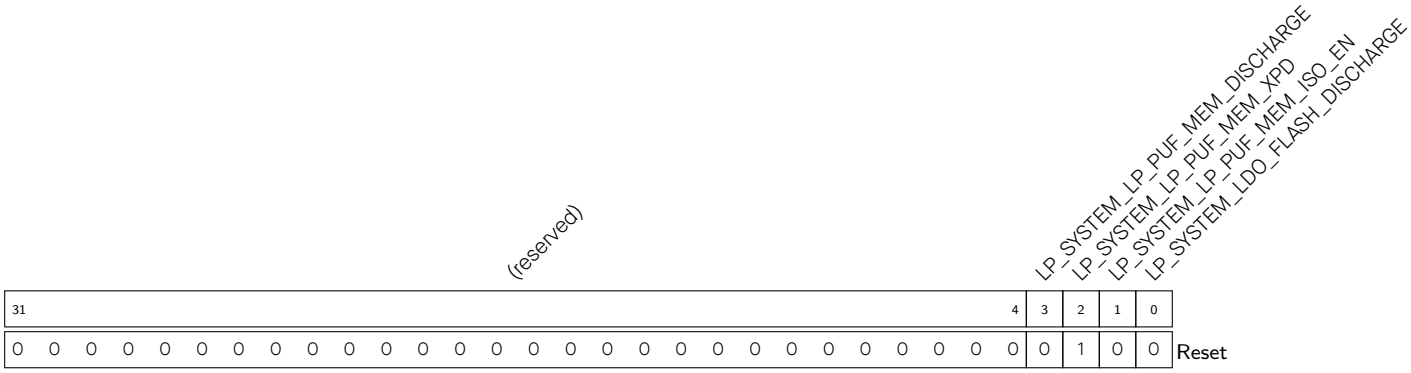
Register 21.133. LP_SYSTEM_DED_PAD_RTC_HOLD_CTRL_REG (0x01CC)

LP_SYSTEM_DED_PAD_RTC_HOLD_CTRL Configures whether to hold pad status.

Bit[0:5]: Flash pads

0: Not hold

1: Hold



Bit[6:25]: PSRAM pads

0: Not hold

1: Hold

(R/W)

Register 21.134. LP_SYSTEM_DISCHARGE_REG (0x0200)

LP_SYSTEM_LDO_FLASH_DISCHARGE Configures whether to discharge LDO flash.

0: No effect

1: Discharge

(R/W)

LP_SYSTEM_LP_PUF_MEM_ISO_EN Configures whether to enable isolation for LP PUF memory.

0: Disable

1: Enable

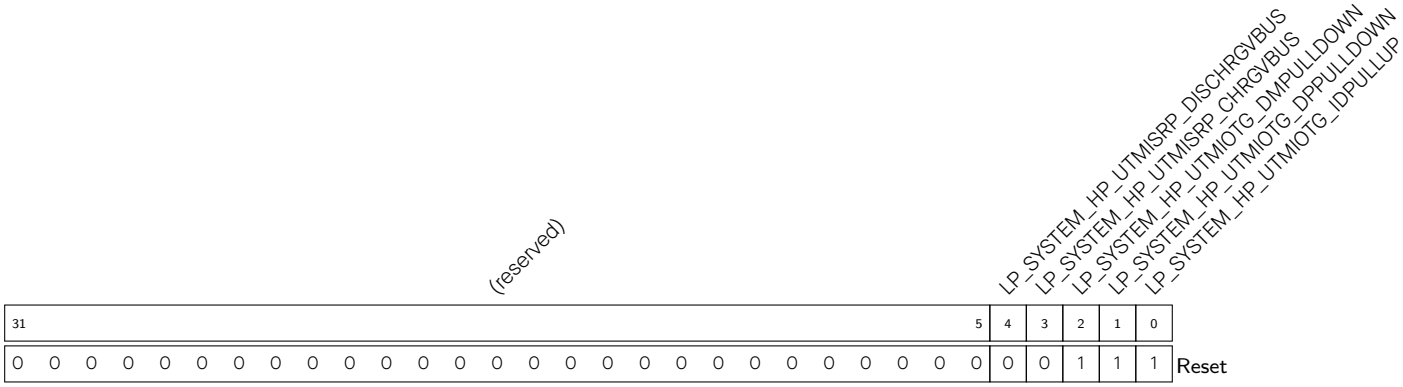
(R/W)

LP_SYSTEM_LP_PUF_MEM_XPD Configures whether to power up LP PUF memory.

0: Power down

1: Power up

(R/W)



LP_SYSTEM_LP_PUF_MEM_DISCHARGE Configures whether to discharge LP PUF memory.

0: No effect

1: Discharge

(R/W)

Register 21.135. LP_SYSTEM_HP_USB_OTGHS_PHY_CTRL_REG (0x0204)

LP_SYSTEM_HP_UTMIOTG_IDPULLUP Configures whether to pull up USB OTG2.0 PHY ID.

0: Not pull up

1: Pull up

(R/W)

LP_SYSTEM_HP_UTMIOTG_DPPULLDOWN Configures whether to pull down USB OTG2.0 PHY DP.

0: Not pull down

1: Pull down

(R/W)

LP_SYSTEM_HP_UTMIOTG_DMPULLDOWN Configures whether to pull down USB OTG2.0 PHY DM.

0: Not pull down

1: Pull down

(R/W)

LP_SYSTEM_HP_UTMISRP_CHRGVBUS Configures whether to charge USB OTG2.0 PHY VBUS.

0: No effect

1: Charge

(R/W)

LP_SYSTEM_HP_UTMISRP_DISCHRGVBUS Configures whether to discharge USB OTG2.0 PHY VBUS.

0: No effect

1: Discharge

(R/W)

Chapter 22

Debug Assistant

22.1 Overview

Debug Assistant is an auxiliary module that features a set of functions to help locate bugs and issues during software debugging.

22.2 Features

- **Read/write monitoring**: Monitors whether the High-Performance dual-core CPU (HP CPU0 and HP CPU1) bus reads from or writes to a specified memory address space. A detected read or write in the monitored address space will trigger an interrupt.
- **Stack pointer (SP) monitoring**: Monitors whether the SP exceeds the specified address space. A bounds violation will trigger an interrupt.
- **Program counter (PC) logging**: Records the PC value. The developer can get the last PC value at the most recent reset of HP CPU0 or HP CPU1.
- **Bus access logging**: Records the information about bus access. When the HP CPU0, HP CPU1, or the Direct Memory Access controller (DMA) writes a specified value, the Debug Assistant module will record the data type, address of this write operation, and additionally the PC value when the write is performed by HP CPU0 or HP CPU1, and push such information to the HP L2MEM.

22.3 Functional Description

22.3.1 Region Read/Write Monitoring

The Debug Assistant module can monitor reads/writes performed by HP CPU0 bus in a certain address space, i.e., memory region. Whenever the bus reads or writes in the specified address space, an interrupt will be triggered. Please refer to Table 2.4-1 in Chapter 2 *High-Performance CPU*. In this chapter, when HP CPU0 bus accesses the data space, it is referred to as the Data bus, and when HP CPU0 bus accesses the AHB peripheral space, it is referred to as the Peripheral bus. The Data bus can monitor two memory regions (assuming they are HP CPU0 region 0 and HP CPU0 region 1, defined by developers' needs) at the same time, and so can Peripheral bus.

This is also the case for HP CPU1.

22.3.2 SP Monitoring

The Debug Assistant module can monitor the SP so as to prevent stack overflow or erroneous push/pop in HP CPU0. When the HP CPU0 SP goes below or beyond the lower or upper bound of the HP CPU0 SP monitored region, the module will record the PC pointer and generate an interrupt. The bound is configured by software.

This is also the case for HP CPU1.

22.3.3 PC Logging

In some cases, software developers want to know the PC at the last reset of HP CPU0. For instance, when the program is stuck and can only be reset, the developer may want to know where the program got stuck in order to debug. The Debug Assistant module can record the PC at the last reset of HP CPU0, which can be then read for software debugging.

This is also the case for HP CPU1.

22.3.4 CPU/DMA Bus Access Logging

The Debug Assistant module can record the information about the HP CPU0 Data bus's, HP CPU1 bus's, and DMA bus's write behaviors in real time. When a write operation occurs in or a specific value is written to a specified address space, the module will record the bus type, the address, PC (only when the write is performed by the HP CPU0 or HP CPU1, will PC be recorded), and other information, and then store the data in the HP L2MEM in a certain format. The specified address range must fall within the permitted memory regions of HP SPM or HP L2MEM.

22.4 Interrupts

The following interrupt sources from the Debug Assistant module can generate the interrupt signal ASSIST_DEBUG_INT.

- ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_RD_INT: Triggered when the HP CPU0 Data bus reads in HP CPU0 region 0.
- ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_WR_INT: Triggered when the HP CPU0 Data bus writes in HP CPU0 region 0.
- ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_RD_INT: Triggered when the HP CPU0 Data bus reads in HP CPU0 region 1.
- ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_WR_INT: Triggered when the HP CPU0 Data bus writes in HP CPU0 region 1.
- ASSIST_DEBUG_CORE_0_AREA_PIF_0_RD_INT: Triggered when the HP CPU0 Peripheral bus reads in HP CPU0 region 0.
- ASSIST_DEBUG_CORE_0_AREA_PIF_0_WR_INT: Triggered when the HP CPU0 Peripheral bus writes in HP CPU0 region 0.
- ASSIST_DEBUG_CORE_0_AREA_PIF_1_RD_INT: Triggered when the HP CPU0 Peripheral bus reads in HP CPU0 region 1.

- ASSIST_DEBUG_CORE_0_AREA_PIF_1_WR_INT: Triggered when the HP CPU0 Peripheral bus writes in HP CPU0 region 1.
- ASSIST_DEBUG_CORE_0_SP_SPILL_MIN_INT: Triggered when the HP CPU0 SP goes below the lower bound of the HP CPU0 SP monitored region.
- ASSIST_DEBUG_CORE_0_SP_SPILL_MAX_INT: Triggered when the HP CPU0 SP goes beyond the upper bound of the HP CPU0 SP monitored region.
- ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_RD_INT: Triggered when the HP CPU1 Data bus reads in HP CPU1 region 0.
- ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_WR_INT: Triggered when the HP CPU1 Data bus writes in HP CPU1 region 0.
- ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_RD_INT: Triggered when the HP CPU1 Data bus reads in HP CPU1 region 1.
- ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_WR_INT: Triggered when the HP CPU1 Data bus writes in HP CPU1 region 1.
- ASSIST_DEBUG_CORE_1_AREA_PIF_0_RD_INT: Triggered when the HP CPU1 Peripheral bus reads in HP CPU1 region 0.
- ASSIST_DEBUG_CORE_1_AREA_PIF_0_WR_INT: Triggered when the HP CPU1 Peripheral bus writes in HP CPU1 region 0.
- ASSIST_DEBUG_CORE_1_AREA_PIF_1_RD_INT: Triggered when the HP CPU1 Peripheral bus reads in HP CPU1 region 1.
- ASSIST_DEBUG_CORE_1_AREA_PIF_1_WR_INT: Triggered when the HP CPU1 Peripheral bus writes in HP CPU1 region 1.
- ASSIST_DEBUG_CORE_1_SP_SPILL_MIN_INT: Triggered when the HP CPU1 SP goes below the lower bound of the HP CPU1 SP monitored region.
- ASSIST_DEBUG_CORE_1_SP_SPILL_MAX_INT: Triggered when the HP CPU1 SP goes beyond the upper bound of the HP CPU1 SP monitored region.

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 22.6 *Register Summary*.

22.5 Recommended Operation

22.5.1 Region Monitoring and SP Monitoring Configuration

The Debug Assistant module can monitor reads and writes performed by the Data bus and Peripheral bus of HP CPU0 and HP CPU1. Two memory regions on each bus can be monitored at the same time. All the

monitoring modes supported by the Debug Assistant module are listed below:

- Monitoring the read/write operations performed by Data bus
  - HP CPU0 Data bus reads in HP CPU0 region 0
  - HP CPU0 Data bus writes in HP CPU0 region 0
  - HP CPU0 Data bus reads in HP CPU0 region 1
  - HP CPU0 Data bus writes in HP CPU0 region 1
  - HP CPU1 Data bus reads in HP CPU1 region 0
  - HP CPU1 Data bus writes in HP CPU1 region 0
  - HP CPU1 Data bus reads in HP CPU1 region 1
  - HP CPU1 Data bus writes in HP CPU1 region 1
- Monitoring the read/write operations performed by Peripheral bus
  - HP CPU0 Peripheral bus reads in HP CPU0 region 0
  - HP CPU0 Peripheral bus writes in HP CPU0 region 0
  - HP CPU0 Peripheral bus reads in HP CPU0 region 1
  - HP CPU0 Peripheral bus writes in HP CPU0 region 1
  - HP CPU1 Peripheral bus reads in HP CPU1 region 0
  - HP CPU1 Peripheral bus writes in HP CPU1 region 0
  - HP CPU1 Peripheral bus reads in HP CPU1 region 1
  - HP CPU1 Peripheral bus writes in HP CPU1 region 1
- Monitoring SP bounds violations
  - HP CPU0 SP goes beyond the upper bound of the HP CPU0 SP monitored region
  - HP CPU0 SP goes below the lower bound of the HP CPU0 SP monitored region
  - HP CPU1 SP goes beyond the upper bound of the HP CPU1 SP monitored region
  - HP CPU1 SP goes below the lower bound of the HP CPU1 SP monitored region

The configuration process for region monitoring and SP monitoring is as follows:

1. Configure the monitored region and SP bounds.
   - Configure HP CPU0 Data bus region 0 with ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MIN_REG and ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MAX_REG.
   - Configure HP CPU0 Data bus region 1 with ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_MIN_REG and ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_MAX_REG.
   - Configure HP CPU0 Peripheral bus region 0 with ASSIST_DEBUG_CORE_0_AREA_PIF_0_MIN_REG and ASSIST_DEBUG_CORE_0_AREA_PIF_0_MAX_REG.
   - Configure HP CPU0 Peripheral bus region 1 with ASSIST_DEBUG_CORE_0_AREA_PIF_1_MIN_REG and ASSIST_DEBUG_CORE_0_AREA_PIF_1_MAX_REG.

- Configure HP CPU0 SP bounds with ASSIST_DEBUG_CORE_0_SP_MIN_REG and ASSIST_DEBUG_CORE_0_SP_MAX_REG.
- Configure HP CPU1 Data bus region 0 with ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_MIN_REG and ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_MAX_REG.
- Configure HP CPU1 Data bus region 1 with ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_MIN_REG and ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_MAX_REG.
- Configure HP CPU1 Peripheral bus region 0 with ASSIST_DEBUG_CORE_1_AREA_PIF_0_MIN_REG and ASSIST_DEBUG_CORE_1_AREA_PIF_0_MAX_REG.
- Configure HP CPU1 Peripheral bus region 1 with ASSIST_DEBUG_CORE_1_AREA_PIF_1_MIN_REG and ASSIST_DEBUG_CORE_1_AREA_PIF_1_MAX_REG.
- Configure HP CPU1 SP bounds with ASSIST_DEBUG_CORE_1_SP_MIN_REG and ASSIST_DEBUG_CORE_1_SP_MAX_REG.

2. Configure interrupts.
   - Configure ASSIST_DEBUG_CORE_0_INTR_ENA_REG or ASSIST_DEBUG_CORE_1_INTR_ENA_REG to enable the interrupt of a monitoring mode.
   - Read ASSIST_DEBUG_CORE_0_INTR_RAW_REG or ASSIST_DEBUG_CORE_1_INTR_RAW_REG to get the raw interrupt status of a monitoring mode.
   - Configure ASSIST_DEBUG_CORE_0_INTR_CLR_REG or ASSIST_DEBUG_CORE_1_INTR_CLR_REG to clear the interrupt of a monitoring mode.
3. Configure ASSIST_DEBUG_CORE_0_MONTR_ENA_REG or ASSIST_DEBUG_CORE_1_MONTR_ENA_REG to enable the monitoring mode(s). Various monitoring modes can be enabled at the same time.

Assuming that Debug Assistant module needs to monitor whether HP CPU0 Data bus has written to [A ~ B] address space, the user can enable monitoring in either HP CPU0 Data bus region 0 or region 1. The following configuration process is based on region 0:

1. Configure ASSIST_DEBUG_CORE_0_RCD_PDEBUGEN to 1 to enable HP CPU0 to update the PC signals to the Debug Assistant module.
2. Configure ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MIN_REG to Address A.
3. Configure ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MAX_REG to Address B.
4. Configure ASSIST_DEBUG_CORE_0_INTR_ENA_REG bit[1] to enable the interrupt for write operations by HP CPU0 Data bus in region 0.
5. Configure ASSIST_DEBUG_CORE_0_MONTR_ENA_REG bit[1] to enable monitoring write operations by HP CPU0 Data bus in region 0.
6. Configure interrupt matrix to map ASSIST_DEBUG_INTR into HP CPU0/1 interrupt (please refer to Chapter 13 *Interrupt Matrix*).
7. After the interrupt is triggered:
   - Read ASSIST_DEBUG_CORE_0_INTR_RAW_REG and ASSIST_DEBUG_CORE_1_INTR_RAW_REG to learn which operation triggered the interrupt.

- If the interrupt is triggered by HP CPU0 region monitoring, read ASSIST_DEBUG_CORE_0_AREA_PC_REG for the HP CPU0 PC value, and ASSIST_DEBUG_CORE_0_AREA_SP_REG for the HP CPU0 SP.
- If the interrupt is triggered by SP monitoring, read ASSIST_DEBUG_CORE_0_SP_PC_REG for the HP CPU0 PC value.
- Write 1 to the corresponding bits of ASSIST_DEBUG_CORE_0_INTR_RAW_REG and ASSIST_DEBUG_CORE_1_INTR_CLR_REG to clear the interrupts.

22.5.2 PC Logging Configuration

Configure ASSIST_DEBUG_CORE_0_RCD_PDEBUGEN to 1 to enable HP CPU0 to update the PC signals to the Debug Assistant module. If ASSIST_DEBUG_CORE_0_RCD_RECORDEN is also configured to 1, ASSIST_DEBUG_CORE_0_RCD_PDEBUGPC_REG will record the HP CPU0's PC signal and ASSIST_DEBUG_CORE_0_RCD_PDEBUGSP_REG will record the HP CPU0 SP value. Otherwise, the two registers keep the original values.

When the HP CPU0 resets, ASSIST_DEBUG_CORE_0_RCD_EN_REG will reset, while ASSIST_DEBUG_CORE_0_RCD_PDEBUGPC_REG and ASSIST_DEBUG_CORE_0_RCD_PDEBUGSP_REG will not. Therefore, the two registers will keep the PC value and SP value at the HP CPU0 reset.

This is also the case for HP CPU1.

22.5.3 CPU/DMA Bus Access Logging Configuration

22.5.3.1 HP CPU0/1 Bus Access Logging Configuration

The configuration process for HP CPU0/1 bus access logging (SPM Monitor) is described below.

1. Configure monitored address space.
   - Configure SPM_MEM_MONITOR_LOG_MIN_REG and SPM_MEM_MONITOR_LOG_MAX_REG to specify monitored address space. The monitored address space should range from 0x3010_0000 to 0x3010_1FFF.
2. Configure the monitoring mode with SPM_MEM_MONITOR_LOG_MODE:
   - Write monitoring (whether the bus has write operations)
   - Word monitoring (whether the bus writes a specific word)
   - Halfword monitoring (whether the bus writes a specific halfword)
   - Byte monitoring (whether the bus writes a specific byte)
3. Configure the specific values to be monitored.
   - In word monitoring mode, SPM_MEM_MONITOR_LOG_CHECK_DATA_REG specifies the monitored word.
   - In halfword monitoring mode, SPM_MEM_MONITOR_LOG_CHECK_DATA_REG[15:0] specifies the monitored halfword.
   - In byte monitoring mode, SPM_MEM_MONITOR_LOG_CHECK_DATA_REG[7:0] specifies the monitored byte.

- SPM_MEM_MONITOR_LOG_DATA_MASK_REG is used to mask the byte specified in SPM_MEM_MONITOR_LOG_CHECK_DATA_REG. A masked byte can be any value. For example, in word monitoring, if SPM_MEM_MONITOR_LOG_CHECK_DATA_REG is configured to 0x01020304 and SPM_MEM_MONITOR_LOG_DATA_MASK_REG is configured to 0x1, then any writes of the data matching the 0x010203XX pattern by the bus will be recorded.

4. Configure the storage space for recorded data.
   - SPM_MEM_MONITOR_LOG_MEM_START_REG and SPM_MEM_MONITOR_LOG_MEM_END_REG specify the storage space for recorded data. The storage space must be in the range of 0x4080_0000 ~ 0x4087_FFFF.
   - Set SPM_MEM_MONITOR_LOG_MEM_ADDR_UPDATE_REG to update the value in SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG to SPM_MEM_MONITOR_LOG_MEM_START_REG.
   - Configure the permission for the SPM Monitor function of Debug Assistant module to access the HP L2MEM. Only when the access permission is enabled can the Debug Assistant module access the HP L2MEM. For more information, please refer to TEE_DMA_SPM_MON_PMS_W_REG and other relevant registers in Chapter 20 *Permission Control (PMS)*.
5. Configure the writing mode for the recorded data: loop mode or non-loop mode.
   - In loop mode, writing to the specified address space is performed in loops. When writing reaches the end address, it will return to the starting address and continue, overwriting the previously recorded data. Set SPM_MEM_MONITOR_LOG_MEM_LOOP_ENABLE to enable loop mode.
     For example, there are 10 write operations (1 ~ 10) to address space 0 ~ 4 during bus access. After the 5th operation writes to address 4, the 6th operation will start writing from address 0. The 6th to 10th operations will overwrite the previous data written by the 1th to 5th operations.
   - In non-loop mode, when writing reaches the end address, it will stop at the end address and dump the remaining data, not overwriting the previously recorded data. Clear SPM_MEM_MONITOR_LOG_MEM_LOOP_ENABLE to use non-loop mode.
     For example, there are 10 write operations (1 ~ 10) to address space 0 ~ 4 during bus access. After the 5th operation writes to address 4, the 6th to 10th write operations will stop at address 4 and will not be performed any more. Therefore, the address 0 ~ 4 stores the values written by the 1 ~ 5 operations and the values of the 6 ~ 10 operations are dumped.
6. Configure bus enable registers.
   - Enable HP CPU0 or HP CPU1 bus access logging with SPM_MEM_MONITOR_LOG_CORE_ENA. They can be enabled at the same time.

The Debug Assistant module first writes the recorded data of HP CPU0 or HP CPU1 to the internal buffer A, and then fetches the data from the buffer and writes it to the configured memory space. When the monitored behaviors are triggered continuously, the generated recording packets may fully occupy the buffer, making it unable to take any incoming packets. At this time, the module dumps these incoming packets and buffers a HP CPU LOST packet instead before the buffer reaches its capacity. However, it is only possible to know the bus type of the dumped packets when the HP CPU LOST packet was generated, but not the number of the dumped packets before the generation.

When bus access logging is finished, the recorded data can be read from memory for decoding. The recorded data is in three packet formats, namely HP CPU0 packet (corresponding to HP CPU0 Data bus), HP

CPU1 packet (corresponding to HP CPU1 Data bus), and HP CPU LOST packet. The packet formats are shown in Table 22.5-1 and 22.5-2.

Table 22.5-1. HP CPU0/1 Packet Format

Bit[63:33]	Bit[32]	Bit[31:3]	Bit[2:1]	Bit[0]
pc_offset	anchored (1)	addr_offset	format	anchored (0)

Table 22.5-2. HP CPU LOST Packet Format

Bit[31:7]	Bit[6:3]	Bit[2:1]	Bit[0]
reserved	lost_source	format	anchored (0)

It can be seen from the data packet formats that the size of the HP CPU0/1 packet is 64 bits and that of the HP CPU LOST packet is 32 bits. These packets contain the following fields:

- **format** – the packet type. 0: HP CPU0 packet; 1: HP CPU1 packet; 2: HP CPU LOST packet; 3: Reserved.
- **pc_offset** - the offset of the HP CPU0/1 PC register at the time of access. Actual PC = pc_offset + 0x0000_0000.
- **addr_offset** - the address offset of a write operation. Actual address = addr_offset + SPM_MEM_MONITOR_LOG_MIN_REG[31:4], 4'h0.
- **lost_source** - the dumped packets when the HP CPU LOST packet was generated.
  - Bit[4:3]: 0 indicates HP CPU0 packets were not dumped. 3 indicates HP CPU0 packets were dumped. Other values are reserved.
  - Bit[6:5]: 0 indicates HP CPU1 packets were not dumped. 3 indicates HP CPU1 packets were dumped. Other values are reserved.
- **anchored** - the location of the 32 bits in the data packet. 0: Lower 32 bits. 1: Higher 32 bits.

The internal buffer of the module is 32 bits wide. When the HP CPU0 and HP CPU1 bus access loggings are both enabled and the record data is generated at the same time, the HP CPU0 data packets are first buffered, then the HP CPU1 packets. The Debug Assistant will automatically fetch the buffered data and store it in 32-bit data width into the specified memory space.

In loop mode, data looping several times in the storage memory may cause residual data, which can interfere with packet parsing. For example, the lower 32 bits of a HP CPU0/1 packet are overwritten, thus making its higher 32 bits residual data. Therefore, users need to filter out the possible residual data in order to determine the starting position of the first valid packet with SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG. Once the starting position of the packet is identified, check the anchored bit value of the packet. If it is 0, the data will be retained. If it is 1, it will be dumped.

The process of packet parsing is described below:

- Determine whether there is a data overflow with SPM_MEM_MONITOR_LOG_MEM_FULL_FLAG.
  - If no, the address space to read is SPM_MEM_MONITOR_LOG_MEM_START_REG ~ SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG - 4.

  - If yes and the loop mode is enabled, the address space is SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG ~ SPM_MEM_MONITOR_LOG_MEM_END_REG and SPM_MEM_MONITOR_LOG_MEM_START_REG ~ SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG - 4.
  - If yes and loop mode is not enabled, the address space is SPM_MEM_MONITOR_LOG_MEM_START_REG ~ SPM_MEM_MONITOR_LOG_MEM_END_REG.
- Read and parse data from the starting address. Read 32 bits each time.

After packet parsing is completed, clear the SPM_MEM_MONITOR_LOG_MEM_FULL_FLAG flag bit by setting SPM_MEM_MONITOR_CLR_LOG_MEM_FULL_FLAG.

22.5.3.2 DMA Bus Access Logging Configuration

The Debug Assistant module supports a total of four DMA bus channel groups, DMA_0, DMA_1, DMA_2, and DMA_3 channel groups. DMA_0 and DMA_1 channel groups are reserved and cannot be used. The DMA bus for the DMA_2 channel group is the bus on which the AXI matrix accesses the HP L2MEM. The DMA bus for the DMA_3 channel group is the bus on which the AHB matrix accesses the HP L2MEM. For more information, see Chapter 9 *System and Memory* > Section 9.3.2. The configuration process for DMA bus access logging (L2MEM Monitor) is described below.

1. Configure monitored address space.
   - Configure L2_MEM_MONITOR_LOG_MIN_REG and L2_MEM_MONITOR_LOG_MAX_REG to specify monitored address space. The monitored address space should range from 0x4FF0_0000 to 0x4FFB_FFFF or from 0x8FF0_0000 to 0x8FFB_FFFF.
2. Configure the monitoring mode with L2_MEM_MONITOR_LOG_MODE:
   - Write monitoring (whether the bus has write operations)
   - Word monitoring (whether the bus writes a specific word)
   - Halfword monitoring (whether the bus writes a specific halfword)
   - Byte monitoring (whether the bus writes a specific byte)
3. Configure the specific values to be monitored.
   - In word monitoring mode, L2_MEM_MONITOR_LOG_CHECK_DATA_REG specifies the monitored word.
   - In halfword monitoring mode, L2_MEM_MONITOR_LOG_CHECK_DATA_REG[15:0] specifies the monitored halfword.
   - In byte monitoring mode, L2_MEM_MONITOR_LOG_CHECK_DATA_REG[7:0] specifies the monitored byte.
   - L2_MEM_MONITOR_LOG_DATA_MASK_REG is used to mask the byte specified in L2_MEM_MONITOR_LOG_CHECK_DATA_REG. A masked byte can be any value. For example, in word monitoring, if L2_MEM_MONITOR_LOG_CHECK_DATA_REG is configured to 0x01020304 and L2_MEM_MONITOR_LOG_DATA_MASK_REG is configured to 0x1, then any writes of the data matching the 0x010203XX pattern by the bus will be recorded.
4. Configure the storage space for recorded data.

- L2_MEM_MONITOR_LOG_MEM_START_REG and L2_MEM_MONITOR_LOG_MEM_END_REG specify the storage space for recorded data. The storage space must be in the range of 0x4080_0000 ~ 0x4087_FFFF.
- Set L2_MEM_MONITOR_LOG_MEM_ADDR_UPDATE_REG to update the value in L2_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG to L2_MEM_MONITOR_LOG_MEM_START_REG.
- Configure the permission for the L2MEM Monitor function of Debug Assistant module to access the HP L2MEM. Only when the access permission is enabled can the Debug Assistant module access the HP L2MEM. For more information, please refer to TEE_DMA_L2MEM_MON_PMS_W_REG and other relevant registers in Chapter 20 *Permission Control (PMS)*.

5. Configure the writing mode for the recorded data: loop mode or non-loop mode.
   - In loop mode, writing to the specified address space is performed in loops. When writing reaches the end address, it will return to the starting address and continue, overwriting the previously recorded data. Set L2_MEM_MONITOR_LOG_MEM_LOOP_ENABLE to enable loop mode.
     For example, there are 10 write operations (1 ~ 10) to address space 0 ~ 4 during bus access. After the 5th operation writes to address 4, the 6th operation will start writing from address 0. The 6th to 10th operations will overwrite the previous data written by the 1th to 5th operations.
   - In non-loop mode, when writing reaches the end address, it will stop at the end address and dump the remaining data, not overwriting the previously recorded data. Clear L2_MEM_MONITOR_LOG_MEM_LOOP_ENABLE to use non-loop mode.
     For example, there are 10 write operations (1 ~ 10) to address space 0 ~ 4 during bus access. After the 5th operation writes to address 4, the 6th to 10th write operations will stop at address 4 and will not be performed any more. Therefore, the address 0 ~ 4 stores the values written by the 1 ~ 5 operations and the values of the 6 ~ 10 operations are dumped.
   - See the example in 22.5.3.1 > step 5.
6. Configure bus enable registers.
   - Enable DMA_2 and DMA_3 channel groups bus access logging with L2_MEM_MONITOR_LOG_DMA_2_ENA and L2_MEM_MONITOR_LOG_DMA_3_ENA respectively. They can be enabled at the same time.

The Debug Assistant module first writes the DMA recorded data to the internal buffer B, and then fetches the data from the buffer and writes it to the configured memory space. When the monitored behaviors are triggered continuously, the generated recording packets may fully occupy the buffer, making it unable to take any incoming packets. At this time, the module dumps these incoming packets and buffers a DMA LOST packet instead before the buffer reaches its capacity. However, it is only possible to know the bus type of the dumped packets when the DMA LOST packet was generated, but not the number of the dumped packets before the generation.

When bus access logging is finished, the recorded data can be read from memory for decoding. The recorded data is in three packet formats, namely DMA_2 packet (corresponding to DMA_2 Data bus), DMA_3 packet (corresponding to DMA_3 Data bus), and DMA LOST packet. The packet formats are shown in Table 22.5-3, 22.5-4, and 22.5-5.

Table 22.5-3. DMA_2 Packet Format

Bit[31:9]	Bit[8:4]	Bit[3:1]	Bit[0]
addr_offset0	reserved	format	anchored (0)

Table 22.5-4. DMA_3 Packet Format

Bit[31:9]	Bit[8:4]	Bit[3:1]	Bit[0]
addr_offset1	reserved	format	anchored (0)

Table 22.5-5. DMA LOST Packet Format

Bit[31:10]	Bit[9:8]	Bit[7:4]	Bit[3:1]	Bit[0]
reserved	lost_source	reserved	format	anchored (0)

It can be seen from the data packet formats that the size of the DMA_2, DMA_3, and DMA LOST packet is 32 bits. These packets contain the following fields:

- **format** – the packet type. 4: DMA_2 packet; 5: DMA_3 packet; 6: DMA LOST packet; other values: Reserved.
- **addr_offset0** - the address offset of a write operation. Actual address = addr_offset0 + L2_MEM_MONITOR_LOG_MIN_REG[31:5],5'h0.
- **addr_offset1** - the address offset of a write operation. Actual address = addr_offset1 + L2_MEM_MONITOR_LOG_MIN_REG[31:2],2'h0.
- **lost_source** - the dumped packets when the DMA LOST packet was generated.
  - Bit[8]: 0 indicates DMA_2 packets were not dumped. 1 indicates DMA_2 packets were dumped.
  - Bit[9]: 0 indicates DMA_3 packets were not dumped. 1 indicates DMA_3 packets were dumped.
- **anchored** - the location of the 32 bits in the data packet. 0: Lower 32 bits. 1: Higher 32 bits.

The internal buffer of the module is 32 bits wide. When the bus access loggings of DMA_2 and DMA_3 channel groups are both enabled and the record data is generated at the same time, the DMA_2 data packets are first buffered, then the DMA_3 packets. The Debug Assistant will automatically fetch the buffered data and store it in 32-bit data width into the specified memory space.

The process of packet parsing is described below:

- Determine whether there is a data overflow with L2_MEM_MONITOR_LOG_MEM_FULL_FLAG.
  - If no, the address space to read is L2_MEM_MONITOR_LOG_MEM_START_REG ~ L2_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG - 4.
  - If yes and the loop mode is enabled, the address space is L2_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG ~ L2_MEM_MONITOR_LOG_MEM_END_REG and L2_MEM_MONITOR_LOG_MEM_START_REG ~ L2_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG - 4.
  - If yes and loop mode is not enabled, the address space is L2_MEM_MONITOR_LOG_MEM_START_REG ~ L2_MEM_MONITOR_LOG_MEM_END_REG.

- Read and parse data from the starting address. Read 32 bits each time.

After packet parsing is completed, clear the L2_MEM_MONITOR_LOG_MEM_FULL_FLAG flag bit by setting L2_MEM_MONITOR_CLR_LOG_MEM_FULL_FLAG.

22.6 Register Summary

The addresses of **HP CPU bus logging configuration registers** (see 22.6.1) in this section are relative to the **SPM Monitor** base address. The addresses of **DMA bus logging configuration registers** (see 22.6.2) in this section are relative to the **L2MEM Monitor** base address. The addresses of other registers (see 22.6.3) are relative to the **Bus Monitor** base address. All base addresses are provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

22.6.1 HP CPU Bus Logging Configuration Register Summary

Name	Description	Address	Access
HP CPU bus logging configuration registers			
SPM_MEM_MONITOR_LOG_SETTING_REG	Configures bus access logging	0x0000	R/W
SPM_MEM_MONITOR_LOG_CHECK_DATA_REG	Configures monitored data in bus access logging	0x0008	R/W
SPM_MEM_MONITOR_LOG_DATA_MASK_REG	Configures masked data in bus access logging	0x000C	R/W
SPM_MEM_MONITOR_LOG_MIN_REG	Configures monitored address space in bus access logging	0x0010	R/W
SPM_MEM_MONITOR_LOG_MAX_REG	Configures monitored address space in bus access logging	0x0014	R/W
SPM_MEM_MONITOR_LOG_MEM_START_REG	Configures the starting address of the memory for recorded data	0x0018	R/W
SPM_MEM_MONITOR_LOG_MEM_END_REG	Configures the end address of the memory for recorded data	0x001C	R/W
SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG	Represents the address for the next write	0x0020	RO
SPM_MEM_MONITOR_LOG_MEM_ADDR_UPDATE_REG	Updates the address for the next write to the starting address for the recorded data	0x0024	WT
SPM_MEM_MONITOR_LOG_MEM_FULL_FLAG_REG	Represents the logging overflow status	0x0028	varies
Clock control register			
SPM_MEM_MONITOR_CLOCK_GATE_REG	Clock control register	0x002C	R/W
Version control register			
SPM_MEM_MONITOR_DATE_REG	Version control register	0x03FC	R/W

22.6.2 DMA Bus Logging Configuration Register Summary

Name	Description	Address	Access
DMA bus logging configuration registers			

Name	Description	Address	Access
L2_MEM_MONITOR_LOG_SETTING_REG	Configures bus access logging	0x0000	R/W
L2_MEM_MONITOR_LOG_SETTING1_REG	Configures bus access logging	0x0004	R/W
L2_MEM_MONITOR_LOG_CHECK_DATA_REG	Configures monitored data in bus access logging	0x0008	R/W
L2_MEM_MONITOR_LOG_DATA_MASK_REG	Configures masked data in bus access logging	0x000C	R/W
L2_MEM_MONITOR_LOG_MIN_REG	Configures monitored address space in bus access logging	0x0010	R/W
L2_MEM_MONITOR_LOG_MAX_REG	Configures monitored address space in bus access logging	0x0014	R/W
L2_MEM_MONITOR_LOG_MEM_START_REG	Configures the starting address of the memory for recorded data	0x0018	R/W
L2_MEM_MONITOR_LOG_MEM_END_REG	Configures the end address of the memory for recorded data	0x001C	R/W
L2_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG	Represents the address for the next write	0x0020	RO
L2_MEM_MONITOR_LOG_MEM_ADDR_UPDATE_REG	Updates the address for the next write to the starting address for the recorded data	0x0024	WT
L2_MEM_MONITOR_LOG_MEM_FULL_FLAG_REG	Represents the logging overflow status	0x0028	varies
Clock control register			
L2_MEM_MONITOR_CLOCK_GATE_REG	Clock control register	0x002C	R/W
Version control register			
L2_MEM_MONITOR_DATE_REG	Version control register	0x03FC	R/W

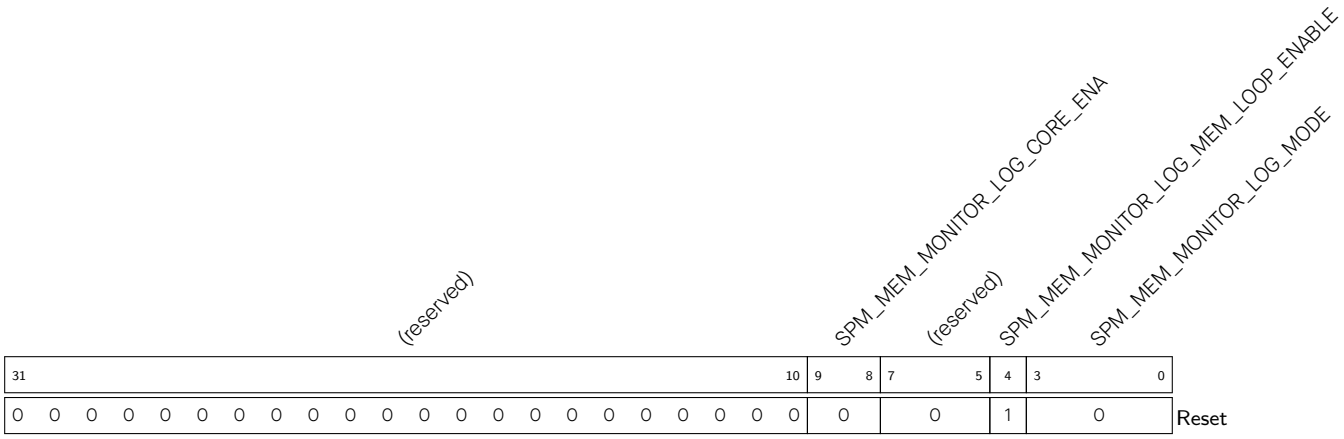
22.6.3 Summary of Other Registers

Name	Description	Address	Access
Monitor configuration registers			
ASSIST_DEBUG_CORE_0_MONTR_ENA_REG	Configures whether to enable HP CPU0 monitoring	0x0000	R/W
ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MIN_REG	Configures the lower bound address of region 0 monitored on HP CPU0 Data bus	0x0010	R/W
ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MAX_REG	Configures the upper bound address of region 0 monitored on HP CPU0 Data bus	0x0014	R/W
ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_MIN_REG	Configures the lower bound address of region 1 monitored on HP CPU0 Data bus	0x0018	R/W

Name	Description	Address	Access
ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_MAX_REG	Configures the upper bound address of region 1 monitored on HP CPU0 Data bus	0x001C	R/W
ASSIST_DEBUG_CORE_0_AREA_PIF_0_MIN_REG	Configures the lower bound address of region 0 monitored on HP CPU0 Peripheral bus	0x0020	R/W
ASSIST_DEBUG_CORE_0_AREA_PIF_0_MAX_REG	Configures the upper bound address of region 0 monitored on HP CPU0 Peripheral bus	0x0024	R/W
ASSIST_DEBUG_CORE_0_AREA_PIF_1_MIN_REG	Configures the lower bound address of region 1 monitored on HP CPU0 Peripheral bus	0x0028	R/W
ASSIST_DEBUG_CORE_0_AREA_PIF_1_MAX_REG	Configures the upper bound address of region 1 monitored on HP CPU0 Peripheral bus	0x002C	R/W
ASSIST_DEBUG_CORE_0_AREA_PC_REG	Represents the PC status under HP CPU0 region monitoring	0x0030	RO
ASSIST_DEBUG_CORE_0_AREA_SP_REG	Represents the SP status under HP CPU0 region monitoring	0x0034	RO
ASSIST_DEBUG_CORE_0_SP_MIN_REG	Configures the lower bound address of the HP CPU0 SP monitored region	0x0038	R/W
ASSIST_DEBUG_CORE_0_SP_MAX_REG	Configures the upper bound address of the HP CPU0 SP monitored region	0x003C	R/W
ASSIST_DEBUG_CORE_0_SP_PC_REG	Represents the PC status under HP CPU0 SP monitoring	0x0040	RO
ASSIST_DEBUG_CORE_1_MONTR_ENA_REG	Configures whether to enable HP CPU1 monitoring	0x0080	R/W
ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_MIN_REG	Configures the lower bound address of region 0 monitored on HP CPU1 Data bus	0x0090	R/W
ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_MAX_REG	Configures the upper bound address of region 0 monitored on HP CPU1 Data bus	0x0094	R/W
ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_MIN_REG	Configures the lower bound address of region 1 monitored on HP CPU1 Data bus	0x0098	R/W
ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_MAX_REG	Configures the upper bound address of region 1 monitored on HP CPU1 Data bus	0x009C	R/W
ASSIST_DEBUG_CORE_1_AREA_PIF_0_MIN_REG	Configures the lower bound address of region 0 monitored on HP CPU1 Peripheral bus	0x00A0	R/W

Name	Description	Address	Access
ASSIST_DEBUG_CORE_1_AREA_PIF_0_MAX_REG	Configures the upper bound address of region 0 monitored on HP CPU1 Peripheral bus	0x00A4	R/W
ASSIST_DEBUG_CORE_1_AREA_PIF_1_MIN_REG	Configures the lower bound address of region 1 monitored on HP CPU1 Peripheral bus	0x00A8	R/W
ASSIST_DEBUG_CORE_1_AREA_PIF_1_MAX_REG	Configures the upper bound address of region 1 monitored on HP CPU1 Peripheral bus	0x00AC	R/W
ASSIST_DEBUG_CORE_1_AREA_PC_REG	Represents the PC status under HP CPU1 region monitoring	0x00B0	RO
ASSIST_DEBUG_CORE_1_AREA_SP_REG	Represents the SP status under HP CPU1 region monitoring	0x00B4	RO
ASSIST_DEBUG_CORE_1_SP_MIN_REG	Configures the lower bound address of the HP CPU1 SP monitored region	0x00B8	R/W
ASSIST_DEBUG_CORE_1_SP_MAX_REG	Configures the upper bound address of the HP CPU1 SP monitored region	0x00BC	R/W
ASSIST_DEBUG_CORE_1_SP_PC_REG	Represents the PC status under HP CPU1 SP monitoring	0x00C0	RO
Interrupt configuration registers			
ASSIST_DEBUG_CORE_0_INTR_RAW_REG	HP CPU0 raw interrupt status register	0x0004	RO
ASSIST_DEBUG_CORE_0_INTR_ENA_REG	HP CPU0 interrupt enable register	0x0008	R/W
ASSIST_DEBUG_CORE_0_INTR_CLR_REG	HP CPU0 interrupt clear register	0x000C	WT
ASSIST_DEBUG_CORE_1_INTR_RAW_REG	HP CPU1 raw interrupt status register	0x0084	RO
ASSIST_DEBUG_CORE_1_INTR_ENA_REG	HP CPU1 interrupt enable register	0x0088	R/W
ASSIST_DEBUG_CORE_1_INTR_CLR_REG	HP CPU1 interrupt clear register	0x008C	WT
PC logging configuration register			
ASSIST_DEBUG_CORE_0_RCD_EN_REG	HP CPU0 PC logging enable register	0x0044	R/W
ASSIST_DEBUG_CORE_1_RCD_EN_REG	HP CPU1 PC logging enable register	0x00C4	R/W
PC logging status registers			
ASSIST_DEBUG_CORE_0_RCD_PDEBUGPC_REG	HP CPU0 PC logging register	0x0048	RO
ASSIST_DEBUG_CORE_0_RCD_PDEBUGSP_REG	HP CPU0 SP logging register	0x004C	RO
ASSIST_DEBUG_CORE_1_RCD_PDEBUGPC_REG	HP CPU1 PC logging register	0x00C8	RO
ASSIST_DEBUG_CORE_1_RCD_PDEBUGSP_REG	HP CPU1 SP logging register	0x00CC	RO
CPU status registers			
ASSIST_DEBUG_CORE_0_LASTPC_BEFORE_EXCEPTION_REG	PC of the last command before HP CPU0 enters exception	0x0070	RO

Name	Description	Address	Access
ASSIST_DEBUG_CORE_0_DEBUG_MODE_REG	HP CPU0 debug mode status register	0x0074	RO
ASSIST_DEBUG_CORE_1_LASTPC_BEFORE_EXCEPTION_REG	PC of the last command before HP CPU1 enters exception	0x00F0	RO
ASSIST_DEBUG_CORE_1_DEBUG_MODE_REG	HP CPU1 debug mode status register	0x00F4	RO
Clock control register			
ASSIST_DEBUG_CLOCK_GATE_REG	Clock control register	0x0108	R/W
Version control register			
ASSIST_DEBUG_DATE_REG	Version control register	0x03FC	R/W



22.7 Registers

The addresses of **HP CPU bus logging configuration registers** (see 22.6.1) in this section are relative to the **SPM Monitor** base address. The addresses of **DMA bus logging configuration registers** (see 22.6.2) in this section are relative to the **L2MEM Monitor** base address. The addresses of other registers (see 22.7.3) are relative to the **Bus Monitor** base address. All base addresses are provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

22.7.1 HP CPU Bus Logging Configuration Registers

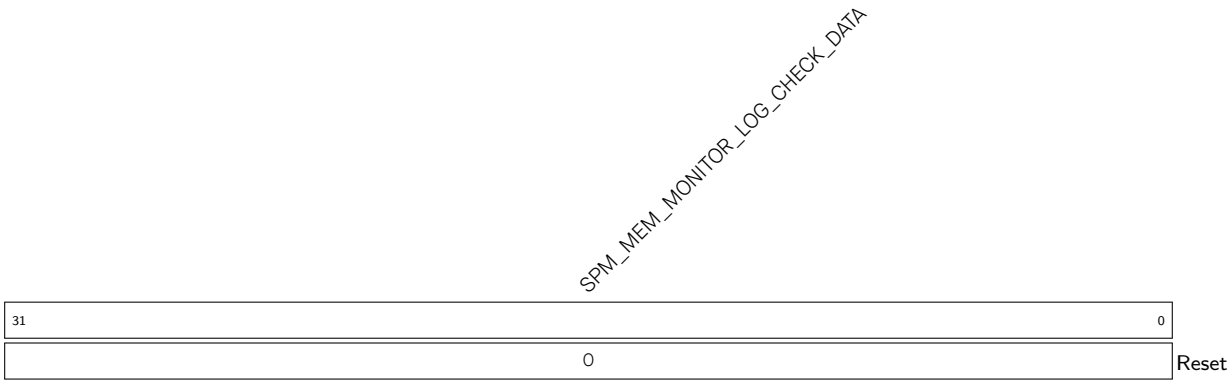
Register 22.1. SPM_MEM_MONITOR_LOG_SETTING_REG (0x0000)

SPM_MEM_MONITOR_LOG_MODE Configures monitoring modes.

bit[0]: Configures write monitoring.
0: Disable
1: Enable
bit[1]: Configures word monitoring.
0: Disable
1: Enable
bit[2]: Configures halfword monitoring.
0: Disable
1: Enable
bit[3]: Configures byte monitoring.
0: Disable
1: Enable
(R/W)

SPM_MEM_MONITOR_LOG_MEM_LOOP_ENABLE Configures the writing mode for recorded data.

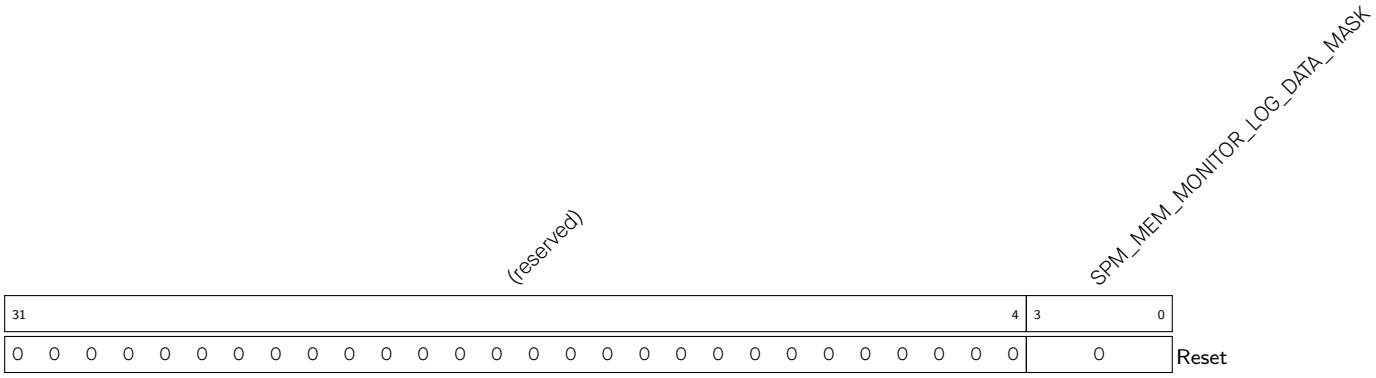
1: Loop mode
0: Non-loop mode
(R/W)



Continued on the next page...

Register 22.1. SPM_MEM_MONITOR_LOG_SETTING_REG (0x0000)

Continued from the previous page...



SPM_MEM_MONITOR_LOG_CORE_ENA Configures whether to enable HP CPU0 or HP CPU1 bus access logging.
bit[0]: Configures whether to enable HP CPU0 bus access logging.
0: Disable
1: Enable
bit[1]: Configures whether to enable HP CPU1 bus access logging.
0: Disable
1: Enable
(R/W)

Register 22.2. SPM_MEM_MONITOR_LOG_CHECK_DATA_REG (0x0008)

SPM_MEM_MONITOR_LOG_CHECK_DATA Configures the data to be monitored during bus accessing. (R/W)

Register 22.3. SPM_MEM_MONITOR_LOG_DATA_MASK_REG (0x000C)

SPM_MEM_MONITOR_LOG_DATA_MASK Configures which byte(s) in SPM_MEM_MONITOR_LOG_CHECK_DATA_REG to mask.

bit[0]: Configures whether to mask the least significant byte of SPM_MEM_MONITOR_LOG_CHECK_DATA_REG.

0: Not mask

1: Mask

bit[1]: Configures whether to mask the second least significant byte of SPM_MEM_MONITOR_LOG_CHECK_DATA_REG.

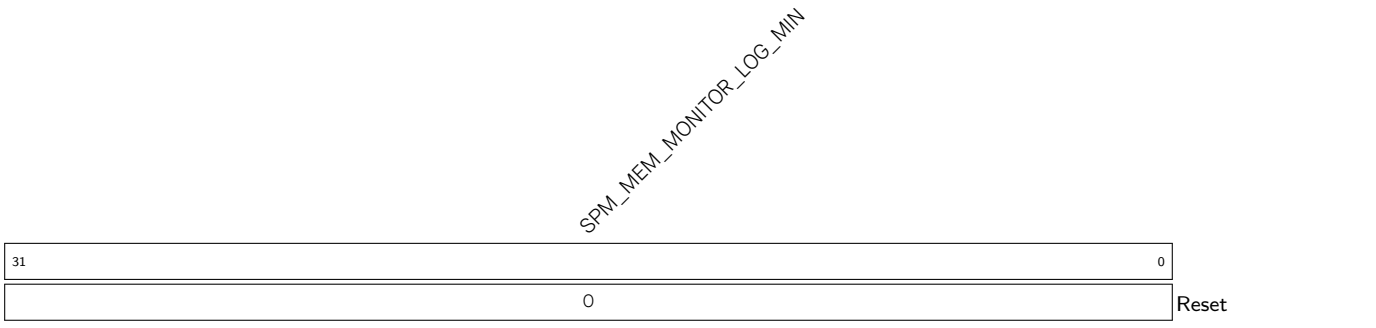
0: Not mask

1: Mask

bit[2]: Configures whether to mask the second most significant byte of SPM_MEM_MONITOR_LOG_CHECK_DATA_REG.

0: Not mask

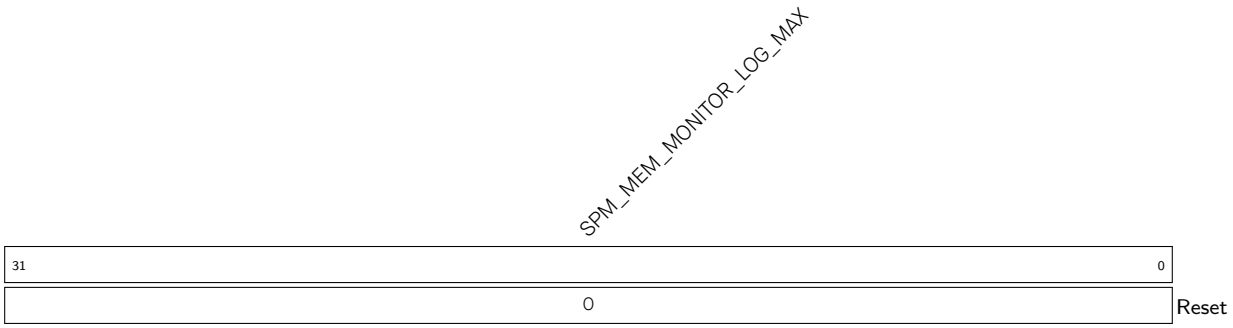
1: Mask



bit[3]: Configures whether to mask the most significant byte of SPM_MEM_MONITOR_LOG_CHECK_DATA_REG.

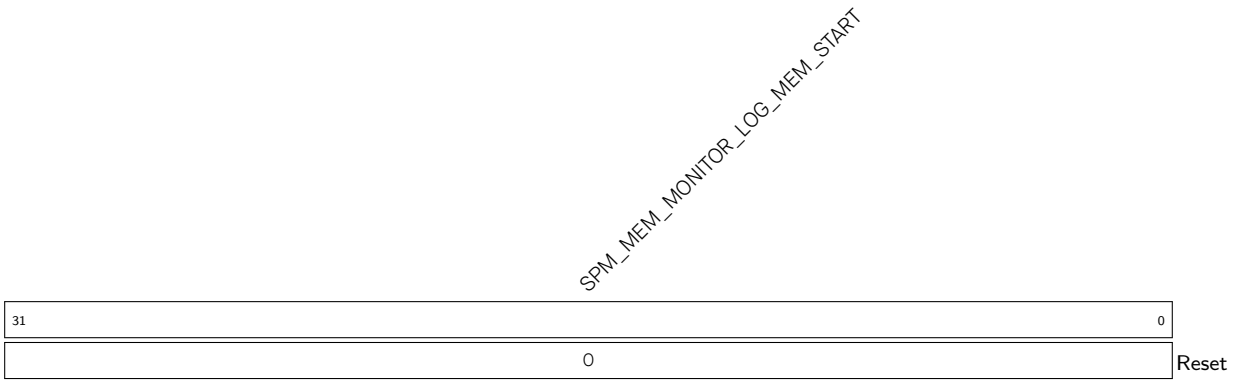
0: Not mask

1: Mask



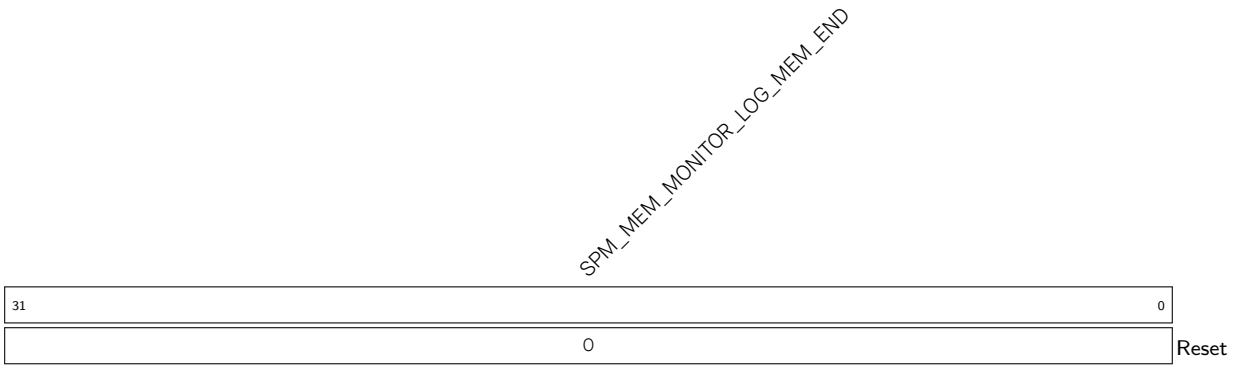
(R/W)

Register 22.4. SPM_MEM_MONITOR_LOG_MIN_REG (0x0010)



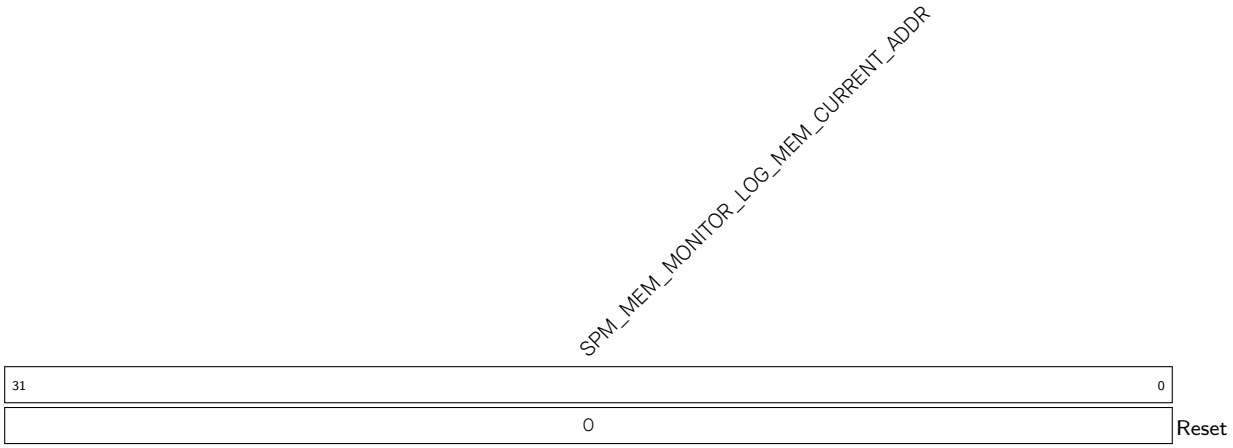
SPM_MEM_MONITOR_LOG_MIN Configures the lower bound address of the monitored address space. (R/W)

Register 22.5. SPM_MEM_MONITOR_LOG_MAX_REG (0x0014)



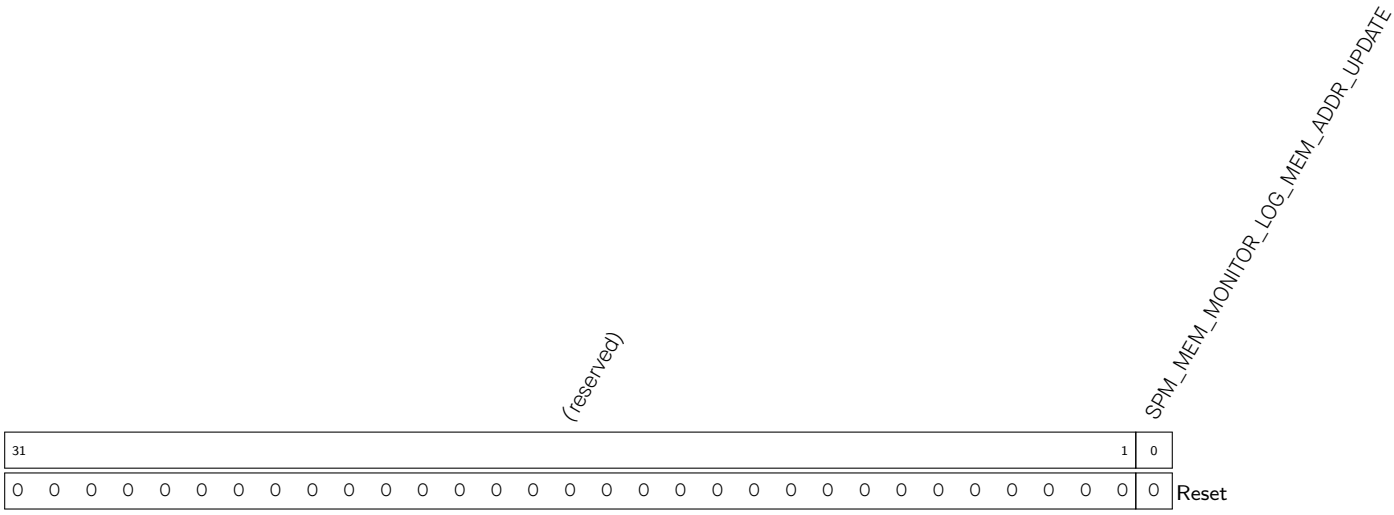
SPM_MEM_MONITOR_LOG_MAX Configures the upper bound address of the monitored address space. (R/W)

Register 22.6. SPM_MEM_MONITOR_LOG_MEM_START_REG (0x0018)



SPM_MEM_MONITOR_LOG_MEM_START Configures the starting address of the storage space for recorded data. (R/W)

Register 22.7. SPM_MEM_MONITOR_LOG_MEM_END_REG (0x001C)

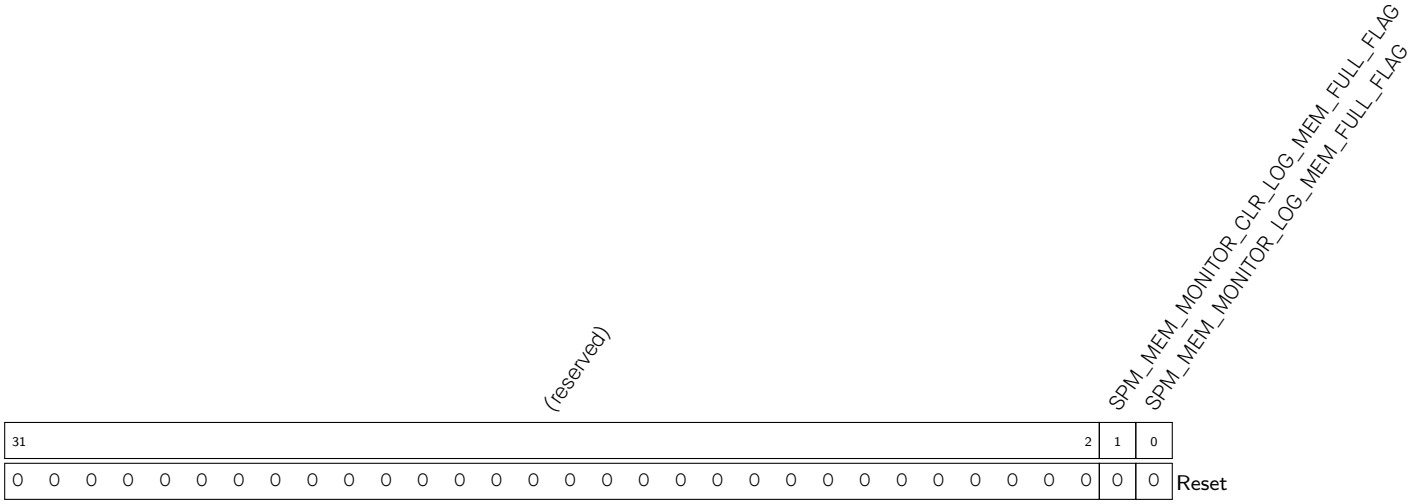


SPM_MEM_MONITOR_LOG_MEM_END Configures the ending address of the storage space for recorded data. (R/W)

Register 22.8. SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG (0x0020)

SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR Represents the address of the next write. (RO)

Register 22.9. SPM_MEM_MONITOR_LOG_MEM_ADDR_UPDATE_REG (0x0024)



SPM_MEM_MONITOR_LOG_MEM_ADDR_UPDATE Configures whether to update the value in SPM_MEM_MONITOR_LOG_MEM_START_REG to SPM_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG.

1: Update

0: Not update

(WT)

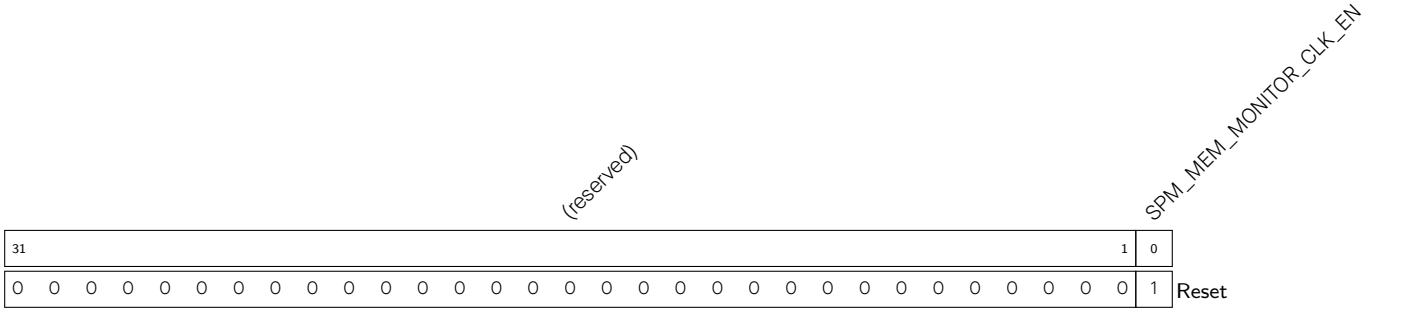
Register 22.10. SPM_MEM_MONITOR_LOG_MEM_FULL_FLAG_REG (0x0028)

SPM_MEM_MONITOR_LOG_MEM_FULL_FLAG Represents whether data overflows the storage space.

0: Not overflow

1: Overflow

(RO)



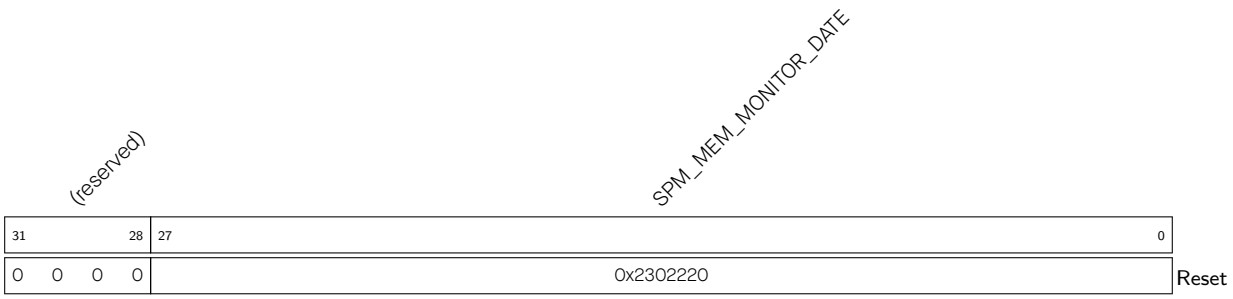
SPM_MEM_MONITOR_CLR_LOG_MEM_FULL_FLAG Configures whether to clear the SPM_MEM_MONITOR_LOG_MEM_FULL_FLAG flag bit.

0: Not clear (default)

1: Clear

(WT)

Register 22.11. SPMMEM_MONITOR_CLOCK_GATE_REG (0x002C)

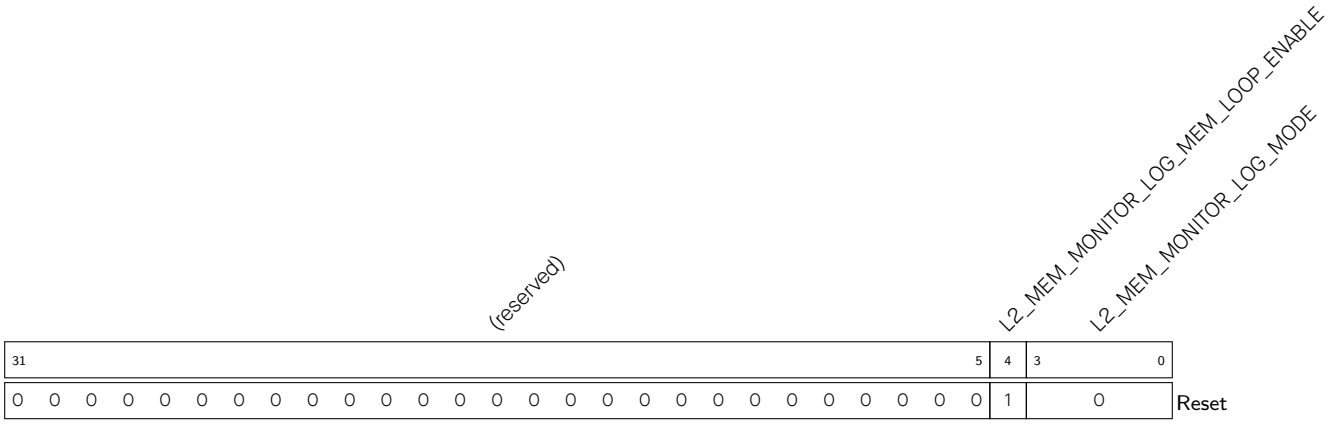


SPM_MEM_MONITOR_CLK_EN Configures whether to enable the register clock gating.

0: Disable

1: Enable

(R/W)



Register 22.12. SPM_MEM_MONITOR_DATE_REG (0x03FC)

SPM_MEM_MONITOR_DATE Version control register. (R/W)

22.7.2 DMA Bus Logging Configuration Registers

Register 22.13. L2_MEM_MONITOR_LOG_SETTING_REG (0x0000)

L2_MEM_MONITOR_LOG_MODE Configures monitoring modes.

bit[0]: Configures write monitoring.

0: Disable

1: Enable

bit[1]: Configures word monitoring.

0: Disable

1: Enable

bit[2]: Configures halfword monitoring.

0: Disable

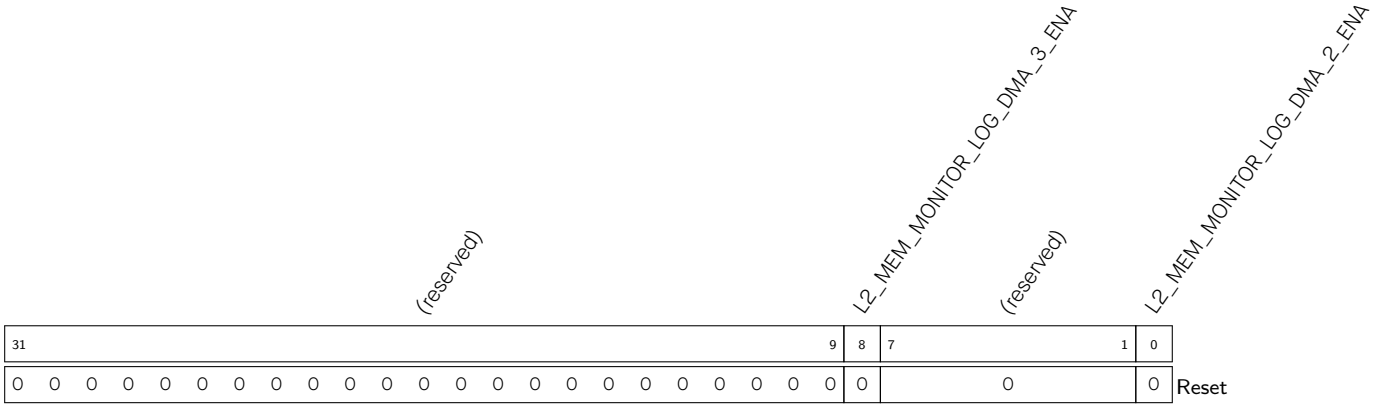
1: Enable

bit[3]: Configures byte monitoring.

0: Disable

1: Enable

(R/W)



L2_MEM_MONITOR_LOG_MEM_LOOP_ENABLE Configures the writing mode for recorded data.

1: Loop mode

0: Non-loop mode

(R/W)

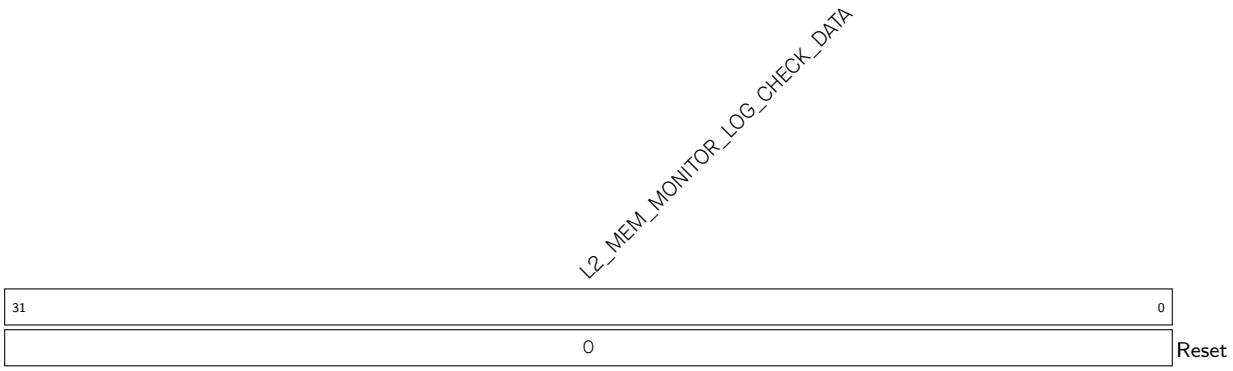
Register 22.14. L2_MEM_MONITOR_LOG_SETTING1_REG (0x0004)

L2_MEM_MONITOR_LOG_DMA_2_ENA Configures whether to enable DMA_2 bus access logging.

0: Disable

1: Enable

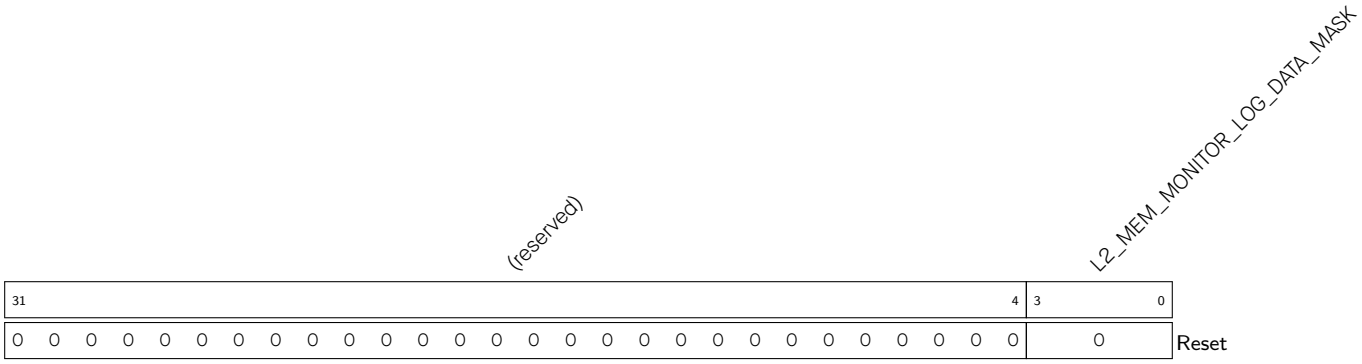
(R/W)



L2_MEM_MONITOR_LOG_DMA_3_ENA Configures whether to enable DMA_3 bus access logging.

0: Disable

1: Enable



(R/W)

Register 22.15. L2_MEM_MONITOR_LOG_CHECK_DATA_REG (0x0008)

L2_MEM_MONITOR_LOG_CHECK_DATA Configures the data to be monitored during bus accessing. (R/W)

Register 22.16. L2_MEM_MONITOR_LOG_DATA_MASK_REG (0x000C)

L2_MEM_MONITOR_LOG_DATA_MASK Configures which byte(s) in L2_MEM_MONITOR_LOG_CHECK_DATA_REG to mask.

bit[0]: Configures whether to mask the least significant byte of L2_MEM_MONITOR_LOG_CHECK_DATA_REG.

0: Not mask

1: Mask

bit[1]: Configures whether to mask the second least significant byte of L2_MEM_MONITOR_LOG_CHECK_DATA_REG.

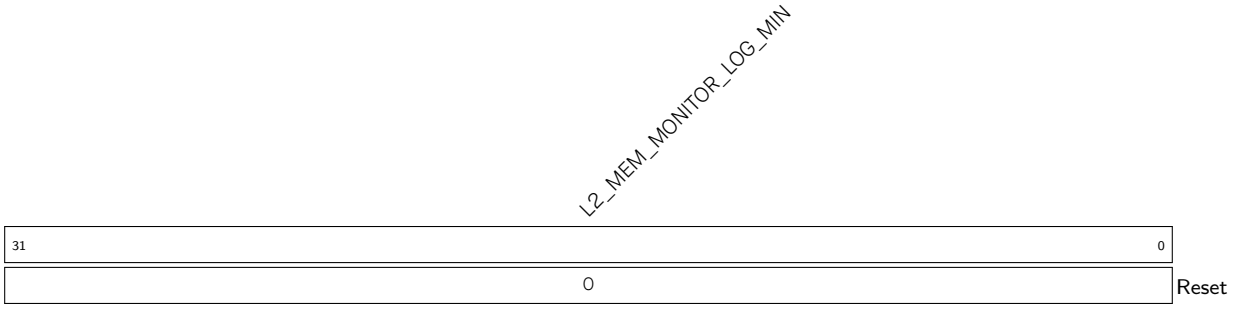
0: Not mask

1: Mask

bit[2]: Configures whether to mask the second most significant byte of L2_MEM_MONITOR_LOG_CHECK_DATA_REG.

0: Not mask

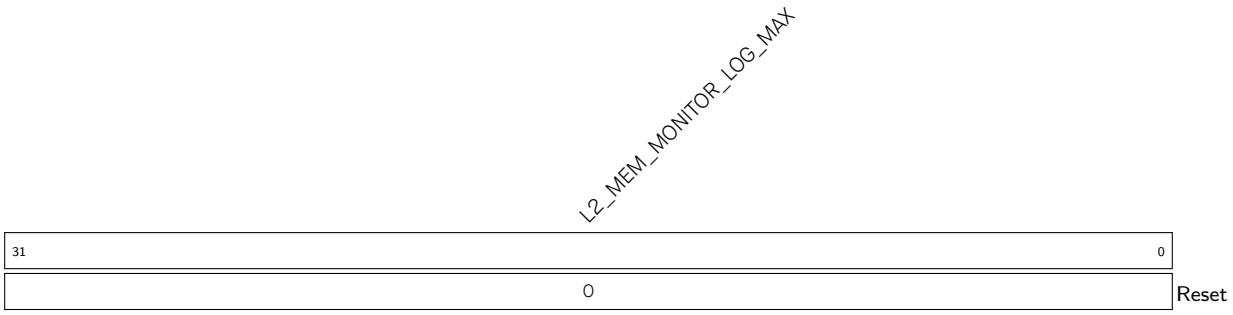
1: Mask



bit[3]: Configures whether to mask the most significant byte of L2_MEM_MONITOR_LOG_CHECK_DATA_REG.

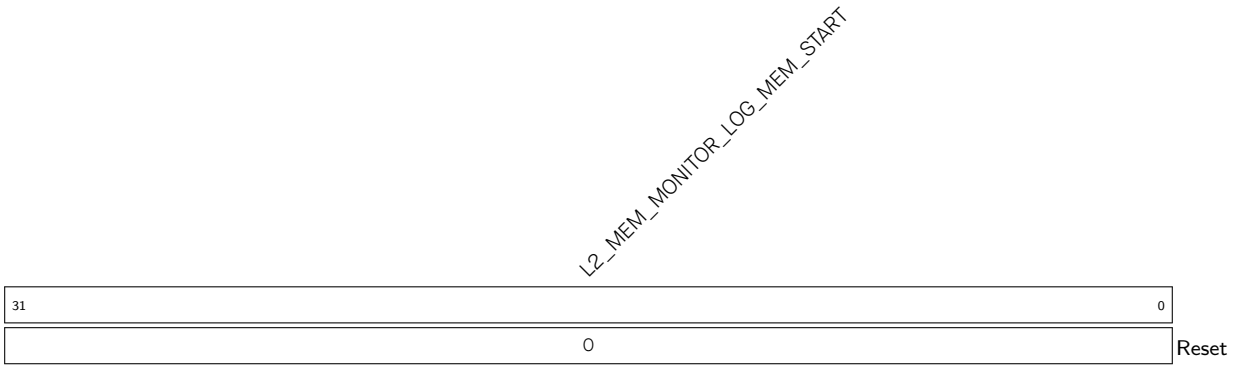
0: Not mask

1: Mask



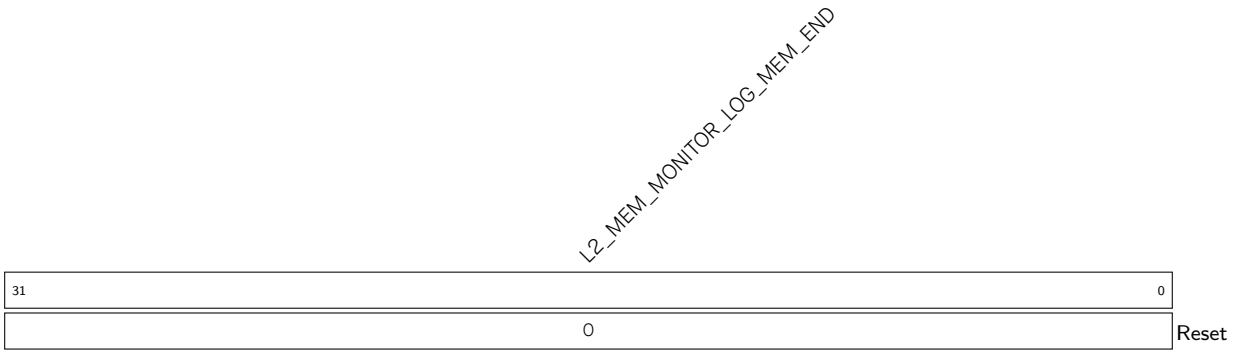
(R/W)

Register 22.17. L2_MEM_MONITOR_LOG_MIN_REG (0x0010)



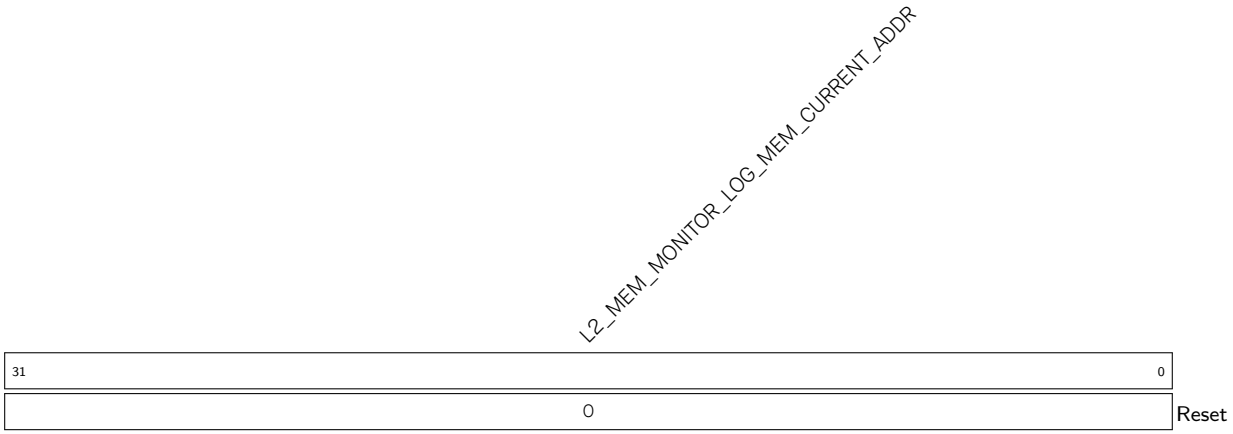
L2_MEM_MONITOR_LOG_MIN Configures the lower bound address of the monitored address space. (R/W)

Register 22.18. L2_MEM_MONITOR_LOG_MAX_REG (0x0014)



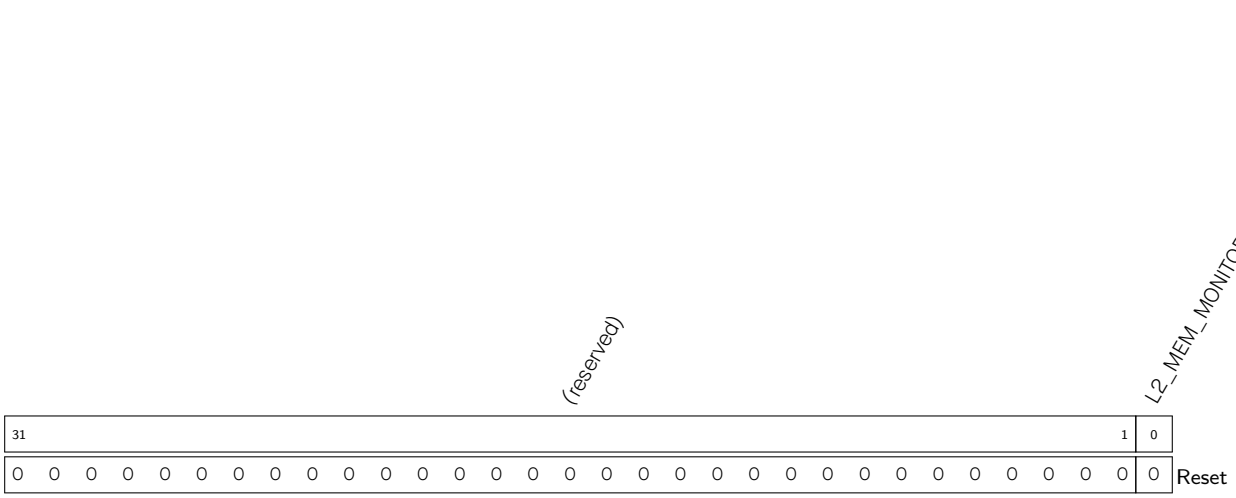
L2_MEM_MONITOR_LOG_MAX Configures the upper bound address of the monitored address space. (R/W)

Register 22.19. L2_MEM_MONITOR_LOG_MEM_START_REG (0x0018)



L2_MEM_MONITOR_LOG_MEM_START Configures the starting address of the storage space for recorded data. (R/W)

Register 22.20. L2_MEM_MONITOR_LOG_MEM_END_REG (0x001C)

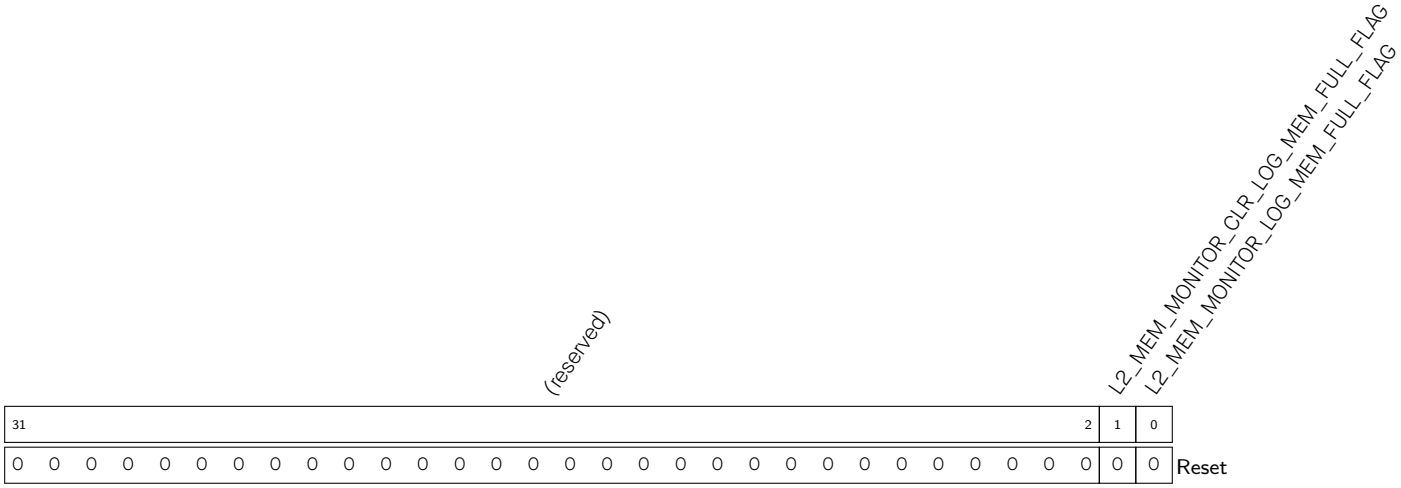


L2_MEM_MONITOR_LOG_MEM_END Configures the ending address of the storage space for recorded data. (R/W)

Register 22.21. L2_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG (0x0020)

L2_MEM_MONITOR_LOG_MEM_CURRENT_ADDR Represents the address of the next write. (RO)

Register 22.22. L2_MEM_MONITOR_LOG_MEM_ADDR_UPDATE_REG (0x0024)



L2_MEM_MONITOR_LOG_MEM_ADDR_UPDATE Configures whether to update the value in L2_MEM_MONITOR_LOG_MEM_START_REG to L2_MEM_MONITOR_LOG_MEM_CURRENT_ADDR_REG.

1: Update

0: Not update (default)

(WT)

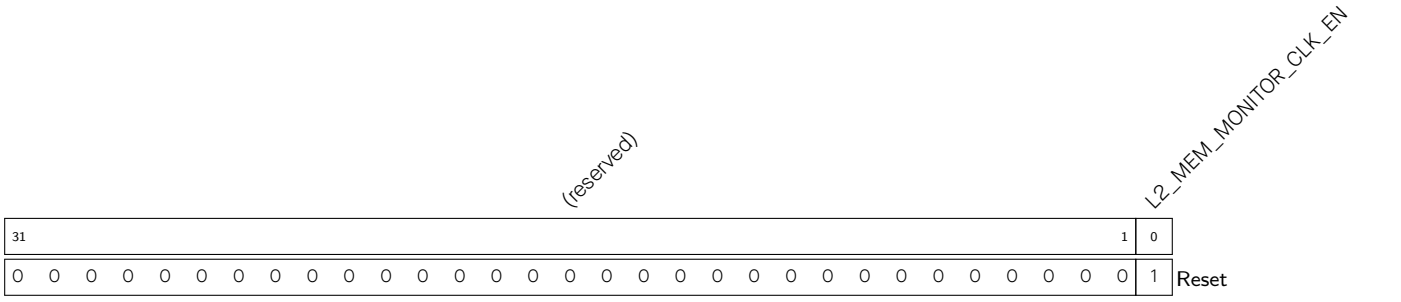
Register 22.23. L2_MEM_MONITOR_LOG_MEM_FULL_FLAG_REG (0x0028)

L2_MEM_MONITOR_LOG_MEM_FULL_FLAG Represents whether data overflows the storage space.

0: Not overflow

1: Overflow

(RO)



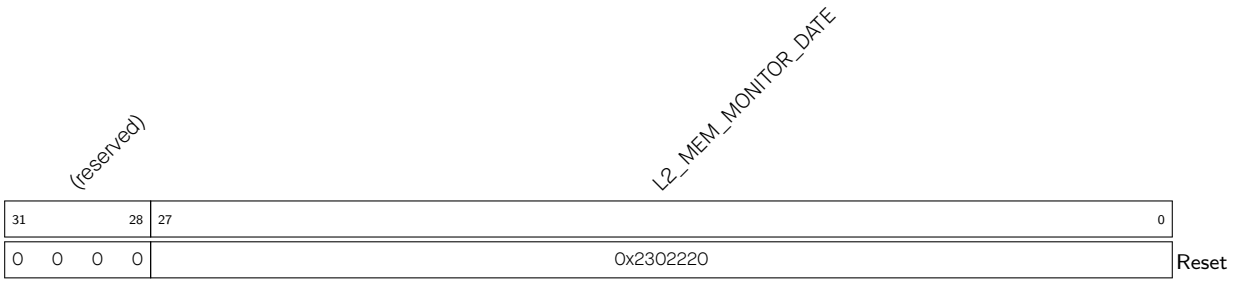
L2_MEM_MONITOR_CLR_LOG_MEM_FULL_FLAG Configures whether to clear the L2_MEM_MONITOR_LOG_MEM_FULL_FLAG flag bit.

0: Not clear (default)

1: Clear

(WT)

Register 22.24. L2_MEM_MONITOR_CLOCK_GATE_REG (0x002C)

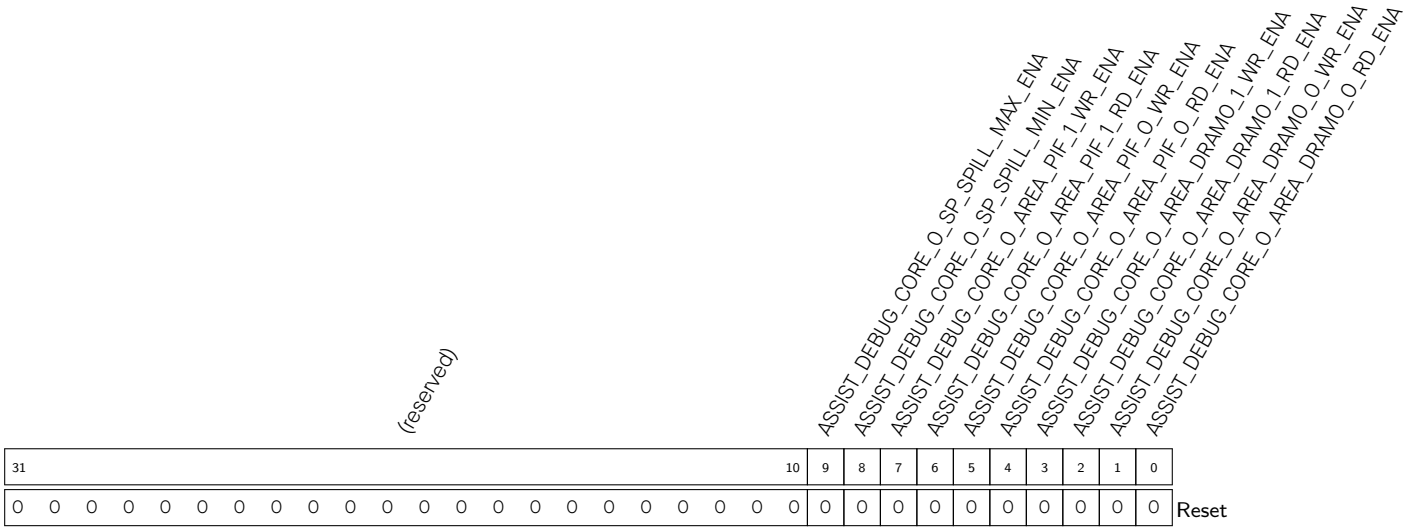


L2_MEM_MONITOR_CLK_EN Configures whether to enable the register clock gating.

0: Disable

1: Enable

(R/W)



Register 22.25. L2_MEM_MONITOR_DATE_REG (0x03FC)

L2_MEM_MONITOR_DATE Version control register. (R/W)

22.7.3 Other Registers

Register 22.26. ASSIST_DEBUG_CORE_0_MONTR_ENA_REG (0x0000)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_RD_ENA Configures whether to monitor read operations in HP CPU0 region 0 by the HP CPU0 Data bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_WR_ENA Configures whether to monitor write operations in HP CPU0 region 0 by the HP CPU0 Data bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_RD_ENA Configures whether to monitor read operations in HP CPU0 region 1 by the HP CPU0 Data bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_WR_ENA Configures whether to monitor write operations in HP CPU0 region 1 by the HP CPU0 Data bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_0_AREA_PIF_0_RD_ENA Configures whether to monitor read operations in region 0 by the Peripheral bus.

0: Not monitor

1: Monitor

(R/W)

Continued on the next page...

Register 22.26. ASSIST_DEBUG_CORE_0_MONTR_ENA_REG (0x0000)

Continued from the previous page...

ASSIST_DEBUG_CORE_0_AREA_PIF_0_WR_ENA Configures whether to monitor write operations in HP CPU0 region 0 by the HP CPU0 Peripheral bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_0_AREA_PIF_1_RD_ENA Configures whether to monitor read operations in HP CPU0 region 1 by the HP CPU0 Peripheral bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_0_AREA_PIF_1_WR_ENA Configures whether to monitor write operations in HP CPU0 region 1 by the HP CPU0 Peripheral bus.

0: Not monitor

1: Monitor

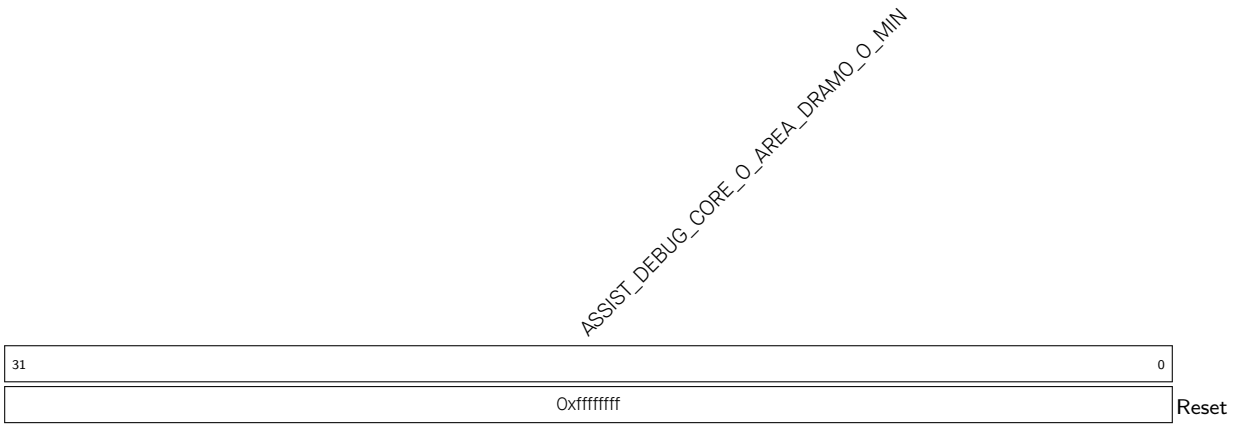
(R/W)

ASSIST_DEBUG_CORE_0_SP_SPILL_MIN_ENA Configures whether to monitor HP CPU0 SP going below the lower bound address of HP CPU0 SP monitored region.

0: Not monitor

1: Monitor

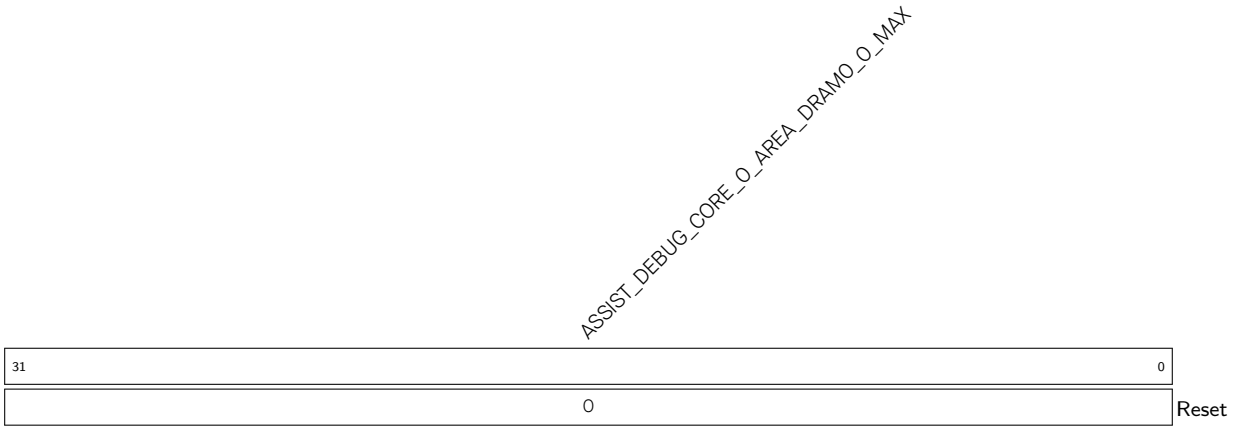
(R/W)



ASSIST_DEBUG_CORE_0_SP_SPILL_MAX_ENA Configures whether to monitor HP CPU0 SP going beyond the upper bound address of HP CPU0 SP monitored region.

0: Not monitor

1: Monitor



(R/W)

Register 22.27. ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MIN_REG (0x0010)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MIN Configures the lower bound address of HP CPU0 Data bus region 0. (R/W)

Register 22.28. ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MAX_REG (0x0014)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_MAX Configures the upper bound address of HP CPU0 Data bus region 0. (R/W)

Register 22.29. ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_MIN_REG (0x0018)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_MIN Configures the lower bound address of HP CPU0 Data bus region 1. (R/W)

Register 22.30. ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_MAX_REG (0x001C)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_MAX Configures the upper bound address of HP CPU0 Data bus region 1. (R/W)

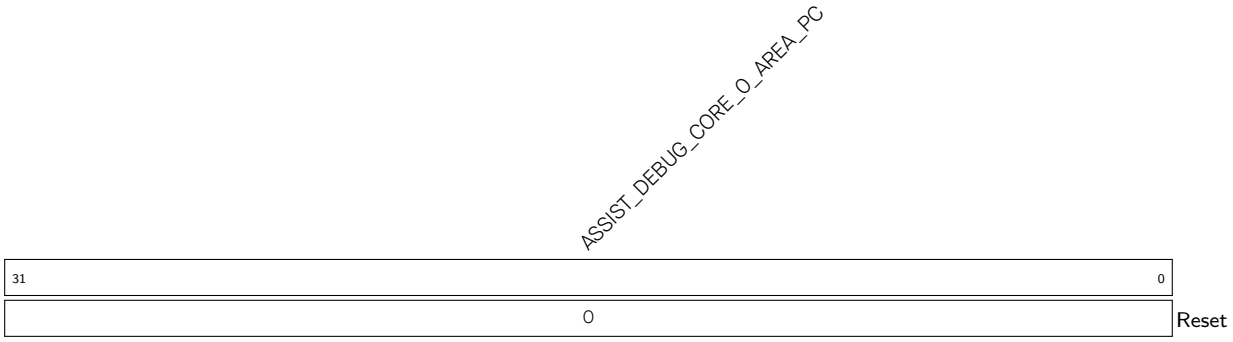
Register 22.31. ASSIST_DEBUG_CORE_0_AREA_PIF_0_MIN_REG (0x0020)

ASSIST_DEBUG_CORE_0_AREA_PIF_0_MIN Configures the lower bound address of HP CPU0 Peripheral bus region 0. (R/W)

Register 22.32. ASSIST_DEBUG_CORE_0_AREA_PIF_0_MAX_REG (0x0024)

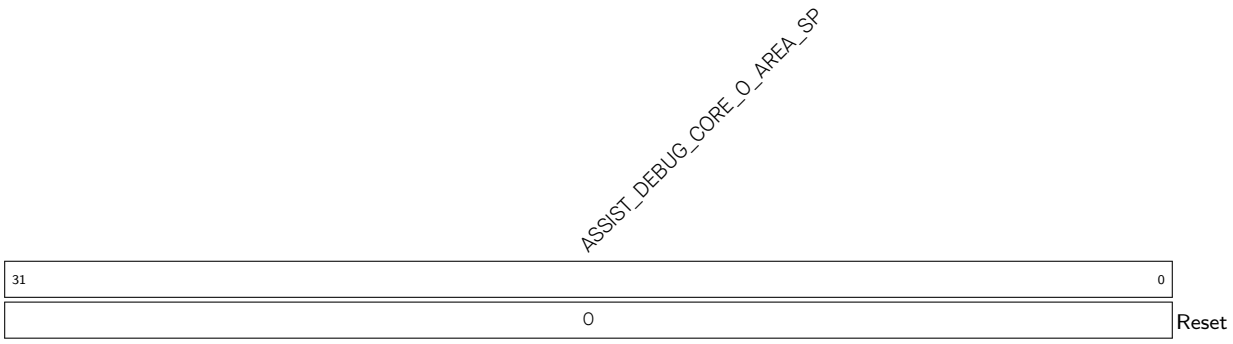
ASSIST_DEBUG_CORE_0_AREA_PIF_0_MAX Configures the upper bound address of HP CPU0 Peripheral bus region 0. (R/W)

Register 22.33. ASSIST_DEBUG_CORE_0_AREA_PIF_1_MIN_REG (0x0028)



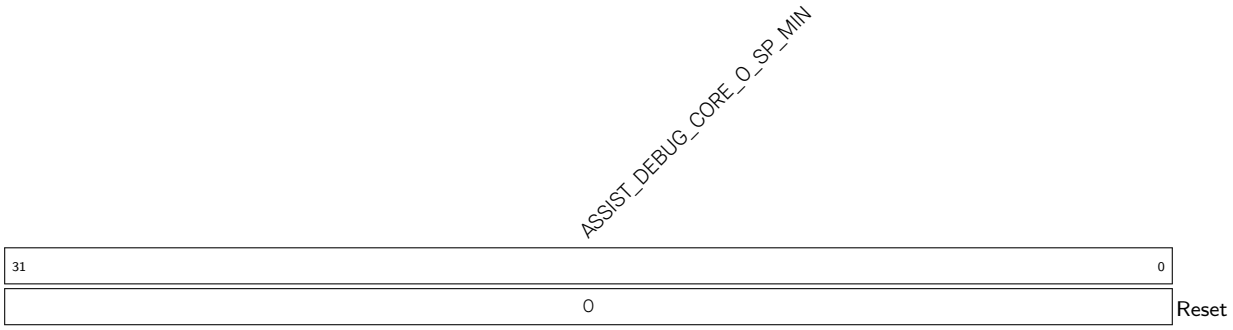
ASSIST_DEBUG_CORE_0_AREA_PIF_1_MIN Configures the lower bound address of HP CPU0 Peripheral bus region 1. (R/W)

Register 22.34. ASSIST_DEBUG_CORE_0_AREA_PIF_1_MAX_REG (0x002C)



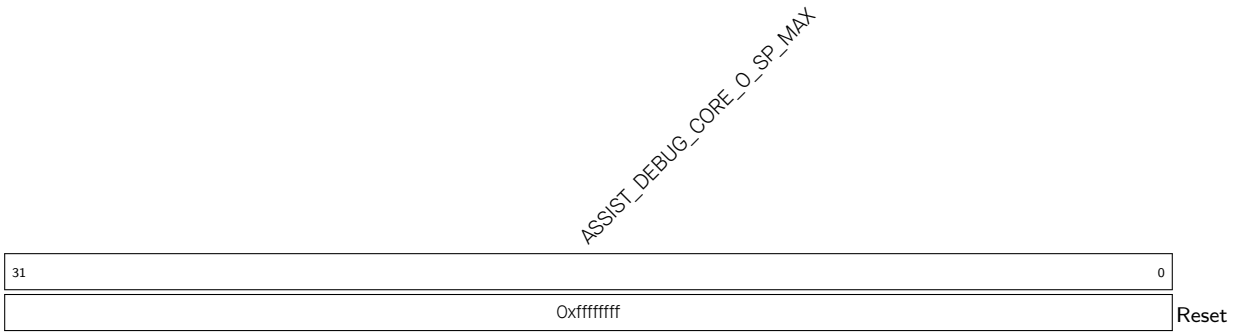
ASSIST_DEBUG_CORE_0_AREA_PIF_1_MAX Configures the upper bound address of HP CPU0 Peripheral bus region 1. (R/W)

Register 22.35. ASSIST_DEBUG_CORE_0_AREA_PC_REG (0x0030)



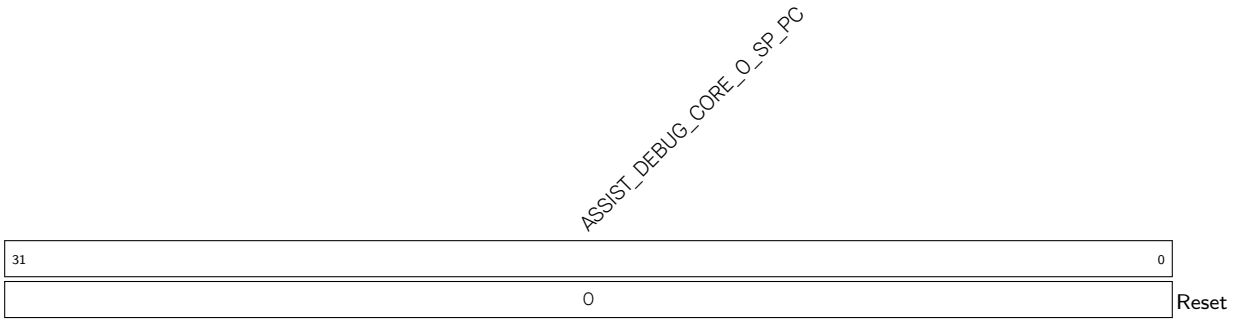
ASSIST_DEBUG_CORE_0_AREA_PC Represents the HP CPU0 PC value when an interrupt is triggered during region monitoring. (RO)

Register 22.36. ASSIST_DEBUG_CORE_0_AREA_SP_REG (0x0034)



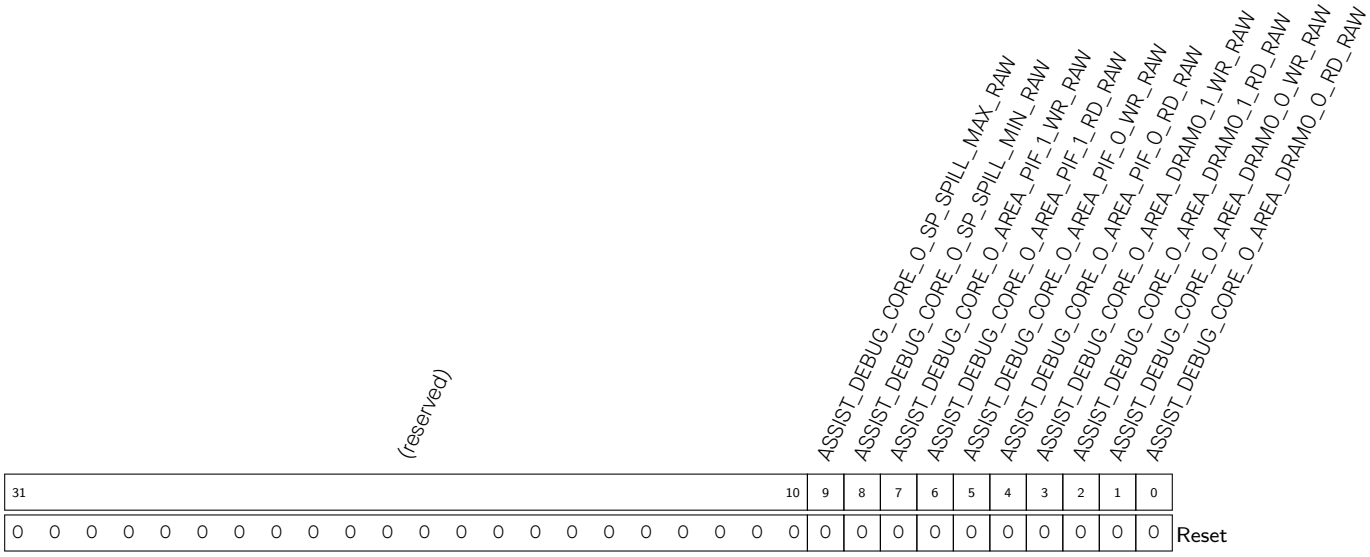
ASSIST_DEBUG_CORE_0_AREA_SP Represents the HP CPU0 SP value when an interrupt is triggered during region monitoring. (RO)

Register 22.37. ASSIST_DEBUG_CORE_0_SP_MIN_REG (0x0038)



ASSIST_DEBUG_CORE_0_SP_MIN Configures the lower bound address of the HP CPU0 SP monitored region. (R/W)

Register 22.38. ASSIST_DEBUG_CORE_0_SP_MAX_REG (0x003C)



ASSIST_DEBUG_CORE_0_SP_MAX Configures the upper bound address of the HP CPU0 SP monitored region. (R/W)

Register 22.39. ASSIST_DEBUG_CORE_0_SP_PC_REG (0x0040)

ASSIST_DEBUG_CORE_0_SP_PC Represents the HP CPU0 PC value during SP monitoring. (RO)

Register 22.40. ASSIST_DEBUG_CORE_0_INTR_RAW_REG (0x0004)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_RD_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_RD_INT. (RO)

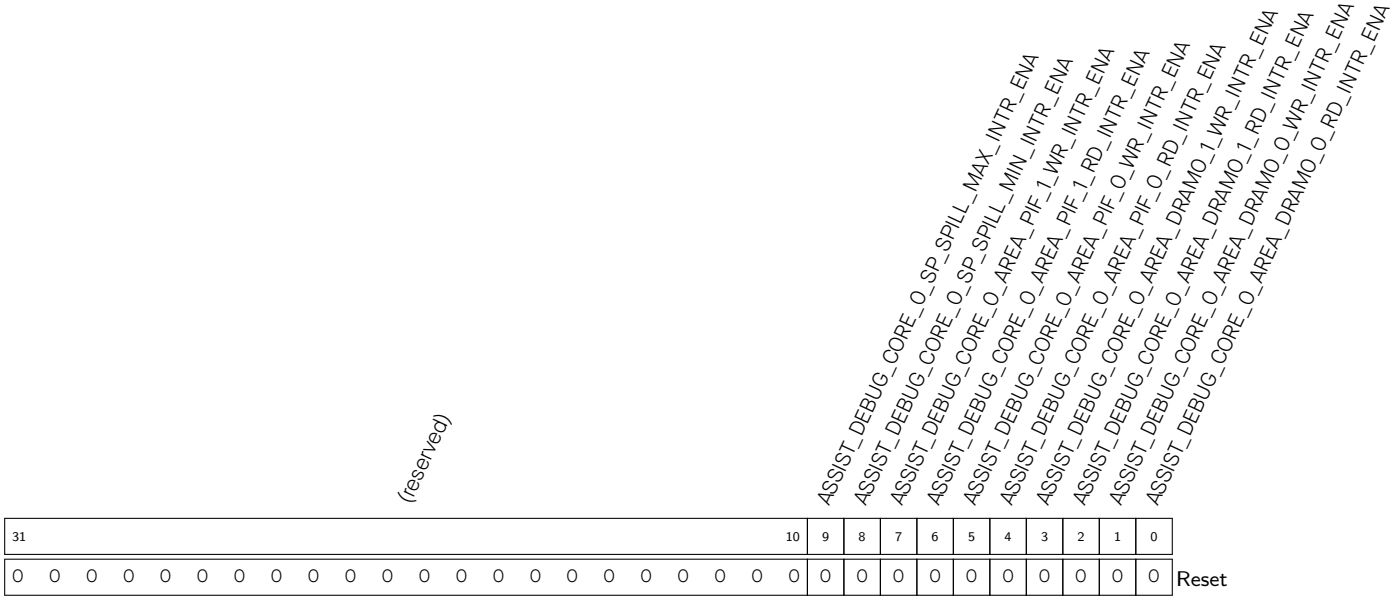
ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_WR_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_WR_INT. (RO)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_RD_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_RD_INT. (RO)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_WR_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_WR_INT. (RO)

ASSIST_DEBUG_CORE_0_AREA_PIF_0_RD_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_AREA_PIF_0_RD_INT. (RO)

ASSIST_DEBUG_CORE_0_AREA_PIF_0_WR_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_AREA_PIF_0_WR_INT. (RO)



ASSIST_DEBUG_CORE_0_AREA_PIF_1_RD_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_AREA_PIF_1_RD_INT. (RO)

ASSIST_DEBUG_CORE_0_AREA_PIF_1_WR_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_AREA_PIF_1_WR_INT. (RO)

ASSIST_DEBUG_CORE_0_SP_SPILL_MIN_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_SP_SPILL_MIN_INT. (RO)

ASSIST_DEBUG_CORE_0_SP_SPILL_MAX_RAW The raw interrupt status of ASSIST_DEBUG_CORE_0_SP_SPILL_MAX_INT. (RO)

Register 22.41. ASSIST_DEBUG_CORE_0_INTR_ENA_REG (0x0008)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_RD_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_RD_INT. (R/W)

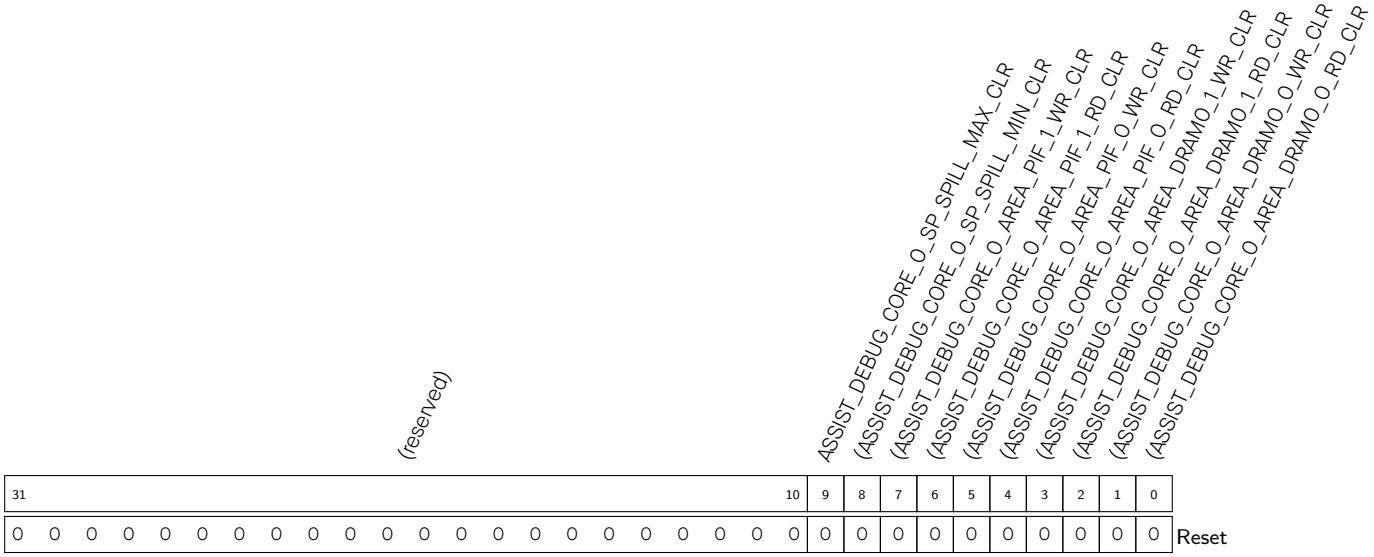
ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_WR_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_WR_INT. (R/W)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_RD_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_RD_INT. (R/W)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_WR_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_WR_INT. (R/W)

ASSIST_DEBUG_CORE_0_AREA_PIF_0_RD_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_AREA_PIF_0_RD_INT. (R/W)

ASSIST_DEBUG_CORE_0_AREA_PIF_0_WR_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_AREA_PIF_0_WR_INT. (R/W)



ASSIST_DEBUG_CORE_0_AREA_PIF_1_RD_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_AREA_PIF_1_RD_INT. (R/W)

ASSIST_DEBUG_CORE_0_AREA_PIF_1_WR_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_AREA_PIF_1_WR_INT. (R/W)

ASSIST_DEBUG_CORE_0_SP_SPILL_MIN_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_SP_SPILL_MIN_INT. (R/W)

ASSIST_DEBUG_CORE_0_SP_SPILL_MAX_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_0_SP_SPILL_MAX_INT. (R/W)

Register 22.42. ASSIST_DEBUG_CORE_0_INTR_CLR_REG (0x000C)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_RD_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_AREA_DRAM0_0_RD_INT. (WT)

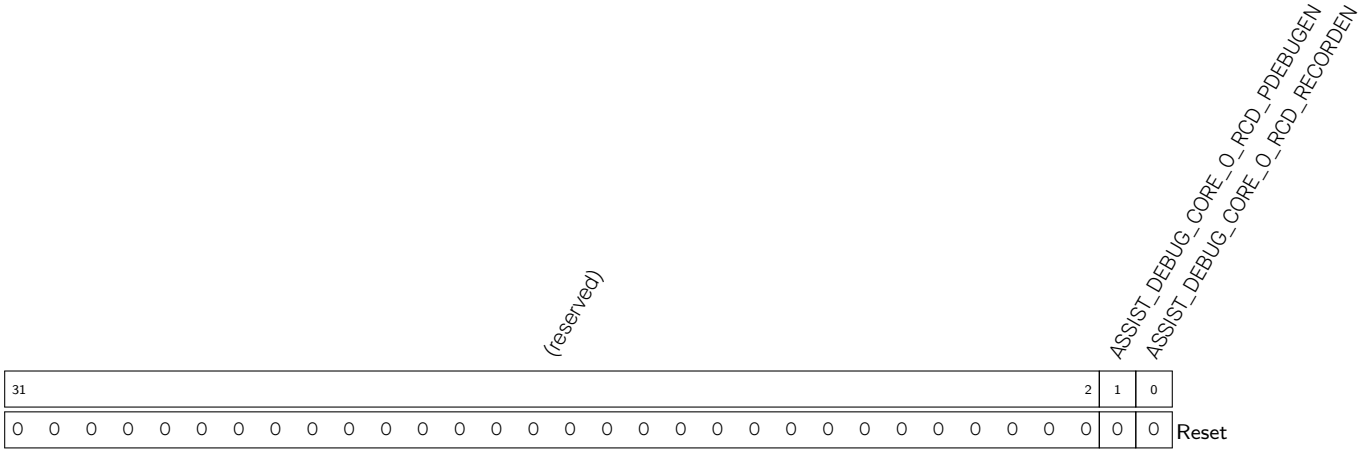
ASSIST_DEBUG_CORE_0_AREA_DRAM0_0_WR_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_AREA_DRAM0_0_WR_INT. (WT)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_RD_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_AREA_DRAM0_1_RD_INT. (WT)

ASSIST_DEBUG_CORE_0_AREA_DRAM0_1_WR_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_AREA_DRAM0_1_WR_INT. (WT)

ASSIST_DEBUG_CORE_0_AREA_PIF_0_RD_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_AREA_PIF_0_RD_INT. (WT)

ASSIST_DEBUG_CORE_0_AREA_PIF_0_WR_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_AREA_PIF_0_WR_INT. (WT)



ASSIST_DEBUG_CORE_0_AREA_PIF_1_RD_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_AREA_PIF_1_RD_INT. (WT)

ASSIST_DEBUG_CORE_0_AREA_PIF_1_WR_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_AREA_PIF_1_WR_INT. (WT)

ASSIST_DEBUG_CORE_0_SP_SPILL_MIN_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_SP_SPILL_MIN_INT. (WT)

ASSIST_DEBUG_CORE_0_SP_SPILL_MAX_CLR Write 1 to clear AS-SIST_DEBUG_CORE_0_SP_SPILL_MAX_INT. (WT)

Register 22.43. ASSIST_DEBUG_CORE_0_RCD_EN_REG (0x0044)

ASSIST_DEBUG_CORE_0_RCD_RECORDEN Configures whether to enable HP CPU0 PC logging.

0: Disable

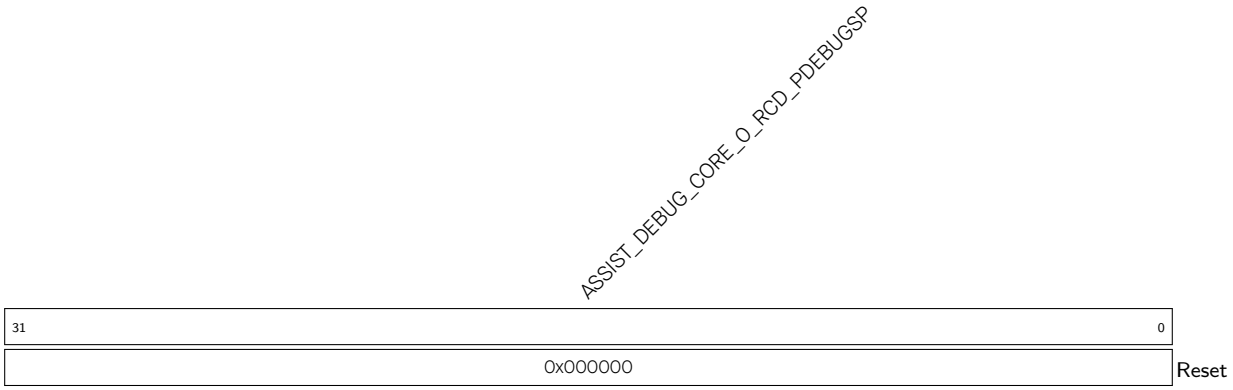
1: ASSIST_DEBUG_CORE_0_RCD_PDEBUGPC_REG starts to record HP CPU0 PC in real time

(R/W)

ASSIST_DEBUG_CORE_0_RCD_PDEBUGEN Configures whether to enable HP CPU0 debugging.

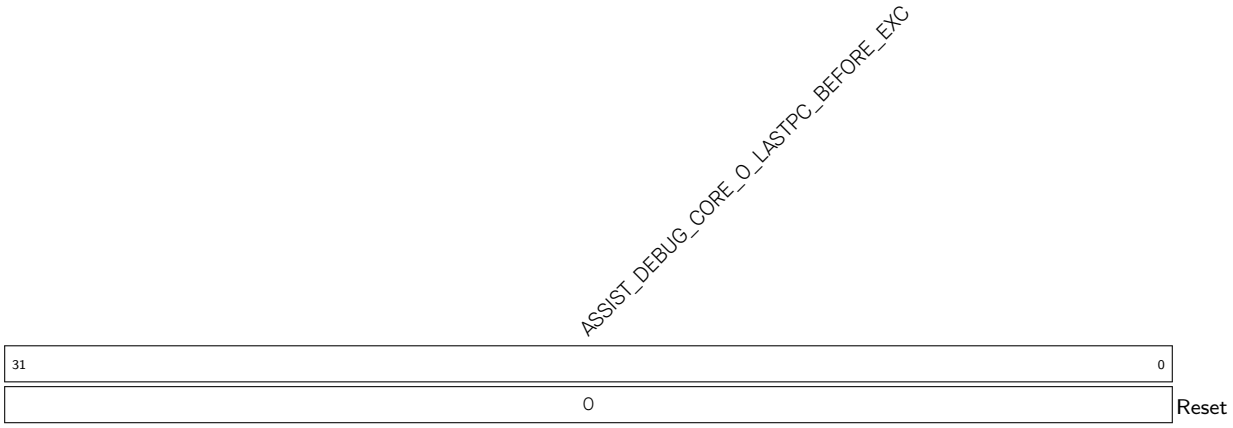
0: Disable

1: HP CPU0 outputs HP CPU0 PC



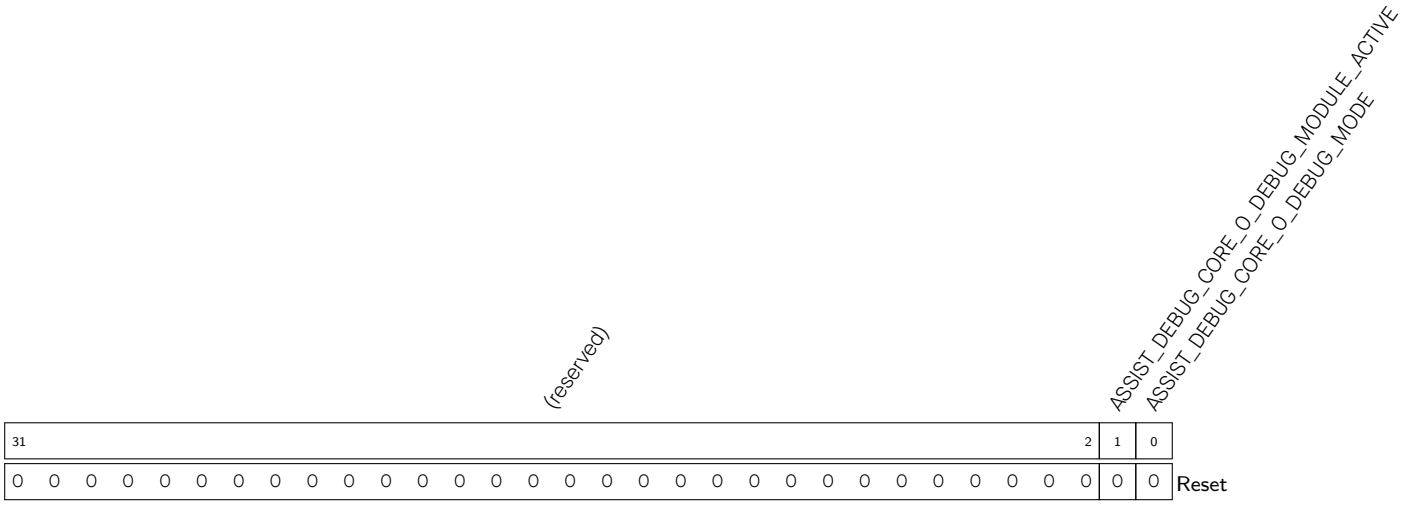
(R/W)

Register 22.44. ASSIST_DEBUG_CORE_0_RCD_PDEBUGPC_REG (0x0048)



ASSIST_DEBUG_CORE_0_RCD_PDEBUGPC Represents the PC value at HP CPU0 reset. (RO)

Register 22.45. ASSIST_DEBUG_CORE_0_RCD_PDEBUGSP_REG (0x004C)



ASSIST_DEBUG_CORE_0_RCD_PDEBUGSP Represents the HP CPU0 SP. (RO)

Register 22.46. ASSIST_DEBUG_CORE_0_LASTPC_BEFORE_EXCEPTION_REG (0x0070)

ASSIST_DEBUG_CORE_0_LASTPC_BEFORE_EXC Represents the HP CPU0 PC of the last command before the HP CPU0 enters exception. (RO)

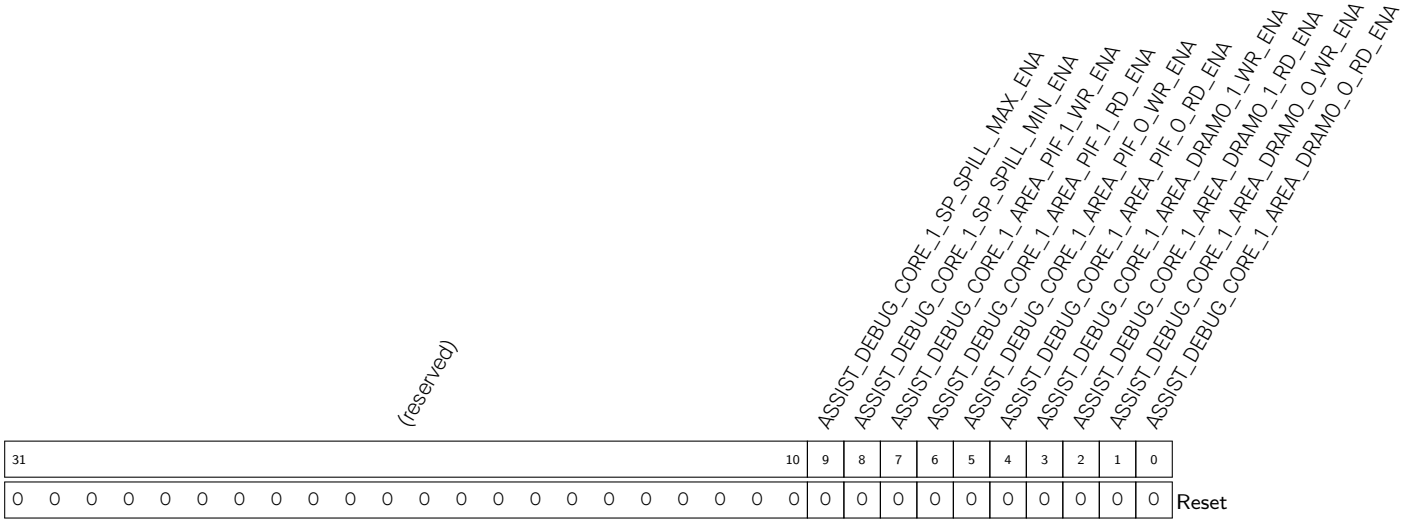
Register 22.47. ASSIST_DEBUG_CORE_0_DEBUG_MODE_REG (0x0074)

ASSIST_DEBUG_CORE_0_DEBUG_MODE Represents whether HP CPU0 is in debugging mode.

1: In debugging mode

0: Not in debugging mode

(RO)



ASSIST_DEBUG_CORE_0_DEBUG_MODULE_ACTIVE Represents the status of the HP CPU0 debug module.

1: Active status

Other: Inactive status

(RO)

Register 22.48. ASSIST_DEBUG_CORE_1_MONTR_ENA_REG (0x0080)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_RD_ENA Configures whether to monitor read operations in HP CPU1 region 0 by the HP CPU1 Data bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_WR_ENA Configures whether to monitor write operations in HP CPU1 region 0 by the HP CPU1 Data bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_RD_ENA Configures whether to monitor read operations in HP CPU1 region 1 by the HP CPU1 Data bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_WR_ENA Configures whether to monitor write operations in HP CPU1 region 1 by the HP CPU1 Data bus.

0: Not monitor

1: Monitor

(R/W)

ASSIST_DEBUG_CORE_1_AREA_PIF_0_RD_ENA Configures whether to monitor read operations in HP CPU1 region 0 by the HP CPU1 Peripheral bus.

0: Not monitor

1: Monitor

(R/W)

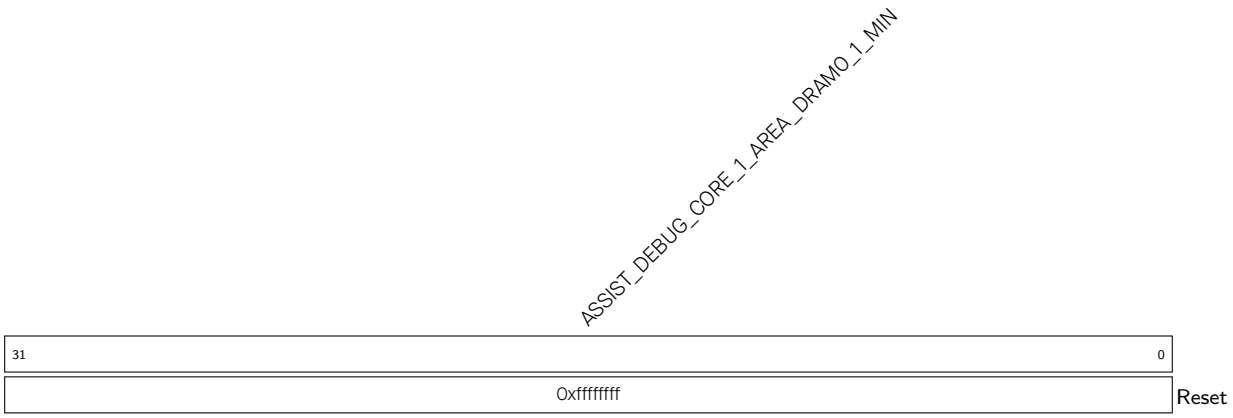
ASSIST_DEBUG_CORE_1_SP_SPILL_MAX_ENA Configures whether to monitor HP CPU1 SP going beyond the upper bound address of HP CPU1 SP monitored region.
0: Not monitor
1: Monitor
(R/W)

Register 22.49. ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_MIN_REG (0x0090)



ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_MIN Configures the lower bound address of HP CPU1 Data bus region 0. (R/W)

Register 22.50. ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_MAX_REG (0x0094)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_MAX Configures the upper bound address of HP CPU1 Data bus region 0. (R/W)

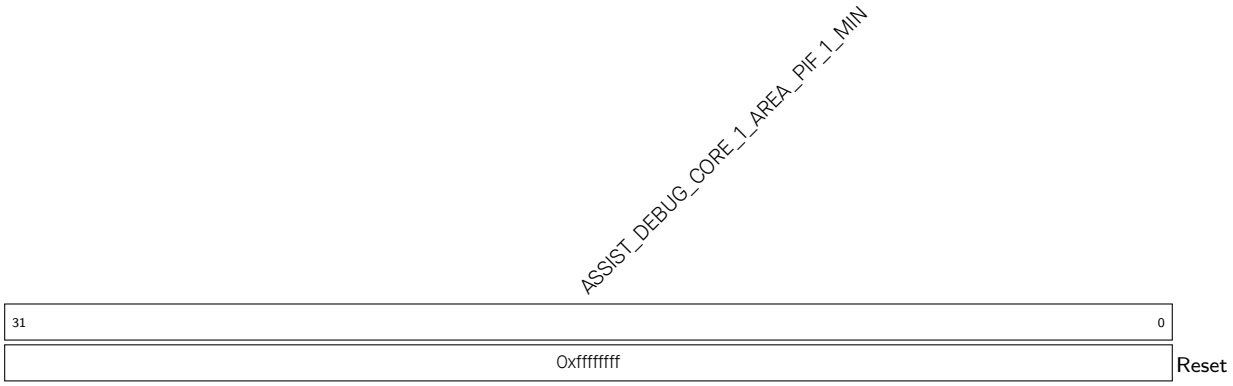
Register 22.51. ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_MIN_REG (0x0098)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_MIN Configures the lower bound address of HP CPU1 Data bus region 1. (R/W)

Register 22.52. ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_MAX_REG (0x009C)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_MAX Configures the upper bound address of HP CPU1 Data bus region 1. (R/W)

Register 22.53. ASSIST_DEBUG_CORE_1_AREA_PIF_0_MIN_REG (0x00A0)

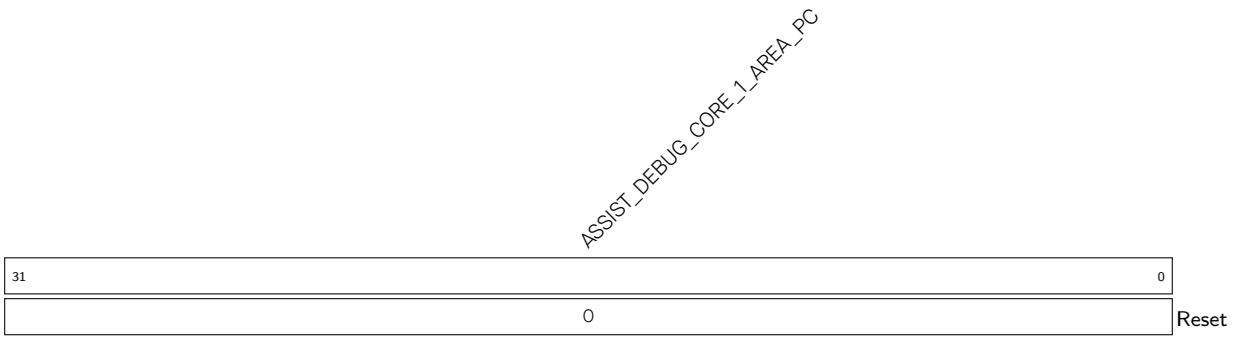


ASSIST_DEBUG_CORE_1_AREA_PIF_0_MIN Configures the lower bound address of HP CPU1 Peripheral bus region 0. (R/W)

Register 22.54. ASSIST_DEBUG_CORE_1_AREA_PIF_0_MAX_REG (0x00A4)

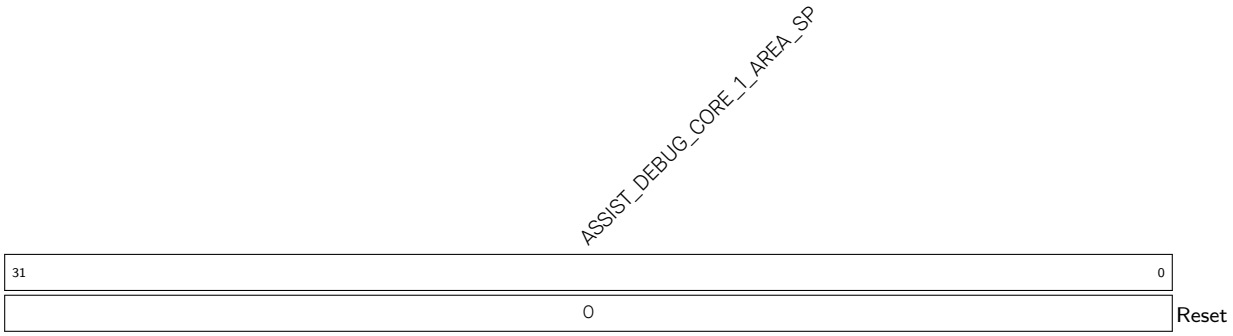
ASSIST_DEBUG_CORE_1_AREA_PIF_0_MAX Configures the upper bound address of HP CPU1 Peripheral bus region 0. (R/W)

Register 22.55. ASSIST_DEBUG_CORE_1_AREA_PIF_1_MIN_REG (0x00A8)



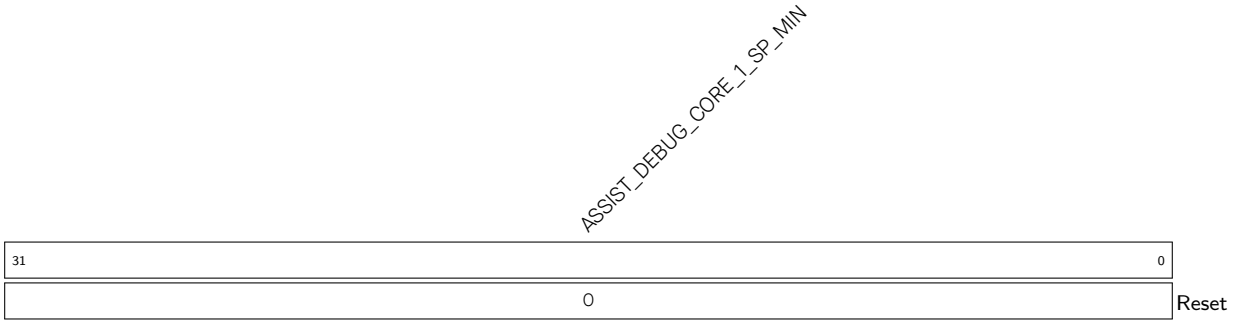
ASSIST_DEBUG_CORE_1_AREA_PIF_1_MIN Configures the lower bound address of HP CPU1 Peripheral bus region 1. (R/W)

Register 22.56. ASSIST_DEBUG_CORE_1_AREA_PIF_1_MAX_REG (0x00AC)



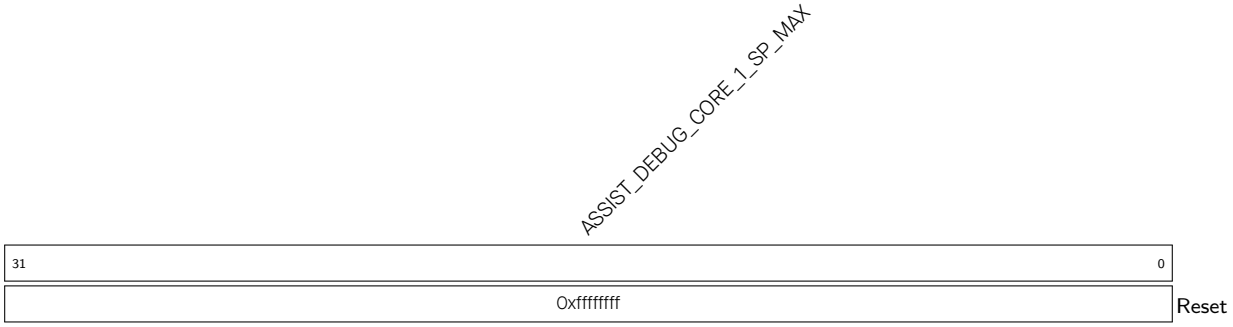
ASSIST_DEBUG_CORE_1_AREA_PIF_1_MAX Configures the upper bound address of HP CPU1 Peripheral bus region 1. (R/W)

Register 22.57. ASSIST_DEBUG_CORE_1_AREA_PC_REG (0x00B0)



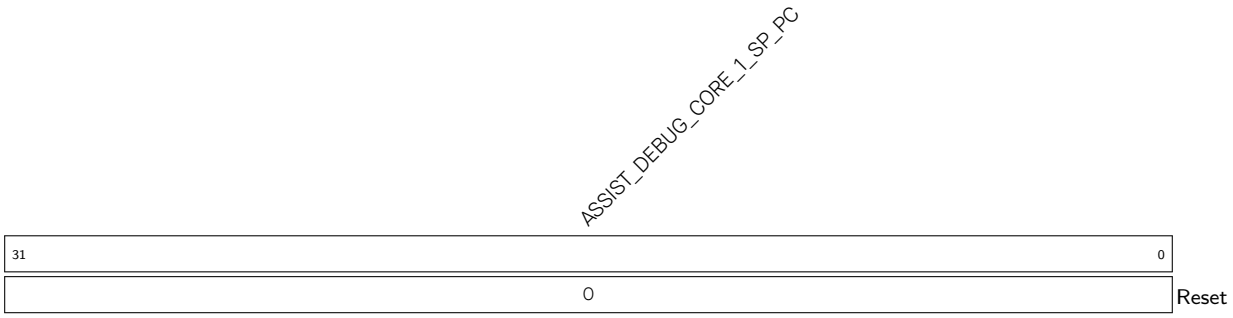
ASSIST_DEBUG_CORE_1_AREA_PC Represents the HP CPU1 PC value when an interrupt is triggered during region monitoring. (RO)

Register 22.58. ASSIST_DEBUG_CORE_1_AREA_SP_REG (0x00B4)



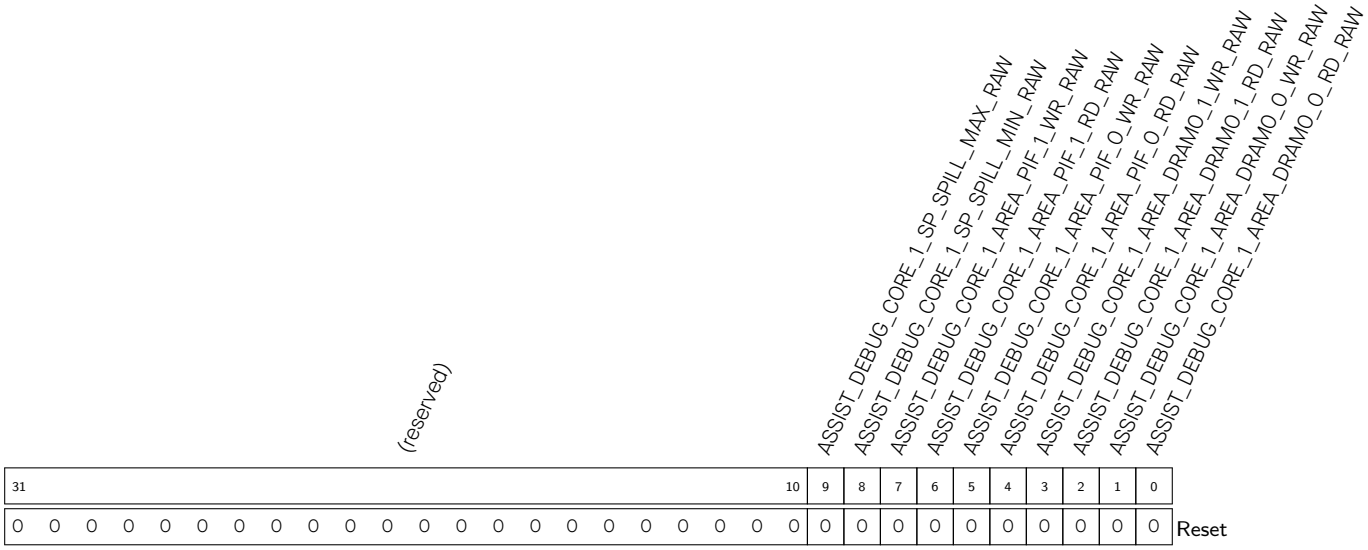
ASSIST_DEBUG_CORE_1_AREA_SP Represents the HP CPU1 SP value when an interrupt is triggered during region monitoring. (RO)

Register 22.59. ASSIST_DEBUG_CORE_1_SP_MIN_REG (0x00B8)



ASSIST_DEBUG_CORE_1_SP_MIN Configures the lower bound address of the HP CPU1 SP monitored region. (R/W)

Register 22.60. ASSIST_DEBUG_CORE_1_SP_MAX_REG (0x00BC)



ASSIST_DEBUG_CORE_1_SP_MAX Configures the upper bound address of the HP CPU1 SP monitored region. (R/W)

Register 22.61. ASSIST_DEBUG_CORE_1_SP_PC_REG (0x00C0)

ASSIST_DEBUG_CORE_1_SP_PC Represents the HP CPU1 PC value during SP monitoring. (RO)

Register 22.62. ASSIST_DEBUG_CORE_1_INTR_RAW_REG (0x0084)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_RD_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_RD_INT. (RO)

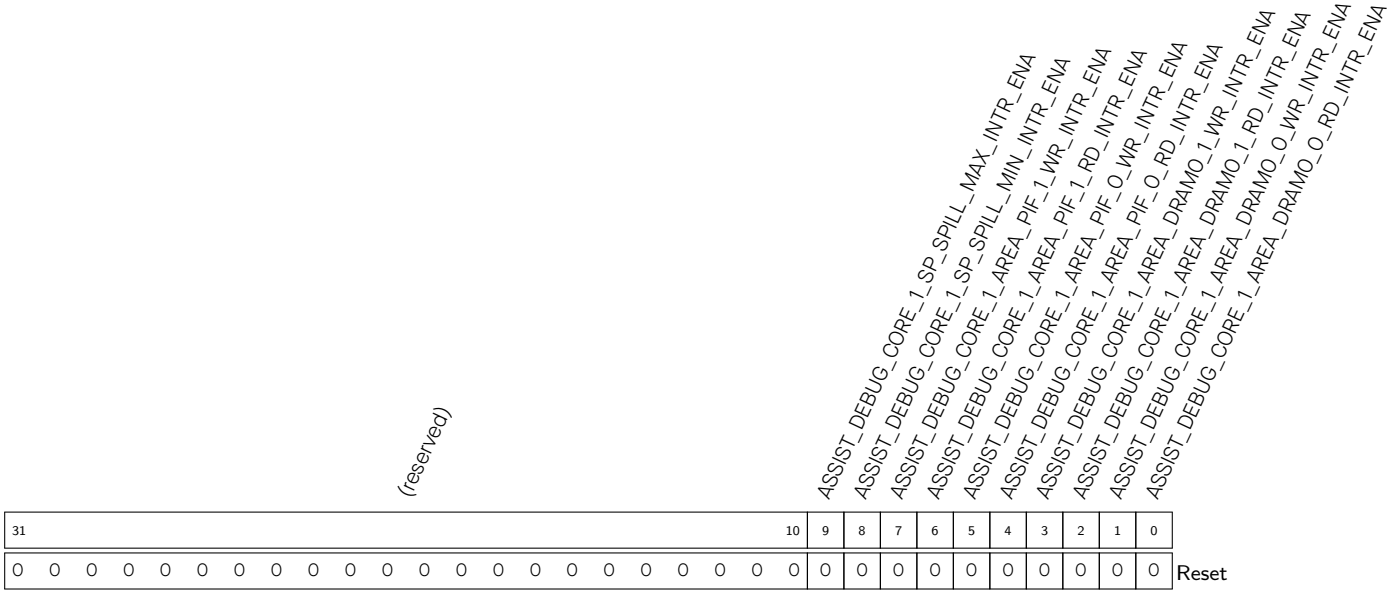
ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_WR_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_WR_INT. (RO)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_RD_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_RD_INT. (RO)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_WR_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_WR_INT. (RO)

ASSIST_DEBUG_CORE_1_AREA_PIF_0_RD_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_AREA_PIF_0_RD_INT. (RO)

ASSIST_DEBUG_CORE_1_AREA_PIF_0_WR_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_AREA_PIF_0_WR_INT. (RO)



ASSIST_DEBUG_CORE_1_AREA_PIF_1_RD_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_AREA_PIF_1_RD_INT. (RO)

ASSIST_DEBUG_CORE_1_AREA_PIF_1_WR_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_AREA_PIF_1_WR_INT. (RO)

ASSIST_DEBUG_CORE_1_SP_SPILL_MIN_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_SP_SPILL_MIN_INT. (RO)

ASSIST_DEBUG_CORE_1_SP_SPILL_MAX_RAW The raw interrupt status of ASSIST_DEBUG_CORE_1_SP_SPILL_MAX_INT. (RO)

Register 22.63. ASSIST_DEBUG_CORE_1_INTR_ENA_REG (0x0088)

ASSIST_DEBUG_CORE_1_AREA_DRAMO_0_RD_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_AREA_DRAMO_0_RD_INT. (R/W)

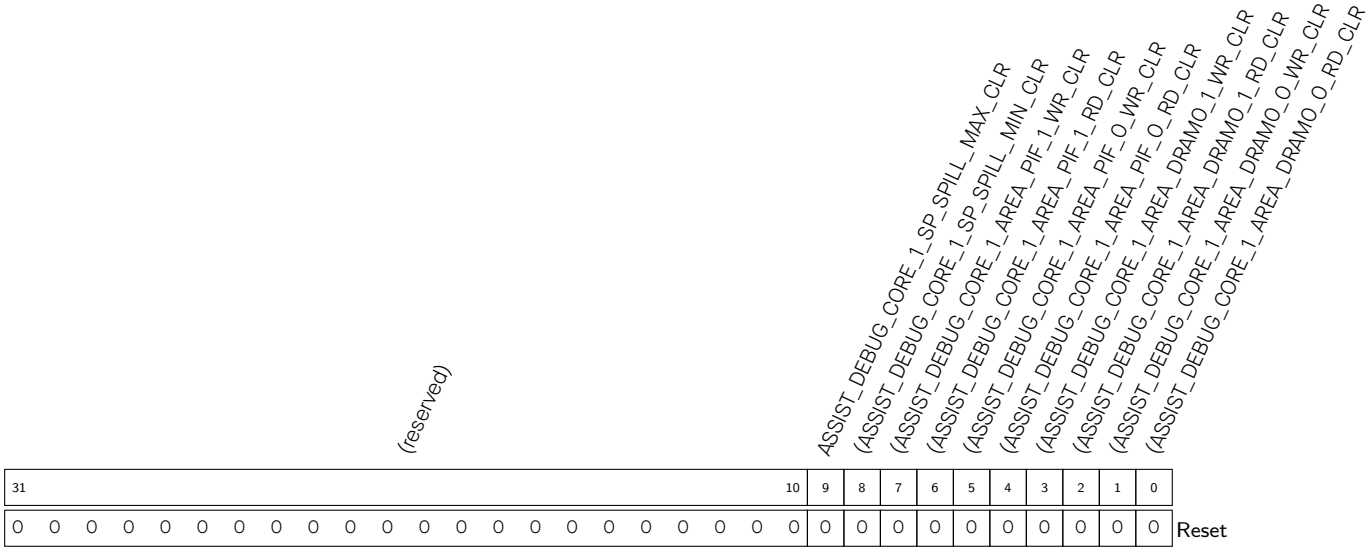
ASSIST_DEBUG_CORE_1_AREA_DRAMO_0_WR_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_AREA_DRAMO_0_WR_INT. (R/W)

ASSIST_DEBUG_CORE_1_AREA_DRAMO_1_RD_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_AREA_DRAMO_1_RD_INT. (R/W)

ASSIST_DEBUG_CORE_1_AREA_DRAMO_1_WR_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_AREA_DRAMO_1_WR_INT. (R/W)

ASSIST_DEBUG_CORE_1_AREA_PIF_0_RD_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_AREA_PIF_0_RD_INT. (R/W)

ASSIST_DEBUG_CORE_1_AREA_PIF_0_WR_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_AREA_PIF_0_WR_INT. (R/W)



ASSIST_DEBUG_CORE_1_AREA_PIF_1_RD_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_AREA_PIF_1_RD_INT. (R/W)

ASSIST_DEBUG_CORE_1_AREA_PIF_1_WR_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_AREA_PIF_1_WR_INT. (R/W)

ASSIST_DEBUG_CORE_1_SP_SPILL_MIN_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_SP_SPILL_MIN_INT. (R/W)

ASSIST_DEBUG_CORE_1_SP_SPILL_MAX_INTR_ENA Write 1 to enable ASSIST_DEBUG_CORE_1_SP_SPILL_MAX_INT. (R/W)

Register 22.64. ASSIST_DEBUG_CORE_1_INTR_CLR_REG (0x008C)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_RD_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_AREA_DRAM0_0_RD_INT. (WT)

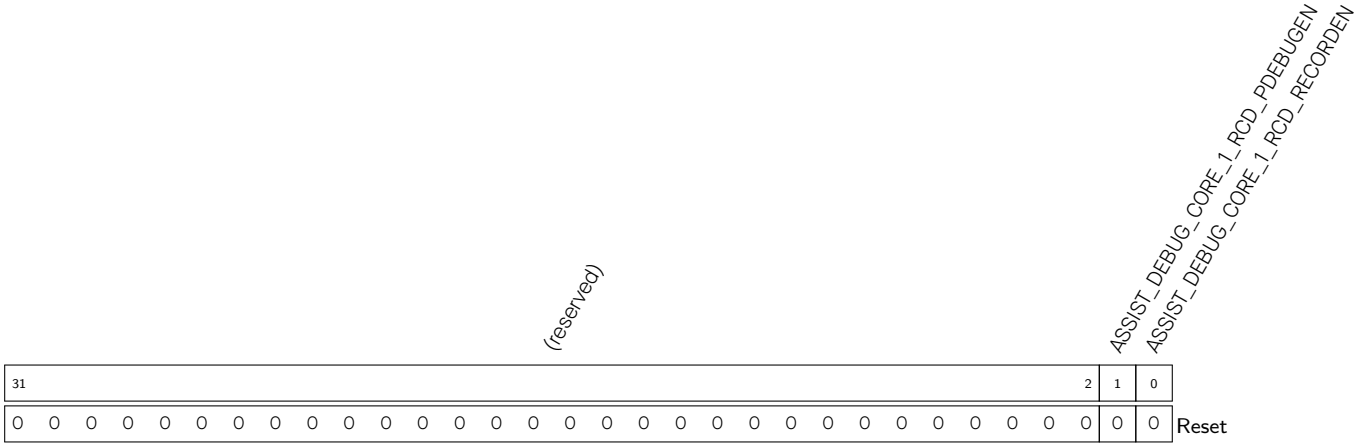
ASSIST_DEBUG_CORE_1_AREA_DRAM0_0_WR_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_AREA_DRAM0_0_WR_INT. (WT)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_RD_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_AREA_DRAM0_1_RD_INT. (WT)

ASSIST_DEBUG_CORE_1_AREA_DRAM0_1_WR_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_AREA_DRAM0_1_WR_INT. (WT)

ASSIST_DEBUG_CORE_1_AREA_PIF_0_RD_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_AREA_PIF_0_RD_INT. (WT)

ASSIST_DEBUG_CORE_1_AREA_PIF_0_WR_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_AREA_PIF_0_WR_INT. (WT)



ASSIST_DEBUG_CORE_1_AREA_PIF_1_RD_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_AREA_PIF_1_RD_INT. (WT)

ASSIST_DEBUG_CORE_1_AREA_PIF_1_WR_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_AREA_PIF_1_WR_INT. (WT)

ASSIST_DEBUG_CORE_1_SP_SPILL_MIN_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_SP_SPILL_MIN_INT. (WT)

ASSIST_DEBUG_CORE_1_SP_SPILL_MAX_CLR Write 1 to clear AS-SIST_DEBUG_CORE_1_SP_SPILL_MAX_INT. (WT)

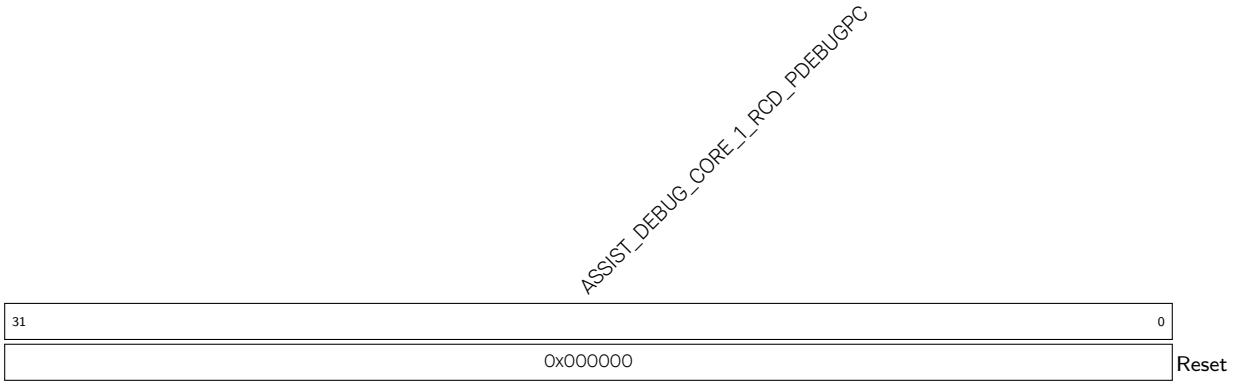
Register 22.65. ASSIST_DEBUG_CORE_1_RCD_EN_REG (0x00C4)

ASSIST_DEBUG_CORE_1_RCD_RECORDEN Configures whether to enable HP CPU1 PC logging.

0: Disable

1: ASSIST_DEBUG_CORE_1_RCD_PDEBUGPC_REG starts to record HP CPU1 PC in real time

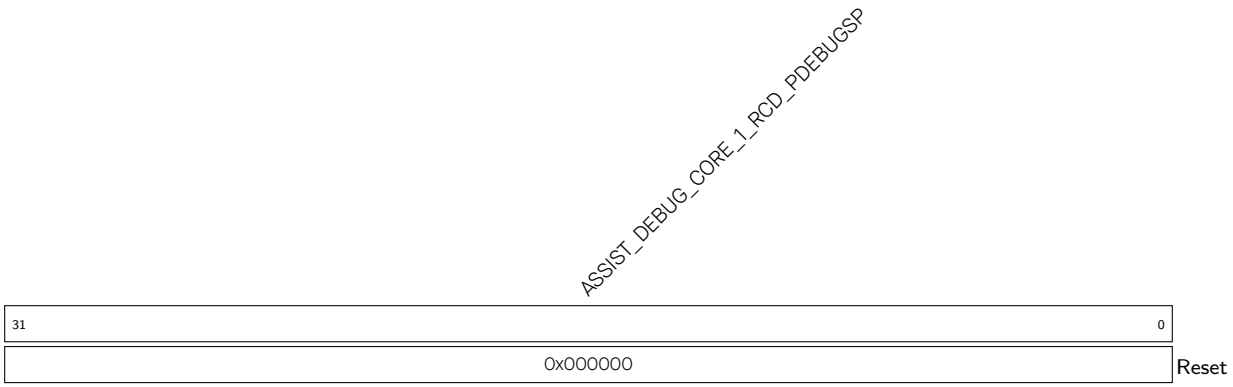
(R/W)



ASSIST_DEBUG_CORE_1_RCD_PDEBUGEN Configures whether to enable HP CPU1 debugging.

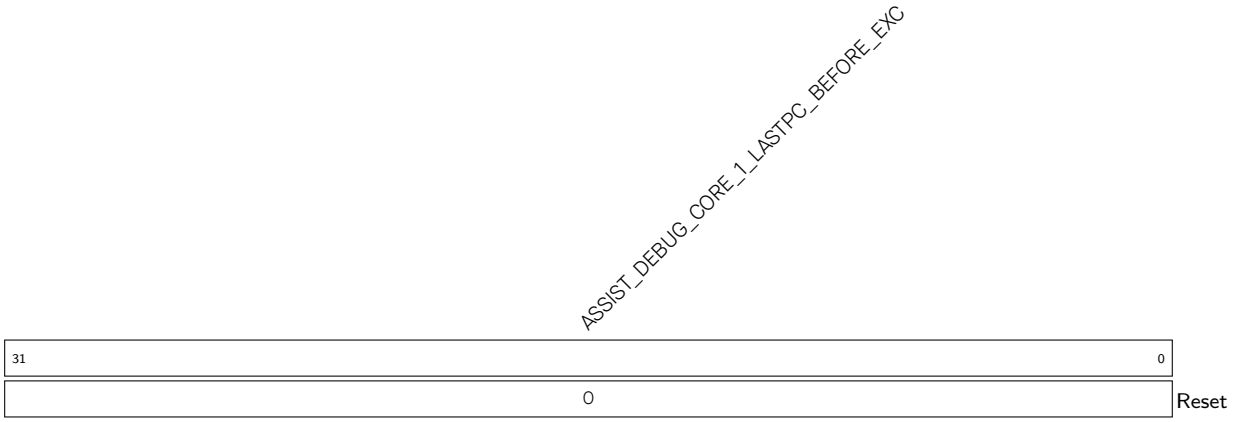
0: Disable

1: HP CPU1 outputs HP CPU1 PC



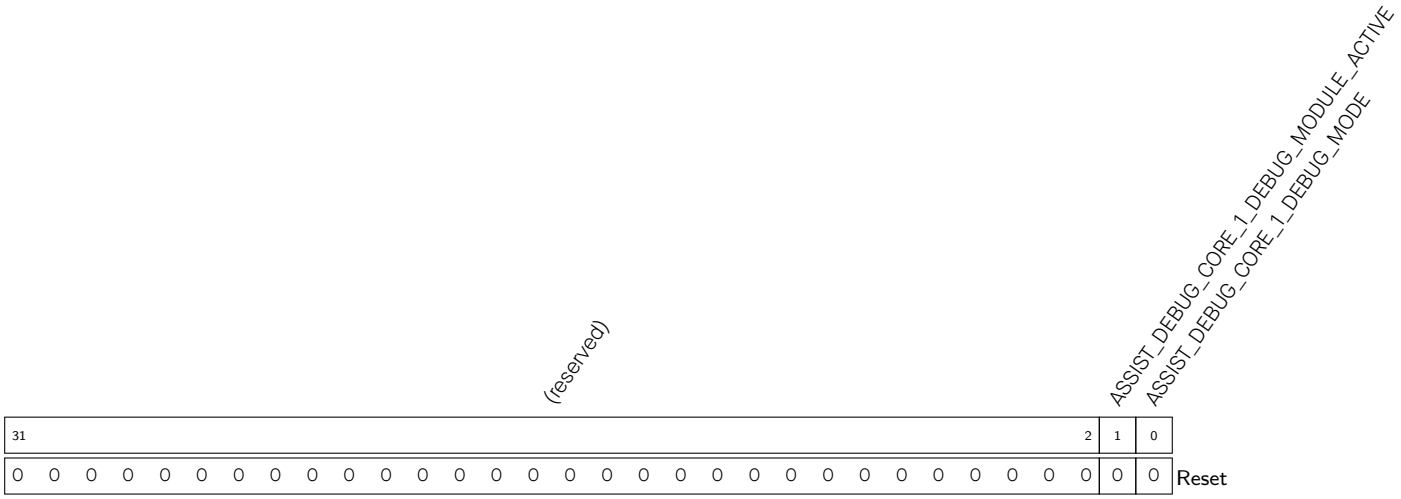
(R/W)

Register 22.66. ASSIST_DEBUG_CORE_1_RCD_PDEBUGPC_REG (0x00C8)



ASSIST_DEBUG_CORE_1_RCD_PDEBUGPC Represents the PC value at HP CPU1 reset. (RO)

Register 22.67. ASSIST_DEBUG_CORE_1_RCD_PDEBUGSP_REG (0x00CC)



ASSIST_DEBUG_CORE_1_RCD_PDEBUGSP Represents the HP CPU1 SP. (RO)

Register 22.68. ASSIST_DEBUG_CORE_1_LASTPC_BEFORE_EXCEPTION_REG (0x00F0)

ASSIST_DEBUG_CORE_1_LASTPC_BEFORE_EXC Represents the HP CPU1 PC of the last command before the HP CPU1 enters exception. (RO)

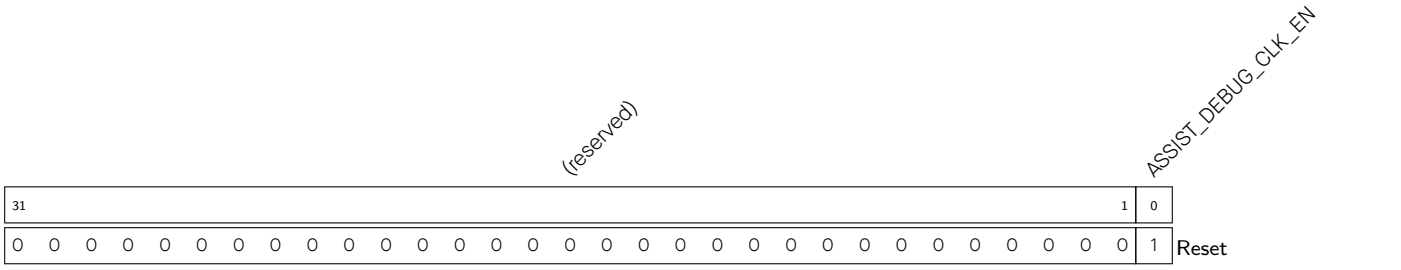
Register 22.69. ASSIST_DEBUG_CORE_1_DEBUG_MODE_REG (0x00F4)

ASSIST_DEBUG_CORE_1_DEBUG_MODE Represents whether HP CPU1 is in debugging mode.

1: In debugging mode

0: Not in debugging mode

(RO)



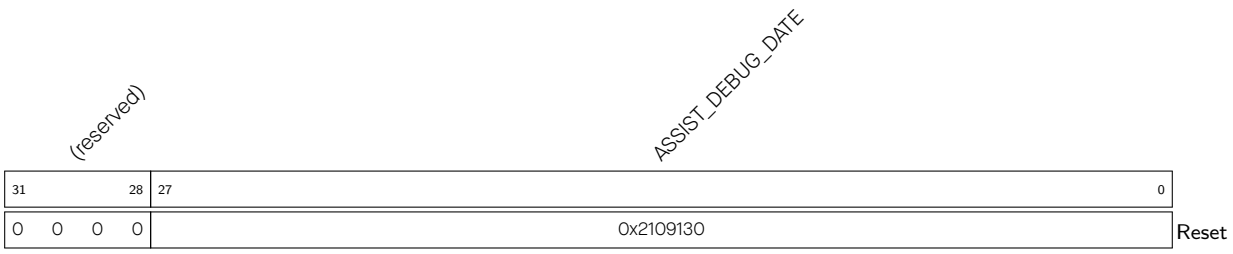
ASSIST_DEBUG_CORE_1_DEBUG_MODULE_ACTIVE Represents the status of the HP CPU1 debug module.

1: Active status

Other: Inactive status

(RO)

Register 22.70. ASSIST_DEBUG_CLOCK_GATE_REG (0x0108)



ASSIST_DEBUG_CLK_EN Configures whether to enable the register clock gating.

0: Disable

1: Enable

(R/W)

Register 22.71. ASSIST_DEBUG_DATE_REG (0x03FC)

ASSIST_DEBUG_DATE Version control register. (R/W)

Chapter 23

AXI Performance Monitor

23.1 Overview

The Advanced eXtensible Interface Performance Monitor (AXI Perf Mon) is used to monitor AXI bus transfer activities in real time and provide monitoring results based on measured metrics. Software can use these results to evaluate the current status of bus transfers, including performance-related data such as bandwidth and latency, for software testing or debugging.

AXI Perf Mon has nine monitoring ports, each corresponding to a device on the AXI matrix, including cache, vdma_mst1, vdma_mst2, 2d-dma, h264-dma_mst1, h264-dma_mst2, psram, camera, and lcd. AXI Perf Mon contains two monitoring units internally. Each monitoring unit is identical and completely independent, and is shared by all monitoring ports. Before starting monitoring, users can assign each unit to any port to monitor the bus behavior of the corresponding port.

23.2 Terminology

To better illustrate the functionality of AXI Perf Mon, the following terms are used in this chapter.

AXI Advanced eXtensible Interface, a part of the AMBA 3 (Advanced Microcontroller Bus Architecture) protocol that provides high-bandwidth, low-latency data transfer between memory and peripherals, or between memory blocks.

agent A device on the AXI bus, including both AXI Master interfaces and Slave interfaces.

outstanding In the AXI protocol, when the address of an AXI transaction has been accepted by the Slave, but the final response (BRESP/RRESP) has not yet been returned to the Master, the transaction is in the outstanding (pending/in-flight) state.

burst In the AXI protocol, burst transfer refers to a mechanism that completes multiple data transfers through consecutive data beats after a single address handshake. Burst is introduced to reduce the repeated overhead of the address channel and improve bus bandwidth utilization and transfer efficiency. A burst transfer consists of one address phase and multiple data phases, where the address phase occurs only once at the beginning of the burst, and subsequent data beats are consecutively transferred according to established rules until the burst ends.

AWVALID/AWREADY Handshake signals for address channel transfer in the AXI protocol. AWVALID asserted high indicates that the upstream initiates a write command transfer request, AWREADY asserted high indicates that the downstream responds to the upstream write command transfer request, and a successful handshake completes one write command transfer. ARVALID/ARREADY work similarly, representing read transfer command handshake.

WVALID/WREADY Handshake signals for data channel transfer in the AXI protocol. WVALID asserted high indicates that the upstream initiates a write data transfer request; WREADY asserted high indicates that the downstream responds to the upstream write data transfer request, and a successful handshake completes one beat of write data transfer. RVALID/RREADY work similarly, but read data originates from the downstream and the upstream receives the data, and a successful handshake completes one beat of read data transfer.

APB Advanced Peripheral Bus (APB) is a low-bandwidth, low-power bus protocol mainly used to connect low-speed peripherals (such as GPIO, timers, UART, ADC, etc.) with the system's main processor or other high-performance modules. APB is part of the ARM AMBA (Advanced Microcontroller Bus Architecture) bus family, forming the bus architecture of AMBA systems together with AHB (Advanced High-performance Bus) and AXI (Advanced eXtensible Interface).

port A logical interface at the boundary of a module for signal communication with external logic.

unit A hardware block that implements a specific function within a larger design. In this article, this refers to the unit responsible for performance monitoring.

n/*m* In the section on registers, the notation *n*/*m* is frequently used for indexing. *n* represents monitoring unit 0 or 1; *m* represents that each monitoring unit has multiple such registers. Refer to the register section for specific register quantities.

region In this design, a "region" is related to the concept of an address range, but with some distinctions. When monitoring instantaneous bandwidth, regions can be used to filter out irrelevant bandwidth statistics. A region must be defined based on complete slave addresses. It may include one or more entire slave address ranges, but it cannot filter only a portion of a single slave's address range.

23.3 Feature List

AXI Perf Mon has the following features:

- AXI3 bus interface compliance
- Two identical and independent monitoring units
- Nine monitoring ports
- Software-configurable mapping between monitoring units and monitoring ports
- Transaction ID filtering to exclude specific transactions from statistics
- Multiple measurement metrics available for user selection
  - Current outstanding transaction count for read/write address channels
  - Read/write address channel latency
  - Read/write data channel latency
  - Total idle cycles on write data channel within a single transaction
  - Read transaction latency
  - Write transaction latency

  - Average bandwidth measurement
  - Instantaneous bandwidth measurement
  - Instantaneous bandwidth range statistics and abnormal bandwidth recording
- Up to 6 measurement metric counters per monitoring unit
- Each counter can be configured independently, and each metric can be assigned to at most one counter within a monitoring unit
- Up to 6 range statistics metric counters per monitoring unit, i.e., supporting up to 6 range divisions for statistical analysis of instantaneous bandwidth monitoring results

23.4 Architectural Overview

Figure 23.4-1 shows the basic architecture of AXI Perf Mon.

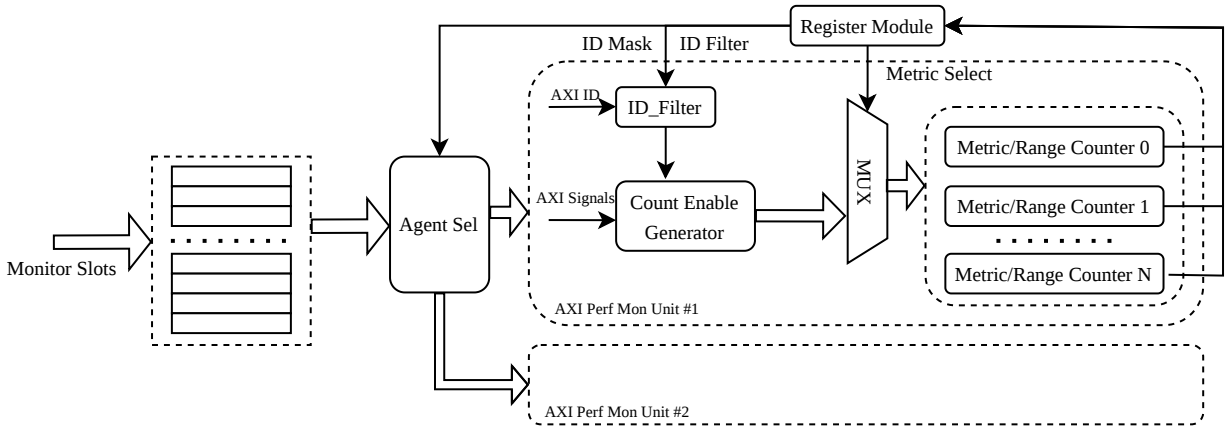


Figure 23.4-1. Architecture of AXI Perf Mon

AXI Perf Mon consists of the following functional modules:

- **Port Selection**: Selects which port to connect to the monitoring unit from the ports connected to AXI Perf Mon
- **ID Filtering**: Classifies monitoring events
- **Count Enable Generator**: Converts the metric information configured by users through registers into counter enable/disable controls
- **Counters**: Performs statistical counting

23.5 Functional Description

23.5.1 Clock

The AXI Perf Mon operates using two independent clock domains, each serving a specific interface:

- APB_CLK: APB bus clock used to configure AXI Perf Mon registers

- AXI_CLK: SoC system AXI bus clock

AXI Perf Mon is a system auxiliary debug component, so the clock is disabled by default during normal operation. To use AXI Perf Mon, the clock must be enabled first in the clock and reset module. The operating clock of the AXI Perf Mon monitoring unit is fully synchronous (same frequency and phase) with the clock of the monitored bus. All clock cycles mentioned in the following sections are based on the AXI_CLK of AXI Perf Mon.

For more information on clocks, see Chapter 11 *Reset and Clock*.

For detailed clock programming procedures, see Section 23.7 *Programming Procedures*.

23.5.2 Reset

AXI Perf Mon supports software reset, which can reset the entire module, including all monitoring units and registers.

Reset is performed by writing 1 and then 0 to the HP_SYS_CLKRST_REG_AXI_PERF_MON_SYS_RST_EN field.

23.5.3 Transaction ID Filtering

- In AXI transfer transactions, each transaction has a corresponding ID used to mark that transaction. Some Masters assign different transaction IDs to different types of transactions. The transaction ID filter is used to mask some transactions that the user is not concerned about, avoiding interference with statistical results.
- ID filtering can be configured through AXI_PERF_MON_SEL_AG*n*_RD_ID_MASK or AXI_PERF_MON_SEL_AG*n*_WR_ID_MASK (ID mask) and AXI_PERF_MON_SEL_AG*n*_RD_ID_FILTER or AXI_PERF_MON_SEL_AG*n*_WR_ID_FILTER (ID filter value).
- In the ID mask, 0 indicates an ignorable bit, and 1 indicates a bit used for filtering. If the transaction ID does not match the filter value on the bits where mask is 1, the transaction is masked and not included in statistics.
- ID filtering can be applied to both Master side and Slave side. Master-side AXI transaction IDs are 4 bits, while Slave-side transaction IDs are 8 bits.

23.5.4 Monitoring Metrics

AXI Perf Mon's port monitoring functionality is implemented by configuring the Metric Select Register (AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m*_REG), where:

- *n* represents which AXI Perf Mon unit does it belong to, ranging from 0 to 1.
- *m* represents the serial number of this register in each unit, ranging from 1 to 2.

Each register is divided into four 8-bit segments, indexed by *i* (ranging from 0 to 3). Within each segment, bits [8**i*+4:8**i*] are used to select a measurement metric, and bits [8**i*+7:8**i*+5] are used to select a range statistics metric.

The following tables show the correspondence between register configuration values and the two types of metrics: measurement metrics and range statistics metrics.

Table 23.5-1. Setting of Measurement Metrics in Metric Select Registers

Metric Select Register [8*i+4:8*i] Value	Measurement Metric
0	Invalid value
1	Write transaction outstanding count
2	Read transaction outstanding count
3	Write address channel latency
4	Read address channel latency
5	Write data channel latency
6	Read data channel latency
7	Write data channel WVALID idle cycles
8	Read transaction transfer latency
9	Write transaction transfer latency
10	Valid data transfer count for read transaction in average bandwidth measurement
11	Time duration for read transfers in average bandwidth measurement
12	Valid data transfer count for write transaction in average bandwidth measurement
13	Time duration for write transfers in average bandwidth measurement
14	Valid data transfer count for read transaction in instantaneous bandwidth measurement
15	Time duration for read transfers in instantaneous bandwidth measurement
16	Valid data transfer count for write transaction in instantaneous bandwidth measurement
17	Time duration for write transfers in instantaneous bandwidth measurement
18–31	Invalid values

Table 23.5-2. Correspondence between Metric Select Registers and Range Statistics Metrics

Metric Select Register [8*i+7:8*i+5] Value	Range Statistics Metric
0	Invalid value
1	Instantaneous bandwidth range distribution for read transactions
2	Instantaneous bandwidth range distribution for write transactions
3–7	Invalid values

By configuring the Agent Select Register (AXI_PERF_MON_AGENT_SELECT_REG), the monitoring port for each monitoring unit can be selected.

This register is divided into two segments, indexed by *i* (ranging from 0 to 1), each corresponding to the port selection configuration of monitoring unit *i*:

- Bits [4:0] select the agent monitored by monitoring unit 0.
- Bits [9:5] select the agent monitored by monitoring unit 1.

The correspondence between the register configuration values and actual agents is shown in the following table 23.5-3.

Table 23.5-3. Correspondence between Agent Select Register Configuration Values and Actual Agents

Agent Select Register [5*i+4:5*i] Value	Agent
0	Invalid value
1	cache
2	vdma_mst1
3	vdma_mst2
4	2d-dma
5	h264-dma_mst1
6	h264-dma_mst2
7	psram
8	camera
9	lcd
10–16	Invalid values

23.5.4.1 Maximum Outstanding Count for Read/Write Address Channel Transactions

Outstanding capability reflects the Master's concurrent capability for issuing AXI transfer transactions. The stronger the outstanding capability, the lower the transfer latency. In actual transfer processes, outstanding capability depends not only on the Master configuration, but also on the outstanding capability of bus components and upstream/downstream devices. AXI Perf Mon supports measuring the outstanding count of transactions on the current monitored port.

- For read transfers, after the address channel information is validly issued and before the data channel completes the last beat of data transfer corresponding to this transaction, one outstanding transfer is accumulated. If the data transfer completes, the outstanding count decreases by one.
- For write transfers, after the address channel information is validly issued and before the write response channel completes the response for this transaction, one outstanding transfer is accumulated. If the corresponding write response is received, the outstanding count decreases by one.
- During transfer, the outstanding value generally changes continuously. AXI Perf Mon writes the maximum outstanding value into the result register for software analysis.

23.5.4.2 Read/Write Address Channel Latency

Address channel latency represents how long it takes for a transfer command to be received after it is issued. AXI Perf Mon supports measuring the read/write address channel latency of transactions on the current monitored port.

- For read transfers, when the address channel ARVALID is asserted high, it indicates that the Master is ready to issue a read transaction command. The Slave asserts ARREADY high according to its current idle status. After ARREADY is asserted high, the address channel completes a transfer command

handshake. The read address channel latency is the number of cycles from ARVALID asserted high to ARREADY asserted high on the monitored port.

- The measurement method for write address channel latency is the same as for read address channel latency.
- During transfer, for the same monitored port, the latency value generally changes continuously. AXI Perf Mon writes the maximum/minimum read/write address channel latency values into the result register for software analysis.

23.5.4.3 Read/Write Data Channel Latency

For AXI transfers, after a burst transfer begins, it cannot be interrupted. However, in actual transfer processes, the data channel does not always perform back-to-back transfers, and idle cycles may exist during transfer. AXI Perf Mon supports measuring the read/write data channel latency of transactions on the current monitored port.

- For read transfers, when the data channel RVALID is asserted high, it indicates that the Slave is ready to send one beat of read transaction data. The Master asserts RREADY high according to its current idle status. After RREADY is asserted high, the read data channel completes one beat of data transfer handshake. The read data channel latency is the number of cycles from RVALID asserted high to RREADY asserted high on the monitored port.
- The measurement method for write data channel latency is the same as for read data channel latency.
- During transfer, for the same monitored port, the latency value generally changes continuously. AXI Perf Mon writes the maximum/minimum read/write data channel latency values into the result register for software analysis.

23.5.4.4 Write Data Channel WVALID Idle Cycles

When the Master begins sending a burst data transfer, idle cycles between data transfers may come from the Slave's wait time to receive data, idle cycles in the Master's WVALID, and significant idle cycles generated when passing through a conversion bridge. AXI Perf Mon supports measuring WVALID idle cycles within a transaction on the current monitored port.

- Within a write transaction, if the transfer is not yet complete and WVALID is deasserted, the total number of cycles that WVALID remains low is counted.
- During transfer, for the same monitored port, the statistics of WVALID idle cycles on the write data channel generally change continuously. AXI Perf Mon writes the maximum/minimum number of WVALID idle cycles on the write data channel into the result register for software analysis.

23.5.4.5 Read/Write Transaction Transfer Latency

During transfer processes, the latencies of the address channel and data channel are individually important. Additionally, the latency from address command issue to data channel ready is also important within a transaction. The transaction latency reflects the time interval from issuing a transfer command to starting data transfer, and can assist in determining the size of the Master-side AXI transfer buffer. AXI Perf Mon supports measuring the read/write transaction transfer latency for a transaction on the current monitored port.

- For read transfers, when ARVALID of a transaction is asserted high, the metric measurement counter starts counting latency until the RVALID signal of the first beat of data for this transaction is asserted high, at which point the counter stops counting, obtaining the read transaction transfer latency.
- For write transfers, when AWVALID of a transaction is asserted high, the metric measurement counter starts counting latency until the first beat of data for this transaction completes transfer (the counting end point differs from read transfers), at which point the counter stops counting, obtaining the write transaction transfer latency.
- A monitored port may have multiple outstanding transfers, but in read/write transaction transfer latency metrics, there is only one metric counter, so only one transaction's latency can be counted at a time. After starting to count a certain transaction, other concurrent transactions will be ignored until that count completes. To make statistics representative, transactions with longer transfer times are preferentially selected.
- During transfer, for the same monitored port, the transfer latency statistics generally change continuously. AXI Perf Mon writes the maximum/minimum transfer latency values into the result register for software analysis.

23.5.4.6 Average Bandwidth Measurement

Bandwidth is one of the most intuitive metrics for evaluating bus performance. AXI Perf Mon supports measuring average bandwidth.

- AXI Perf Mon does not have internal calculation units and does not directly calculate bandwidth values. Instead, it indirectly measures bandwidth by counting time (number of bus cycles) and data transfer amount (number of data units).
- Since both time and data amount need to be observed, average bandwidth measurement requires using two metric counters simultaneously. Bandwidth statistics ignore the impact of data strobes and count all data, including invalid data.
- When average bandwidth measurement is enabled, the time counter increments with the bus cycle, while the data amount increments according to the current data channel handshake status. After each burst transfer completes, the current time and data amount statistics are updated to the result register. If average bandwidth measurement is not turned off after data transfer completes and the data channel remains idle, the statistical results will remain at the time and data amount statistics from the end of the last burst transfer, without adding idle time. Software needs to calculate the actual average bandwidth based on the bus frequency and the number of data bytes per beat.

23.5.4.7 Instantaneous Bandwidth Measurement

Average bandwidth reflects device bandwidth demand over a longer period, but when evaluating bus performance, device bandwidth changes within shorter time windows (instantaneous bandwidth) should also be considered. AXI Perf Mon also supports measuring instantaneous bandwidth.

- Instantaneous bandwidth is measured through sliding time windows. After configuring the time window length (in basic units of bus cycles) and enabling instantaneous bandwidth measurement, measurement proceeds in a manner invisible to software. The start and stop behavior of measurement is completely controlled by hardware. When one time window measurement ends, the next time window measurement begins, performing continuous measurement.

- Instantaneous bandwidth measurement is basically the same as average bandwidth measurement and also requires two metric counters to measure time duration and data amount respectively. When the time counter reaches the register-configured time window value, it indicates that one instantaneous bandwidth measurement is complete. The counted data amount is fed back to the next-level extreme value comparator, and both the data amount counter and time counter are cleared to begin the next round of counting.
- Range statistics. If instantaneous bandwidth only records extreme values, it is insufficient to reflect bus transfer conditions. Therefore, range statistics are introduced. Range statistics are based on range statistics counters with software-configured range upper and lower limits. The number of these counters is the same as metric counters. After a metric counter completes its measurement, its result is compared against the ranges defined by the range counters for classification. This provides a better reflection of system behavior.
- Event recording. During instantaneous bandwidth measurement, the most recent four instantaneous bandwidth measurement values (the current uncompleted instantaneous bandwidth value is not counted) and the most recent four AXI interface transfer information (ID/Burst length) are written to registers. Address channel information is recorded during address channel handshake, while instantaneous bandwidth measurement values are recorded at the end of measurement windows, creating a time difference in recording. This information is updated synchronously according to actual transfer conditions, facilitating software understanding of current transfer basics.
- Abnormal feedback. During instantaneous bandwidth measurement, abnormal bandwidth changes are also reported. A minimum instantaneous bandwidth threshold (based on data amount) is set for the monitored port, representing the minimum instantaneous bandwidth value considered non-abnormal for this port during transfer. Once the metric counter result is less than this threshold, an interrupt flag signal is triggered and broadcast to all AXI Perf Mon Units, stopping instantaneous bandwidth measurement for all ports. Event recording stops and the scene is preserved. Based on event recording results, it assists in determining which device seized bandwidth. Software can also configure AXI_PERF_MON_SEL_AG0_SW_RECORD_STOP_EN or AXI_PERF_MON_SEL_AG1_SW_RECORD_STOP_EN to pause event recording for the corresponding monitoring unit.
- Address filtering. Generally, accessing internal storage does not require additional bandwidth attention. During instantaneous bandwidth measurement, if abnormal feedback is needed, it is generally when multiple Masters simultaneously access the same external storage such as PSRAM. When analyzing abnormal results, other Masters' access to other Slaves needs to be excluded, as this bandwidth is invalid for the analyzed scenario. Therefore, address filtering functionality is added to filter based on access addresses, obtaining the true instantaneous bandwidth of competing multiple Masters. The basic unit of address filtering is Slave, meaning it supports address filtering for different Slaves, but does not support filtering partial address spaces of the same Slave.
- Monitoring recovery. After abnormal bandwidth behavior is discovered and broadcast, each AXI Perf Mon will pause instantaneous bandwidth measurement. After software completes analysis of the current scene results, if continued instantaneous bandwidth monitoring is desired without system reset, it can be configured through AXI_PERF_MON_SEL_AG0_SW_RECORD_STOP_CLR or AXI_PERF_MON_SEL_AG1_SW_RECORD_STOP_CLR to clear the stagnation state.

23.6 Interrupts

ESP32-P4's AXI Perf Mon can generate the following interrupt signal that will be sent to the Interrupt Matrix.

- AXI_PERF_MON_INTR

This interrupt signal is generated by AXI Perf Mon's internal interrupt sources. Table 23.6-1 lists AXI Perf Mon's internal interrupt sources, interrupt trigger conditions, and the generated interrupt signal.

Table 23.6-1. AXI PERF MON Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
AXI_PERF_MON_SEL_AG*n*_RECORD_-CNT_UNDER_LIMIT_INT (*n* = 0, 1)	Instantaneous bandwidth measurement value is less than the set minimum instantaneous bandwidth threshold	AXI_PERF_MON_INTR

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 23.8 *Register Summary*.

23.7 Programming Procedures

23.7.1 Using AXI Perf Mon to Measure Outstanding Transactions

To use AXI Perf Mon to monitor the outstanding capability of a port:

1. Configure register AXI_PERF_MON_AGENT_SELECT_REG, where every 5 bits represent an agent selected by the corresponding monitoring unit. Bits [4:0] indicate the port to be monitored selected by AXI Perf Mon Unit 0, and bits [9:5] represent the port to be monitored selected by AXI Perf Mon Unit 1.
2. Configure register AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m*_REG (*n* represents monitoring unit 0 or 1; *m* represents that each monitoring unit has multiple such registers, refer to the register section for specific register quantities, here *m* = 1, 2) to select the monitoring metric. Every 8 bits represent the metric corresponding to a metric counter. The value of AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT1 [4:0] represents the monitoring metric corresponding to measurement metric counter 0, and its [7:5] value represents the monitoring metric corresponding to range statistics metric counter 0. The value of AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT2 [4:0] represents the monitoring metric corresponding to measurement metric counter 4, and its [7:5] value represents the monitoring metric corresponding to range statistics metric counter 4, and so on. After configuration is complete, monitoring begins.
3. Obtain status information by reading AXI_PERF_MON_SEL_AG*n*_COUNTER*m*_RESULT. Bits [15:0] are the counted minimum value, and bits [31:16] are the counted maximum value. The result counter number corresponds to the selected metric counter.

4. Configure the 8 bits of the corresponding metric counter in register AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m*_REG to 0 to stop that metric counter from monitoring this metric on this port and reset the counter.

Outstanding count, address channel latency, data channel latency, and read/write transaction transfer latency can all be monitored through this programming procedure—simply set register AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m*_REG to the desired monitoring metric.

23.7.2 Using AXI Perf Mon to Measure Read Average Bandwidth

To use AXI Perf Mon to monitor the average bandwidth of a port over a period of time:

1. Configure register AXI_PERF_MON_AGENT_SELECT_REG to select the port to be monitored.
2. Configure register AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m*_REG to select the following metrics for read average bandwidth measurement: time duration and data amount.
3. Configure AXI_PERF_MON_SEL_AG*n*_RD_BANDW_TIME_CNT_VALID_STROBE_NUM and AXI_PERF_MON_SEL_AG*n*_RD_BANDW_DATA_CNT_VALID_STROBE_NUM to select the counting interval for time and data. If the counting interval is configured as 3, then every 4 valid cycles increment the counter by 1, and every 4 valid data beats increment the counter by 1.
4. Configure AXI_PERF_MON_SEL_AG0_RD_BANDW_TEST_EN or AXI_PERF_MON_SEL_AG1_RD_BANDW_TEST_EN to enable average bandwidth measurement. Configure AXI_PERF_MON_SEL_AG0_RD_BANDW_TEST_STOP or AXI_PERF_MON_SEL_AG1_RD_BANDW_TEST_STOP to stop average bandwidth measurement.
5. Measurement results can be read from register AXI_PERF_MON_SEL_AG*n*_COUNTER*m*_RESULT_REG. The result counter number corresponds to the selected metric counter. The high 16 bits in the result register represent the average bandwidth data/time statistics. A value of 16'hFFFF indicates that the counter has overflowed and the result is invalid. Configure AXI_PERF_MON_SEL_AG*n*_RD_BANDW_TIME_CNT_VALID_STROBE_NUM and AXI_PERF_MON_SEL_AG*n*_RD_BANDW_DATA_CNT_VALID_STROBE_NUM to increase the counting interval, or reduce the counting time and data amount.

23.7.3 Using AXI Perf Mon to Measure Read Instantaneous Bandwidth

To use AXI Perf Mon to monitor the instantaneous bandwidth of a port:

1. Configure register AXI_PERF_MON_AGENT_SELECT_REG to select the port to be monitored.
2. Configure register AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m*_REG to select the following metrics for read instantaneous bandwidth measurement: time duration and data amount.
3. When measuring instantaneous bandwidth, software specifies the time duration for each measurement segment. After reaching the measurement duration, software can read the data statistics result register to obtain the data amount transferred during that time duration. At the same time, counting for the next measurement segment begins. Configure register AXI_PERF_MON_SEL_AG*n*_RD_INS_BANDW_TIME_THR_REG to determine the measurement time duration. Configure AXI_PERF_MON_SEL_AG0_RD_INS_BANDW_TEST_EN or AXI_PERF_MON_SEL_AG1_RD_INS_BANDW_TEST_EN to enable instantaneous bandwidth measurement.

4. When measuring instantaneous bandwidth, if you wish to report abnormal conditions where port bandwidth drops sharply in dense data transfer scenarios, configure AXI_PERF_MON_SEL_AG*n*_SW_RECORD_STOP_RD_DATA_LIMIT to set the data amount lower threshold for bandwidth. Once the counted instantaneous bandwidth data amount is less than this lower limit, AXI Perf Mon will generate an interrupt and stop measuring instantaneous bandwidth in the AXI Perf Mon Unit.
5. Recorded event information for instantaneous bandwidth can be queried from registers AXI_PERF_MON_SEL_AG*n*_INS_BANDW_DATA*m*_REG and AXI_PERF_MON_SEL_AG*n*_RD_AXI_INFO_RECORD*m*_REG. These register values are updated according to real-time counting conditions. When an interrupt occurs, these registers will pause updating to preserve the scene. AXI_PERF_MON_SEL_AG0_SW_RECORD_STOP_EN or AXI_PERF_MON_SEL_AG1_SW_RECORD_STOP_EN can be used to stop register updates. AXI_PERF_MON_SEL_AG0_SW_RECORD_STOP_CLR or AXI_PERF_MON_SEL_AG1_SW_RECORD_STOP_CLR can be used to clear the stagnation state and resume recording updates.
6. When measuring instantaneous bandwidth, address filtering for data is supported. Address filtering is performed on a per-region basis. Three regions are filtered using AXI_PERF_MON_SEL_AG*n*_RD_ADDR_MASK*m* and AXI_PERF_MON_SEL_AG*n*_RD_ADDR_FILTER*m*. The valid destination addresses among these regions are then selected via AXI_PERF_MON_SEL_AG0_RD_ADDR_REGION_SEL or AXI_PERF_MON_SEL_AG1_RD_ADDR_REGION_SEL.
7. Instantaneous bandwidth statistics support presenting bandwidth distribution systematically through range statistics. Configure the latter 3 bits of every 8 bits in register AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m*_REG to specify the statistics metric for range counters. AXI_PERF_MON__SEL_AG*n*_METRIC_RANGE_CNT_LOW and AXI_PERF_MON__SEL_AG*n*_METRIC_RANGE_CNT_HIGH are used to specify the upper and lower limits for each range. Range statistics for instantaneous bandwidth can be queried through register AXI_PERF_MON_SEL_AG*n*_RANGE*m*_REG.

23.8 Register Summary

The addresses in this section are relative to AXI Perf Mon base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Configuration Registers			
AXI_PERF_MON_CLK_EN_REG	Reserved	0x0000	R/W
AXI_PERF_MON_SEL_AG0_METRIC_RANGE0_REG	Configuration register 0 for upper and lower limits of range statistics in monitoring unit 0	0x00C8	R/W
AXI_PERF_MON_SEL_AG1_METRIC_RANGE0_REG	Configuration register 0 for upper and lower limits of range statistics in monitoring unit 1	0x00CC	R/W
AXI_PERF_MON_SEL_AG0_METRIC_RANGE1_REG	Configuration register 1 for upper and lower limits of range statistics in monitoring unit 0	0x00D0	R/W
AXI_PERF_MON_SEL_AG1_METRIC_RANGE1_REG	Configuration register 1 for upper and lower limits of range statistics in monitoring unit 1	0x00D4	R/W
AXI_PERF_MON_SEL_AG0_METRIC_RANGE2_REG	Configuration register 2 for upper and lower limits of range statistics in monitoring unit 0	0x00D8	R/W
AXI_PERF_MON_SEL_AG1_METRIC_RANGE2_REG	Configuration register 2 for upper and lower limits of range statistics in monitoring unit 1	0x00DC	R/W
AXI_PERF_MON_SEL_AG0_METRIC_RANGE3_REG	Configuration register 3 for upper and lower limits of range statistics in monitoring unit 0	0x00E0	R/W
AXI_PERF_MON_SEL_AG1_METRIC_RANGE3_REG	Configuration register 3 for upper and lower limits of range statistics in monitoring unit 1	0x00E4	R/W
AXI_PERF_MON_SEL_AG0_METRIC_RANGE4_REG	Configuration register 4 for upper and lower limits of range statistics in monitoring unit 0	0x00E8	R/W
AXI_PERF_MON_SEL_AG1_METRIC_RANGE4_REG	Configuration register 4 for upper and lower limits of range statistics in monitoring unit 1	0x00EC	R/W
AXI_PERF_MON_SEL_AG0_METRIC_RANGE5_REG	Configuration register 5 for upper and lower limits of range statistics in monitoring unit 0	0x00F0	R/W
AXI_PERF_MON_SEL_AG1_METRIC_RANGE5_REG	Configuration register 5 for upper and lower limits of range statistics in monitoring unit 1	0x00F4	R/W

Name	Description	Address	Access
AXI_PERF_MON_SEL_AG0_RD_ADDR_MASK0_REG	Read address filter mask register for monitoring unit 0 (region 0)	0x00F8	R/W
AXI_PERF_MON_SEL_AG1_RD_ADDR_MASK0_REG	Read address filter mask register for monitoring unit 1 (region 0)	0x00FC	R/W
AXI_PERF_MON_SEL_AG0_RD_ADDR_MASK1_REG	Read address filter mask register for monitoring unit 0 (region 1)	0x0100	R/W
AXI_PERF_MON_SEL_AG1_RD_ADDR_MASK1_REG	Read address filter mask register for monitoring unit 1 (region 1)	0x0104	R/W
AXI_PERF_MON_SEL_AG0_RD_ADDR_MASK2_REG	Read address filter mask register for monitoring unit 0 (region 2)	0x0108	R/W
AXI_PERF_MON_SEL_AG1_RD_ADDR_MASK2_REG	Read address filter mask register for monitoring unit 1 (region 2)	0x010C	R/W
AXI_PERF_MON_SEL_AG0_WR_ADDR_MASK0_REG	Write address filter mask register for monitoring unit 0 (region 0)	0x0110	R/W
AXI_PERF_MON_SEL_AG1_WR_ADDR_MASK0_REG	Write address filter mask register for monitoring unit 1 (region 0)	0x0114	R/W
AXI_PERF_MON_SEL_AG0_WR_ADDR_MASK1_REG	Write address filter mask register for monitoring unit 0 (region 1)	0x0118	R/W
AXI_PERF_MON_SEL_AG1_WR_ADDR_MASK1_REG	Write address filter mask register for monitoring unit 1 (region 1)	0x011C	R/W
AXI_PERF_MON_SEL_AG0_WR_ADDR_MASK2_REG	Write address filter mask register for monitoring unit 0 (region 2)	0x0120	R/W
AXI_PERF_MON_SEL_AG1_WR_ADDR_MASK2_REG	Write address filter mask register for monitoring unit 1 (region 2)	0x0124	R/W
AXI_PERF_MON_SEL_AG0_RD_ADDR_FILTER0_REG	Read address filter value register for monitoring unit 0 (region 0)	0x0128	R/W
AXI_PERF_MON_SEL_AG1_RD_ADDR_FILTER0_REG	Read address filter value register for monitoring unit 1 (region 0)	0x012C	R/W
AXI_PERF_MON_SEL_AG0_RD_ADDR_FILTER1_REG	Read address filter value register for monitoring unit 0 (region 1)	0x0130	R/W
AXI_PERF_MON_SEL_AG1_RD_ADDR_FILTER1_REG	Read address filter value register for monitoring unit 1 (region 1)	0x0134	R/W
AXI_PERF_MON_SEL_AG0_RD_ADDR_FILTER2_REG	Read address filter value register for monitoring unit 0 (region 2)	0x0138	R/W
AXI_PERF_MON_SEL_AG1_RD_ADDR_FILTER2_REG	Read address filter value register for monitoring unit 1 (region 2)	0x013C	R/W
AXI_PERF_MON_SEL_AG0_WR_ADDR_FILTER0_REG	Write address filter value register for monitoring unit 0 (region 0)	0x0140	R/W
AXI_PERF_MON_SEL_AG1_WR_ADDR_FILTER0_REG	Write address filter value register for monitoring unit 1 (region 0)	0x0144	R/W
AXI_PERF_MON_SEL_AG0_WR_ADDR_FILTER1_REG	Write address filter value register for monitoring unit 0 (region 1)	0x0148	R/W
AXI_PERF_MON_SEL_AG1_WR_ADDR_FILTER1_REG	Write address filter value register for monitoring unit 1 (region 1)	0x014C	R/W

Name	Description	Address	Access
AXI_PERF_MON_SEL_AG0_WR_ADDR_FILTER2_REG	Write address filter value register for monitoring unit 0 (region 2)	0x0150	R/W
AXI_PERF_MON_SEL_AG1_WR_ADDR_FILTER2_REG	Write address filter value register for monitoring unit 1 (region 2)	0x0154	R/W

AXI_PERF_MON_SEL_AG_INT_CLR_REG	Interrupt clear register	0x01CC	WT

23.9 Registers

The addresses in this section are relative to AXI Perf Mon base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

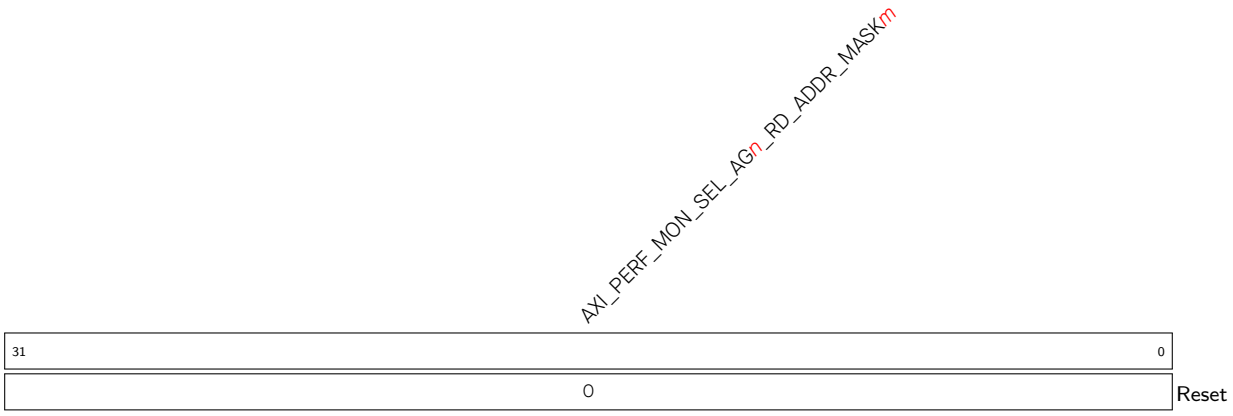
Register 23.1. AXI_PERF_MON_CLK_EN_REG (0x0000)

AXI_PERF_MON_CLK_EN Configures whether to force enable the AXI performance monitor register module clock.

0: AXI performance monitor register module clock is automatically enabled or disabled

1: Force enable the AXI performance monitor register module clock

(R/W)



Register 23.2. AXI_PERF_MON_SEL_AG*n*_METRIC_RANGE*m*_REG (*n*: 0-1, *m*: 0-5) (0x00C8+0x4*n*+0x8*m*)

AXI_PERF_MON_SEL_AG*n*_METRIC_RANGE*m*_CNT_HIGH (*n*: 0-1, *m*: 0-5) Configures the upper limit of the range statistics for the selected metric in the selected monitoring unit. (R/W)

AXI_PERF_MON_SEL_AG*n*_METRIC_RANGE*m*_CNT_LOW (*n*: 0-1, *m*: 0-5) Configures the lower limit of the range statistics for the selected metric in the selected monitoring unit. (R/W)

Register 23.3. AXI_PERF_MON_SEL_AG*n*_RD_ADDR_MASK*m*_REG (*n*: 0-1, *m*: 0-2) (0x00F8+0x4n*+0x8**m*)**

AXI_PERF_MON_SEL_AG*n*_RD_ADDR_MASK*m* (*n*: 0-1, *m*: 0-2) Configures the read address mask for the address filter function of the selected monitoring unit. Masked bits are not compared. Valid only when AXI_PERF_MON_SEL_AG*n*_RD_ADDR_FILTER_EN is 1.
(R/W)

Register 23.4. AXI_PERF_MON_SEL_AG*n*_WR_ADDR_MASK*m*_REG (*n*: 0-1, *m*: 0-2) (0x0110+0x4n*+0x8**m*)**

AXI_PERF_MON_SEL_AG*n*_WR_ADDR_MASK*m* (*n*: 0-1, *m*: 0-2) Configures the write address mask for the address filter function of the selected monitoring unit. Masked bits are not compared.
Valid only when AXI_PERF_MON_SEL_AG*n*_WR_ADDR_FILTER_EN is 1.
(R/W)

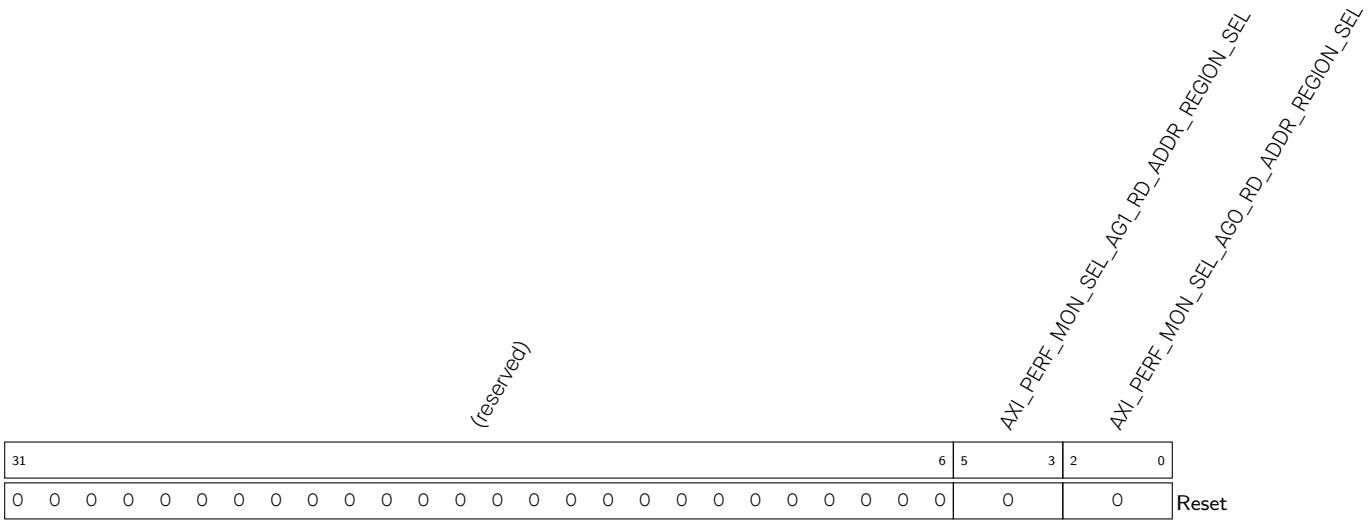
Register 23.5. AXI_PERF_MON_SEL_AG*n*_RD_ADDR_FILTER*m*_REG (*n*: 0-1, *m*: 0-2) (0x0128+0x4n*+0x8**m*)**

AXI_PERF_MON_SEL_AG*n*_RD_ADDR_FILTER*m* (*n*: 0-1, *m*: 0-2) Configures the read address filter value for the selected monitoring unit. Bits that are not masked are compared with this value. Valid only when AXI_PERF_MON_SEL_AG*n*_RD_ADDR_FILTER_EN is 1.

(R/W)

Register 23.6. AXI_PERF_MON_SEL_AG*n*_WR_ADDR_FILTER*m*_REG (*n*: 0-1, *m*: 0-2) (0x0140+0x4n*+0x8**m*)**

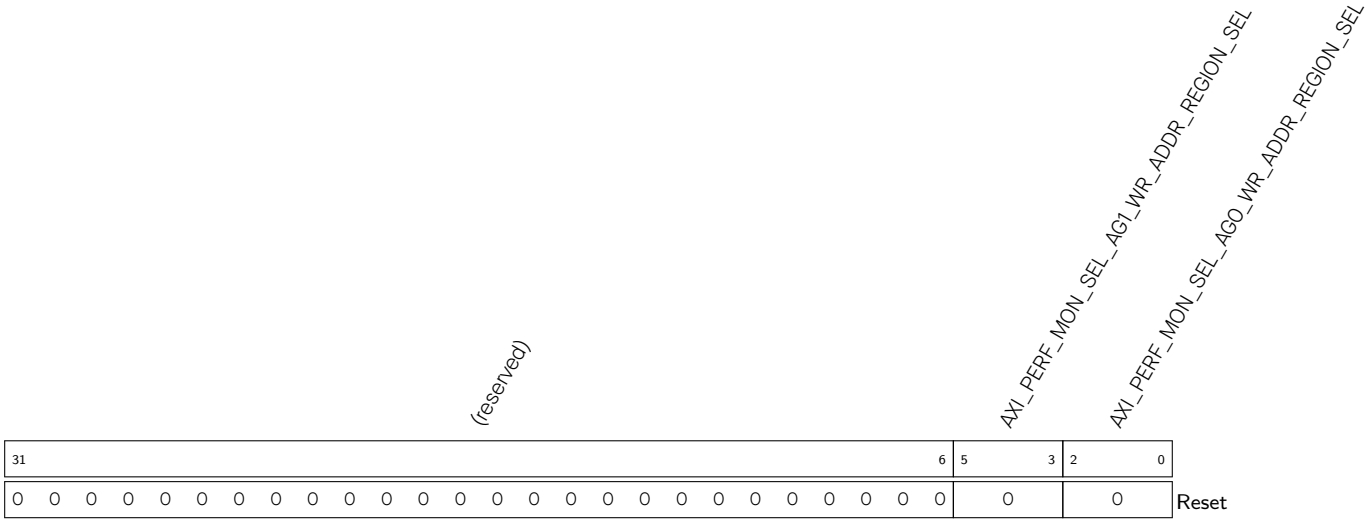
AXI_PERF_MON_SEL_AG*n*_WR_ADDR_FILTER*m* (*n*: 0-1, *m*: 0-2) Configures the write address filter value for the selected monitoring unit. Bits that are not masked are compared with this value. Valid only when AXI_PERF_MON_SEL_AG*n*_WR_ADDR_FILTER_EN is 1.



(R/W)

Register 23.7. AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m*_REG (*n*: 0-1, *m*: 1-2) (0x0158+0x4*n*+0x8*(*m*-1))

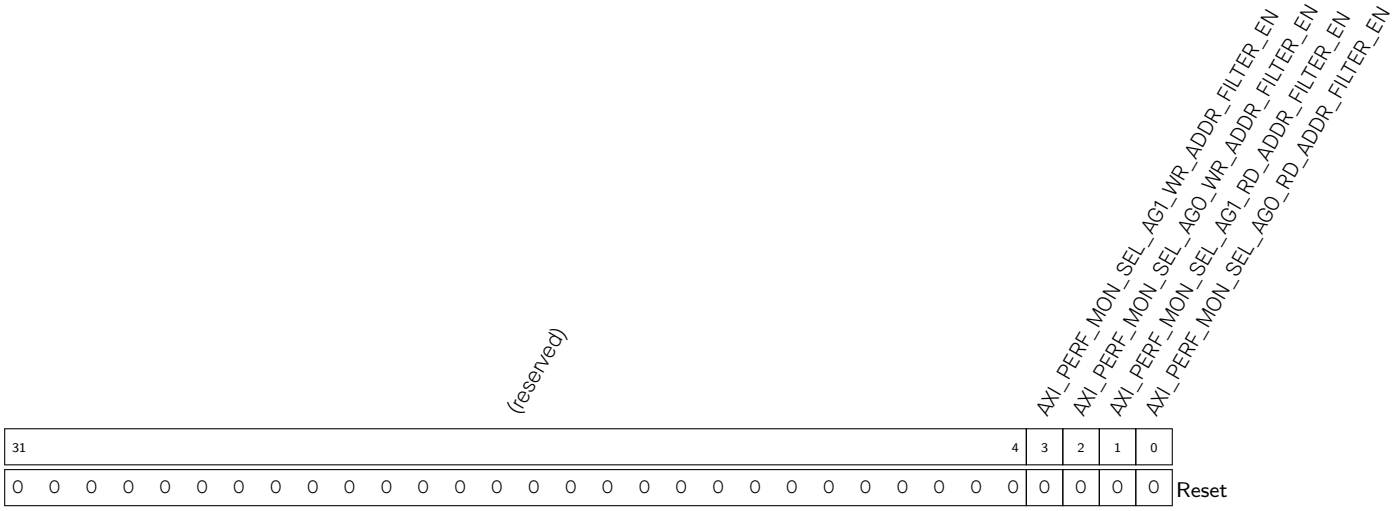
AXI_PERF_MON_SEL_AG*n*_METRIC_SELECT*m* (*n*: 0-1, *m*: 1-2) Configures metric selection for the selected monitoring unit. Each counter uses 8 bits. In each 8-bit group, bits [4:0] select the measurement metric and bits [7:5] select the range statistics metric. Metric measurement and range statistics can be performed at the same time. (R/W)



Register 23.8. AXI_PERF_MON_SEL_AG_RD_ADDR_REGION_SEL_REG (0x0168)

AXI_PERF_MON_SEL_AG0_RD_ADDR_REGION_SEL Configures the read region selection for monitoring unit 0. It operates in conjunction with the address mask and filter values. Only transactions with addresses falling within the selected region are counted. (R/W)

AXI_PERF_MON_SEL_AG1_RD_ADDR_REGION_SEL Configures the read region selection for monitoring unit 1. It operates in conjunction with the address mask and filter values. Only transactions with addresses falling within the selected region are counted. (R/W)



Register 23.9. AXI_PERF_MON_SEL_AG_WR_ADDR_REGION_SEL_REG (0x016C)

AXI_PERF_MON_SEL_AG0_WR_ADDR_REGION_SEL Configures the write region selection for monitoring unit 0. It operates in conjunction with the address mask and filter values. Only transactions with addresses falling within the selected region are counted. (R/W)

AXI_PERF_MON_SEL_AG1_WR_ADDR_REGION_SEL Configures the write region selection for monitoring unit 1. It operates in conjunction with the address mask and filter values. Only transactions with addresses falling within the selected region are counted. (R/W)

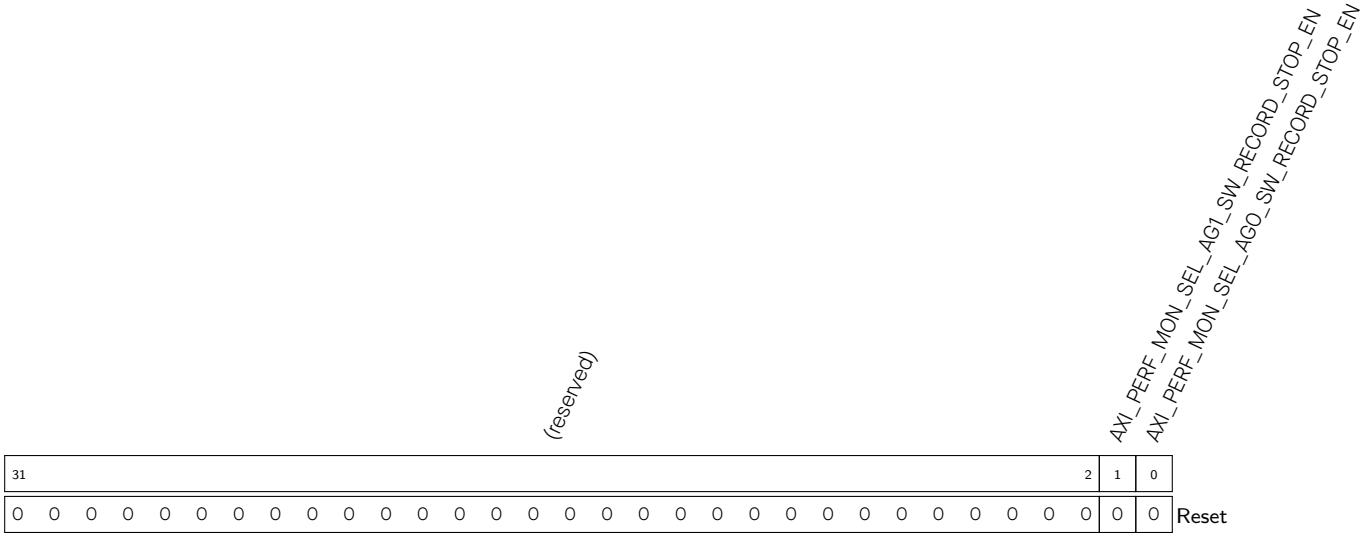
Register 23.10. AXI_PERF_MON_SEL_AG_ADDR_FILTER_EN_REG (0x0170)

AXI_PERF_MON_SEL_AG*n*_RD_ADDR_FILTER_EN (*n*: 0-1) Configures whether or not to enable the read address filter function.

0: Disable. All read address accesses are recorded

1: Enable

(R/W)

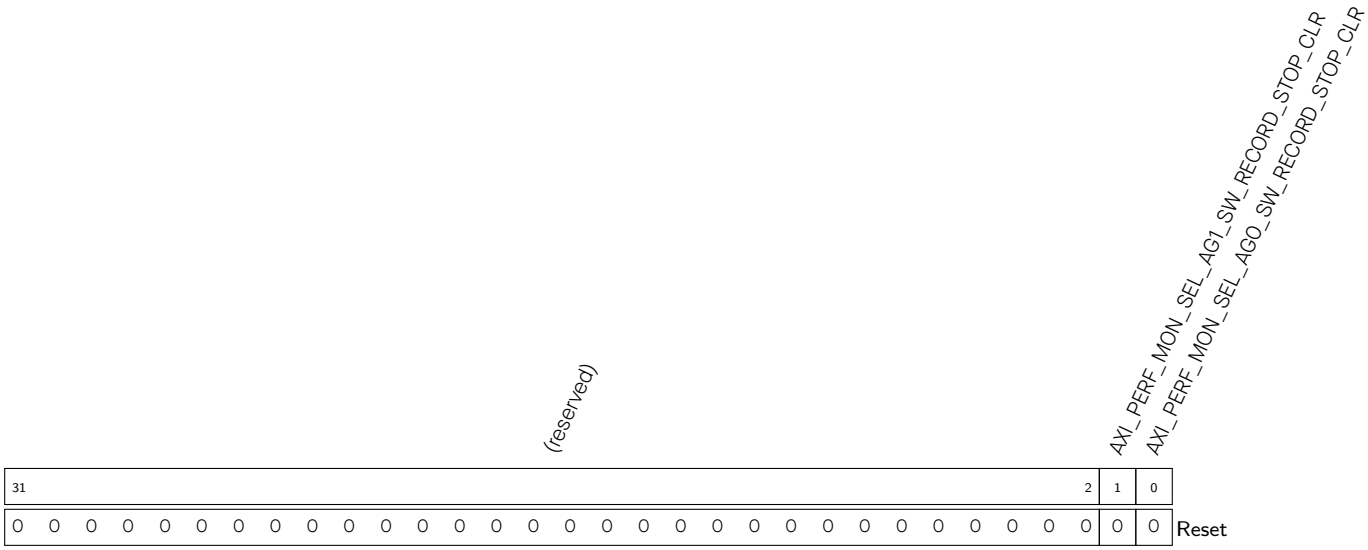


AXI_PERF_MON_SEL_AG*n*_WR_ADDR_FILTER_EN (*n*: 0-1) Configures whether or not to enable the write address filter function.

0: Disable. All write address accesses are recorded

1: Enable

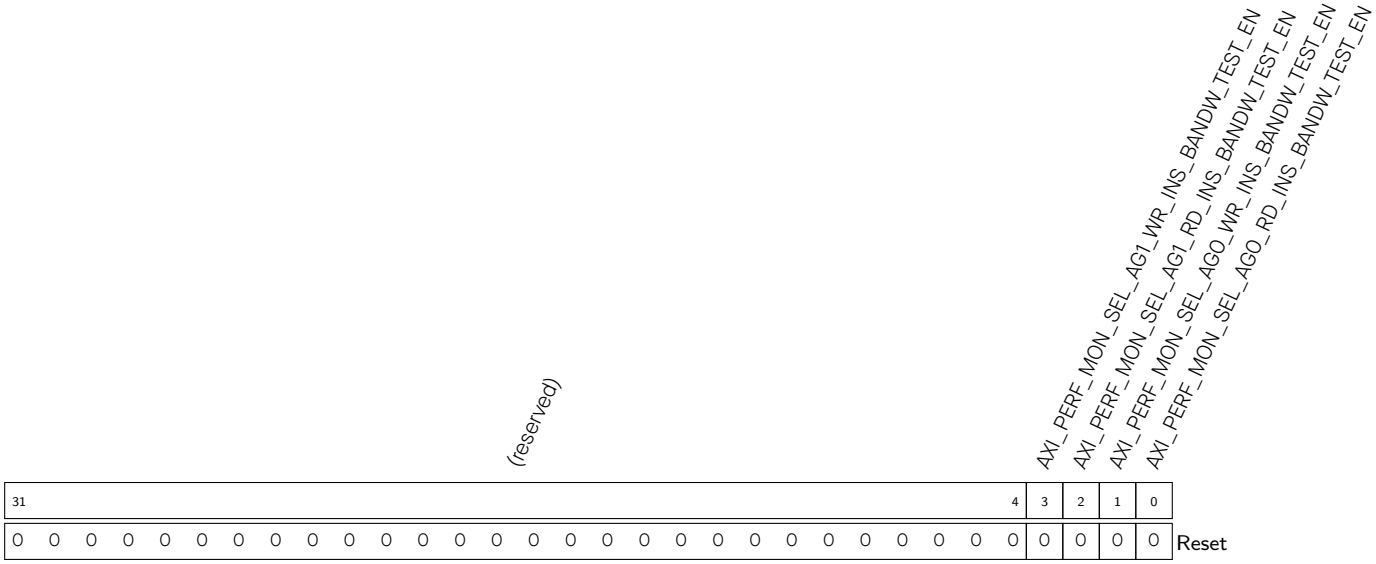
(R/W)



Register 23.11. AXI_PERF_MON_SEL_AG_SW_RECORD_STOP_EN_REG (0x0174)

AXI_PERF_MON_SEL_AG0_SW_RECORD_STOP_EN Write 1 to stop the event log function. The recorded information is kept. (WT)

AXI_PERF_MON_SEL_AG1_SW_RECORD_STOP_EN Write 1 to stop the event log function. The recorded information is kept. (WT)



Register 23.12. AXI_PERF_MON_SEL_AG_SW_RECORD_STOP_CLR_REG (0x0178)

AXI_PERF_MON_SEL_AG0_SW_RECORD_STOP_CLR Write 1 to clear the event log stop status. Recording new transactions starts from now. (WT)

AXI_PERF_MON_SEL_AG1_SW_RECORD_STOP_CLR Write 1 to clear the event log stop status. Recording new transactions starts from now. (WT)

Register 23.13. AXI_PERF_MON_SEL_AG_INS_BANDW_TEST_EN_REG (0x017C)

AXI_PERF_MON_SEL_AG0_RD_INS_BANDW_TEST_EN Configures whether or not to enable the read instantaneous bandwidth test for monitoring unit 0.

0: Disable

1: Enable

(R/W)

AXI_PERF_MON_SEL_AG0_WR_INS_BANDW_TEST_EN Configures whether or not to enable the write instantaneous bandwidth test for monitoring unit 0.

0: Disable

1: Enable

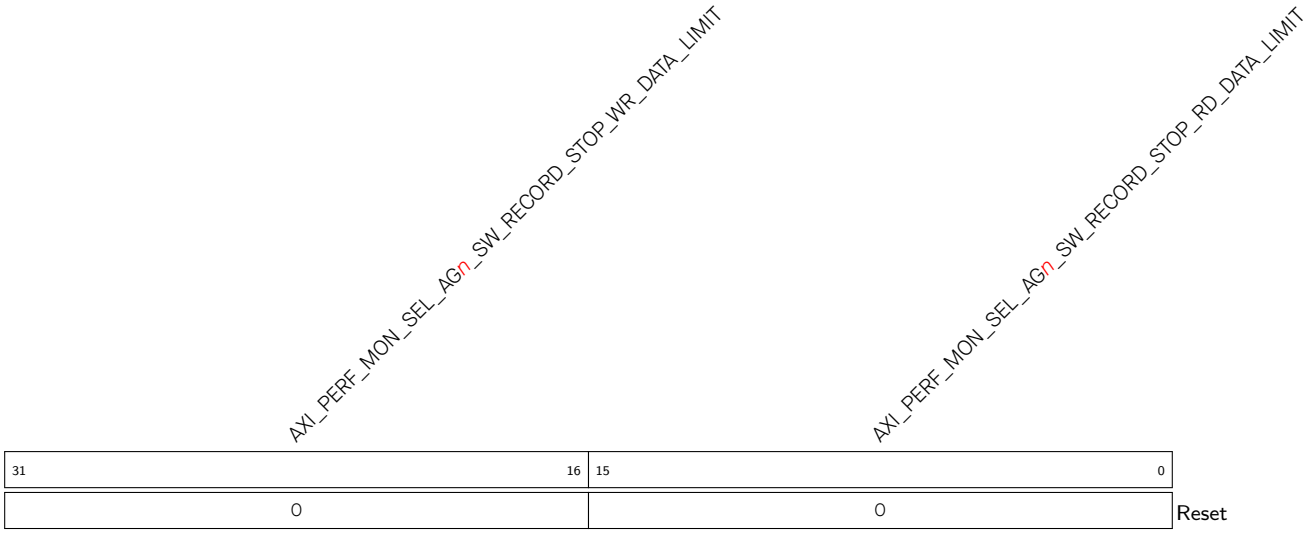
(R/W)

AXI_PERF_MON_SEL_AG1_RD_INS_BANDW_TEST_EN Configures whether or not to enable the read instantaneous bandwidth test for monitoring unit 1.

0: Disable

1: Enable

(R/W)

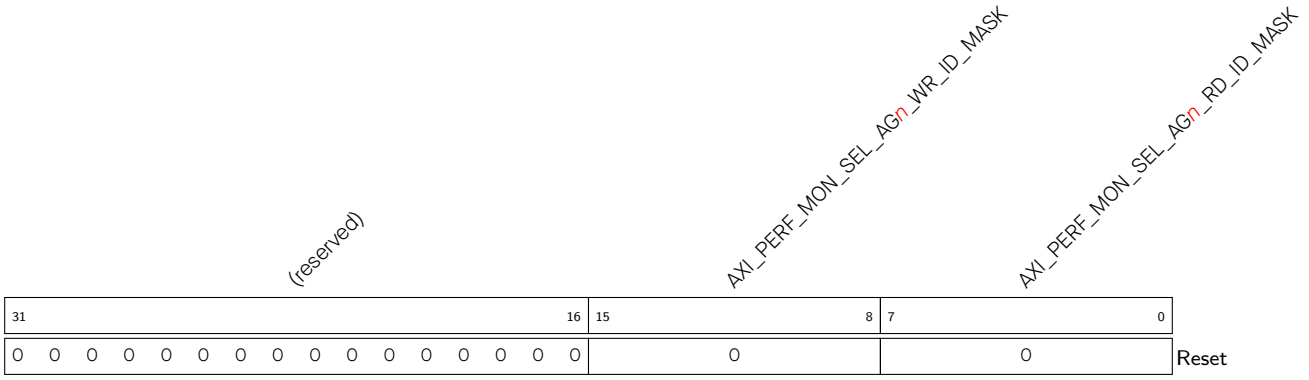


AXI_PERF_MON_SEL_AG1_WR_INS_BANDW_TEST_EN Configures whether or not to enable the write instantaneous bandwidth test for monitoring unit 1.

0: Disable

1: Enable

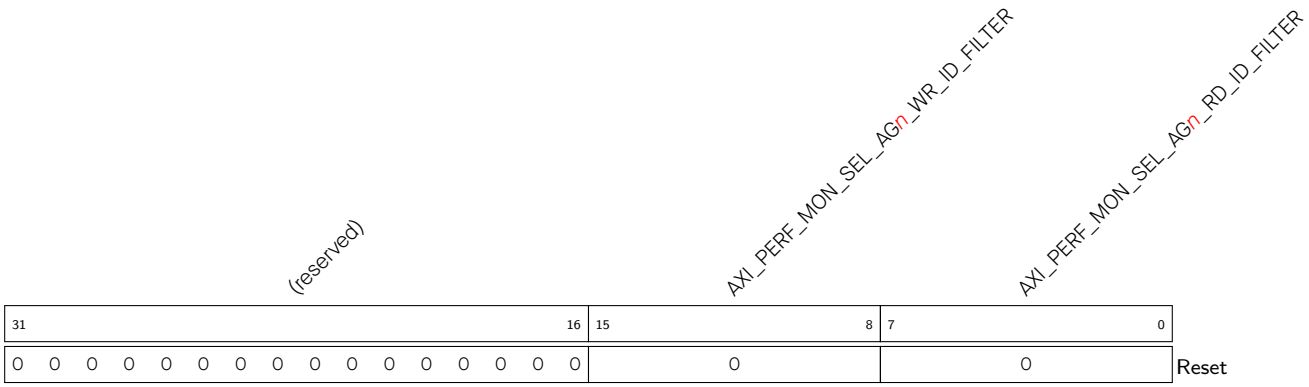
(R/W)



Register 23.14. AXI_PERF_MON_SEL_AG*n*_SW_RECORD_STOP_DATA_LIMIT_REG (*n*: 0-1) (0x0180+0x4n*)**

AXI_PERF_MON_SEL_AG*n*_SW_RECORD_STOP_RD_DATA_LIMIT (*n*: 0-1) Configures the lower threshold for read instantaneous bandwidth measurement. When the measured data reaches this lower limit, the interrupt is enabled. (R/W)

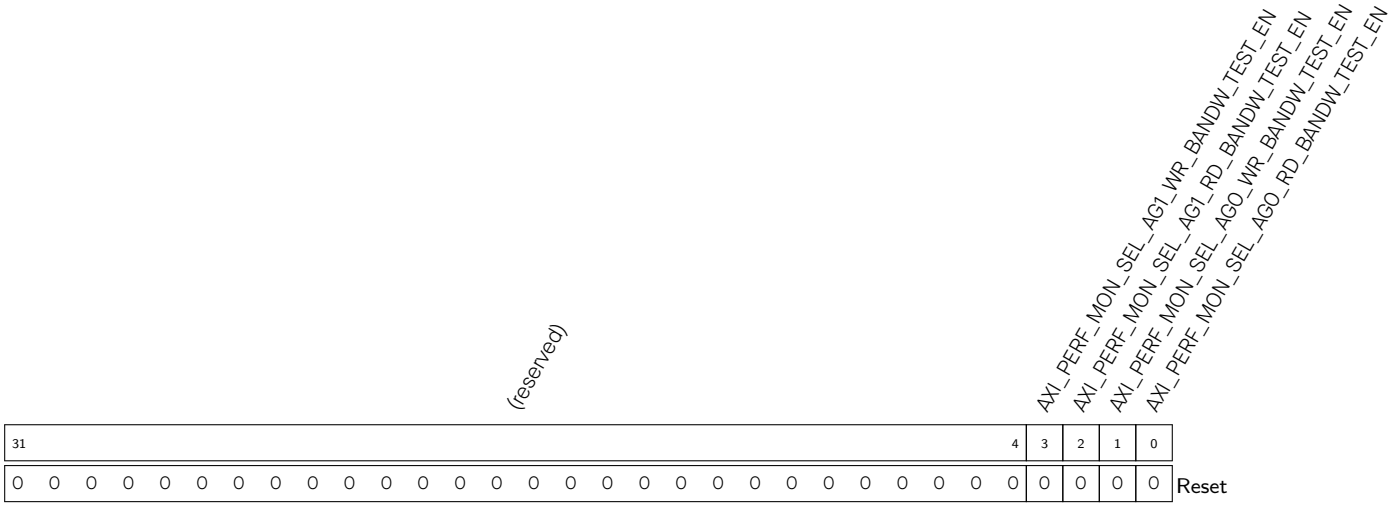
AXI_PERF_MON_SEL_AG*n*_SW_RECORD_STOP_WR_DATA_LIMIT (*n*: 0-1) Configures the lower threshold for write instantaneous bandwidth measurement. When the measured data reaches this lower limit, the interrupt is enabled. (R/W)



Register 23.15. AXI_PERF_MON_SEL_AG*n*_ID_MASK_REG (*n*: 0-1) (0x0188+0x4n*)**

AXI_PERF_MON_SEL_AG*n*_RD_ID_MASK (*n*: 0-1) Configures the read ID mask. Masked ID bits are not compared. (R/W)

AXI_PERF_MON_SEL_AG*n*_WR_ID_MASK (*n*: 0-1) Configures the write ID mask. Masked ID bits are not compared. (R/W)



Register 23.16. AXI_PERF_MON_SEL_AG*n*_ID_FILTER_REG (*n*: 0-1) (0x0190+0x4n*)**

AXI_PERF_MON_SEL_AG*n*_RD_ID_FILTER (*n*: 0-1) Configures the read ID filter value. Bits that are not masked must match this value to pass the filter. (R/W)

AXI_PERF_MON_SEL_AG*n*_WR_ID_FILTER (*n*: 0-1) Configures the write ID filter value. Bits that are not masked must match this value to pass the filter. (R/W)

Register 23.17. AXI_PERF_MON_SEL_AG_BANDW_TEST_EN_REG (0x0198)

AXI_PERF_MON_SEL_AG0_RD_BANDW_TEST_EN Configures whether or not to enable the read average bandwidth test for monitoring unit 0.

0: Disable

1: Enable

(R/W)

AXI_PERF_MON_SEL_AG0_WR_BANDW_TEST_EN Configures whether or not to enable the write average bandwidth test for monitoring unit 0.

0: Disable

1: Enable

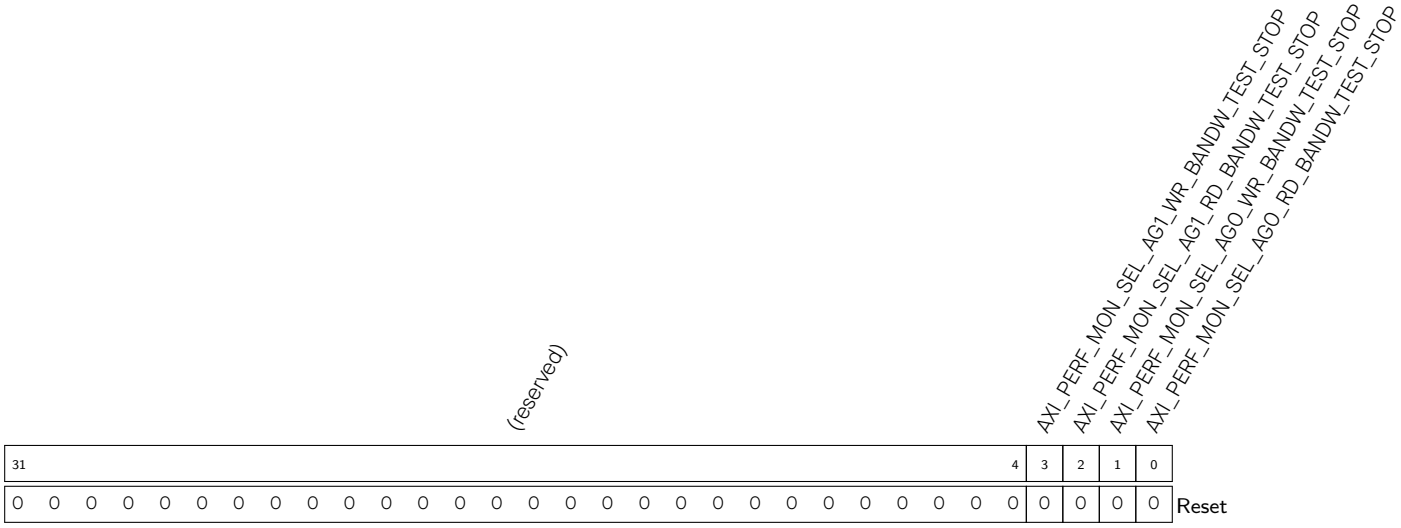
(R/W)

AXI_PERF_MON_SEL_AG1_RD_BANDW_TEST_EN Configures whether or not to enable the read average bandwidth test for monitoring unit 1.

0: Disable

1: Enable

(R/W)



AXI_PERF_MON_SEL_AG1_WR_BANDW_TEST_EN Configures whether or not to enable the write average bandwidth test for monitoring unit 1.

0: Disable

1: Enable

(R/W)

Register 23.18. AXI_PERF_MON_SEL_AG_BANDW_TEST_STOP_REG (0x019C)

AXI_PERF_MON_SEL_AG0_RD_BANDW_TEST_STOP Configures whether or not to stop the read average bandwidth test for monitoring unit 0.

0: Continue

1: Stop

(R/W)

AXI_PERF_MON_SEL_AG0_WR_BANDW_TEST_STOP Configures whether or not to stop the write average bandwidth test for monitoring unit 0.

0: Continue

1: Stop

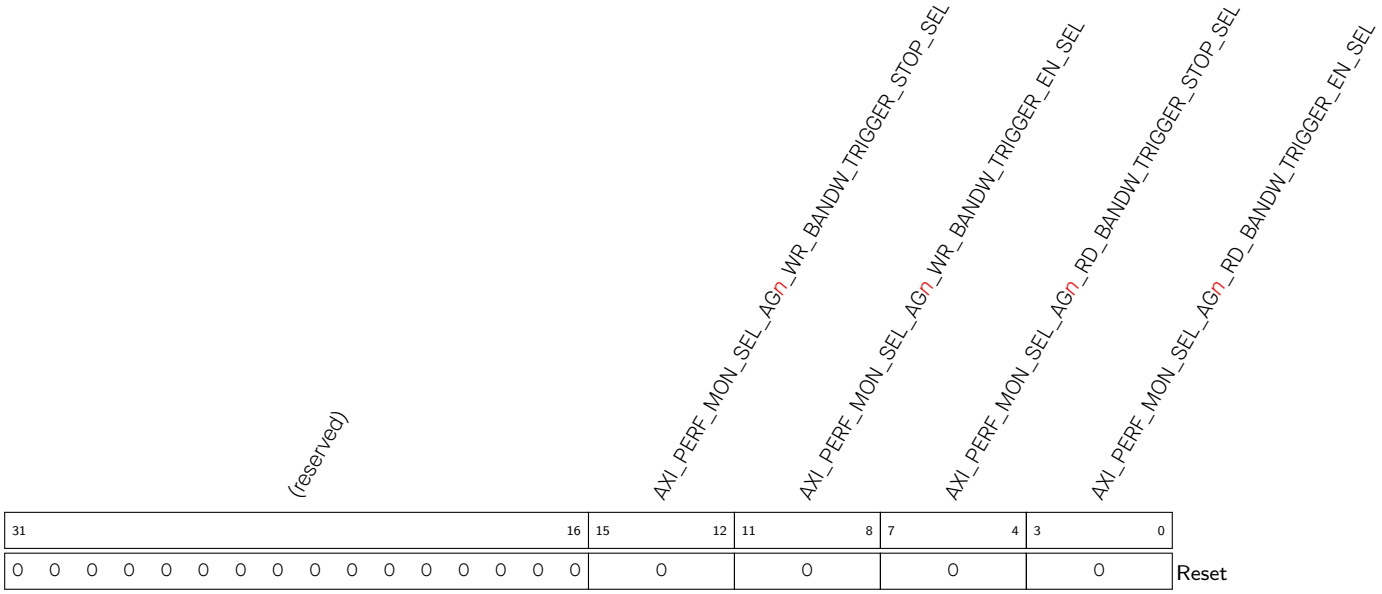
(R/W)

AXI_PERF_MON_SEL_AG1_RD_BANDW_TEST_STOP Configures whether or not to stop the read average bandwidth test for monitoring unit 1.

0: Continue

1: Stop

(R/W)



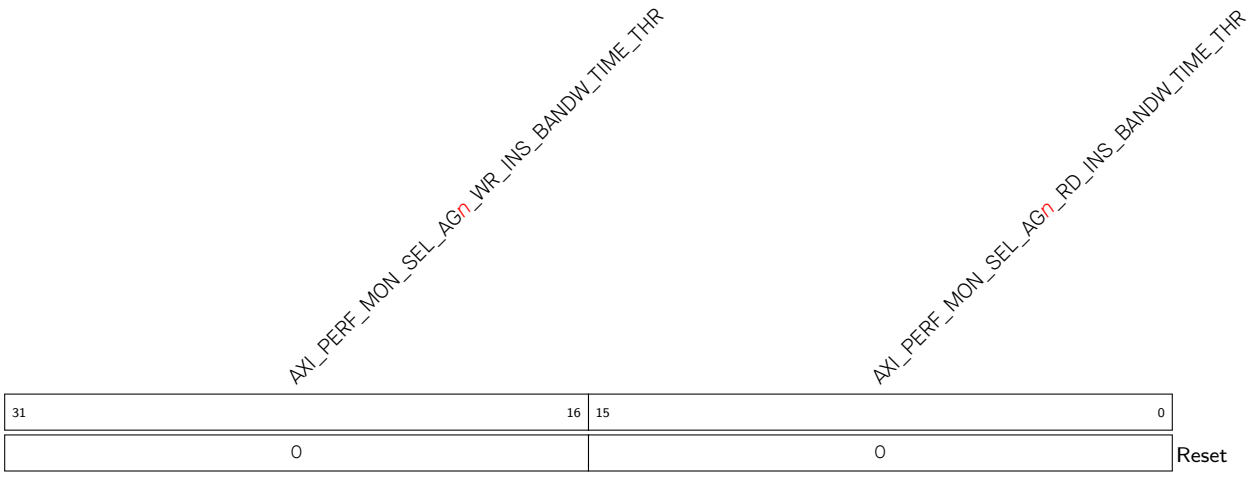
AXI_PERF_MON_SEL_AG1_WR_BANDW_TEST_STOP Configures whether or not to stop the write average bandwidth test for monitoring unit 1.

0: Continue

1: Stop

(R/W)

Register 23.19. AXI_PERF_MON_SEL_AG*n*_BANDW_TRIGGER_IN_SEL_REG (*n*: 0-1) (0x01A0+0x4n*)**

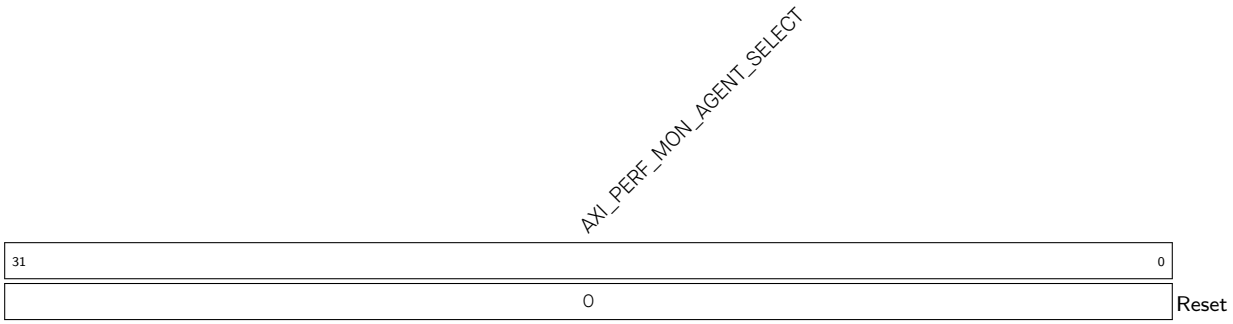


AXI_PERF_MON_SEL_AG*n*_RD_BANDW_TRIGGER_EN_SEL (*n*: 0-1) Configures the trigger enable source for the read average bandwidth test. The trigger enable signal can be sourced from the SoC hardware or issued via software configuration. (R/W)

AXI_PERF_MON_SEL_AG*n*_RD_BANDW_TRIGGER_STOP_SEL (*n*: 0-1) Configures the trigger stop source for the read average bandwidth test. The stop trigger can be sourced from the SoC hardware or via software configuration. (R/W)

AXI_PERF_MON_SEL_AG*n*_WR_BANDW_TRIGGER_EN_SEL (*n*: 0-1) Configures the trigger enable source for the write average bandwidth test. The trigger enable signal can be sourced from the SoC hardware or issued via software configuration. (R/W)

AXI_PERF_MON_SEL_AG*n*_WR_BANDW_TRIGGER_STOP_SEL (*n*: 0-1) Configures the trigger stop source for the write average bandwidth test. The stop trigger can be sourced from the SoC hardware or via software configuration. (R/W)

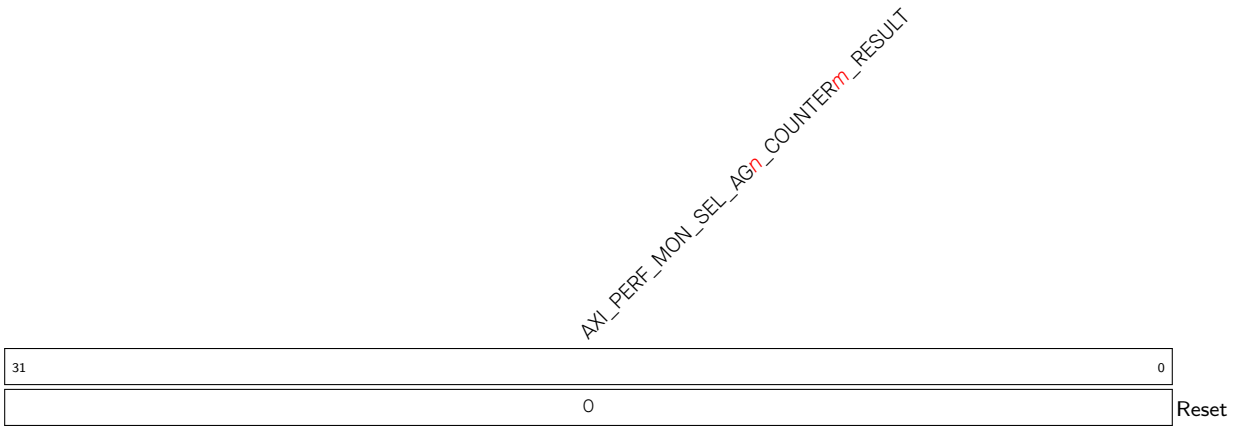


Register 23.20. AXI_PERF_MON_SEL_AG*n*_INS_BANDW_TIME_THR_REG (*n*: 0-1) (0x01B8+0x4**n*)

AXI_PERF_MON_SEL_AG*n*_RD_INS_BANDW_TIME_THR (*n*: 0-1) Configures the time threshold for the read instantaneous bandwidth test. The counter records the data amount within this time window and then refreshes to count again. (R/W)

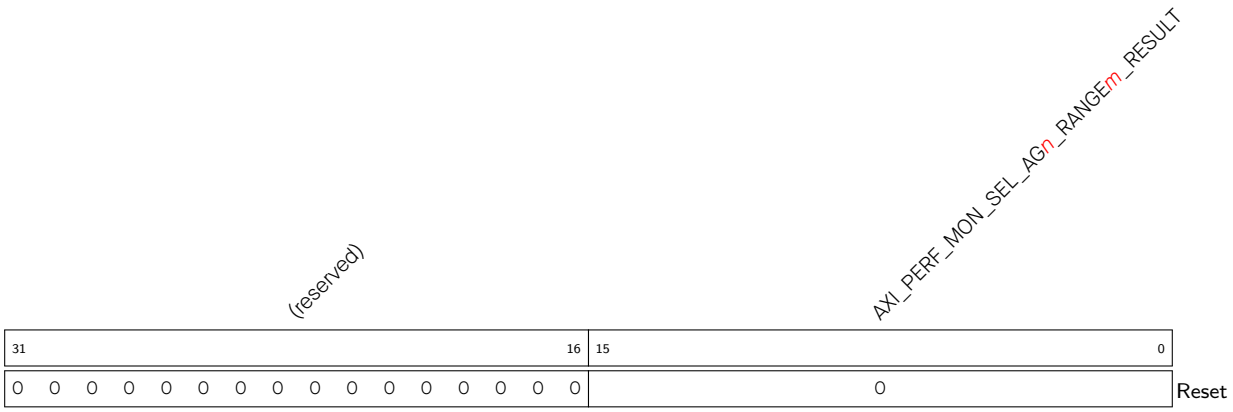
AXI_PERF_MON_SEL_AG*n*_WR_INS_BANDW_TIME_THR (*n*: 0-1) Configures the time threshold for the write instantaneous bandwidth test. The counter records the data amount within this time window and then refreshes to count again. (R/W)

Register 23.21. AXI_PERF_MON_AGENT_SELECT_REG (0x0004)



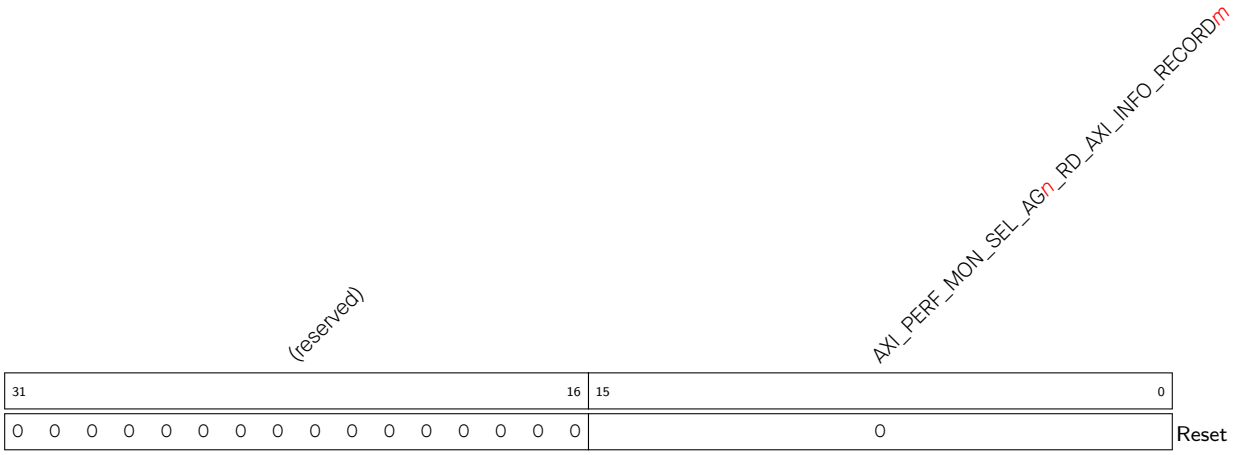
AXI_PERF_MON_AGENT_SELECT Configures the agent selection for each monitoring unit. Each agent selection uses 5 bits.

- Bits [4:0]: Selected agent for monitoring unit 0
- Bits [9:5]: Selected agent for monitoring unit 1
- Bits [31:10]: Reserved



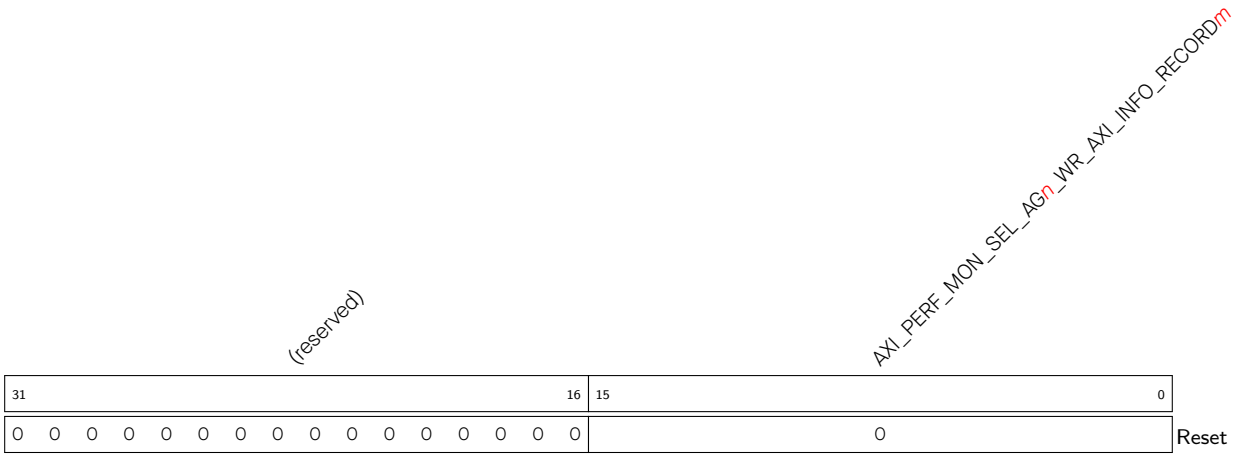
(R/W)

Register 23.22. AXI_PERF_MON_SEL_AG*n*_COUNTER*m*_REG (*n*: 0-1, *m*: 0-5) (0x0008+0x4*n*+0x8*m*)



AXI_PERF_MON_SEL_AG*n*_COUNTER*m*_RESULT (*n*: 0-1, *m*: 0-5) Represents the metric measurement result for the selected monitoring unit in this counter. [15:0] is the minimum result and [31:16] is the maximum result. (RO)

Register 23.23. AXI_PERF_MON_SEL_AG*n*_RANGE*m*_REG (*n*: 0-1, *m*: 0-5) (0x0038+0x4*n*+0x8*m*)

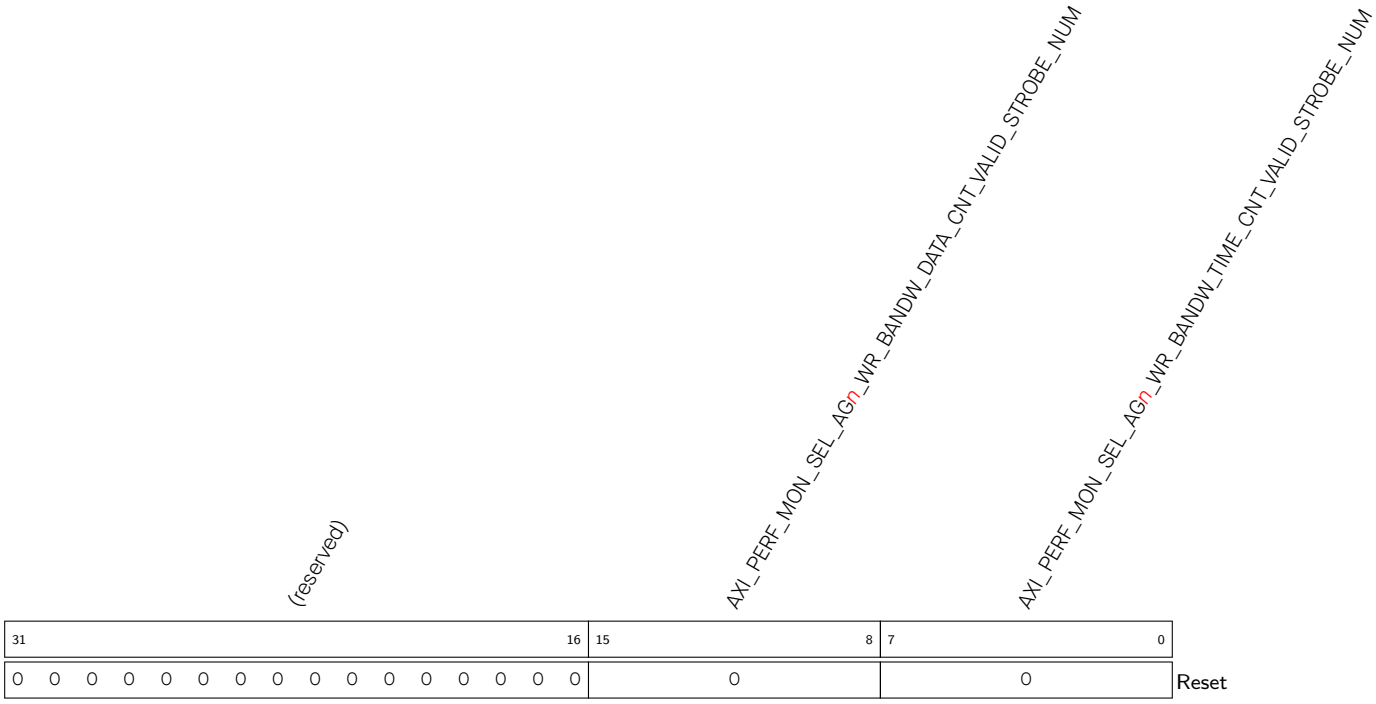


AXI_PERF_MON_SEL_AG*n*_RANGE*m*_RESULT (*n*: 0-1, *m*: 0-5) Represents the range statistics in this counter for the selected monitoring unit. (RO)

Register 23.24. AXI_PERF_MON_SEL_AG*n*_RD_AXI_INFO_RECORD*m*_REG (*n*: 0-1, *m*: 0-3) (0x0068+0x4n*+0x8**m*)**

AXI_PERF_MON_SEL_AG*n*_RD_AXI_INFO_RECORD*m* (*n*: 0-1, *m*: 0-3) Represents the record of the latest AXI read transaction information for the selected monitoring unit. [7:0] is ARLEN and [15:8] is ARID. (RO)

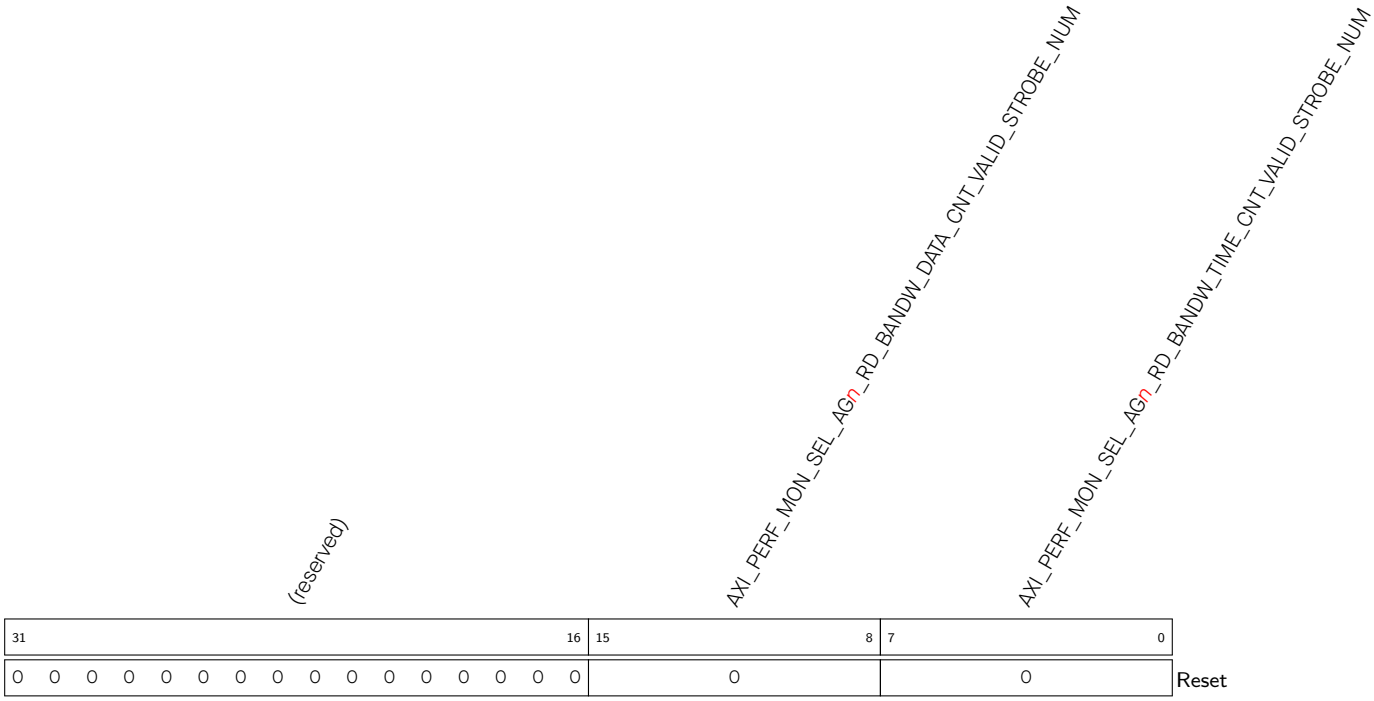
Register 23.25. AXI_PERF_MON_SEL_AG*n*_WR_AXI_INFO_RECORD*m*_REG (*n*: 0-1, *m*: 0-3) (0x0088+0x4n*+0x8**m*)**



AXI_PERF_MON_SEL_AG*n*_WR_AXI_INFO_RECORD*m* (*n*: 0-1, *m*: 0-3) Represents the record of the latest AXI write transaction information for the selected monitoring unit. [7:0] is AWLEN and [15:8] is AWID. (RO)

Register 23.26. AXI_PERF_MON_SEL_AG*n*_INS_BANDW_DATA*m*_REG (*n*: 0-1, *m*: 0-3) (0x00A8+0x4n*+0x8**m*)**

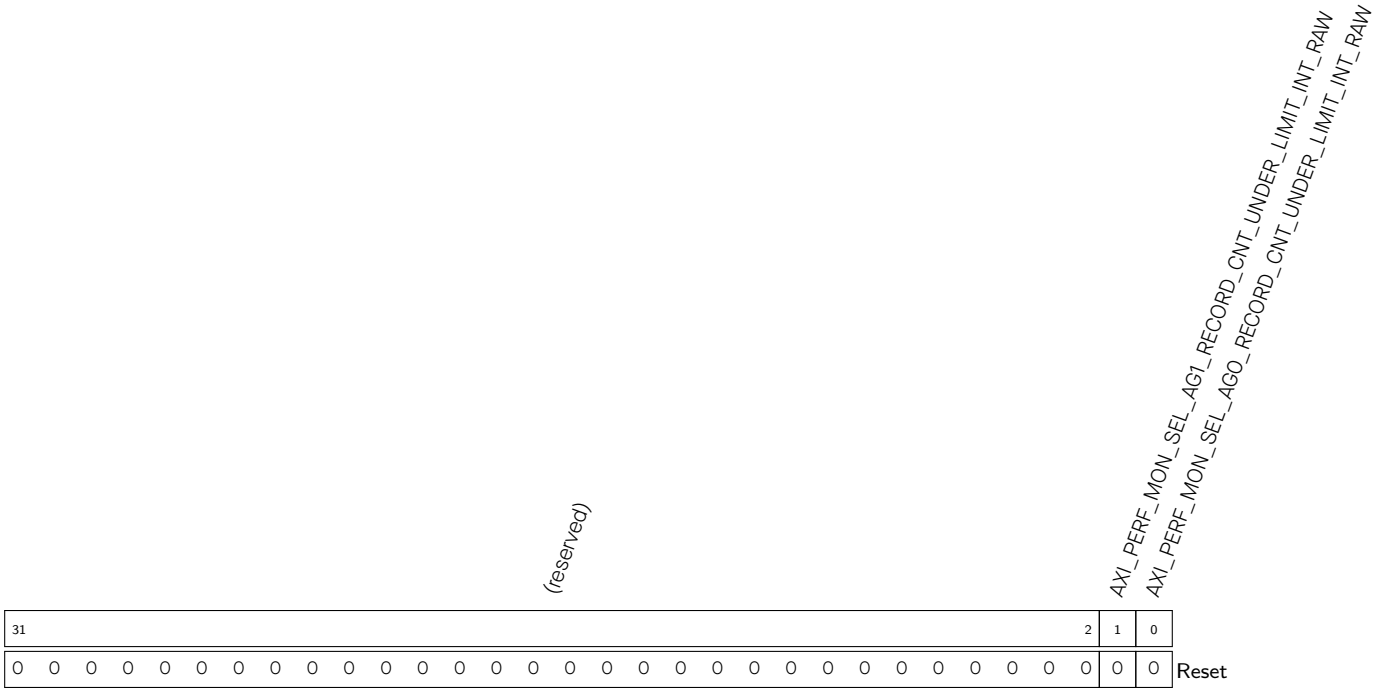
AXI_PERF_MON_SEL_AG*n*_INS_BANDW_DATA*m* (*n*: 0-1, *m*: 0-3) Represents the latest instantaneous bandwidth measurement within the configured time window for the selected monitoring unit. [15:0] is read and [31:16] is write. (RO)



Register 23.27. AXI_PERF_MON_SEL_AG*n*_WR_BANDW_CNT_VALID_STROBE_NUM_REG (*n*: 0-1) (0x01A8+0x4n*)**

AXI_PERF_MON_SEL_AG*n*_WR_BANDW_TIME_CNT_VALID_STROBE_NUM (*n*: 0-1) Represents the scaling factor for the time counter in write bandwidth tests. (R/W)

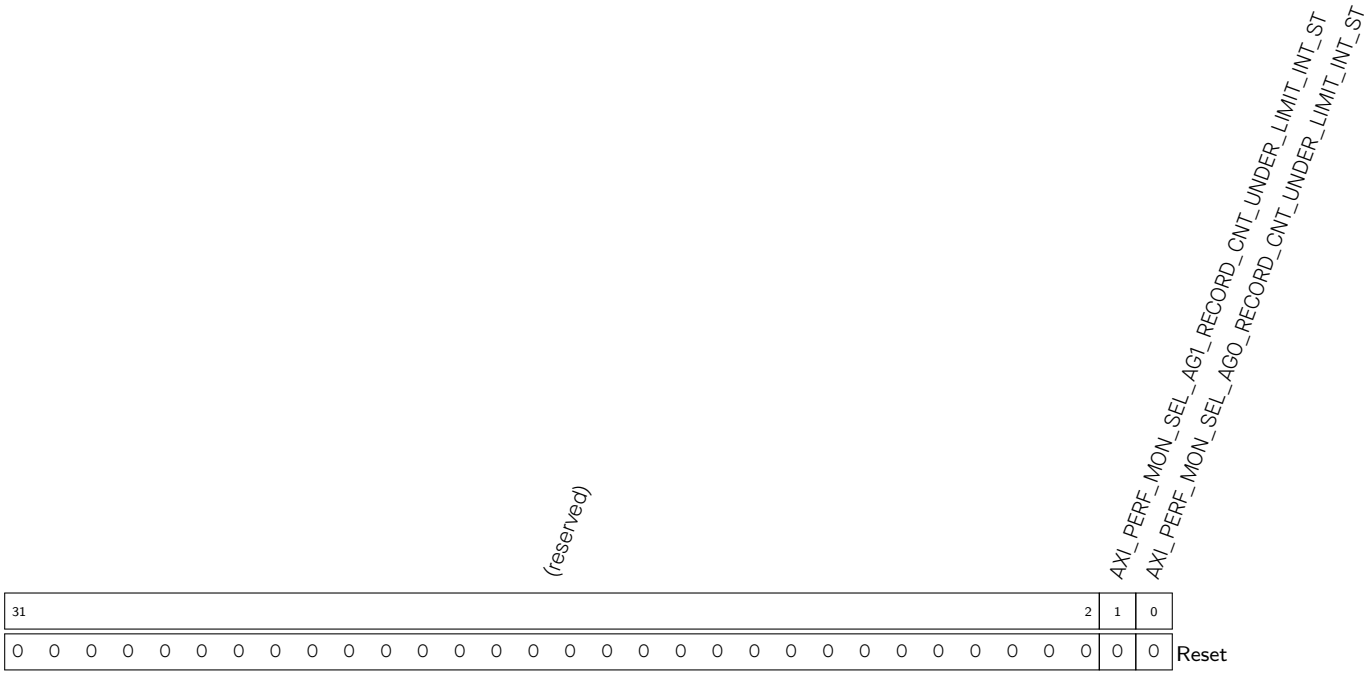
AXI_PERF_MON_SEL_AG*n*_WR_BANDW_DATA_CNT_VALID_STROBE_NUM (*n*: 0-1) Represents the scaling factor for the data counter in write bandwidth tests. (R/W)



Register 23.28. AXI_PERF_MON_SEL_AG*n*_RD_BANDW_CNT_VALID_STROBE_NUM_REG (*n*: 0-1) (0x01B0+0x4n*)**

AXI_PERF_MON_SEL_AG*n*_RD_BANDW_TIME_CNT_VALID_STROBE_NUM (*n*: 0-1) Represents the scaling factor for the time counter in read bandwidth tests. (R/W)

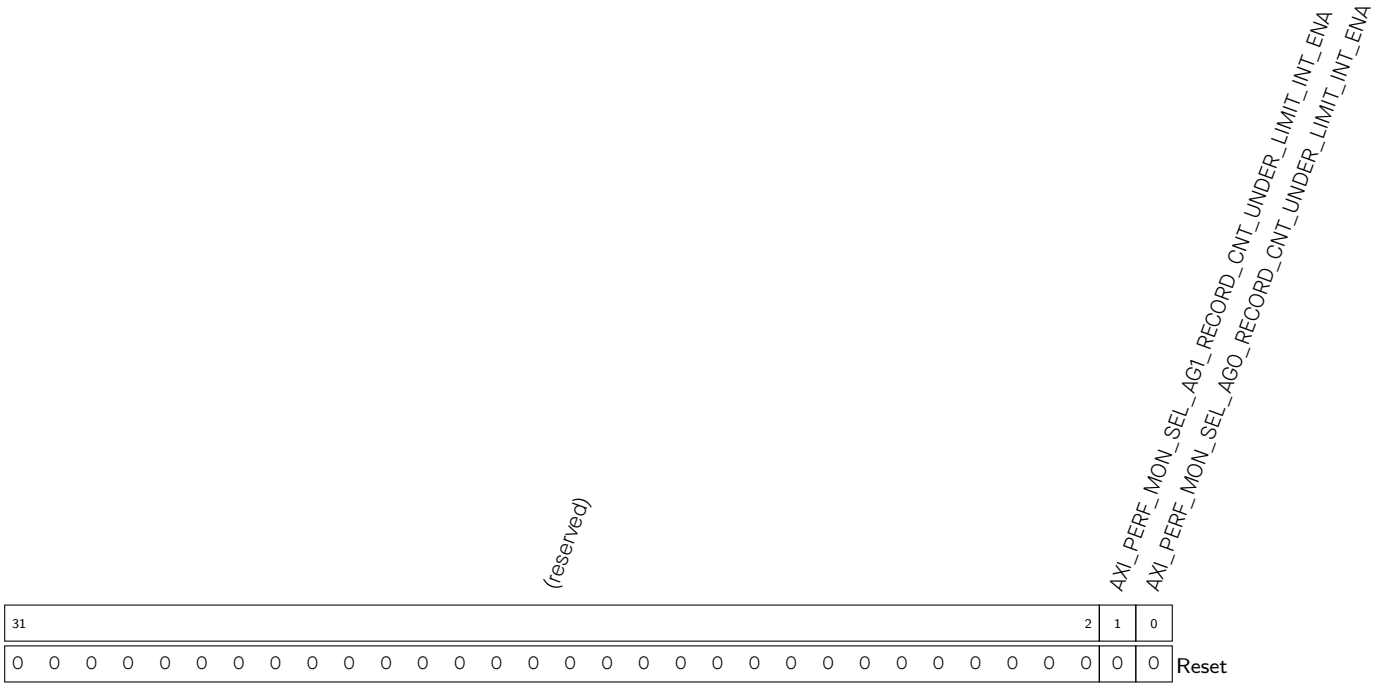
AXI_PERF_MON_SEL_AG*n*_RD_BANDW_DATA_CNT_VALID_STROBE_NUM (*n*: 0-1) Represents the scaling factor for the data counter in read bandwidth tests. (R/W)



Register 23.29. AXI_PERF_MON_SEL_AG_INT_RAW_REG (0x01C0)

AXI_PERF_MON_SEL_AG0_RECORD_CNT_UNDER_LIMIT_INT_RAW The raw interrupt status of AXI_PERF_MON_SEL_AG0_RECORD_CNT_UNDER_LIMIT_INT. (R/WTC/SS)

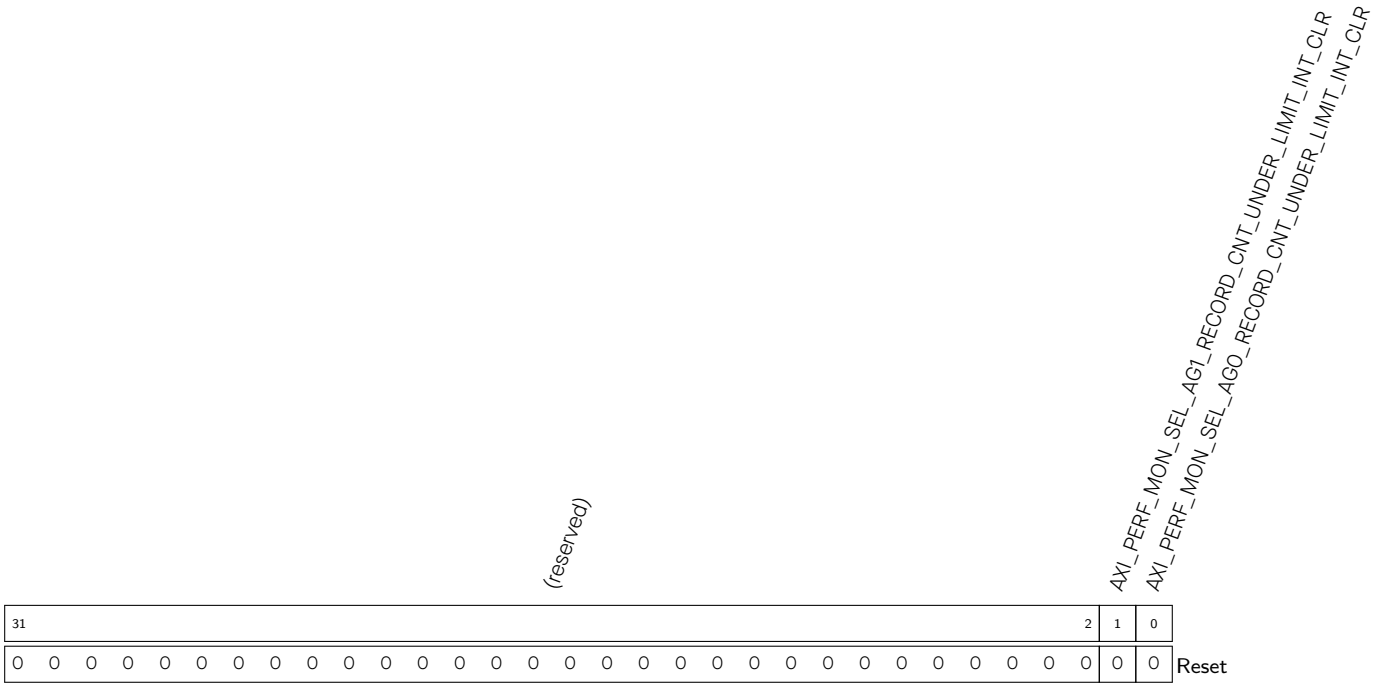
AXI_PERF_MON_SEL_AG1_RECORD_CNT_UNDER_LIMIT_INT_RAW The raw interrupt status of AXI_PERF_MON_SEL_AG1_RECORD_CNT_UNDER_LIMIT_INT. (R/WTC/SS)



Register 23.30. AXI_PERF_MON_SEL_AG_INT_ST_REG (0x01C4)

AXI_PERF_MON_SEL_AG0_RECORD_CNT_UNDER_LIMIT_INT_ST The masked interrupt status of AXI_PERF_MON_SEL_AG0_RECORD_CNT_UNDER_LIMIT_INT. (RO)

AXI_PERF_MON_SEL_AG1_RECORD_CNT_UNDER_LIMIT_INT_ST The masked interrupt status of AXI_PERF_MON_SEL_AG1_RECORD_CNT_UNDER_LIMIT_INT. (RO)



Register 23.31. AXI_PERF_MON_SEL_AG_INT_ENA_REG (0x01C8)

AXI_PERF_MON_SEL_AG0_RECORD_CNT_UNDER_LIMIT_INT_ENA Write 1 to enable AXI_PERF_MON_SEL_AG0_RECORD_CNT_UNDER_LIMIT_INT. (R/W)

AXI_PERF_MON_SEL_AG1_RECORD_CNT_UNDER_LIMIT_INT_ENA Write 1 to enable AXI_PERF_MON_SEL_AG1_RECORD_CNT_UNDER_LIMIT_INT. (R/W)

Register 23.32. AXI_PERF_MON_SEL_AG_INT_CLR_REG (0x01CC)

AXI_PERF_MON_SEL_AG0_RECORD_CNT_UNDER_LIMIT_INT_CLR Write 1 to clear
AXI_PERF_MON_SEL_AG0_RECORD_CNT_UNDER_LIMIT_INT. (WT)

AXI_PERF_MON_SEL_AG1_RECORD_CNT_UNDER_LIMIT_INT_CLR Write 1 to clear
AXI_PERF_MON_SEL_AG1_RECORD_CNT_UNDER_LIMIT_INT. (WT)

Chapter 24

LP Mailbox

24.1 Overview

ESP32-P4 integrates an LP Mailbox module which provides an efficient inter-core communication mechanism between the LP CPU and HP CPU0/1. The LP Mailbox module comprises of sixteen 32-bit message registers that the LP CPU and HP CPU0/1 can use to store and exchange message. Inter-core communication between LP CPU and HP CPU0/1 is achieved through an interrupt mechanism implemented within the LP Mailbox module.

24.2 Features

ESP32-P4 LP Mailbox has the following features:

- Sixteen 32-bit message registers for inter-core communication
- LP CPU external interrupt signal: MB_LP_INTR
- HP CPU*x* (*x*: 0 ~ 1) external interrupt signal: MB_HP_INTR

24.3 Functional Description

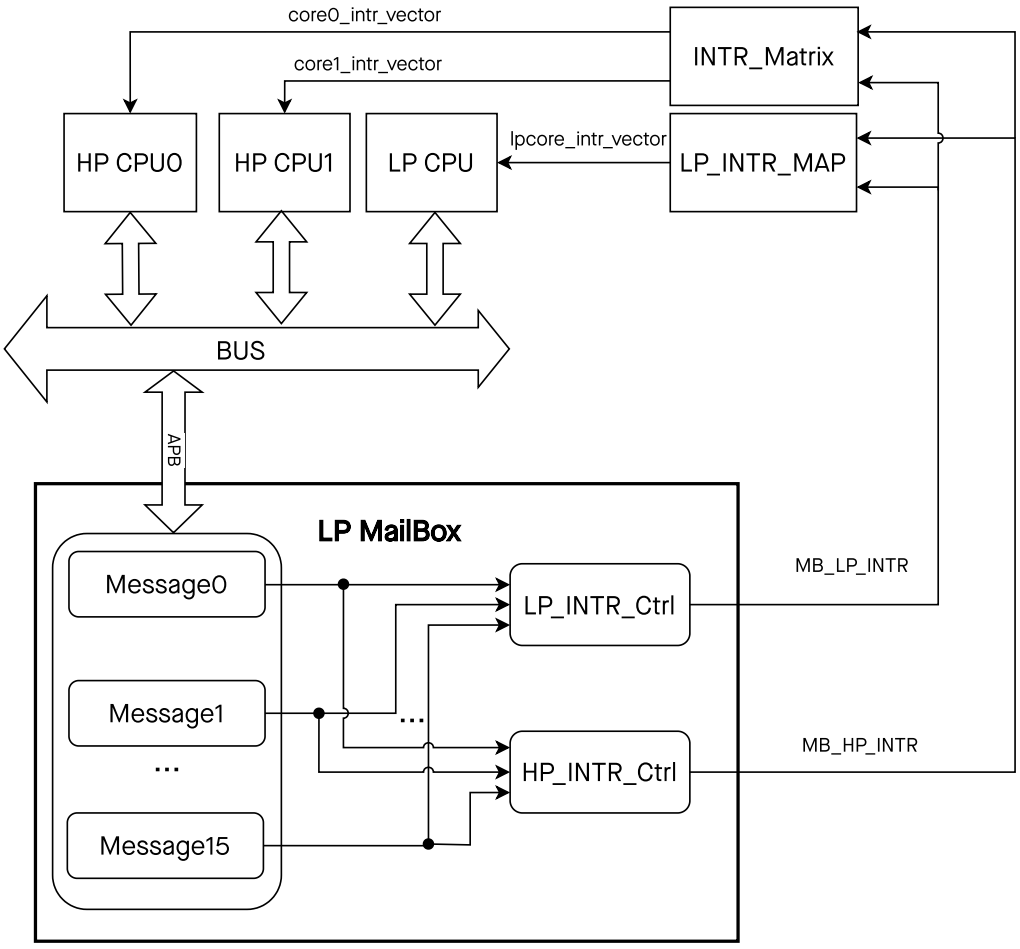


Figure 24.3-1. LP Mailbox Block Diagram

24.3.1 Message Registers

The LP Mailbox provides sixteen 32-bit message registers in total, denoted as MB_MESSAGE_0_REG ~ MB_MESSAGE_15_REG, for caching inter-core communication messages. Both LP CPU and HP CPU0/1 can read and write these message registers to pass or retrieve message.

Read and write message registers is done through the APB bus, using APB_CLK, which is the only one clock in LP Mailbox. For more information about the clock, please refer to Chapter 11 *Reset and Clock*.

24.3.2 Interrupts

ESP32-P4 LP Mailbox can generate the following external interrupt signals:

- MB_LP_INTR
- MB_HP_INTR

MB_LP_INTR is directly mapped to LP CPU (see *Low-Power CPU*), and MB_HP_INTR can be mapped to HP CPU0/1 through the Interrupt Matrix. These interrupt signals are generated by internal interrupt sources of the

LP Mailbox module. Table 24.3-1 lists the internal interrupt sources, interrupt trigger conditions, and generated interrupt signals of the LP Mailbox.

Table 24.3-1. LP Mailbox's Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
MB_HP_*m*_INT	Write to MB_MESSAGE_*m*_REG	MB_HP_INTR
MB_LP_*n*_INT	Write to MB_MESSAGE_*n*_REG	MB_LP_INTR

Note:

- *m* and *n* can be 0 ~ 15.
- MB_HP_INTR can also serve as an external interrupt source for LP CPU and be mapped to LP CPU by LP_INTR_MAP as illustrated in Figure 24.3-1. For more information about LP_INTR_MAP, please refer to Chapter 5 *Low-Power CPU*.
- MB_LP_INTR can also serve as an external interrupt source for HP CPU*x* and can be mapped to HP CPU*x* through the Interrupt Matrix.
- When the LP Mailbox is required to assign different interrupt sources for HP CPU0 and HP CPU1, it can map MB_HP_INTR and MB_LP_INTR independently to HP CPU0 and HP CPU1 using the Interrupt Matrix.

24.3.3 Inter-Core Communication

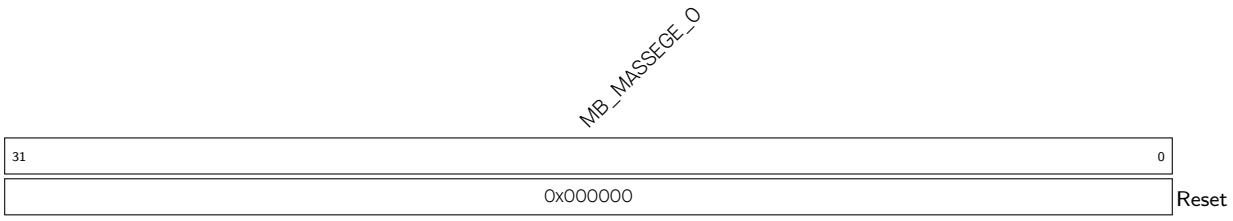
When communication is required between LP CPU and HP CPU*x*, subset of or all message registers in the LP Mailbox can be utilized to share message as needed. The synchronization of message can be achieved through the corresponding interrupts. During communication, software must ensure that only the sender is allowed to write to the message registers to prevent data corruption.

- Example of initiating communication from HP CPU0 to LP CPU using MB_MESSAGE_*n*_REG:
  - Set MB_LP_*n*_INT_ENA to enable the MB_LP_*n*_INT interrupt.
  - HP CPU0 writes to MB_MASSEGE_*n*_REG, caching shared message.
  - LP CPU checks MB_LP_INT_ST_REG interrupt status register, finding the MB_LP_*n*_ST status bit set.
  - LP CPU reads MB_MASSEGE_*n*_REG to retrieve shared message.
- Example of initiating communication from LP CPU to HP CPU0:
  - Set MB_HP_*m*_INT_ENA to enable the MB_HP_*m*_INT interrupt.
  - Configure the Interrupt Matrix to map MB_HP_INTR to HP CPU0. See Chapter 13 *Interrupt Matrix*.
  - LP CPU writes to MB_MASSEGE_*m*_REG, caching shared messages.
  - HP CPU0 checks the MB_HP_INT_ST_REG interrupt status register, finding the MB_HP_*m*_ST status bit set.
  - HP CPU0 reads MB_MASSEGE_*m*_REG to retrieve shared messages.

24.4 Register Summary

The addresses in this section are relative to LP Mailbox base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

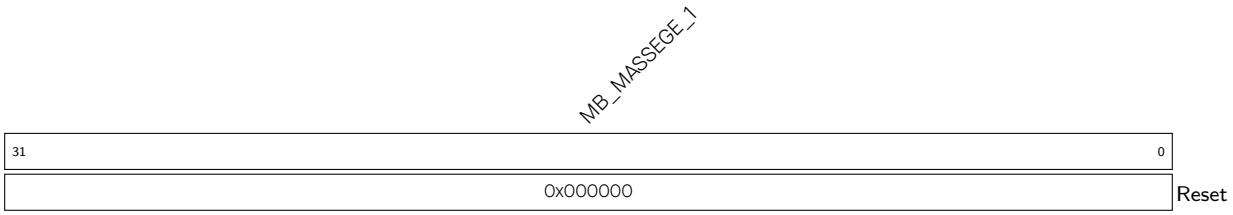
The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Configuration Registers			
MB_MASSEGE_0_REG	Message register 0	0x0000	R/W
MB_MASSEGE_1_REG	Message register 1	0x0004	R/W
MB_MASSEGE_2_REG	Message register 2	0x0008	R/W
MB_MASSEGE_3_REG	Message register 3	0x000C	R/W
MB_MASSEGE_4_REG	Message register 4	0x0010	R/W
MB_MASSEGE_5_REG	Message register 5	0x0014	R/W
MB_MASSEGE_6_REG	Message register 6	0x0018	R/W
MB_MASSEGE_7_REG	Message register 7	0x001C	R/W
MB_MASSEGE_8_REG	Message register 8	0x0020	R/W
MB_MASSEGE_9_REG	Message register 9	0x0024	R/W
MB_MASSEGE_10_REG	Message register 10	0x0028	R/W
MB_MASSEGE_11_REG	Message register 11	0x002C	R/W
MB_MASSEGE_12_REG	Message register 12	0x0030	R/W
MB_MASSEGE_13_REG	Message register 13	0x0034	R/W
MB_MASSEGE_14_REG	Message register 14	0x0038	R/W
MB_MASSEGE_15_REG	Message register 15	0x003C	R/W
MB_REG_CLK_EN_REG	Clock gate register	0x0060	R/W
Interrupt Registers			
MB_LP_INT_RAW_REG	MB_LP_INTR raw bits	0x0040	RO
MB_LP_INT_ST_REG	MB_LP_INTR status bits	0x0044	RO
MB_LP_INT_ENA_REG	MB_LP_INTR enable bits	0x0048	R/W
MB_LP_INT_CLR_REG	MB_LP_INTR clear bits	0x004C	WO
MB_HP_INT_RAW_REG	MB_HP_INTR raw bits	0x0050	RO
MB_HP_INT_ST_REG	MB_HP_INTR status bits	0x0054	RO
MB_HP_INT_ENA_REG	MB_HP_INTR enable bits	0x0058	R/W
MB_HP_INT_CLR_REG	MB_HP_INTR clear bits	0x005C	WO

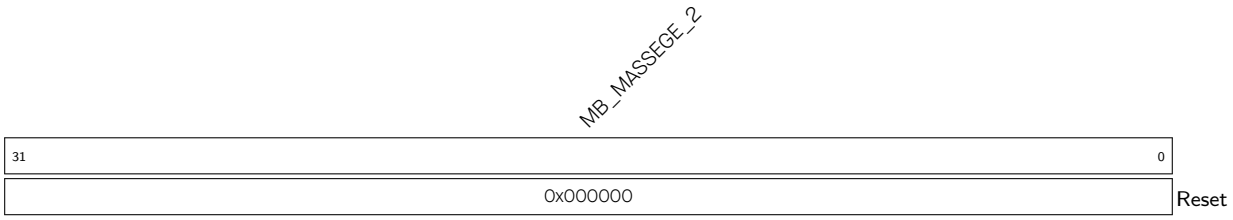
24.5 Registers

The addresses in this section are relative to LP Mailbox base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



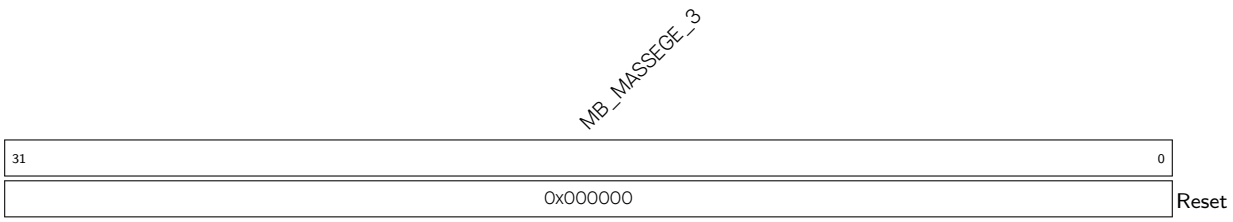
For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 24.1. MB_MASSEGE_0_REG (0x0000)



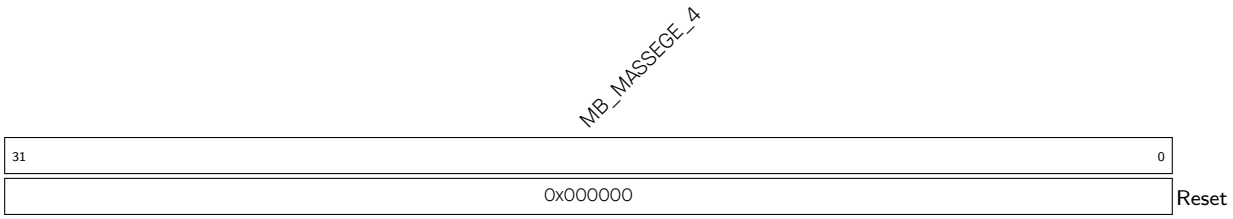
MB_MASSEGE_0 Message register 0. (R/W)

Register 24.2. MB_MASSEGE_1_REG (0x0004)



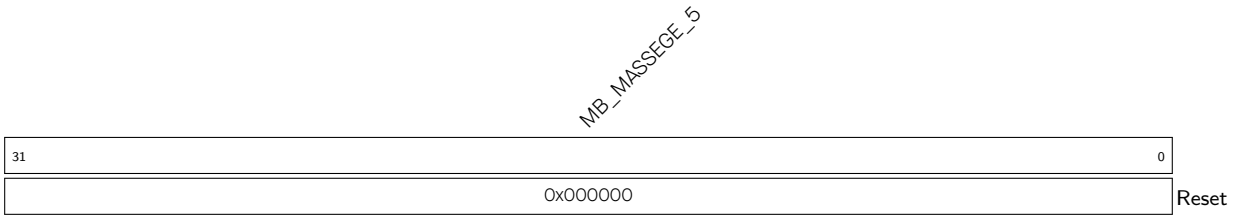
MB_MASSEGE_1 Message register 1. (R/W)

Register 24.3. MB_MASSEGE_2_REG (0x0008)



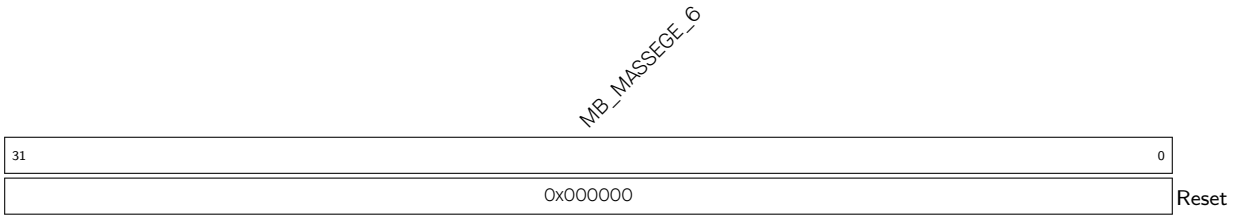
MB_MASSEGE_2 Message register 2. (R/W)

Register 24.4. MB_MASSEGE_3_REG (0x000C)



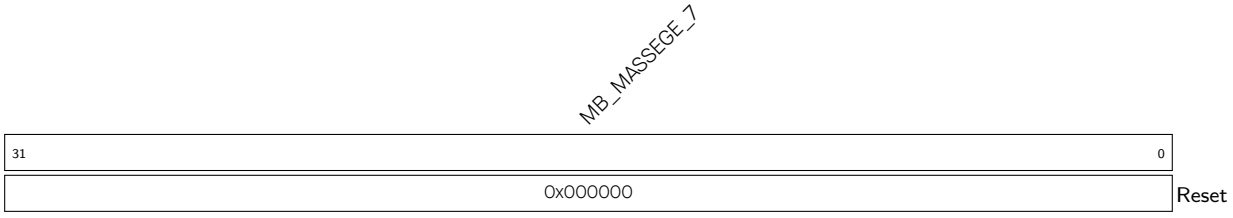
MB_MASSEGE_3 Message register 3. (R/W)

Register 24.5. MB_MASSEGE_4_REG (0x0010)



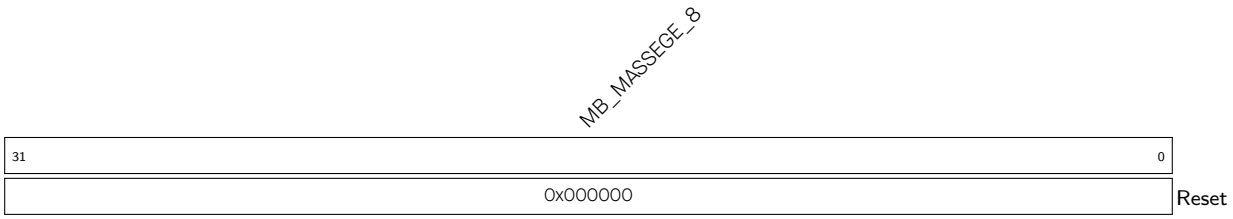
MB_MASSEGE_4 Message register 4. (R/W)

Register 24.6. MB_MASSEGE_5_REG (0x0014)



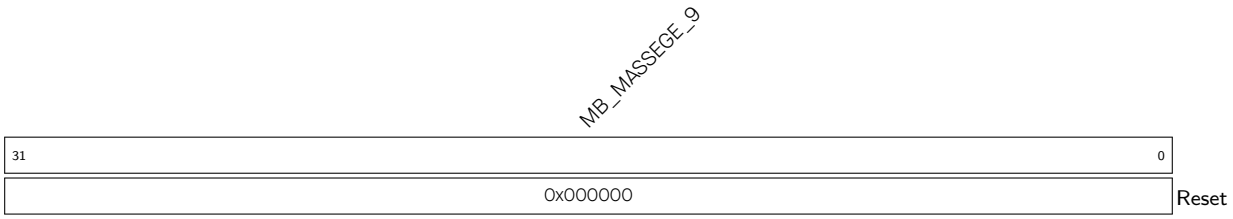
MB_MASSEGE_5 Message register 5. (R/W)

Register 24.7. MB_MASSEGE_6_REG (0x0018)



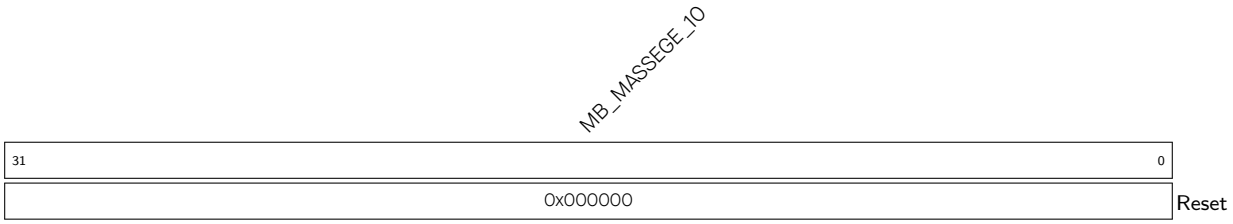
MB_MASSEGE_6 Message register 6. (R/W)

Register 24.8. MB_MASSEGE_7_REG (0x001C)



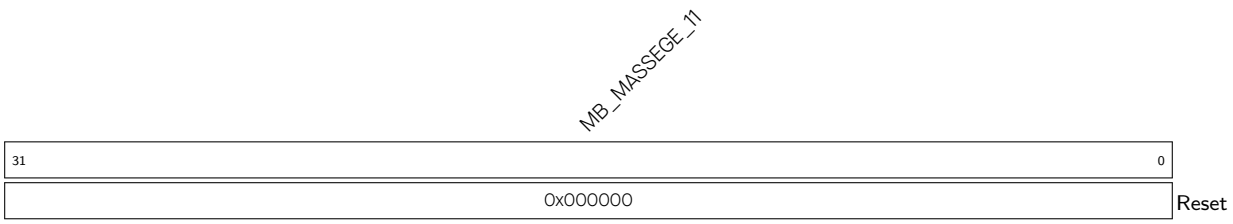
MB_MASSEGE_7 Message register 7. (R/W)

Register 24.9. MB_MASSEGE_8_REG (0x0020)



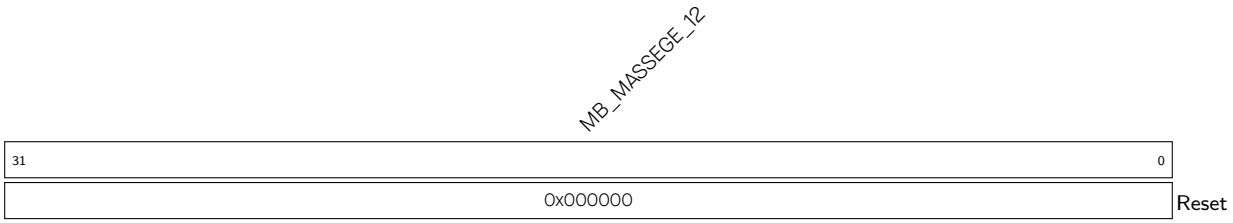
MB_MASSEGE_8 Message register 8. (R/W)

Register 24.10. MB_MASSEGE_9_REG (0x0024)



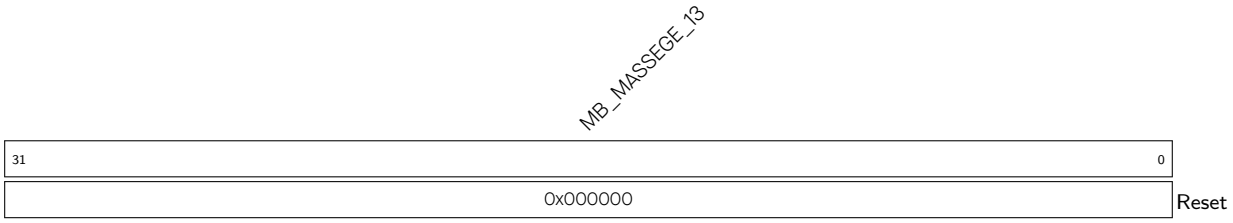
MB_MASSEGE_9 Message register 9. (R/W)

Register 24.11. MB_MASSEGE_10_REG (0x0028)



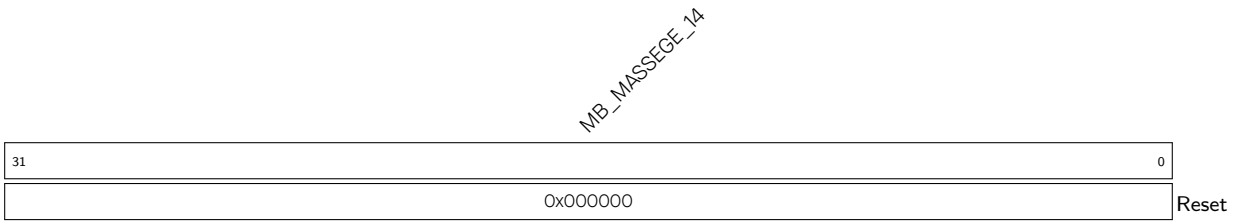
MB_MASSEGE_10 Message register 10. (R/W)

Register 24.12. MB_MASSEGE_11_REG (0x002C)



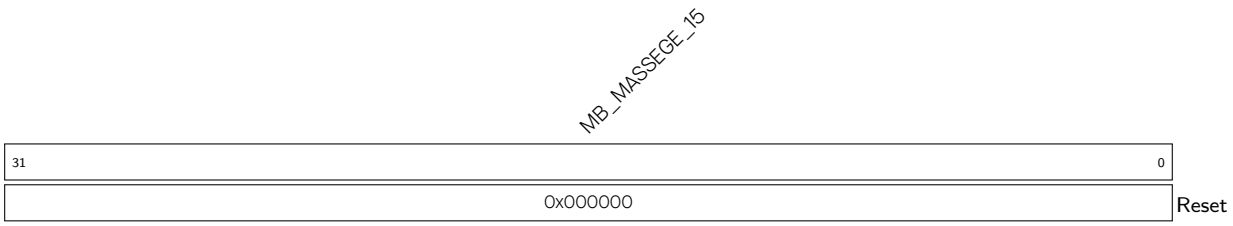
MB_MASSEGE_11 Message register 11. (R/W)

Register 24.13. MB_MASSEGE_12_REG (0x0030)



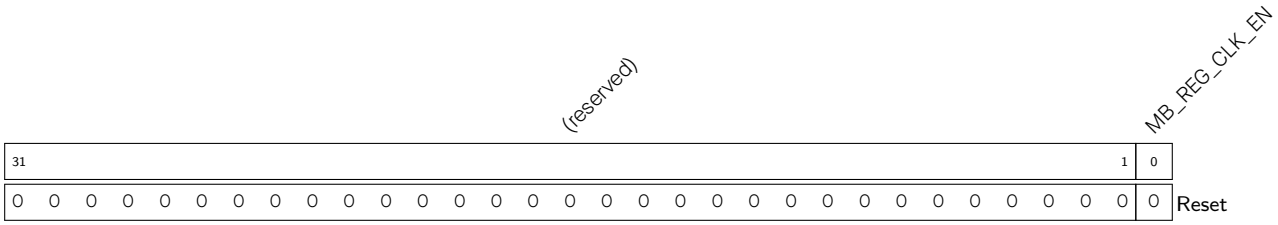
MB_MASSEGE_12 Message register 12. (R/W)

Register 24.14. MB_MASSEGE_13_REG (0x0034)



MB_MASSEGE_13 Message register 13. (R/W)

Register 24.15. MB_MASSEGE_14_REG (0x0038)

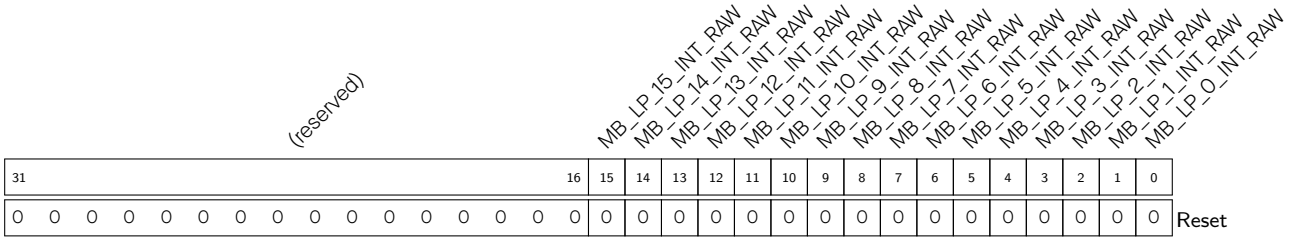


MB_MASSEGE_14 Message register 14. (R/W)

Register 24.16. MB_MASSEGE_15_REG (0x003C)

MB_MASSEGE_15 Message register 15. (R/W)

Register 24.17. MB_REG_CLK_EN_REG (0x0060)



MB_REG_CLK_EN Configures register clock gating.

1: Register clock is always enabled for read and write operations.

0: Only enable clock for register read or write operations.

(R/W)

Register 24.18. MB_LP_INT_RAW_REG (0x0040)

MB_LP_0_INT_RAW The raw interrupt bit of the MB_LP_0_INT interrupt. (RO)

MB_LP_1_INT_RAW The raw interrupt bit of the MB_LP_1_INT interrupt. (RO)

MB_LP_2_INT_RAW The raw interrupt bit of the MB_LP_2_INT interrupt. (RO)

MB_LP_3_INT_RAW The raw interrupt bit of the MB_LP_3_INT interrupt. (RO)

MB_LP_4_INT_RAW The raw interrupt bit of the MB_LP_4_INT interrupt. (RO)

MB_LP_5_INT_RAW The raw interrupt bit of the MB_LP_5_INT interrupt. (RO)

MB_LP_6_INT_RAW The raw interrupt bit of the MB_LP_6_INT interrupt. (RO)

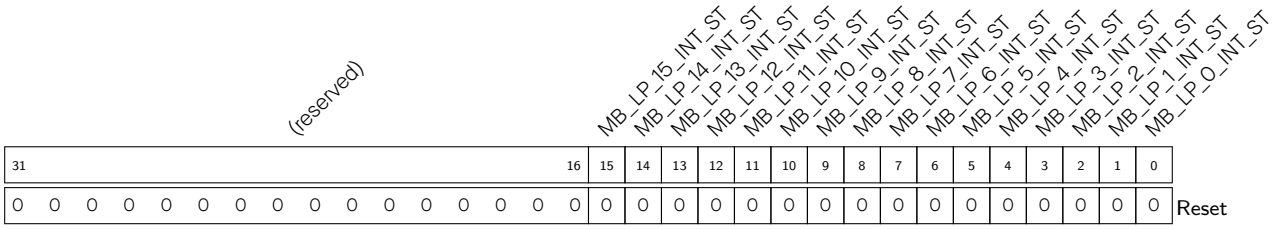
MB_LP_7_INT_RAW The raw interrupt bit of the MB_LP_7_INT interrupt. (RO)

MB_LP_8_INT_RAW The raw interrupt bit of the MB_LP_8_INT interrupt. (RO)

MB_LP_9_INT_RAW The raw interrupt bit of the MB_LP_9_INT interrupt. (RO)

MB_LP_10_INT_RAW The raw interrupt bit of the MB_LP_10_INT interrupt. (RO)

MB_LP_11_INT_RAW The raw interrupt bit of the MB_LP_11_INT interrupt. (RO)



MB_LP_12_INT_RAW The raw interrupt bit of the MB_LP_12_INT interrupt. (RO)

MB_LP_13_INT_RAW The raw interrupt bit of the MB_LP_13_INT interrupt. (RO)

MB_LP_14_INT_RAW The raw interrupt bit of the MB_LP_14_INT interrupt. (RO)

MB_LP_15_INT_RAW The raw interrupt bit of the MB_LP_15_INT interrupt. (RO)

Register 24.19. MB_LP_INT_ST_REG (0x0044)

MB_LP_0_INT_ST The masked interrupt status bit of the MB_LP_0_INT interrupt. (RO)

MB_LP_1_INT_ST The masked interrupt status bit of the MB_LP_1_INT interrupt. (RO)

MB_LP_2_INT_ST The masked interrupt status bit of the MB_LP_2_INT interrupt. (RO)

MB_LP_3_INT_ST The masked interrupt status bit of the MB_LP_3_INT interrupt. (RO)

MB_LP_4_INT_ST The masked interrupt status bit of the MB_LP_4_INT interrupt. (RO)

MB_LP_5_INT_ST The masked interrupt status bit of the MB_LP_5_INT interrupt. (RO)

MB_LP_6_INT_ST The masked interrupt status bit of the MB_LP_6_INT interrupt. (RO)

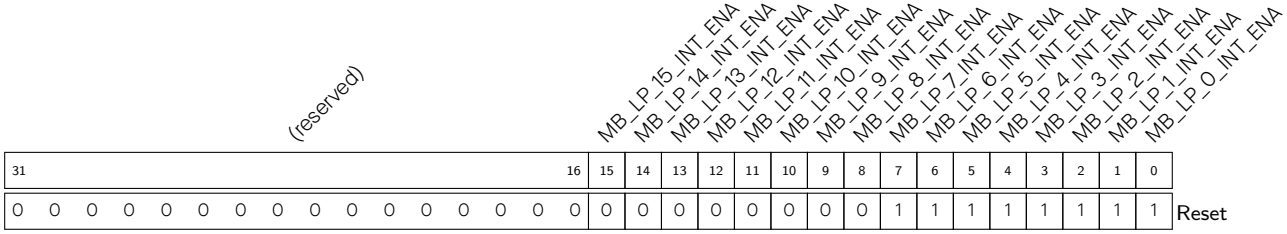
MB_LP_7_INT_ST The masked interrupt status bit of the MB_LP_7_INT interrupt. (RO)

MB_LP_8_INT_ST The masked interrupt status bit of the MB_LP_8_INT interrupt. (RO)

MB_LP_9_INT_ST The masked interrupt status bit of the MB_LP_9_INT interrupt. (RO)

MB_LP_10_INT_ST The masked interrupt status bit of the MB_LP_10_INT interrupt. (RO)

MB_LP_11_INT_ST The masked interrupt status bit of the MB_LP_11_INT interrupt. (RO)



MB_LP_12_INT_ST The masked interrupt status bit of the MB_LP_12_INT interrupt. (RO)

MB_LP_13_INT_ST The masked interrupt status bit of the MB_LP_13_INT interrupt. (RO)

MB_LP_14_INT_ST The masked interrupt status bit of the MB_LP_14_INT interrupt. (RO)

MB_LP_15_INT_ST The masked interrupt status bit of the MB_LP_15_INT interrupt. (RO)

Register 24.20. MB_LP_INT_ENA_REG (0x0048)

MB_LP_0_INT_ENA Write 1 to enable the MB_LP_0_INT interrupt. (R/W)

MB_LP_1_INT_ENA Write 1 to enable the MB_LP_1_INT interrupt. (R/W)

MB_LP_2_INT_ENA Write 1 to enable the MB_LP_2_INT interrupt. (R/W)

MB_LP_3_INT_ENA Write 1 to enable the MB_LP_3_INT interrupt. (R/W)

MB_LP_4_INT_ENA Write 1 to enable the MB_LP_4_INT interrupt. (R/W)

MB_LP_5_INT_ENA Write 1 to enable the MB_LP_5_INT interrupt. (R/W)

MB_LP_6_INT_ENA Write 1 to enable the MB_LP_6_INT interrupt. (R/W)

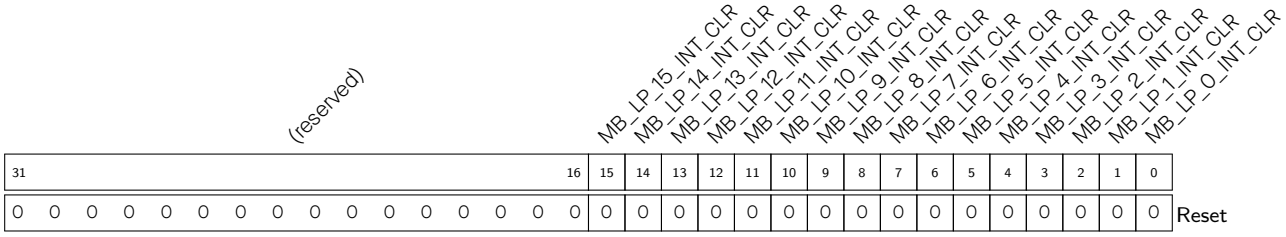
MB_LP_7_INT_ENA Write 1 to enable the MB_LP_7_INT interrupt. (R/W)

MB_LP_8_INT_ENA Write 1 to enable the MB_LP_8_INT interrupt. (R/W)

MB_LP_9_INT_ENA Write 1 to enable the MB_LP_9_INT interrupt. (R/W)

MB_LP_10_INT_ENA Write 1 to enable the MB_LP_10_INT interrupt. (R/W)

MB_LP_11_INT_ENA Write 1 to enable the MB_LP_11_INT interrupt. (R/W)



MB_LP_12_INT_ENA Write 1 to enable the MB_LP_12_INT interrupt. (R/W)

MB_LP_13_INT_ENA Write 1 to enable the MB_LP_13_INT interrupt. (R/W)

MB_LP_14_INT_ENA Write 1 to enable the MB_LP_14_INT interrupt. (R/W)

MB_LP_15_INT_ENA Write 1 to enable the MB_LP_15_INT interrupt. (R/W)

Register 24.21. MB_LP_INT_CLR_REG (0x004C)

MB_LP_0_INT_CLR Write 1 to clear the MB_LP_0_INT interrupt. (WO)

MB_LP_1_INT_CLR Write 1 to clear the MB_LP_1_INT interrupt. (WO)

MB_LP_2_INT_CLR Write 1 to clear the MB_LP_2_INT interrupt. (WO)

MB_LP_3_INT_CLR Write 1 to clear the MB_LP_3_INT interrupt. (WO)

MB_LP_4_INT_CLR Write 1 to clear the MB_LP_4_INT interrupt. (WO)

MB_LP_5_INT_CLR Write 1 to clear the MB_LP_5_INT interrupt. (WO)

MB_LP_6_INT_CLR Write 1 to clear the MB_LP_6_INT interrupt. (WO)

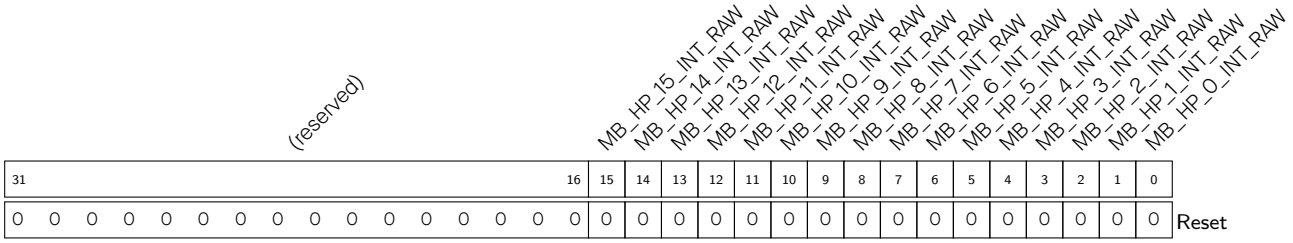
MB_LP_7_INT_CLR Write 1 to clear the MB_LP_7_INT interrupt. (WO)

MB_LP_8_INT_CLR Write 1 to clear the MB_LP_8_INT interrupt. (WO)

MB_LP_9_INT_CLR Write 1 to clear the MB_LP_9_INT interrupt. (WO)

MB_LP_10_INT_CLR Write 1 to clear the MB_LP_10_INT interrupt. (WO)

MB_LP_11_INT_CLR Write 1 to clear the MB_LP_11_INT interrupt. (WO)



MB_LP_12_INT_CLR Write 1 to clear the MB_LP_12_INT interrupt. (WO)

MB_LP_13_INT_CLR Write 1 to clear the MB_LP_13_INT interrupt. (WO)

MB_LP_14_INT_CLR Write 1 to clear the MB_LP_14_INT interrupt. (WO)

MB_LP_15_INT_CLR Write 1 to clear the MB_LP_15_INT interrupt. (WO)

Register 24.22. MB_HP_INT_RAW_REG (0x0050)

MB_HP_0_INT_RAW The raw interrupt bit of the MB_HP_0_INT interrupt. (RO)

MB_HP_1_INT_RAW The raw interrupt bit of the MB_HP_1_INT interrupt. (RO)

MB_HP_2_INT_RAW The raw interrupt bit of the MB_HP_2_INT interrupt. (RO)

MB_HP_3_INT_RAW The raw interrupt bit of the MB_HP_3_INT interrupt. (RO)

MB_HP_4_INT_RAW The raw interrupt bit of the MB_HP_4_INT interrupt. (RO)

MB_HP_5_INT_RAW The raw interrupt bit of the MB_HP_5_INT interrupt. (RO)

MB_HP_6_INT_RAW The raw interrupt bit of the MB_HP_6_INT interrupt. (RO)

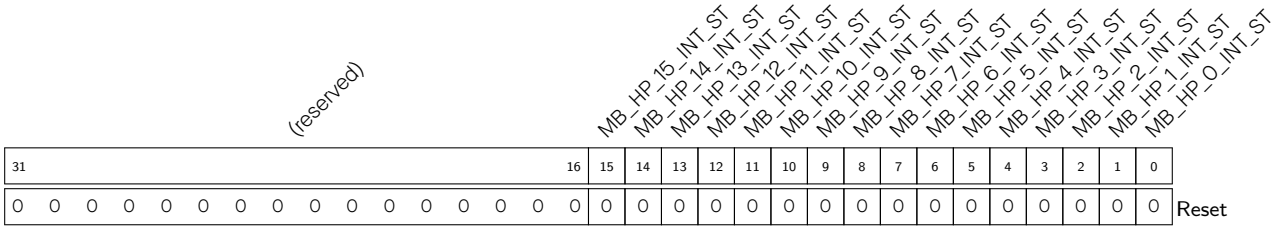
MB_HP_7_INT_RAW The raw interrupt bit of the MB_HP_7_INT interrupt. (RO)

MB_HP_8_INT_RAW The raw interrupt bit of the MB_HP_8_INT interrupt. (RO)

MB_HP_9_INT_RAW The raw interrupt bit of the MB_HP_9_INT interrupt. (RO)

MB_HP_10_INT_RAW The raw interrupt bit of the MB_HP_10_INT interrupt. (RO)

MB_HP_11_INT_RAW The raw interrupt bit of the MB_HP_11_INT interrupt. (RO)



MB_HP_12_INT_RAW The raw interrupt bit of the MB_HP_12_INT interrupt. (RO)

MB_HP_13_INT_RAW The raw interrupt bit of the MB_HP_13_INT interrupt. (RO)

MB_HP_14_INT_RAW The raw interrupt bit of the MB_HP_14_INT interrupt. (RO)

MB_HP_15_INT_RAW The raw interrupt bit of the MB_HP_15_INT interrupt. (RO)

Register 24.23. MB_HP_INT_ST_REG (0x0054)

MB_HP_0_INT_ST The masked interrupt status bit of the MB_HP_0_INT interrupt. (RO)

MB_HP_1_INT_ST The masked interrupt status bit of the MB_HP_1_INT interrupt. (RO)

MB_HP_2_INT_ST The masked interrupt status bit of the MB_HP_2_INT interrupt. (RO)

MB_HP_3_INT_ST The masked interrupt status bit of the MB_HP_3_INT interrupt. (RO)

MB_HP_4_INT_ST The masked interrupt status bit of the MB_HP_4_INT interrupt. (RO)

MB_HP_5_INT_ST The masked interrupt status bit of the MB_HP_5_INT interrupt. (RO)

MB_HP_6_INT_ST The masked interrupt status bit of the MB_HP_6_INT interrupt. (RO)

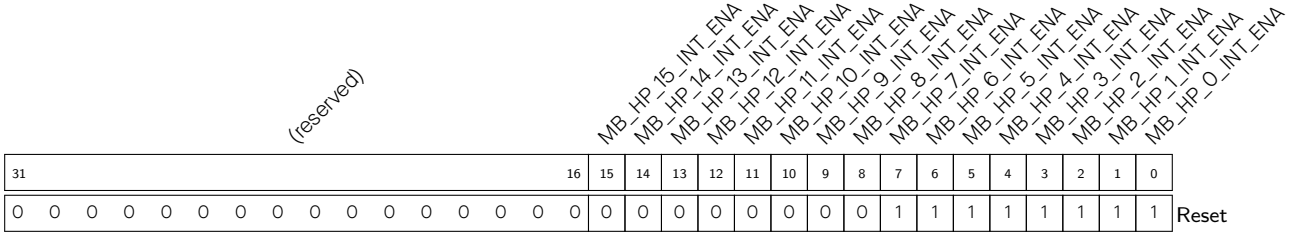
MB_HP_7_INT_ST The masked interrupt status bit of the MB_HP_7_INT interrupt. (RO)

MB_HP_8_INT_ST The masked interrupt status bit of the MB_HP_8_INT interrupt. (RO)

MB_HP_9_INT_ST The masked interrupt status bit of the MB_HP_9_INT interrupt. (RO)

MB_HP_10_INT_ST The masked interrupt status bit of the MB_HP_10_INT interrupt. (RO)

MB_HP_11_INT_ST The masked interrupt status bit of the MB_HP_11_INT interrupt. (RO)



MB_HP_12_INT_ST The masked interrupt status bit of the MB_HP_12_INT interrupt. (RO)

MB_HP_13_INT_ST The masked interrupt status bit of the MB_HP_13_INT interrupt. (RO)

MB_HP_14_INT_ST The masked interrupt status bit of the MB_HP_14_INT interrupt. (RO)

MB_HP_15_INT_ST The masked interrupt status bit of the MB_HP_15_INT interrupt. (RO)

Register 24.24. MB_HP_INT_ENA_REG (0x0058)

MB_HP_0_INT_ENA Write 1 to enable the MB_HP_0_INT interrupt. (R/W)

MB_HP_1_INT_ENA Write 1 to enable the MB_HP_1_INT interrupt. (R/W)

MB_HP_2_INT_ENA Write 1 to enable the MB_HP_2_INT interrupt. (R/W)

MB_HP_3_INT_ENA Write 1 to enable the MB_HP_3_INT interrupt. (R/W)

MB_HP_4_INT_ENA Write 1 to enable the MB_HP_4_INT interrupt. (R/W)

MB_HP_5_INT_ENA Write 1 to enable the MB_HP_5_INT interrupt. (R/W)

MB_HP_6_INT_ENA Write 1 to enable the MB_HP_6_INT interrupt. (R/W)

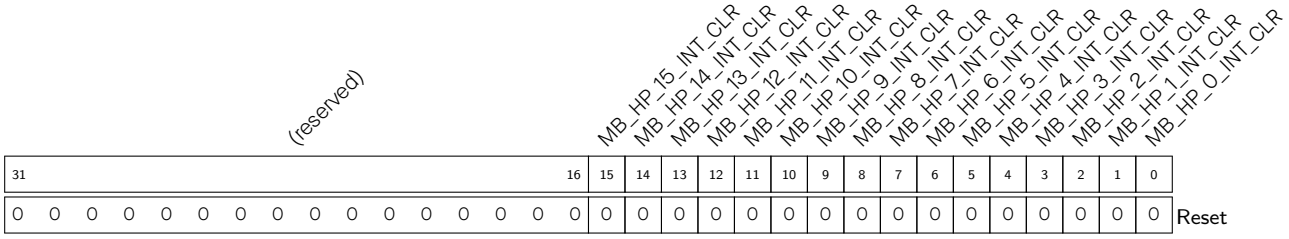
MB_HP_7_INT_ENA Write 1 to enable the MB_HP_7_INT interrupt. (R/W)

MB_HP_8_INT_ENA Write 1 to enable the MB_HP_8_INT interrupt. (R/W)

MB_HP_9_INT_ENA Write 1 to enable the MB_HP_9_INT interrupt. (R/W)

MB_HP_10_INT_ENA Write 1 to enable the MB_HP_10_INT interrupt. (R/W)

MB_HP_11_INT_ENA Write 1 to enable the MB_HP_11_INT interrupt. (R/W)



MB_HP_12_INT_ENA Write 1 to enable the MB_HP_12_INT interrupt. (R/W)

MB_HP_13_INT_ENA Write 1 to enable the MB_HP_13_INT interrupt. (R/W)

MB_HP_14_INT_ENA Write 1 to enable the MB_HP_14_INT interrupt. (R/W)

MB_HP_15_INT_ENA Write 1 to enable the MB_HP_15_INT interrupt. (R/W)

Register 24.25. MB_HP_INT_CLR_REG (0x005C)

MB_HP_0_INT_CLR Write 1 to clear the MB_HP_0_INT interrupr. (WO)

MB_HP_1_INT_CLR Write 1 to clear the MB_HP_1_INT interrupr. (WO)

MB_HP_2_INT_CLR Write 1 to clear the MB_HP_2_INT interrupr. (WO)

MB_HP_3_INT_CLR Write 1 to clear the MB_HP_3_INT interrupr. (WO)

MB_HP_4_INT_CLR Write 1 to clear the MB_HP_4_INT interrupr. (WO)

MB_HP_5_INT_CLR Write 1 to clear the MB_HP_5_INT interrupr. (WO)

MB_HP_6_INT_CLR Write 1 to clear the MB_HP_6_INT interrupr. (WO)

MB_HP_7_INT_CLR Write 1 to clear the MB_HP_7_INT interrupr. (WO)

MB_HP_8_INT_CLR Write 1 to clear the MB_HP_8_INT interrupr. (WO)

MB_HP_9_INT_CLR Write 1 to clear the MB_HP_9_INT interrupr. (WO)

MB_HP_10_INT_CLR Write 1 to clear the MB_HP_10_INT interrupr. (WO)

MB_HP_11_INT_CLR Write 1 to clear the MB_HP_11_INT interrupr. (WO)

MB_HP_12_INT_CLR Write 1 to clear the MB_HP_12_INT interrupr. (WO)

MB_HP_13_INT_CLR Write 1 to clear the MB_HP_13_INT interrupr. (WO)

MB_HP_14_INT_CLR Write 1 to clear the MB_HP_14_INT interrupr. (WO)

MB_HP_15_INT_CLR Write 1 to clear the MB_HP_15_INT interrupr. (WO)

Chapter 25

Brown-out Detector

25.1 Introduction

The brown-out detector of ESP32-P4 monitors the voltage levels of pins VDD_ANA and VDD_BAT. If the voltage on these pins drops below the predefined threshold (defaulting to 2.4 V), the detector triggers signals to shut down certain power-consuming blocks (e.g., flash), ensuring that the digital module has sufficient time to save and transfer important data.

25.2 Feature List

- Two monitored sources
  - Monitors the voltage level of pin VDD_ANA, which supplies power to the analog circuit.
  - Monitors the voltage level of pin VDD_BAT, which connects the external battery to the chip.
- Two configurable monitoring modes
  - Mode 0: The brown-out detector triggers interrupts when the brown-out counter reaches the predefined threshold and selects the reset mode according to the configuration.
  - Mode 1: The brown-out detector triggers a system reset when the voltage falls below the threshold.
- Configurable voltage-monitoring thresholds and noise tolerance
- Configurable handling modes for under-voltage events

25.3 Architectural Overview

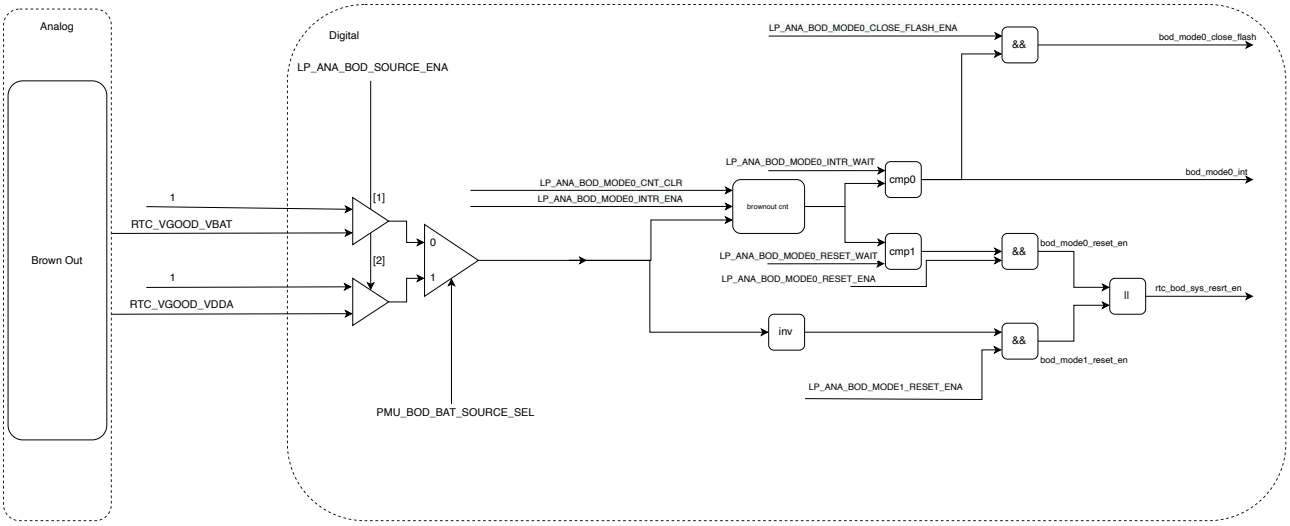


Figure 25.3-1. Brown-out Detector Overview

- Source selection for detection: The brown-out detector can select which power source to monitor by configuring LP_ANA_BOD_SOURCE_ENA. RTC_VGOOD_VBAT indicates the detection result of VDD_BAT, and RTC_VGOOD_VDDA indicates the detection result of VDD_ANA.
- Brown-out detector (Brown Out): An analog circuit designed to monitor the voltage of power pins and generate brown-out signals. It compares the voltage with the predefined threshold. When the voltage falls below this threshold, the detector outputs brown-out signals.
- Brown-out counter (brownout cnt): A counter used for filtering voltage noise on the detected power pins. When the brown-out signal is received, the counter starts counting based on the clock source LP_DYN_FAST_CLK. If the brown-out signal ceases during the counting process, the counter resets to 0. This counter can be cleared by configuring LP_ANA_BOD_MODE0_CNT_CLR.
- Interrupt comparator (cmp0): The comparator generates interrupts by comparing the counter value with the threshold. When the counter value exceeds the threshold, the comparator generates the interrupt signal bod_mode0_int. If LP_ANA_BOD_MODE0_CLOSE_FLASH_ENA is enabled, bod_mode0_close_flash will be triggered, causing flash to enter the SUSPEND state.
- Reset comparator (cmp1): The comparator triggers reset signals by comparing the counter value with the threshold. When the counter value exceeds the threshold, the comparator triggers reset signals.

25.4 Functional Description

- Monitored sources
  - VDD_ANA: Power pin for the analog circuit, supporting both Mode 0 and Mode 1.
  - VDD_BAT: Power pin connected to the battery, supporting both Mode 0 and Mode 1. In addition, it supports two configurable voltage thresholds:
    * VBAT_BOD: Used for brown-out detection of VDD_BAT

    * VBAT_CHARGER: Indicates whether the battery connected to VDD_BAT needs charging.

  These thresholds trigger different interrupts.

- Monitoring modes
  There are two monitoring modes based on the way the brown-out detector handles the brown-out signal:
  - Mode 0: When Mode 0 is enabled, the brown-out counter starts counting after detecting a brown-out signal. Interrupt and reset signals are generated when the counter reaches the thresholds defined by LP_ANA_BOD_MODE0_RESET_WAIT and LP_ANA_BOD_MODE0_INTR_WAIT, respectively. This helps filter out noise on the monitored pins. Configure LP_ANA_BOD_MODE0_RESET_SEL to select the reset options:
    * 0: Reset the chip.
    * 1: Reset the system.
  - Mode 1: Mode 1 is the default mode, which resets the system immediately upon detecting under-voltage.
- Voltage-monitoring thresholds
  The voltage-monitoring threshold is configured in the analog circuit by the analog I2C master. The threshold configuration registers are as follows. BIAS is the slave of the analog I2C master. The address of BIAS is 0x6a. REGXX indicates the register address of BIAS, and [x:x] indicates the bits of this register.
  - BIAS_OR_DREFL_VBAT (REG08[7:5]): threshold for releasing the under-voltage state of VDD_BAT
  - BIAS_OR_DREFH_VBAT (REG08[4:2]): under-voltage threshold of VDD_BAT
  - BIAS_OR_DREFL_VDDA (REG09[7:5]): threshold for releasing the under-voltage state of VDD_ANA
  - BIAS_OR_DREFH_VDDA (REG09[4:2]): under-voltage threshold of VDD_ANA
  - BIAS_OR_DREFL_VBAT_CHARGER (REG10[7:5]): threshold for releasing the under-voltage state of battery connected to VDD_BAT
  - BIAS_OR_DREFH_VBAT_CHARGER (REG10[4:2]): under-voltage threshold of battery connected to VDD_BAT

  The relationship between the threshold configuration of VBAT/VDDA and voltage is:
  - 0: 2.0 V
  - 1: 2.1 V
  - 2: 2.2 V
  - 3: 2.3 V
  - 4: 2.4 V
  - 5: 2.5 V
  - 6: 2.6 V
  - 7: 2.7 V

  The relationship between the threshold configuration of VBAT_CHARGER and voltage is:
  - 0: 2.2 V

- 1: 2.3 V
- 2: 2.4 V
- 3: 2.5 V
- 4: 2.6 V
- 5: 2.7 V
- 6: 2.8 V
- 7: 2.9 V

- Voltage-monitoring filter
  A dedicated glitch filter is used to process the detection results of VDD_BAT, as shown in the figure below.

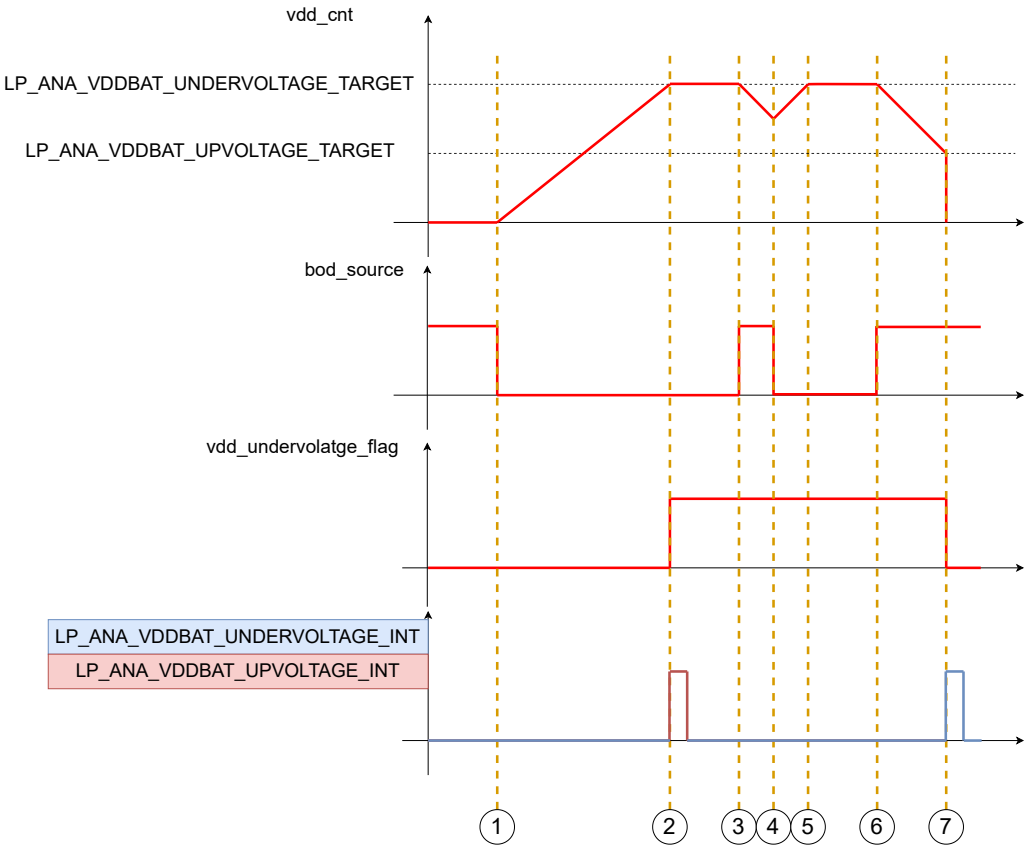

Figure 25.4-1. Structure of Brown-out Detector

- vdd_cnt: the value of the brown-out counter.
- bod_source: the monitored source, which is VDD_BAT in the figure.
- vdd_undervoltage_flag: the under-voltage flag.
- Stage 0 ~ 1: When bod_source is 1, it indicates the voltage is normal, and the brown-out counter (vdd_cnt) remains 0.
- Stage 1 ~ 2: When bod_source is 0, it indicates under-voltage happens, and the brown-out counter will start to count. When the counter value reaches the corresponding threshold, vdd_undervoltage_flag will be set to 1, and the interrupt is generated.

- Stage 2 ~ 3: When vdd_underboltage_flag is 1, the brown-out counter will stop counting, and stabilize at LP_ANA_VDDBAT_UNDERVOLTAGE_TARGET.
- Stage 3 ~ 4 ~ 5: When bod_source changes back to 0 for a short period, the value in the brown-out counter will decrease. However, as the value does not reach to LP_ANA_VDDBAT_UPVOLTAGE_TARGET, vdd_underboltage_flag will not be toggled.
- Stage 6 ~ 7: After bod_source remains 0 for a certain period, i.e., the counter value decreases to LP_ANA_VDDBAT_UPVOLTAGE_TARGET, vdd_underboltage_flag is reset to 0. Then the counter is cleared to 0.

25.5 Interrupts

ESP32-P4's brown-out detector can generate the following interrupt and send it to Interrupt Matrix.

- LP_ANAPERI_INT

The interrupt is generated by the internal interrupt sources of the brown-out detector.

- LP_ANA_VDDBAT_CHARGE_UPVOLTAGE_INT: Triggered when the voltage of VDD_BAT increases to the predefined charging threshold.
- LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_INT: Triggered when the voltage of VDD_BAT decreases to the predefined charging threshold.
- LP_ANA_VDDBAT_UPVOLTAGE_INT: Triggered when the voltage of VDD_BAT increases to the predefined brown-out threshold.
- LP_ANA_VDDBAT_UNDERVOLTAGE_INT: Triggered when the voltage of VDD_BAT reduces to the predefined brown-out threshold.
- LP_ANA_BOD_MODE0_INT: Triggered when the value of the brown-out counter reaches the predefined threshold in Mode 0.

Each interrupt source can be configured by a common set of registers that are described in Chapter *Interrupt Configuration Registers*. The specific registers can be found in Section 25.7 *Register Summary*.

25.6 Programming Procedures

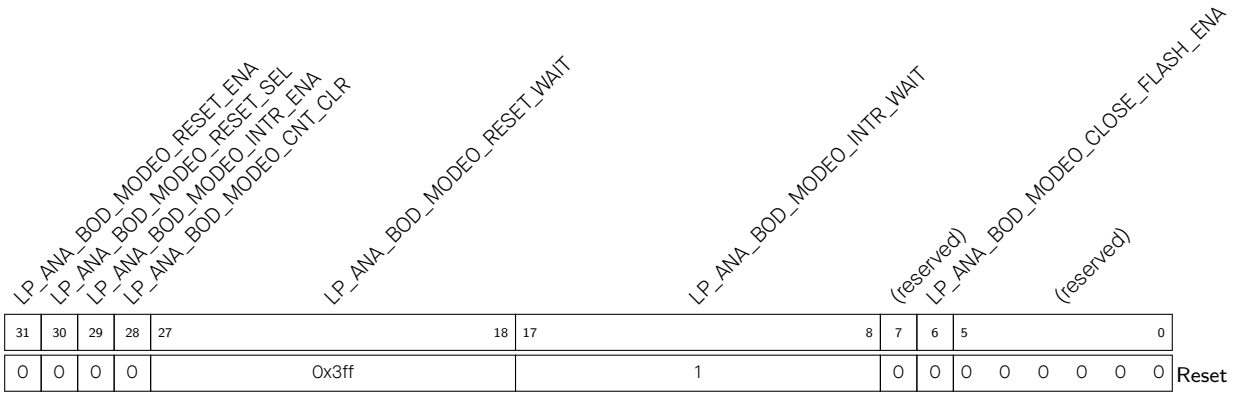
- Mode 0
  - Configure LP_ANA_BOD_MODE0_RESET_WAIT to set the counter threshold for triggering the reset signal.
  - Configure LP_ANA_BOD_MODE0_INTR_WAIT to set the counter threshold for triggering interrupts.
  - Set LP_ANA_BOD_MODE0_RESET_SEL to select the reset way in Mode 0.
  - Configure LP_ANA_BOD_SOURCE_ENA to enable the power pin to be detected.
  - Set LP_ANA_BOD_MODE0_RESET_ENA to enable the brown-out reset functionality.
  - Set LP_ANA_BOD_MODE0_INTR_ENA to enable the noise-filtering counter and interrupts.
- Mode 1

- Configure LP_ANA_BOD_SOURCE_ENA to enable the power pin to be detected.

25.7 Register Summary

The addresses in this section are relative to Brown-out Detector base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
LP_ANA_BOD_MODE0_CNTL_REG	Control register of Mode 0	0x0000	R/W
LP_ANA_VDD_SOURCE_CNTL_REG	Control register of monitoring sources	0x0008	varies
LP_ANA_VDDBAT_BOD_CNTL_REG	Control register of brown-out detecting for VDD_BAT	0x000C	varies
LP_ANA_VDDBAT_CHARGE_CNTL_REG	Pre-charge control register for under-voltage of VDD_BAT	0x0010	varies
LP_ANA_INT_RAW_REG	Raw interrupt status	0x0020	RO
LP_ANA_INT_ST_REG	Interrupt state register	0x0024	RO
LP_ANA_INT_ENA_REG	Interrupt enable register	0x0028	R/W
LP_ANA_INT_CLR_REG	Interrupt clear register	0x002C	WT

25.8 Registers

The addresses in this section are relative to Brown-out Detector base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 25.1. LP_ANA_BOD_MODE0_CNTL_REG (0x0000)

LP_ANA_BOD_MODE0_CLOSE_FLASH_ENA Configure to close the flash functionality when under-voltage happens in Mode 0.

0: Disable

1: Enable

(R/W)

LP_ANA_BOD_MODE0_INTR_WAIT Configure the counter threshold that triggers interrupts in Mode 0. (R/W)

LP_ANA_BOD_MODE0_RESET_WAIT Configure the counter threshold that triggers reset in Mode 0. (R/W)

LP_ANA_BOD_MODE0_CNT_CLR Clear counter value in Mode 0. (R/W)

LP_ANA_BOD_MODE0_INTR_ENA Configure to enable the counter and interrupts in Mode 0.

0: Disable

1: Enable

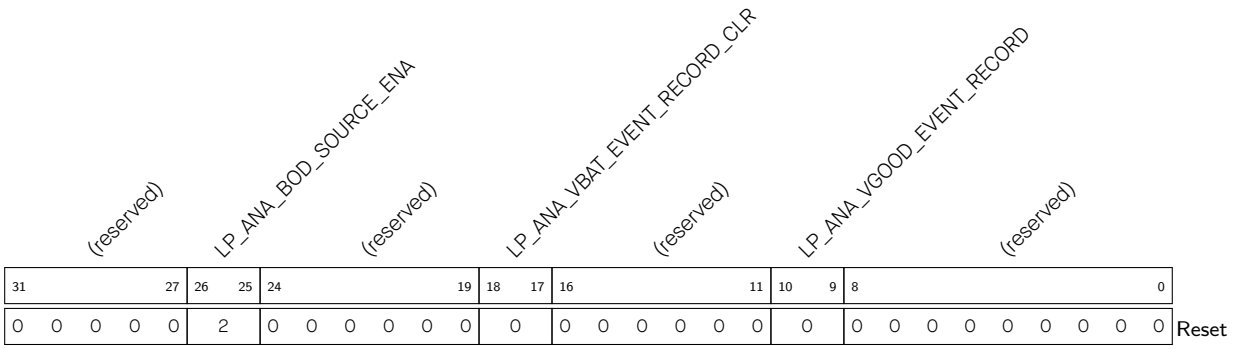
(R/W)

LP_ANA_BOD_MODE0_RESET_SEL Configure the reset way when under-voltage happens in Mode 0.

0: Reset the chip

1: Reset the system

(R/W)



LP_ANA_BOD_MODE0_RESET_ENA Configure to enable reset in Mode 0.

0: Disable

1: Enable

(R/W)

Register 25.2. LP_ANA_VDD_SOURCE_CNTL_REG (0x0008)

LP_ANA_VGOOD_EVENT_RECORD Flags for indicating pins whose voltage is lower than the threshold.

0: Under-voltage does not happen on either VDD_BAT or VDD_ANA;

1: Under-voltage happens on VDD_BAT;

2: Under-voltage happens on VDD_ANA;

3: Under-voltage happens on both VDD_BAT and VDD_ANA.

(RO)

LP_ANA_VBAT_EVENT_RECORD_CLR Clear the flags.

0: Not clear

1: Clear the brown-out flag of VDD_BAT

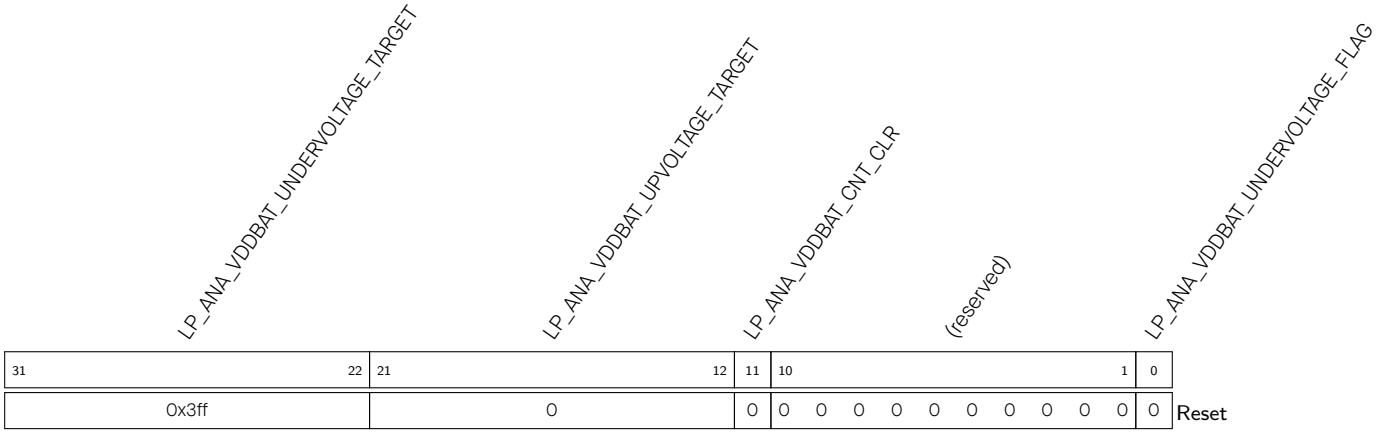
2: Clear the brown-out flag of VDD_ANA

3: No effect

(WT)

LP_ANA_BOD_SOURCE_ENA Configure to detect monitoring sources.

0: Not detecting any pins;



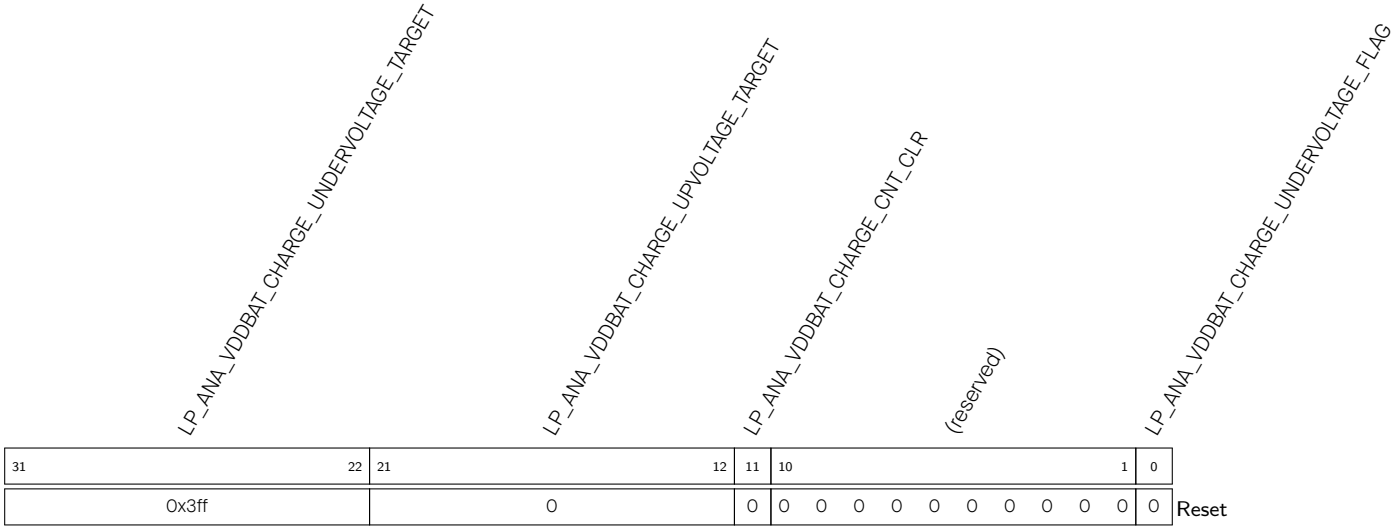
1: Only detect VDD_BAT;

2: Only detect VDD_ANA;

3: Detect both VDD_BAT and VDD_ANA.

(R/W)

Register 25.3. LP_ANA_VDDBAT_BOD_CNTL_REG (0x000C)



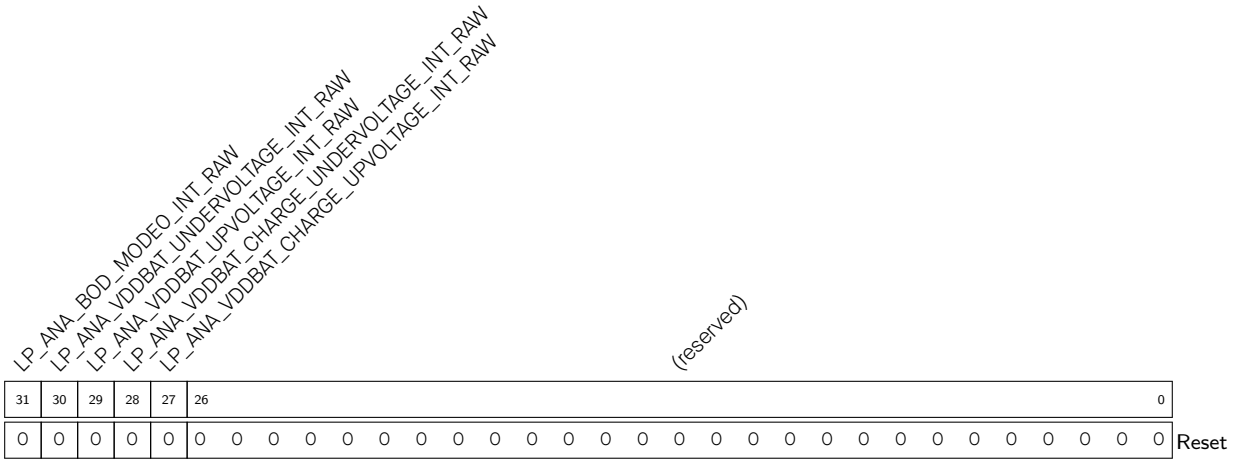
LP_ANA_VDDBAT_UNDERVOLTAGE_FLAG Flag indicating that under-voltage occurs on VDD_BAT. (RO)

LP_ANA_VDDBAT_CNT_CLR Clear the brown-out counter of VDD_BAT. (WT)

LP_ANA_VDDBAT_UPVOLTAGE_TARGET Configure the voltage-recovery threshold for the brown-out counter of VDD_BAT. When the counter decreases to this threshold, LP_ANA_VDDBAT_UNDERVOLTAGE_FLAG is cleared to 0. (R/W)

LP_ANA_VDDBAT_UNDERVOLTAGE_TARGET Configure the brown-out threshold for the brown-out counter of VDD_BAT. When the counter increases to this threshold, LP_ANA_VDDBAT_UNDERVOLTAGE_FLAG is set to 1. (R/W)

Register 25.4. LP_ANA_VDDBAT_CHARGE_CNTL_REG (0x0010)



LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_FLAG Flag indicating that VDD_BAT is charging. (RO)

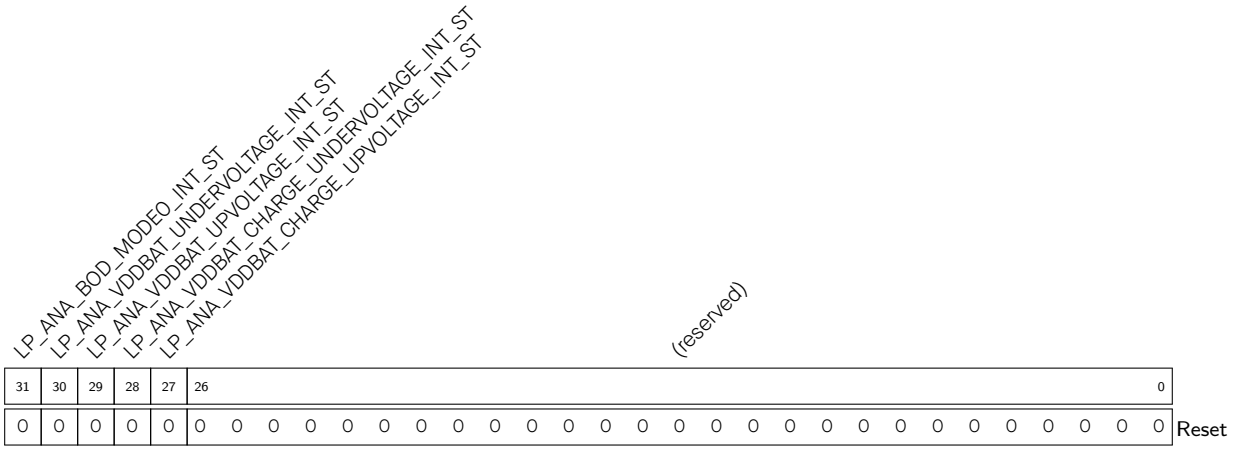
LP_ANA_VDDBAT_CHARGE_CNT_CLR Clear the brown-out counter of VDD_BAT. (WT)

LP_ANA_VDDBAT_CHARGE_UPVOLTAGE_TARGET Configure the voltage-recovery threshold for the brown-out counter of VDD_BAT. When the counter decreases to this threshold, LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_FLAG is cleared to 0. (R/W)

LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_TARGET Configure the brown-out threshold for the brown-out counter of VDD_BAT. When the counter increases to this threshold, LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_FLAG is set to 1. (R/W)

Register 25.5. LP_ANA_INT_RAW_REG (0x0020)

LP_ANA_VDDBAT_CHARGE_UPVOLTAGE_INT_RAW The interrupt is triggered when the voltage of VDD_BAT increases to the charging threshold. (RO)



LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_INT_RAW The interrupt is triggered when the voltage of VDD_BAT decreases to the charging threshold. (RO)

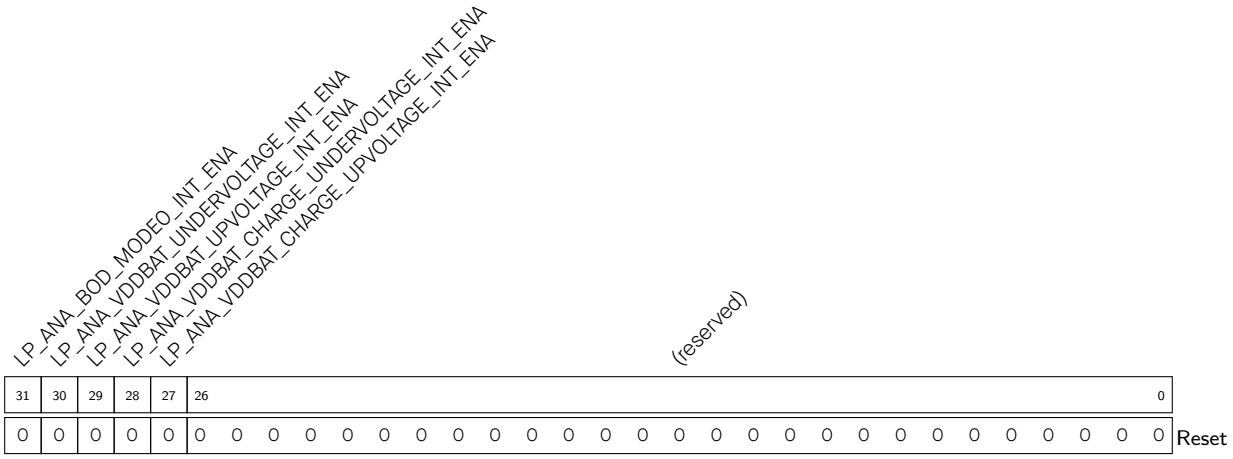
LP_ANA_VDDBAT_UPVOLTAGE_INT_RAW The interrupt is triggered when the voltage of VDD_BAT increases to the brown-out threshold. (RO)

LP_ANA_VDDBAT_UNDERVOLTAGE_INT_RAW The interrupt is triggered when the voltage of VDD_BAT decreases to the brown-out threshold. (RO)

LP_ANA_BOD_MODE0_INT_RAW Brown-out interrupt in Mode 0. (RO)

Register 25.6. LP_ANA_INT_ST_REG (0x0024)

LP_ANA_VDDBAT_CHARGE_UPVOLTAGE_INT_ST The interrupt is triggered and sent to CPU when the voltage of VDD_BAT increases to the charging threshold. (RO)



LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_INT_ST The interrupt is triggered and sent to CPU when the voltage of VDD_BAT decreases to the charging threshold. (RO)

LP_ANA_VDDBAT_UPVOLTAGE_INT_ST The interrupt is triggered and sent to CPU when the voltage of VDD_BAT increases to the brown-out threshold. (RO)

LP_ANA_VDDBAT_UNDERVOLTAGE_INT_ST The interrupt is triggered and sent to CPU when the voltage of VDD_BAT decreases to the brown-out threshold. (RO)

LP_ANA_BOD_MODE0_INT_ST The brown-out interrupt in Mode 0 is triggered and sent to CPU. (RO)

Register 25.7. LP_ANA_INT_ENA_REG (0x0028)

LP_ANA_VDDBAT_CHARGE_UPVOLTAGE_INT_ENA Configure whether to enable the interrupt which is triggered when the voltage of VDD_BAT increases to the charging threshold.

0: No

1: Yes

(R/W)

LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_INT_ENA Configures whether to enable the interrupt which is triggered when the voltage of VDD_BAT reduces to the charging threshold.

0: Yes

1: No

(R/W)

LP_ANA_VDDBAT_UPVOLTAGE_INT_ENA Configures whether to enable the interrupt which is triggered when the voltage of VDD_BAT increases to the brown-out threshold.

0: Yes

1: No

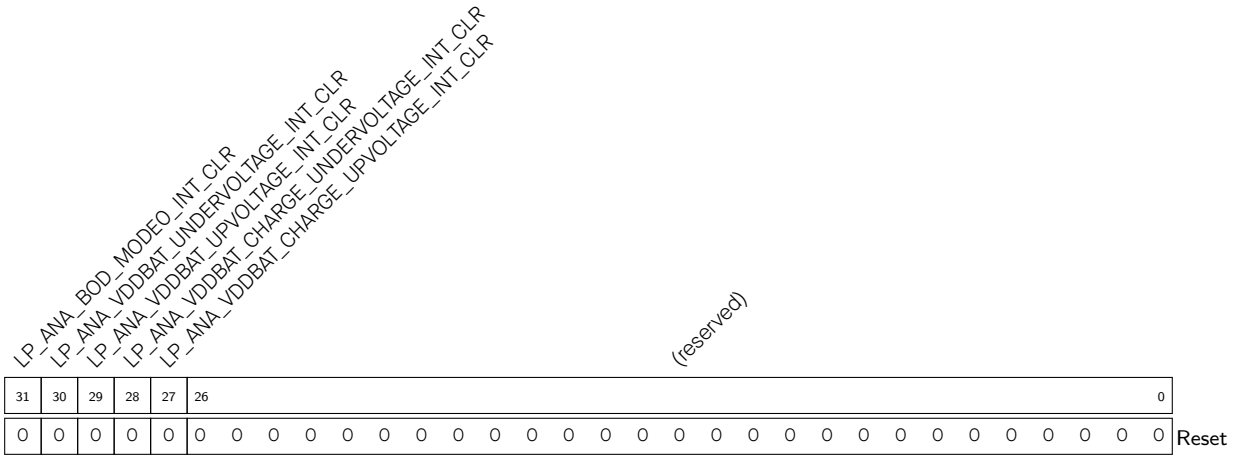
(R/W)

LP_ANA_VDDBAT_UNDERVOLTAGE_INT_ENA Configures whether to enable the interrupt which is triggered when the voltage of VDD_BAT reduces to the brown-out threshold.

0: No

1: Yes

(R/W)



LP_ANA_BOD_MODE0_INT_ENA Configures whether to enable the brown-out interrupt in Mode 0.

0: No

1: Yes

(R/W)

Register 25.8. LP_ANA_INT_CLR_REG (0x002C)

LP_ANA_VDDBAT_CHARGE_UPVOLTAGE_INT_CLR Configures whether to clear the interrupt triggered by the VDD_BAT voltage increasing to the charging threshold. (WT)

LP_ANA_VDDBAT_CHARGE_UNDERVOLTAGE_INT_CLR Configures whether to clear the interrupt triggered by the VDD_BAT voltage reducing to the charging threshold. (WT)

LP_ANA_VDDBAT_UPVOLTAGE_INT_CLR Configures whether to clear the interrupt triggered by the VDD_BAT voltage increasing to the brown-out threshold. (WT)

LP_ANA_VDDBAT_UNDERVOLTAGE_INT_CLR Configures whether to clear the interrupt triggered by the VDD_BAT voltage reducing to the brown-out threshold. (WT)

LP_ANA_BOD_MODE0_INT_ST Configures whether to clear the brown-out interrupt in Mode 0. (WT)

Chapter 26

Power Supply Detector (PSDET)

26.1 Overview

The ESP32-P4 chip integrates a power supply detector, which is used to monitor the voltage of the on-chip HP system regulator. Specifically, this function is implemented by a voltage glitch detector, which prevents abnormal fluctuations and glitch attacks by real-time monitoring of the supply voltage. The power supply detector can operate continuously during the HP system operation.

26.2 Features

- Maintains monitoring during the chip's normal operation without requiring software intervention
- Automatically triggers a system reset when a voltage glitch of approximately 50 ns or longer is detected

26.3 Functional Description

The structure of the power supply detector based on voltage glitch detection is shown below:

Figure 26.3-1. Structure of the ESP32-P4 Power Supply Detector

The power supply detector of ESP32-P4 can continuously monitor the voltage of the power supply network while the chip is working. When an instantaneous voltage glitch—either with a fluctuation depth greater than 100 mV and a duration longer than 50 ns is detected, it automatically triggers a system reset. The detection does not require register configuration. System resets triggered by this function will be recorded by the HP CPU0 reset cause register LP_CLKRST_HPCORE0_RESET_CAUSE, corresponding to the reset value 0x1B.

This function is disabled by default. To enable it, please flash the EFUSE_PVT_GLITCH_EN and EFUSE_PVT_GLITCH_MODE fields. For more information about eFuses, please refer to Chapter 9.4 *eFuse Controller (EFUSE)*.

For information about reset, please refer to Chapter 11 *Reset and Clock*.

Part V

Cryptography/Security Component

Dedicated to security features, this part explores cryptographic accelerators like AES and ECC. It also covers digital signatures, random number generation, and encryption/decryption algorithms, showcasing the SoC's capabilities in cryptography and secure data processing.

Chapter 27

AES Accelerator (AES)

27.1 Introduction

ESP32-P4 integrates an Advanced Encryption Standard (AES) accelerator, which is a hardware device that speeds up computation using AES algorithm significantly, compared to AES algorithms implemented solely in software. The AES accelerator integrated in ESP32-P4 has two working modes, which are Typical AES and DMA-AES.

27.2 Features

The following functionality is supported:

- Typical AES working mode
  - AES-128/AES-256 encryption and decryption
- DMA-AES working mode
  - AES-128/AES-256 encryption and decryption
  - Block cipher mode
    - ECB (Electronic Codebook)
    - CBC (Cipher Block Chaining)
    - OFB (Output Feedback)
    - CTR (Counter)
    - CFB8 (8-bit Cipher Feedback)
    - CFB128 (128-bit Cipher Feedback)
  - GCM (Galois/Counter Mode)
  - Interrupt on completion of computation

27.3 Clock and Reset

The AES accelerator is activated by setting the HP_SYS_CLKRST_CRYPTO_AES_CLK_EN bit in the HP_SYS_CLKRST_PERI_CLK_CTRL25_REG register and clearing the HP_SYS_CLKRST_RST_EN_AES bit in the HP_SYS_CLKRST_HP_RST_EN2_REG register. Besides, due to resource reuse between cryptography accelerator modules, users also need to additionally clear the HP_SYS_CLKRST_RST_EN_DS bit and the HP_SYS_CLKRST_RST_EN_KM bit in the HP_SYS_CLKRST_HP_RST_EN2_REG register.

27.4 AES Working Modes

The AES accelerator integrated in ESP32-P4 has two working modes, which are Typical AES and DMA-AES.

- Typical AES Working Mode:
  - Supports encryption and decryption using cryptographic keys of 128 and 256 bits, specified in NIST FIPS 197.

  In this working mode, the plaintext and ciphertext is written and read via CPU directly.
- DMA-AES Working Mode:
  - Supports encryption and decryption using cryptographic keys of 128 and 256 bits, specified in NIST FIPS 197;
  - Supports block cipher modes ECB, CBC, OFB, CTR, CFB8, and CFB128 under NIST SP 800-38A.
  - Supports GCM under NIST SP 800-38D.

  In this working mode, the plaintext and ciphertext are written and read via DMA. An interrupt will be generated when operation completes.

Users can choose the working mode for AES accelerator by configuring the AES_DMA_ENABLE_REG register according to Table 27.4-1 below.

Table 27.4-1. AES Accelerator Working Mode

AES_DMA_ENABLE_REG	Working Mode
0	Typical AES
1	DMA-AES

Users can choose the length of cryptographic keys and encryption/decryption by configuring the AES_MODE_REG register according to Table 27.4-2 below.

Table 27.4-2. Key Length and Encryption/Decryption

AES_MODE_REG[2:0]	Key Length and Encryption/Decryption
0	AES-128 encryption
1	reserved
2	AES-256 encryption
3	reserved
4	AES-128 decryption
5	reserved
6	AES-256 decryption
7	reserved

For a detailed introduction to these two working modes, please refer to Section 27.5 and Section 27.6 below.

Notice:

ESP32-P4's RSA Digital Signature Peripheral (RSA_DS) module will call the AES accelerator. Therefore, users cannot access the AES accelerator when RSA Digital Signature Peripheral (RSA_DS) module is working.

27.5 Typical AES Working Mode

In the Typical AES working mode, users can check the working status of the AES accelerator by inquiring the AES_STATE_REG register and comparing the return value against the Table 27.5-1 below.

Table 27.5-1. Working Status under Typical AES Working Mode

AES_STATE_REG	Status	Description
0	IDLE	The AES accelerator is idle or completed operation.
1	WORK	The AES accelerator is in the middle of an operation.

27.5.1 Key, Plaintext, and Ciphertext

The encryption or decryption key is stored in AES_KEY_*n*_REG, which is a set of eight 32-bit registers.

- For AES-128 encryption or decryption, the 128-bit key is stored in AES_KEY_0_REG ~ AES_KEY_3_REG.
- For AES-256 encryption or decryption, the 256-bit key is stored in AES_KEY_0_REG ~ AES_KEY_7_REG.

The plaintext and ciphertext are stored in AES_TEXT_IN_*m*_REG and AES_TEXT_OUT_*m*_REG, which are two sets of four 32-bit registers.

- For AES-128 or AES-256 encryption, the AES_TEXT_IN_*m*_REG registers are initialized with plaintext. Then, the AES accelerator stores the ciphertext into AES_TEXT_OUT_*m*_REG after operation.
- For AES-128 or AES-256 decryption, the AES_TEXT_IN_*m*_REG registers are initialized with ciphertext. Then, the AES accelerator stores the plaintext into AES_TEXT_OUT_*m*_REG after operation.

27.5.2 Endianness

Text Endianness

In Typical AES working mode, the AES accelerator uses cryptographic keys to encrypt and decrypt data in blocks of 128 bits. When filling data into AES_TEXT_IN_*m*_REG register or reading result from AES_TEXT_OUT_*m*_REG registers, users should follow the text endianness type specified in Table 27.5-2.

Table 27.5-2. Text Endianness Type for Typical AES

Plaintext/Ciphertext					
State[1]		c[2]			
		0	1	2	3
r	0	AES_TEXT_*x*_0_REG[7:0]	AES_TEXT_*x*_1_REG[7:0]	AES_TEXT_*x*_2_REG[7:0]	AES_TEXT_*x*_3_REG[7:0]
	1	AES_TEXT_*x*_0_REG[15:8]	AES_TEXT_*x*_1_REG[15:8]	AES_TEXT_*x*_2_REG[15:8]	AES_TEXT_*x*_3_REG[15:8]
	2	AES_TEXT_*x*_0_REG[23:16]	AES_TEXT_*x*_1_REG[23:16]	AES_TEXT_*x*_2_REG[23:16]	AES_TEXT_*x*_3_REG[23:16]

Table 27.5-2. Text Endianness Type for Typical AES

Plaintext/Ciphertext					
	3	AES_TEXT_*x*_0_REG[31:24]	AES_TEXT_*x*_1_REG[31:24]	AES_TEXT_*x*_2_REG[31:24]	AES_TEXT_*x*_3_REG[31:24]

[1] The definition of "State (including c and r)" is described in Section 3.4 *The State* in NIST FIPS 197.
[2] Where *x* = IN or OUT.

Key Endianness

In Typical AES working mode, when filling keys into AES_KEY_*m*_REG registers, users should follow the key endianness type specified in Table 27.5-3 and Table 27.5-4.

Table 27.5-3. Key Endianness Type for AES-128 Encryption and Decryption

Bit[1]	w[0]	w[1]	w[2]	w[3][2]
[31:24]	AES_KEY_0_REG[7:0]	AES_KEY_1_REG[7:0]	AES_KEY_2_REG[7:0]	AES_KEY_3_REG[7:0]
[23:16]	AES_KEY_0_REG[15:8]	AES_KEY_1_REG[15:8]	AES_KEY_2_REG[15:8]	AES_KEY_3_REG[15:8]
[15:8]	AES_KEY_0_REG[23:16]	AES_KEY_1_REG[23:16]	AES_KEY_2_REG[23:16]	AES_KEY_3_REG[23:16]
[7:0]	AES_KEY_0_REG[31:24]	AES_KEY_1_REG[31:24]	AES_KEY_2_REG[31:24]	AES_KEY_3_REG[31:24]

[1] Column "Bit" specifies the bytes of each word stored in w[0] ~ w[3].

[2] w[0] ~ w[3] are "the first Nk words of the expanded key" as specified in Section 5.2 *Key Expansion* in NIST FIPS 197.

Table 27.5-4. Key Endianness Type for AES-256 Encryption and Decryption

Bit [1]	w[0]	w[1]	w[2]	w[3]	w[4]	w[5]	w[6]	w[7] [2]
[31:24]	AES_KEY_0_REG[7:0]	AES_KEY_1_REG[7:0]	AES_KEY_2_REG[7:0]	AES_KEY_3_REG[7:0]	AES_KEY_4_REG[7:0]	AES_KEY_5_REG[7:0]	AES_KEY_6_REG[7:0]	AES_KEY_7_REG[7:0]
[23:16]	AES_KEY_0_REG[15:8]	AES_KEY_1_REG[15:8]	AES_KEY_2_REG[15:8]	AES_KEY_3_REG[15:8]	AES_KEY_4_REG[15:8]	AES_KEY_5_REG[15:8]	AES_KEY_6_REG[15:8]	AES_KEY_7_REG[15:8]
[15:8]	AES_KEY_0_REG[23:16]	AES_KEY_1_REG[23:16]	AES_KEY_2_REG[23:16]	AES_KEY_3_REG[23:16]	AES_KEY_4_REG[23:16]	AES_KEY_5_REG[23:16]	AES_KEY_6_REG[23:16]	AES_KEY_7_REG[23:16]
[7:0]	AES_KEY_0_REG[31:24]	AES_KEY_1_REG[31:24]	AES_KEY_2_REG[31:24]	AES_KEY_3_REG[31:24]	AES_KEY_4_REG[31:24]	AES_KEY_5_REG[31:24]	AES_KEY_6_REG[31:24]	AES_KEY_7_REG[31:24]

[1] Column "Bit" specifies the bytes of each word stored in w[0] ~ w[7].

[2] w[0] ~ w[7] are "the first Nk words of the expanded key" as specified in Chapter 5.2 *Key Expansion* in NIST FIPS 197.

27.5.3 Operation Process

Single Operation

1. Write 0 to the AES_DMA_ENABLE_REG register.
2. Initialize registers AES_MODE_REG, AES_KEY_*n*_REG, and AES_TEXT_IN_*m*_REG.
3. Start operation by writing 1 to the AES_TRIGGER_REG register.
4. Wait till the content of the AES_STATE_REG register becomes 0, which indicates the operation is completed.
5. Read results from the AES_TEXT_OUT_*m*_REG register.

Consecutive Operations

In consecutive operations, primarily the input AES_TEXT_IN_*m*_REG and output AES_TEXT_OUT_*m*_REG registers (*m*: 0-3) are being written and read, while the content of AES_DMA_ENABLE_REG, AES_MODE_REG, and AES_KEY_*n*_REG is kept unchanged. Therefore, the initialization can be simplified during the consecutive operation.

1. Write 0 to the AES_DMA_ENABLE_REG register before starting the first operation.
2. Initialize registers AES_MODE_REG and AES_KEY_*n*_REG before starting the first operation.
3. Update the content of AES_TEXT_IN_*m*_REG.
4. Start operation by writing 1 to the AES_TRIGGER_REG register.
5. Wait till the content of the AES_STATE_REG register becomes 0, which indicates the operation completes.
6. Read results from the AES_TEXT_OUT_*m*_REG register, and return to Step 3 to continue the next operation.

27.6 DMA-AES Working Mode

In the DMA-AES working mode, the AES accelerator supports six block cipher modes: ECB, CBC, OFB, CTR, CFB8, and CFB128. Users can choose the block cipher mode by configuring the AES_BLOCK_MODE_REG register according to Table 27.6-1 below.

Table 27.6-1. Block Cipher Mode

AES_BLOCK_MODE_REG[2:0]	Block Cipher Mode
0	ECB (Electronic Codebook)
1	CBC (Cipher Block Chaining)
2	OFB (Output Feedback)
3	CTR (Counter)
4	CFB8 (8-bit Cipher Feedback)
5	CFB128 (128-bit Cipher Feedback)
6	GCM (Galois/Counter Mode)
7	reserved

Users can check the working status of the AES accelerator by inquiring the AES_STATE_REG register and comparing the return value against the Table 27.6-2 below.

Table 27.6-2. Working Status under DMA-AES Working mode

AES_STATE_REG[1:0]	Status	Description
0	IDLE	The AES accelerator is idle.
1	WORK	The AES accelerator is in the middle of an operation.
2	DONE	The AES accelerator completed operations.

When working in the DMA-AES working mode, the AES accelerator supports interrupt on the completion of computation. To enable this function, write 1 to the AES_INT_ENA_REG register. By default, the interrupt function is disabled. Also, note that the interrupt should be cleared by software after use.

27.6.1 Key, Plaintext, and Ciphertext

Block Operation

During the block operations, the AES accelerator reads source data from DMA, and writes result data to DMA after the computation.

- For encryption, DMA reads plaintext from memory, then passes it to AES as source data. After computation, AES passes ciphertext as result data back to DMA to write into memory.
- For decryption, DMA reads ciphertext from memory, then passes it to AES as source data. After computation, AES passes plaintext as result data back to DMA to write into memory.

During block operations, the lengths of the source data and result data are the same. The total computation time is reduced because the DMA data operation and AES computation can happen concurrently.

The length of source data for AES accelerator under DMA-AES working mode must be 128 bits or the integral multiples of 128 bits. Otherwise, trailing zeros will be added to the original source data, so the length of source data equals to the nearest integral multiples of 128 bits. Please see details in Table 27.6-3 below.

Table 27.6-3. TEXT-PADDING

Function : TEXT-PADDING( )
Input : X, bit string.
Output : Y = **TEXT-PADDING**(X), whose length is the nearest integral multiples of 128 bits.

Steps
Let us assume that X is a data-stream that can be split into *n* parts as following:
$X = X_1 \| \| X_2 \| \| \cdots \| \| X_{n-1} \| \| X_n$
Here, the lengths of $X_1, X_2, \cdots, X_{n-1}$ all equal to 128 bits, and the length of X_n is *t* (0<=*t*<=127).
If $t = 0$, then
TEXT-PADDING(X) = X;
If $0 < t <= 127$, define a 128-bit block, X_n^*, and let $X_n^* = X_n \| \| 0^{128-t}$, then
TEXT-PADDING(X) = $X_1 \| \| X_2 \| \| \cdots \| \| X_{n-1} \| \| X_n^*$ = $X \| \| 0^{128-t}$

27.6.2 Endianness

Under the DMA-AES working mode, the transmission of source data and result data for AES accelerator is solely controlled by DMA. Therefore, the AES accelerator cannot control the Endianness of the source data and result data, but does have requirement on how these data should be stored in memory and on the length of the data.

For example, let us assume DMA needs to write the following data into memory at address 0x0280.

- Data represented in hexadecimal:
  - 000102030405060708090A0B0C0D0E0F101112131415161718191A1B1C1D1E1F20
- Data Length:
  - Equals to 2 blocks.

Then, this data will be stored in memory as shown in Table 27.6-4 below.

Table 27.6-4. Text Endianness for DMA-AES

Address	Byte	Address	Byte	Address	Byte	Address	Byte
0x0280	0x01	0x0281	0x02	0x0282	0x03	0x0283	0x04
0x0284	0x05	0x0285	0x06	0x0286	0x07	0x0287	0x08
0x0288	0x09	0x0289	0x0A	0x028A	0x0B	0x028B	0x0C
0x028C	0x0D	0x028D	0x0E	0x028E	0x0F	0x028F	0x10
0x0290	0x11	0x0291	0x12	0x0292	0x13	0x0293	0x14
0x0294	0x15	0x0295	0x16	0x0296	0x17	0x0297	0x18
0x0298	0x19	0x0299	0x1A	0x029A	0x1B	0x029B	0x1C
0x029C	0x1D	0x029D	0x1E	0x029E	0x1F	0x029F	0x20

27.6.3 Standard Incrementing Function

AES accelerator provides two Standard Incrementing Functions for the CTR block operation, which are INC_{32} and INC_{128} Standard Incrementing Functions. By setting the AES_INC_SEL_REG register to 0 or 1, users can choose the INC_{32} or INC_{128} functions respectively. For details on the Standard Incrementing Function, please see Chapter B.1 *The Standard Incrementing Function* in NIST SP 800-38A.

27.6.4 Block Number

Register AES_BLOCK_NUM_REG stores the Block Number of plaintext P or ciphertext C. The length of this register equals to length(**TEXT-PADDING**(P))/128 or length(**TEXT-PADDING**(C))/128. The AES accelerator only uses this register when working in the DMA-AES mode.

27.6.5 Initialization Vector

AES_IV_MEM is a 16-byte memory, which is only available for AES accelerator working in block operations. For CBC/OFB/CFB8/CFB128 operations, the AES_IV_MEM memory stores the Initialization Vector (IV). For the CTR operation, the AES_IV_MEM memory stores the Initial Counter Block (ICB).

Both IV and ICB are 128-bit strings, which can be divided into Byte0, Byte1, Byte2 $\cdots$ Byte15 (from left to right). AES_IV_MEM stores data following the Endianness pattern presented in Table 27.6-4, i.e., the most significant (i.e., left-most) byte Byte0 is stored at the lowest address while the least significant (i.e., right-most) byte Byte15 at the highest address.

For more details on IV and ICB, please refer to NIST SP 800-38A.

27.6.6 Block Operation Process

1. Select one of DMA channels to connect with AES, configure the DMA linked list, and then start DMA. For details, please refer to Chapter 6 *GDMA Controller (GDMA-AHB, GDMA-AXI)*.
2. Initialize the AES accelerator-related registers:
   - Write 1 to the AES_DMA_ENABLE_REG register.
   - Configure the AES_INT_ENA_REG register to enable or disable the interrupt function.
   - Initialize registers AES_MODE_REG and AES_KEY_*n*_REG.
   - Select block cipher mode by configuring the AES_BLOCK_MODE_REG register. For details, see Table 27.6-1.
   - Initialize the AES_BLOCK_NUM_REG register. For details, see Section 27.6.4.
   - Initialize the AES_INC_SEL_REG register (only needed when AES accelerator is working under CTR block operation).
   - Initialize the AES_IV_MEM memory (This is always needed except for ECB block operation).
3. Start operation by writing 1 to the AES_TRIGGER_REG register.
4. Wait for the completion of computation, which happens when the content of AES_STATE_REG becomes 2 or the AES interrupt occurs.

5. Check if DMA completes data transmission from AES to memory. At this time, DMA had already written the result data in memory, which can be accessed directly. For details on DMA, please refer to Chapter 6 *GDMA Controller (GDMA-AHB, GDMA-AXI)*.
6. Clear interrupt by writing 1 to the AES_INT_CLR_REG register, if any AES interrupt occurred during the computation.
7. Release the AES accelerator by writing 1 to the AES_DMA_EXIT_REG register. After this, the content of the AES_STATE_REG register becomes 0. Note that, you can release DMA earlier, but only after Step 4 is completed.

27.6.7 GCM Operation Process

1. Configure DMA chain and start DMA. For details on DMA, please refer to Chapter 6 *GDMA Controller (GDMA-AHB, GDMA-AXI)*.
2. Initialize the AES accelerator-related registers:
   - Write 1 to the AES_DMA_ENABLE_REG register.
   - Configure the AES_INT_ENA_REG register to enable or disable the interrupt function.
   - Initialize registers AES_MODE_REG and AES_KEY_*n*_REG.
   - Write 6 to the AES_BLOCK_MODE_REG register.
   - Initialize the AES_BLOCK_NUM_REG register. Details about this register are described in Section 27.6.4 *Block Number*.
   - Initialize the AES_AAD_BLOCK_NUM_REG register. Details about this register are described in Section 27.7.4 *AAD Block Number*.
   - Initialize the AES_REMAINDER_BIT_NUM_REG register. Details about this register is described in Section 27.7.5 *Number of Effective Bits of Incomplete Blocks*.
3. Start operation by writing 1 to the AES_TRIGGER_REG register.
4. Wait for the completion of computation, which happens when the content of AES_STATE_REG becomes 2. For details on the working status of AES Accelerator, please refer to Table 27.6-2 *Working Status under DMA-AES Working mode*. At this step, no interrupt occurs.
5. Obtain the H value from the AES_H_MEM memory.
6. Generate J_0 and write it to the AES_J0_MEM memory.
7. Continue operating by writing 1 to the AES_CONTINUE_OP_REG register.
8. Wait for the completion of computation, which happens when the content of AES_STATE_REG becomes 2 or the AES interrupt occurs. For details on the working status of AES Accelerator, please refer to Table 27.6-2 *Working Status under DMA-AES Working mode*.
9. Obtain T_0 by reading AES_T0_MEM.
10. Check if DMA completes data transmission from AES to memory. At this time, DMA had already written the result data in memory, which can be accessed directly. For details on DMA, please refer to Chapter 6 *GDMA Controller (GDMA-AHB, GDMA-AXI)*.

11. Clear interrupt by writing 1 to the AES_INT_CLR_REG register, if any AES interrupt occurred during the computation.
12. Exit DMA by writing 1 to the AES_DMA_EXIT_REG register. After this, the content of the AES_STATE_REG becomes 0. Note that, you can exit DMA earlier, but only after Step 8 is completed.

27.7 GCM Algorithm

ESP32-P4's AES accelerator fully supports GCM Algorithm. In reality, the AAD, C and P that are longer than 2^{32}-1 bits are seldom used. Therefore, we specify that the length of AAD, C and P should be no longer than 2^{32}-1 here. Figure 27.7-1 below demonstrates how GCM encryption is implemented in the AES Accelerator of ESP32-P4.

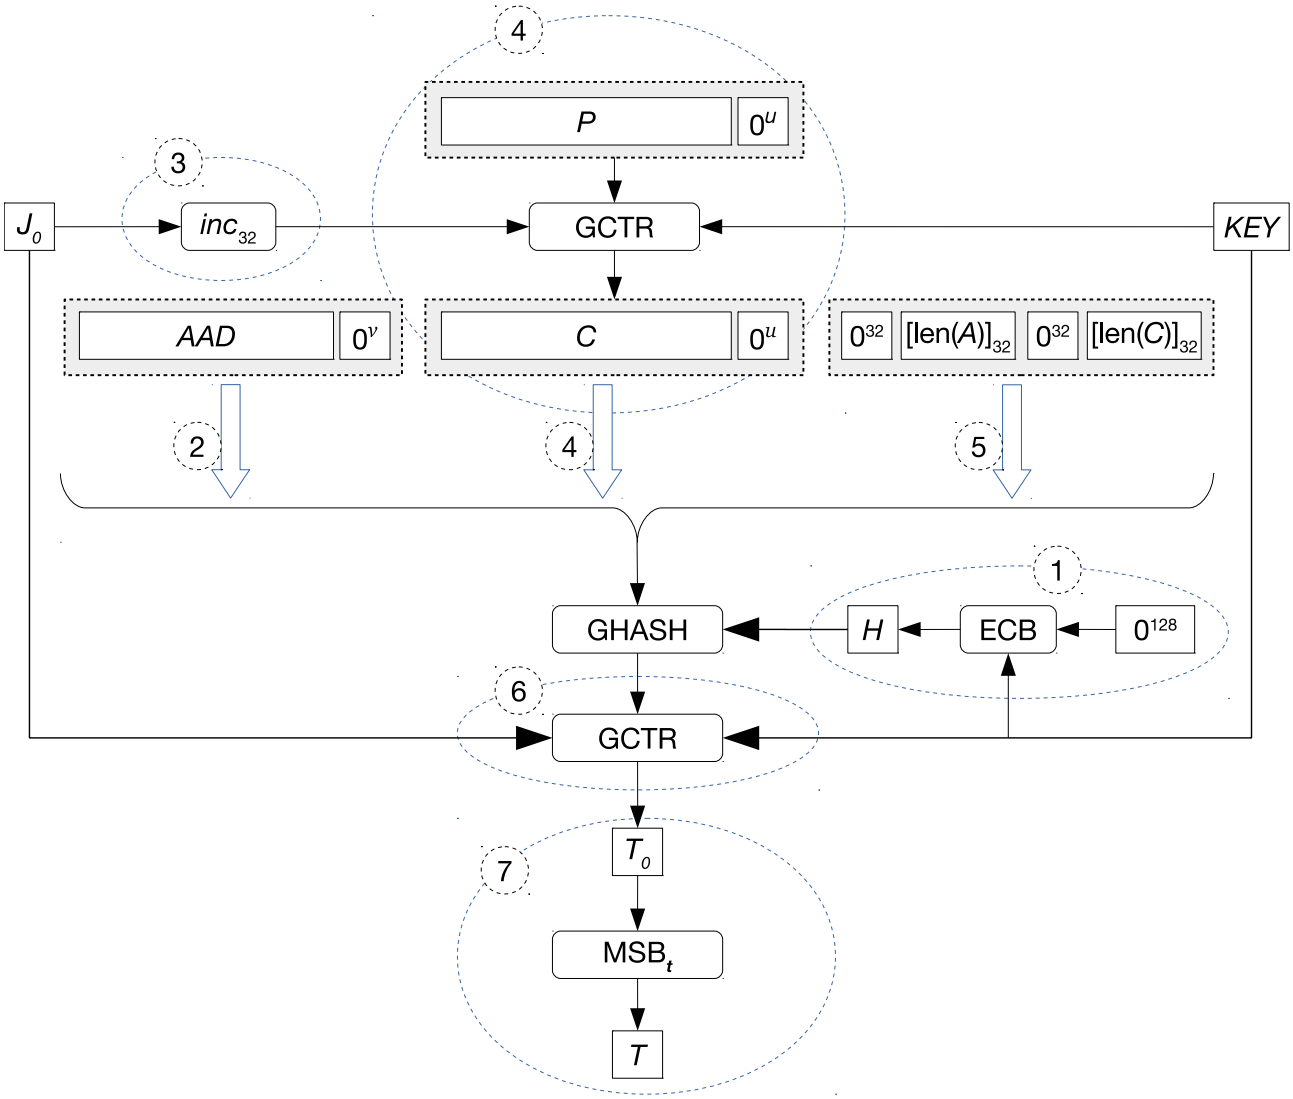


Figure 27.7-1. GCM Encryption Process

GCM encryption is implemented as follows:

1. Hardware executes the ECB Algorithm to obtain the Hash subkey H, which is needed in the Hash computation.
2. Hardware executes the GHASH Algorithm to perform Hash computation with the padded AAD.

3. Hardware gets ready for CTR encryption by obtaining the result of applying Standard Incrementing Function INC_{32} to J_0.
4. Hardware executes the GCTR Algorithm to encrypt the padded plaintext P, then executes the GHASH Algorithm to perform Hash computation on the padded ciphertext C.
5. Hardware executes the GHASH Algorithm to perform Hash computation on AAD Blocks, obtaining a 128-bit Hash result.
6. Hardware executes the GCTR Algorithm to encrypt J_0, obtaining T_0.
7. Software obtains the result T_0 from hardware, and executes MSB_t Algorithm to obtain the final authentication tag T.

The only difference between GCM decryption and GCM encryption lies in Step 4 in Figure 27.7-1. To be more specific, instead of executing GCTR Algorithm to encrypt the padded plaintext, the AES Accelerator executes the same algorithm to decrypt the padded ciphertext in GCM decryption. For details, please see NIST SP 800-38D.

27.7.1 Hash Subkey

During GCM operation, the Hash subkey H is a 128-bit value computed by hardware, which is demonstrated in Step 1 in Figure 27.7-1. Also you can find more information about Hash subkey at "Step 1. Let H = $\text{CIPH}_K(0^{128})$" in Chapter 7 GCM Specification of NIST SP 800-38D.

The Hash subkey H is stored in the AES_H_MEM memory. Just like other endianness, its most significant (i.e., left-most) byte Byte0 is stored at the lowest address in the memory while least significant (i.e., right-most) byte Byte15 at the highest address. For details, see Table 27.5-2.

27.7.2 J_0

J_0 is a 128-bit value computed by hardware, which is required during Step 3 and Step 6 in Figure 27.7-1. For details on the generation of J_0, please see Chapter 7 GCM Specification in NIST SP 800-38D.

J_0 is stored in the AES_J0_MEM memory. Just like other endianness, its most significant (i.e., left-most) byte Byte0 is stored at the lowest address in the memory while least significant (i.e., right-most) byte Byte15 at the highest address. For details, see Table 27.5-2.

27.7.3 Authentication Tag

Authentication Tag (Tag for short) is one of the key results of GCM computation, which is demonstrated in Step 7 of Figure 27.7-1. The value of the Tag is determined by its length t ($1 <= t <= 128$):

- When $t = 128$, the value of Tag equals to T_0, a 128-bit string that is stored in the AES_T0_MEM. Just like other endianness, its most significant (i.e., left-most) byte Byte0 is stored at the lowest address in the memory while least significant (i.e., right-most) byte Byte15 at the highest address. For details, see Table 27.5-2.
- When $1 <= t < 128$, the value of Tag equals to the t most significant (i.e., left-most) bits of T_0. In this case, Tag is represented as $\text{MSB}_t(T_0)$, which returns the t most significant bits of T_0. For example, MSB_4(111011010) = 1110 and MSB_5(11010011010) = 11010. For details on the $\text{MSB}_t(\,)$ function, please refer to Chapter 6 Mathematical Components of GCM in NIST SP 800-38D.

27.7.4 AAD Block Number

Register AES_AAD_BLOCK_NUM_REG stores the Block Number of Additional Authenticated Data (AAD). The length of this register equals to (**TEXT-PADDING**(AAD) length)/128. AES Accelerator only uses this register when working in the DMA-AES mode.

27.7.5 Number of Effective Bits of Incomplete Blocks

Register AES_REMAINDER_BIT_NUM_REG stores the Remainder Bit Number, which indicates the number of effective bits of incomplete blocks in plaintext/ciphertext. The value stored in this register equals to length(P)/128 or length(C)/128. AES Accelerator only uses this register when working in the DMA-AES mode.

Register AES_REMAINDER_BIT_NUM_REG does not affect the results of plaintext or ciphertext, but does impact the value of T_0, therefore the Tag value too.

The GCM Algorithm can be viewed as the combination of GCTR operation and GHASH operation, among which, the GCTR performs the encryption and decryption, while the GHASH sloves the Tag.

Note that the AES_REMAINDER_BIT_NUM_REG register is only effective for GCM encryption. To be more specific:

- For GCM encryption, the Hardware firstly computes C, then passes it in the form of **TEXT-PADDING**(C) as the input of GHASH operation. In this case, hardware determines how many trailing "0" should be added based on the content of AES_REMAINDER_BIT_NUM_REG.
- For GCM decrpytion, the padding is completed with the **TEXT-PADDING**(C) function. In this case, the AES_REMAINDER_BIT_NUM_REG register is not effective.

27.8 Pseudo-Round Anti-DPA Function

The pseudo-round function of ESP32-P4's AES can achieve higher anti-attack performance. When the pseudo-round function is enabled, AES will randomly add pseudo-rounds before and after the original operation rounds. In a pseudo-round, AES will use the pseudo-key, which is automatically generated by the hardware, to perform a round of fake operations. The operations in the pseudo-round do not affect the original AES operation results.

The configuration related to pseudo-round is as follows:

Mode of Pseudo-Round Function

Users can choose to enable pseudo-round function by configuring the AES_PSEUDO_EN register:

- 0: Not enable pseudo-round function;
- 1: Enable pseudo-round function.

Total number of Pseudo-Round

The total number of pseudo-rounds that will be randomly inserted into each AES operation round is controlled by:

- pseudo_base: Equal to the value of AES_PSEUDO_BASE, which configures the basic number of pseudo-rounds.

- pseudo_inc: Equal to the value of AES_PSEUDO_INC, which configures the random incremental number of pseudo-rounds.

The total number of pseudo-rounds will be randomly in the range

$$[pseudo_base, pseudo_base + (2^{pseudo_inc} - 1)]$$

Random Number Update Frequency

AES_PSEUDO_RNG_CNT configures the frequency of random key updates in the pseudo-round function. The higher the configured value, the higher the update frequency. This value is usually recommended to be set to maximum (7).

27.9 Interrupts

ESP32-P4's AES can generate the following interrupt signal(s) that will be sent to the Interrupt Matrix.

- AES_INTR

There is one internal interrupt source from AES that can generate the above interrupt signal(s). The interrupt source from AES are listed with its trigger condition and the resulted interrupt signal(s) in Table 27.9-1.

Table 27.9-1. AES's Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
AES_DMA_DONE_INT	Completion of an AES DMA operation	AES_INTR

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

27.10 Memory Summary

The addresses in this section are relative to the AES accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

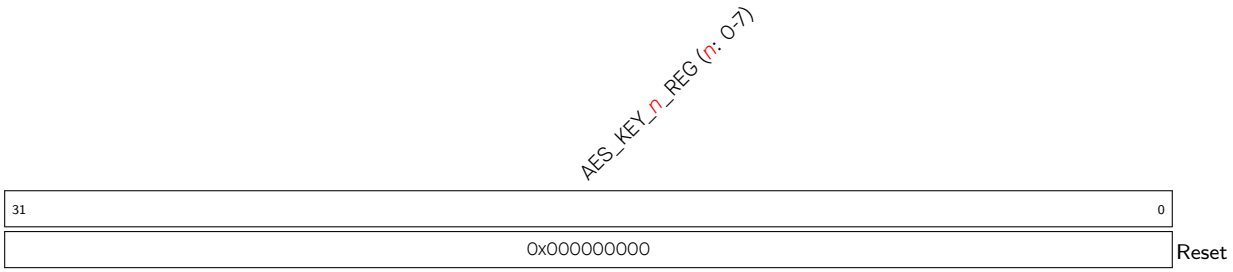
The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Size (byte)	Starting Address	Ending Address	Access
AES_IV_MEM	Memory IV	16 bytes	0x0050	0x005F	R/W
AES_H_MEM	Memory H	16 bytes	0x0060	0x006F	RO
AES_J0_MEM	Memory J0	16 bytes	0x0070	0x007F	R/W
AES_T0_MEM	Memory T0	16 bytes	0x0080	0x008F	RO

27.11 Register Summary

The addresses in this section are relative to the AES accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

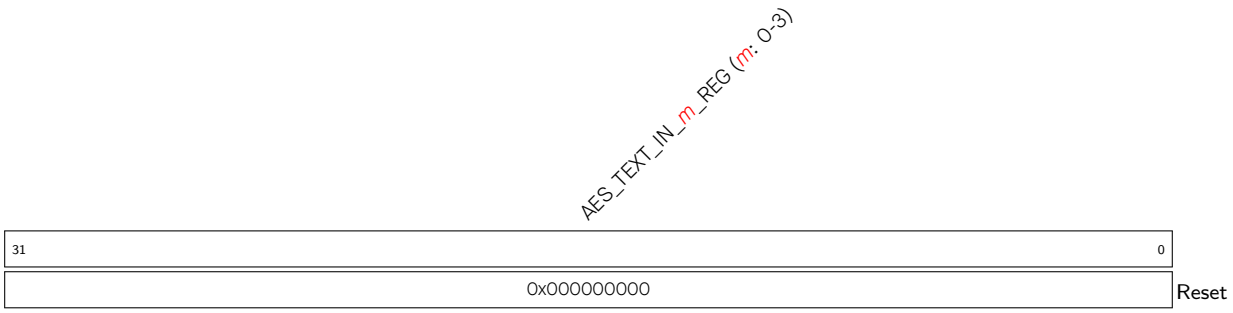
The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Key Registers			
AES_KEY_0_REG	AES key data register 0	0x0000	R/W
AES_KEY_1_REG	AES key data register 1	0x0004	R/W
AES_KEY_2_REG	AES key data register 2	0x0008	R/W
AES_KEY_3_REG	AES key data register 3	0x000C	R/W
AES_KEY_4_REG	AES key data register 4	0x0010	R/W
AES_KEY_5_REG	AES key data register 5	0x0014	R/W
AES_KEY_6_REG	AES key data register 6	0x0018	R/W
AES_KEY_7_REG	AES key data register 7	0x001C	R/W
TEXT_IN Registers			
AES_TEXT_IN_0_REG	Source text data register 0	0x0020	R/W
AES_TEXT_IN_1_REG	Source text data register 1	0x0024	R/W
AES_TEXT_IN_2_REG	Source text data register 2	0x0028	R/W
AES_TEXT_IN_3_REG	Source text data register 3	0x002C	R/W
TEXT_OUT Registers			
AES_TEXT_OUT_0_REG	Result text data register 0	0x0030	RO
AES_TEXT_OUT_1_REG	Result text data register 1	0x0034	RO
AES_TEXT_OUT_2_REG	Result text data register 2	0x0038	RO
AES_TEXT_OUT_3_REG	Result text data register 3	0x003C	RO
Control or Configuration Registers			
AES_MODE_REG	Defines key length and encryption/decryption	0x0040	R/W
AES_DMA_ENABLE_REG	Selects the working mode of the AES accelerator	0x0090	R/W
AES_BLOCK_MODE_REG	Defines the block cipher mode	0x0094	R/W
AES_BLOCK_NUM_REG	Block number configuration register	0x0098	R/W
AES_INC_SEL_REG	Standard incrementing function register	0x009C	R/W
AES_AAD_BLOCK_NUM_REG	AAD block number configuration register	0x00A0	R/W
AES_REMAINDER_BIT_NUM_REG	Remainder bit number of plaintext/ciphertext	0x00A4	R/W
AES_TRIGGER_REG	Operation start controlling register	0x0048	WT
AES_CONTINUE_OP_REG	Operation continue controlling register	0x00A8	WO
AES_DMA_EXIT_REG	Operation exit controlling register	0x00B8	WO
AES_PSEUDO_REG	Pseudo-round function configuration register	0x00D0	R/W
Status Register			
AES_STATE_REG	Operation status register	0x004C	RO
Interrupt Registers			
AES_INT_CLR_REG	DMA-AES interrupt clear register	0x00AC	WT
AES_INT_ENA_REG	DMA-AES interrupt enable register	0x00B0	R/W

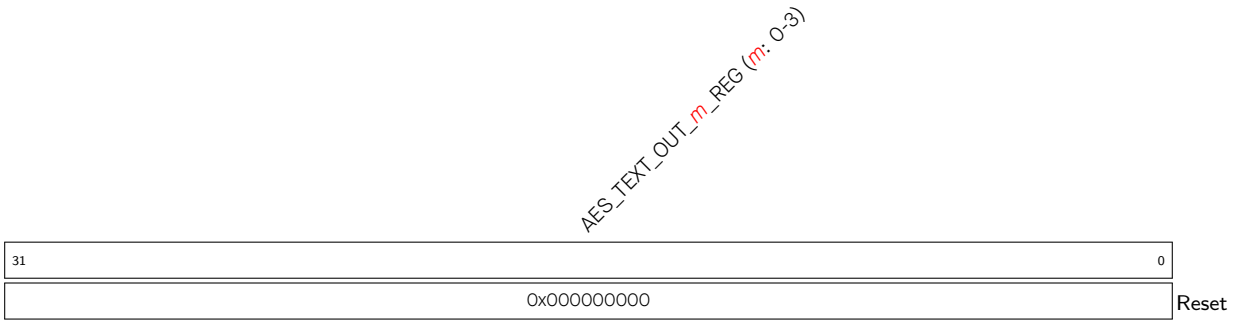
27.12 Registers

The addresses in this section are relative to the AES accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



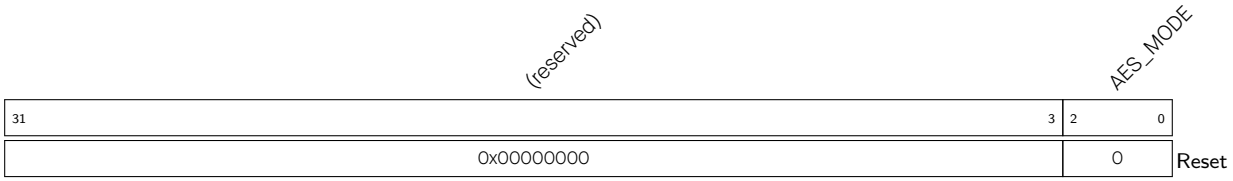
For how to program reserved fields, please refer to Section IX .

Register 27.1. AES_KEY_*n*_REG (*n*: 0-7) (0x0000+4n*)**



AES_KEY_*n*_REG (*n*: 0-7) Represents AES key data. (R/W)

Register 27.2. AES_TEXT_IN_*m*_REG (*m*: 0-3) (0x0020+4m*)**



AES_TEXT_IN_*m*_REG (*m*: 0-3) Represents the source text data when the AES accelerator operates in the Typical AES working mode. (R/W)

Register 27.3. AES_TEXT_OUT_*m*_REG (*m*: 0-3) (0x0030+4m*)**

AES_TEXT_OUT_*m*_REG (*m*: 0-3) Represents the result text data when the AES accelerator operates in the Typical AES working mode. (RO)

Register 27.4. AES_MODE_REG (0x0040)

AES_MODE Configures the key length and encryption/decryption of the AES accelerator.

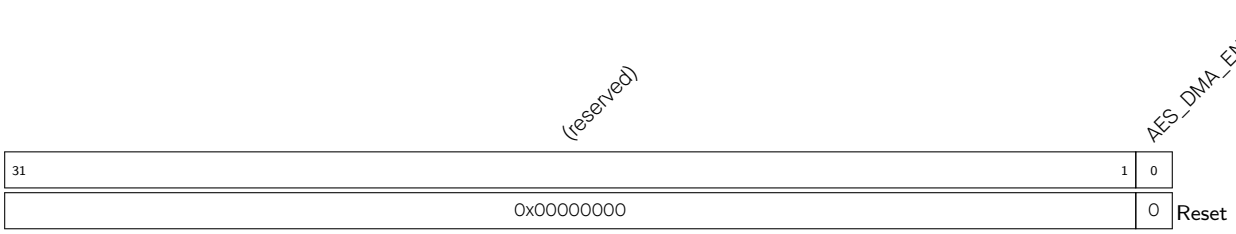
0: AES-128 encryption

1: Reserved

2: AES-256 encryption

3: Reserved

4: AES-128 decryption



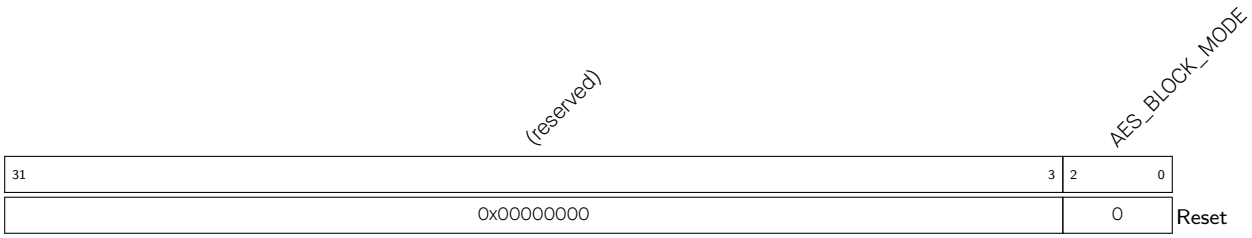
5: Reserved

6: AES-256 decryption

7: Reserved

(R/W)

Register 27.5. AES_DMA_ENABLE_REG (0x0090)



AES_DMA_ENABLE Configures the working mode of the AES accelerator.

0: Typical AES

1: DMA-AES

(R/W)

Register 27.6. AES_BLOCK_MODE_REG (0x0094)

AES_BLOCK_MODE Configures the block cipher mode of the AES accelerator operating under the DMA-AES working mode.

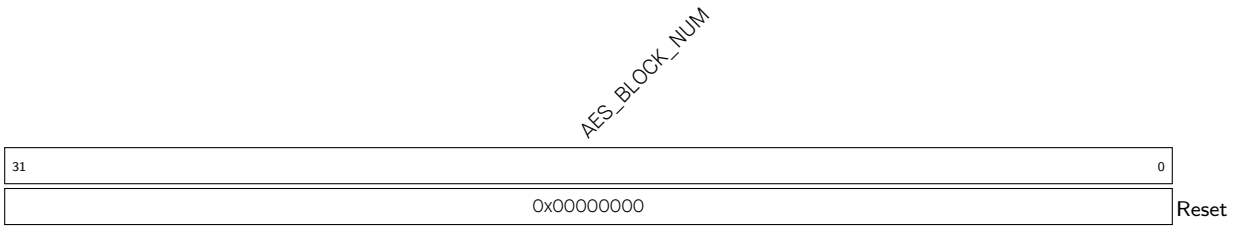
0: ECB (Electronic Code Block)

1: CBC (Cipher Block Chaining)

2: OFB (Output FeedBack)

3: CTR (Counter)

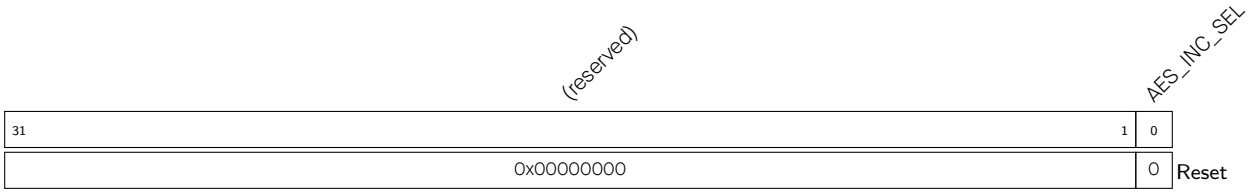
4: CFB8 (8-bit Cipher FeedBack)



5: CFB128 (128-bit Cipher FeedBack)

6: GCM (Galois/Counter Mode)

7: Reserved

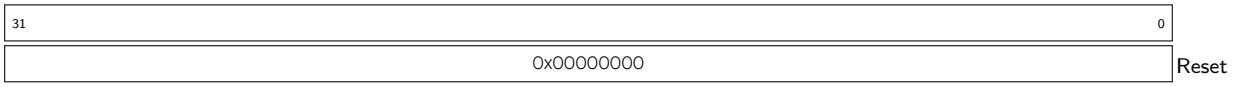


(R/W)

Register 27.7. AES_BLOCK_NUM_REG (0x0098)

AES_BLOCK_NUM Represents the Block Number of plaintext or ciphertext when the AES accelerator operates under the DMA-AES working mode. For details, see Section 27.6.4. (R/W)

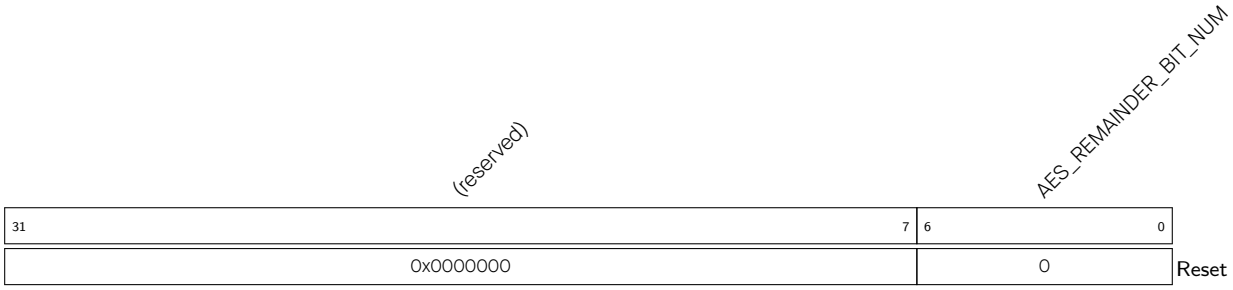
Register 27.8. AES_INC_SEL_REG (0x009C)



AES_INC_SEL Configures the Standard Incrementing Function for CTR block operation.

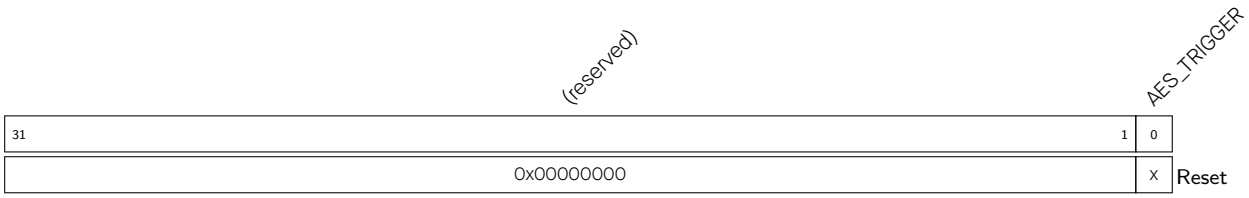
0: INC_{32}

1: INC_{128}



(R/W)

Register 27.9. AES_AAD_BLOCK_NUM_REG (0x00A0)

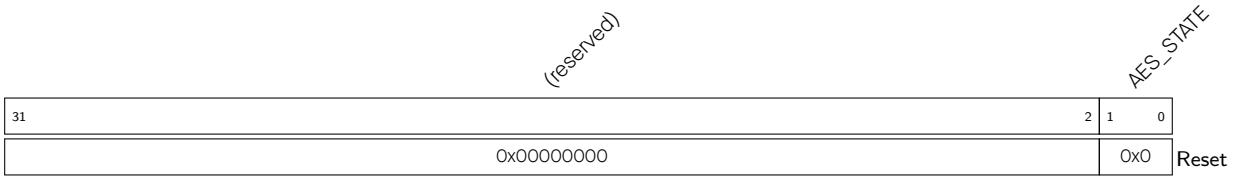


AES_AAD_BLOCK_NUM Stores the ADD block number for the GCM operation. For details, see Section 27.7.4. (R/W)

Register 27.10. AES_REMAINDER_BIT_NUM_REG (0x00A4)

AES_REMAINDER_BIT_NUM Stores the Remainder Bit Number for the GCM operation. For details, see Section 27.7.5. (R/W)

Register 27.11. AES_TRIGGER_REG (0x0048)



AES_TRIGGER Configures whether to start AES operation.

0: No effect

1: Start

(WT)

Register 27.12. AES_STATE_REG (0x004C)

AES_STATE Represents the working status of the AES accelerator.

In Typical AES working mode:

0: IDLE

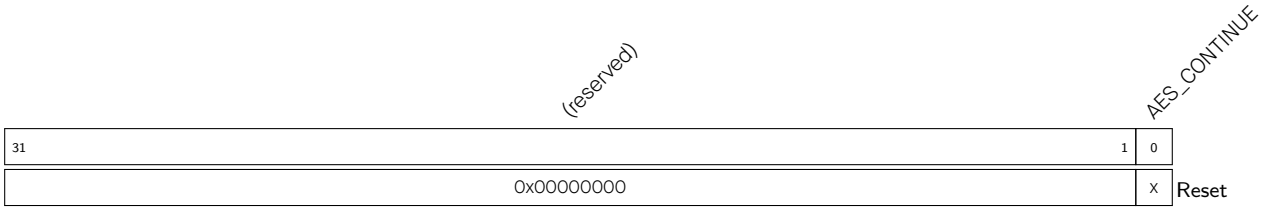
1: WORK

2: No effect

3: No effect

In DMA-AES working mode:

0: IDLE



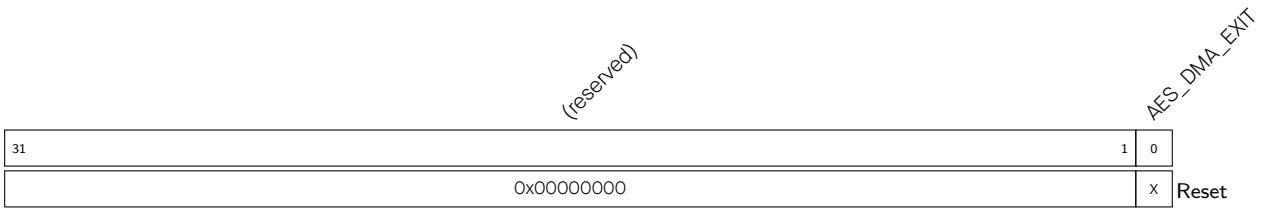
1: WORK

2: DONE

3: No effect

(RO)

Register 27.13. AES_CONTINUE_OP_REG (0x00A8)



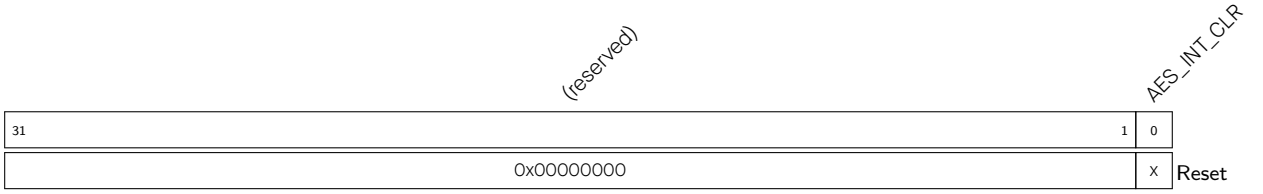
AES_CONTINUE_OP Configures whether to continue AES operation.

0: No effect

1: Continue

(WO)

Register 27.14. AES_DMA_EXIT_REG (0x00B8)



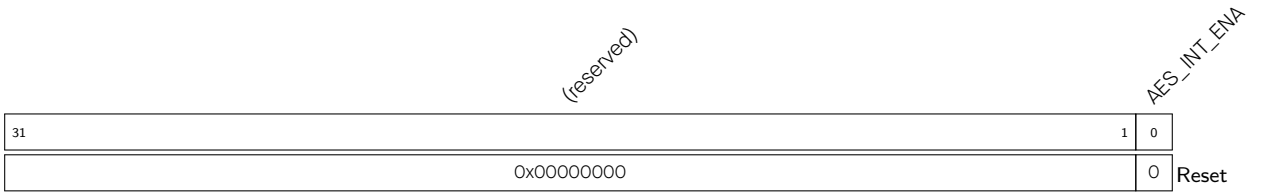
AES_DMA_EXIT Configures whether to exit AES operation.

0: No effect

1: Exit

Only valid for DMA-AES operation. (WO)

Register 27.15. AES_INT_CLR_REG (0x00AC)



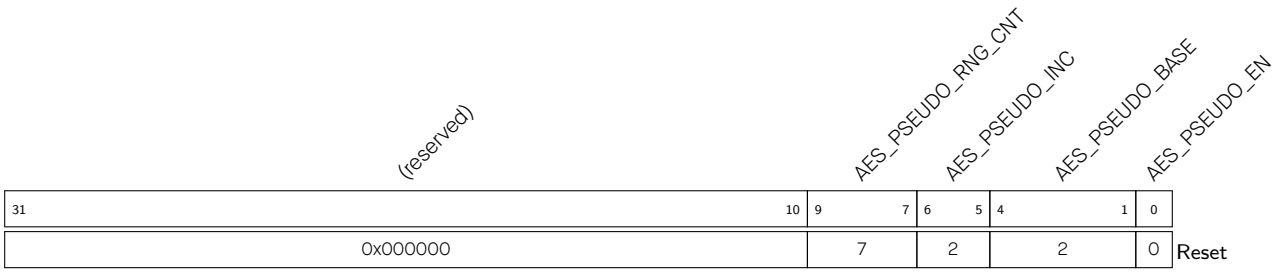
AES_INT_CLR Configures whether to clear AES interrupt.

0: No effect

1: Clear

(WT)

Register 27.16. AES_INT_ENA_REG (0x00B0)



AES_INT_ENA Configures whether to enable AES interrupt.

0: Disable

1: Enable

(R/W)

Register 27.17. AES_PSEUDO_REG (0x00D0)

AES_PSEUDO_EN Configures whether to enable the pseudo-round function of AES.

0: Disable

1: Enable

(R/W)

AES_PSEUDO_BASE Configures the basic number of pseudo-rounds. (R/W)

AES_PSEUDO_INC Configures the random incremental number of pseudo-rounds. (R/W)

AES_PSEUDO_RNG_CNT Configures the frequency of pseudo-key updates in the pseudo-round function. (R/W)

Chapter 28

ECC Accelerator (ECC)

28.1 Overview

Elliptic Curve Cryptography (ECC) is an approach to public-key cryptography based on the algebraic structure of elliptic curves. ECC uses smaller keys compared to RSA cryptography while providing equivalent security.

ESP32-P4's ECC accelerator can complete various calculations based on different elliptic curves, thus accelerating the ECC algorithm and ECC-derived algorithms such as ECDSA.

28.2 Feature List

ESP32-P4's ECC accelerator has the following features:

- Three different elliptic curves, namely, P-192, P-256, and P-384 defined in FIPS 186-5
- 11 working modes
- Enhanced anti-attack performance
- Interrupt upon completion of calculation

28.3 ECC Basics

To better illustrate the functionality of the ECC accelerator, the basic knowledge and terminology used in this chapter are introduced in this section.

28.3.1 Elliptic Curve and Points on the Curves

The ECC algorithm is based on elliptic curves over prime fields, which can be represented as:

$$y^2 = x^3 + ax + b \bmod p$$

where,

- p is a prime number,
- a and b are two non-negative integers smaller than p,
- and (x, y) is a point on the curve satisfying the representation.

28.3.2 Affine Coordinates and Jacobian Coordinates

An elliptic curve can be represented as below:

- In affine coordinates:

$$y^2 = x^3 + ax + b \bmod p$$

- In Jacobian coordinates:

$$Y^2 = X^3 + aXZ^4 + bZ^6 \bmod p$$

To convert affine coordinates (x, y) to/from Jacobian coordinates (X, Y, Z):

- From Jacobian to Affine coordinates:

$$x = X/Z^2 \bmod p$$

$$y = Y/Z^3 \bmod p$$

- From Affine to Jacobian coordinates:

$$X = x$$

$$Y = y$$

$$Z = 1$$

28.3.3 Memory Blocks

ECC's memory blocks store the input and output data of the ECC operation.

Table 28.3-1. ECC Accelerator Memory Blocks

Memory Block	Size (byte)	Starting Address*	Ending Address*	Access
ECC_MULT_Mem_k	32	0x100	0x11F	R/W
ECC_MULT_Mem_Px	32	0x120	0x13F	R/W
ECC_MULT_Mem_Py	32	0x140	0x15F	R/W
ECC_MULT_Mem_Qx	32	0x160	0x17F	R/W
ECC_MULT_Mem_Qy	32	0x180	0x19F	R/W
ECC_MULT_Mem_Qz	32	0x1A0	0x1BF	R/W

* Address offset related to the ECC accelerator base address is provided in Table 9.3-2 in Chapter 9 *System and Memory*.

28.3.4 Data and Data Block

ESP32-P4's ECC can operate on 192-bit, 256-bit, or 384-bit data, depending on the elliptic curves.

For example, the 256-bit data $D[255:0]$ can be divided into eight 32-bit data blocks $D[n][31:0](n = 0, 1, \cdots, 7)$. Data blocks with smaller indexes correspond to lower binary bits. To be specific:

$$D[255:0] = D[7][31:0], D[6][31:0], D[5][31:0], D[4][31:0], D[3][31:0], D[2][31:0], D[1][31:0], D[0][31:0]$$

28.3.5 Writing Data

Writing data means writing data to an ECC memory block and using this data as the input to the ECC algorithm. To be specific, writing data to an ECC memory block means writing $D[n][31:0](n = 0, 1, \cdots, 7)$ to the "starting address of this ECC memory block + $4 \times n$" sequentially:

- write $D[0]$ to "starting address"
- write $D[1]$ to "starting address + 4"
- $\cdots$
- write $D[7]$ to "starting address + 28"

Note:
When storing data, write only the data block of the required length. Do not append a 0 to the most significant bit. For example, for 192-bit data, store only the 192 bits without appending 0.

28.3.6 Reading Data

Read data means reading data from the starting address of an ECC memory block and using this data as the output from the ECC algorithm. To be specific, read data from an ECC memory block means reading $D[n][31:0](n = 0, 1, \cdots, 7)$ from the "starting address of this ECC memory block + $4 \times n$" successively:

- read $D[0]$ from "starting address"
- read $D[1]$ from "starting address + 4"
- $\cdots$
- read $D[7]$ from "starting address + 28"

Note:
When reading data, only the data block of the required length needs to be read. For example, to read 192-bit data, simply read the lower 192 bits (i.e., 6 data blocks).

28.3.7 Standard Calculation and Jacobian Calculation

ESP32-P4's ECC performs Affine Point Calculation (including Affine Point Verification, Affine Point Add, and Affine Point Multiplication) using the affine coordinates and Jacobian Calculation (including Jacobian Point Verification, Jacobian Point Add, and Jacobian Point Multiplication) using the Jacobian coordinates.

28.4 Function Description

28.4.1 Curve Mode

ESP32-P4's ECC supports acceleration based on three curve modes, each corresponding to an elliptic curve. By configuring the ECC_MULT_CURVE_MODE field, users can select the desired key size. For details, see Table 28.4-1 below.

Table 28.4-1. ECC Accelerator Curve Mode Selection

ECC_MULT_CURVE_MODE	Elliptic Curves*
0	FIPS P-192
1	FIPS P-256
2	FIPS P-384

* See definition of FIPS P-192, P-256, and P-384 defined in FIPS 186-5.

28.4.2 Working Modes

ESP32-P4's ECC accelerator supports 11 working modes based on two elliptic curves described in the above section. By configuring the ECC_MULT_WORK_MODE field, users can select the desired working mode. For details, see Table 28.4-2.

Table 28.4-2. Working Modes of ECC Accelerator

ECC_MULT_WORK_MODE	Working Modes
0	Affine Point Multi
1	**Reserved**
2	Affine Point Verif
3	Affine Point Verif + Multi
4	Jacobian Point Multi
5	Point Add
6	Jacobian Point Verif
7	Affine Point Verif + Jacobian Point Multi
8	Mod Add
9	Mod Sub
10	Mod Multi
11	Mod Div

Note:
Note that the calculation of Jacobian Point Multi mode is about 10% faster than that of the Affine Point Multi mode.

Detailed descriptions about different working modes are provided in the following sections.

28.4.2.1 Affine Point Multiplication (Affine Point Multi)

Affine Point Multiplication can be represented as:

$$Q = (Q_x, Q_y) = (J_x, J_y, J_z) = k \cdot (P_x, P_y)$$

where,

- (Q_x, Q_y) is the affine expression of point Q.
- (J_x, J_y, J_z) is the Jacobian expression of point Q.

- Input: P_x, P_y, and k are stored in ECC_MULT_Mem_Px, ECC_MULT_Mem_Py, and ECC_MULT_Mem_k respectively.
- Output: Q_x and Q_y are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py respectively.

28.4.2.2 Affine Point Verification (Affine Point Verif)

Affine Point Verification can be used to verify if a point (P_x, P_y) is on a selected elliptic curve.

- Input: P_x and P_y are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py respectively.
- Output: The verification result is stored in the ECC_MULT_VERIFICATION_RESULT bit.

28.4.2.3 Affine Point Verification + Affine Point Multiplication (Affine Point Verif + Multi)

In this mode, ECC first verifies if point (P_x, P_y) is on the selected elliptic curve. If so, the following multiplication is performed:

$$Q = (Q_x, Q_y) = (J_x, J_y, J_z) = k \cdot (P_x, P_y)$$

where,

- (Q_x, Q_y) is the affine expression of point Q.
- (J_x, J_y, J_z) is the Jacobian expression of point Q.
- Input: P_x, P_y, and k are stored in ECC_MULT_Mem_Px, ECC_MULT_Mem_Py, and ECC_MULT_Mem_k respectively.
- Output:
  - The verification result is stored in the ECC_MULT_VERIFICATION_RESULT bit.
  - Q_x and Q_y are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py respectively.
  - J_x, J_y, and J_z are stored in ECC_MULT_Mem_Qx, ECC_MULT_Mem_Qy, and ECC_MULT_Mem_Qz.

28.4.2.4 Jacobian Point Multiplication (Jacobian Point Multi)

Jacobian Point Multiplication can be represented as:

$$Q = (Q_x, Q_y, Q_z) = k \cdot (P_x, P_y, 1)$$

where,

- (Q_x, Q_y, Q_z) is the Jacobian expression of point Q.
- 1 in the point's Jacobian coordinates is automatically completed by hardware.
- Input: P_x, P_y, and k are stored in ECC_MULT_Mem_Px, ECC_MULT_Mem_Py, and ECC_MULT_Mem_k respectively.
- Output: Q_x, Q_y, and Q_z are stored in ECC_MULT_Mem_Qx, ECC_MULT_Mem_Qy, and ECC_MULT_Mem_Qz respectively.

28.4.2.5 Point Addition (Point Add)

Point Addition can be represented as:

$$R = (R_x, R_y) = (J_x, J_y, J_z) = (P_x, P_y, 1) + (Q_x, Q_y, Q_z)$$

where,

- (R_x, R_y) is the affine expression of point R.
- (J_x, J_y, J_z) is the Jacobian expression of point R.
- 1 in the point's Jacobian coordinates is automatically completed by hardware.
- Input:
  - P_x and P_y are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py.
  - Q_x, Q_y, and Q_z are stored in ECC_MULT_Mem_Qx, ECC_MULT_Mem_Qy, and ECC_MULT_Mem_Qz.
- Output:
  - R_x and R_y are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py.
  - J_x, J_y and J_z are stored in ECC_MULT_Mem_Qx, ECC_MULT_Mem_Qy, and ECC_MULT_Mem_Qz.

28.4.2.6 Jacobian Point Verification (Jacobian Point Verif)

Jacobian Point Verification can be used to verify if point (Q_x, Q_y, Q_z) is on a selected elliptic curve.

- (Q_x, Q_y, Q_z) is the Jacobian expression of point Q.
- Input: Q_x, Q_y, and Q_z are stored in ECC_MULT_Mem_Qx, ECC_MULT_Mem_Qy, and ECC_MULT_Mem_Qz respectively.
- Output: The verification result is stored in the ECC_MULT_VERIFICATION_RESULT bit.

28.4.2.7 Affine Point Verification + Jacobian Point Multiplication (Affine Point Verif + Jacobian Point Multi)

In this mode, ECC first verifies if point (P_x, P_y) is on the selected elliptic curve. If so, the following multiplication is performed:

$$Q = (Q_x, Q_y, Q_z) = k \cdot (P_x, P_y, 1)$$

where,

- (Q_x, Q_y, Q_z) is the Jacobian expression of point Q.
- 1 in the point's Jacobian coordinates is automatically completed by hardware.
- Input: P_x, P_y, and k are stored in ECC_MULT_Mem_Px, ECC_MULT_Mem_Py, and ECC_MULT_Mem_k.
- Output:
  - The verification result is stored in the ECC_MULT_VERIFICATION_RESULT bit.
  - Q_x, Q_y, and Q_z are stored in ECC_MULT_Mem_Qx, ECC_MULT_Mem_Qy, and ECC_MULT_Mem_Qz.

28.4.2.8 Mod Addition (Mod Add)

Mod Addition can be represented as:

$$R = A + B \bmod N$$

where,

- Input:
  - A and B are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py.
  - The value of N is related to the register fields below:
    * ECC_MULT_CURVE_MODE to select the related curve.
    * ECC_MULT_MOD_BASE to choose using mod base or order of the base point.
- Output: R is stored in ECC_MULT_Mem_Px.

28.4.2.9 Mod Subtraction (Mod Sub)

Mod Subtraction can be represented as:

$$R = A - B \bmod N$$

where,

- Input:
  - A and B are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py.
  - The value of N is related to the register fields below:
    * ECC_MULT_CURVE_MODE to select the related curve.
    * ECC_MULT_MOD_BASE to choose using mod base or order of the base point.
- Output: R is stored in ECC_MULT_Mem_Px.

28.4.2.10 Mod Multiplication (Mod Multi)

Mod Multiplication can be represented as:

$$R = A \cdot B \bmod N$$

where,

- Input:
  - A and B are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py.
  - The value of N is related to the register fields below:
    * ECC_MULT_CURVE_MODE to select the related curve.
    * ECC_MULT_MOD_BASE to choose using mod base or order of the base point.
- Output: R is stored in ECC_MULT_Mem_Py.

28.4.2.11 Mod Division (Mod Div)

Mod Division can be represented as:

$$R = A \cdot B^{-1} \bmod N$$

where,

- Input:
  - A and B are stored in ECC_MULT_Mem_Px and ECC_MULT_Mem_Py.
  - The value of N is related to the register fields below:
    * ECC_MULT_CURVE_MODE to select the related curve.
    * ECC_MULT_MOD_BASE to choose using mod base or order of the base point.
- Output: R is stored in ECC_MULT_Mem_Py.

28.4.3 Enhancing Anti-Attack Performance

When performing different types of point multiplication calculations, i.e., mode 0, 3, 4, and 7, ESP32-P4's ECC accelerator offers an additional option to further enhance its anti-attack performance by ensuring that all point multiplication calculations take the same maximum runtime.

To enable the enhanced anti-attack performance, set ECC_MULT_SECURITY_MODE to 1. If this setting is enabled, each time the ECC accelerator perform a point multiplication calculation:

- The execution latency is constant for a given operation.
- Power consumption variations are minimized.

28.5 Clock and Reset

ESP32-P4's ECC only has one clock module (CRYPTO_ECC_CLK) and one reset module (CRYPTO_ECC_RST).

ECC's clock and reset is handled by the the Power/Clock/Reset (PCR) module (see Chapter 11 *Reset and Clock* for more information). Users should enable the ECC clock by setting HP_SYS_CLKRST_CRYPTO_ECC_CLK_EN and release the ECC reset by clearing HP_SYS_CLKRST_RST_EN_ECC before starting the ECC accelerator. Besides, due to resource reuse between cryptography accelerator modules, users also need to additionally clear the HP_SYS_CLKRST_RST_EN_ECDSA bit.

28.6 Interrupts

ESP32-P4's ECC accelerator can generate the ECC_INTR interrupt signal that will be sent to the Interrupt Matrix.

ECC_INTR has only one interrupt source to generate the ECC_INTR interrupt signal, i.e., ECC_MULT_CALC_DONE_INT, which is triggered on the completion of an ECC calculation.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The ECC_MULT_CALC_DONE_INT interrupt source is configured by the following registers (refer to Section 28.8 *Register Summary* for more information):

- ECC_MULT_CALC_DONE_INT_RAW: Stores the raw interrupt status of ECC_MULT_CALC_DONE_INT.
- ECC_MULT_CALC_DONE_INT_ST: Indicates the status of the ECC_MULT_CALC_DONE_INT interrupt. This bit is generated by enabling or disabling the ECC_MULT_CALC_DONE_INT_RAW bit via ECC_MULT_CALC_DONE_INT_ENA.
- ECC_MULT_CALC_DONE_INT_ENA: Enables or disables the ECC_MULT_CALC_DONE_INT interrupt.
- ECC_MULT_CALC_DONE_INT_CLR: Set this bit to clear the ECC_MULT_CALC_DONE_INT interrupt status. By setting this bit to 1, the ECC_MULT_CALC_DONE_INT_RAW and ECC_MULT_CALC_DONE_INT_ST bits will be cleared.

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

28.7 Programming Procedures

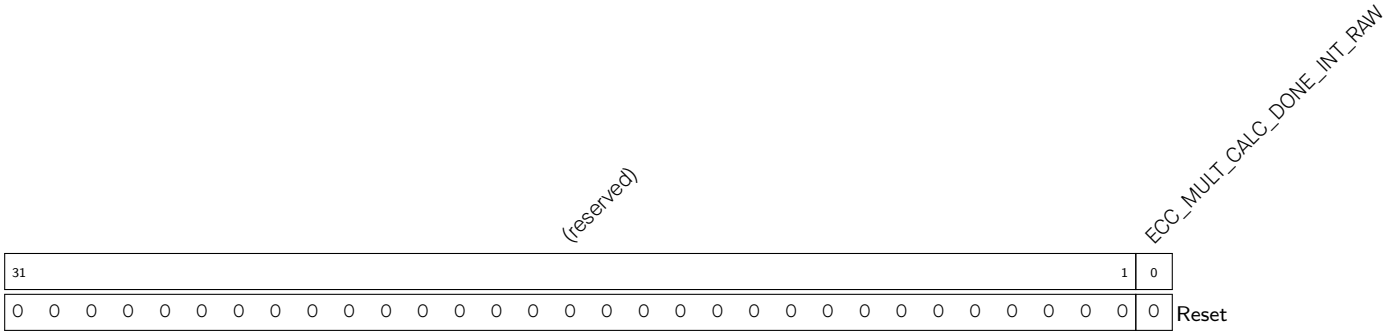
The programming procedure for configuring ECC is described below:

1. Configure the ECC clock and reset. Refer to Section 28.5 for detailed information.
2. Select the key size and working mode as described in Section 28.4.
3. Enable the ECC_MULT_CALC_DONE_INT interrupt as described in Section 28.6.
4. Set the ECC_MULT_START field to start ECC calculation.
5. Wait for the ECC_MULT_CALC_DONE_INT interrupt, which indicates the completion of the ECC calculation.
6. Check the result as described in Section 28.4.

28.8 Register Summary

The addresses in this section are relative to ECC Accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

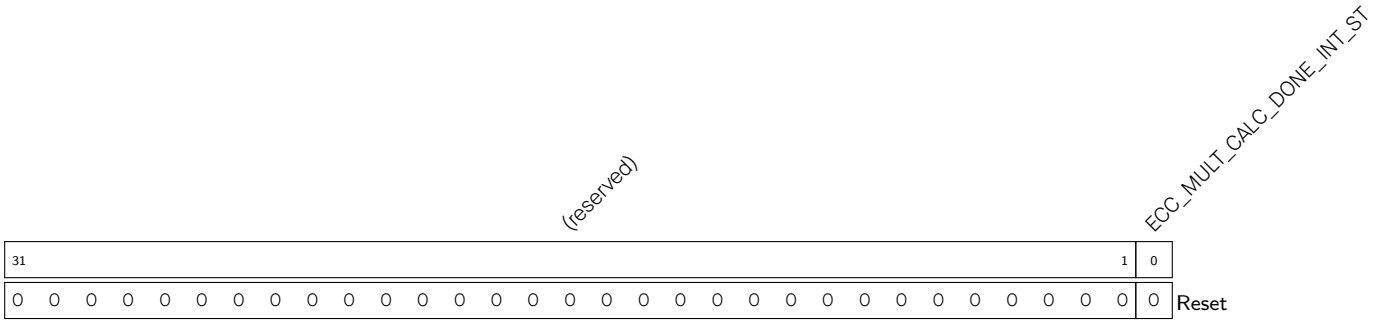
The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Interrupt Registers			
ECC_MULT_INT_RAW_REG	ECC raw interrupt status register	0x000C	R/SS/WTC
ECC_MULT_INT_ST_REG	ECC masked interrupt status register	0x0010	RO
ECC_MULT_INT_ENA_REG	ECC interrupt enable register	0x0014	R/W
ECC_MULT_INT_CLR_REG	ECC interrupt clear register	0x0018	WT
Configuration Register			
ECC_MULT_CONF_REG	ECC configuration register	0x001C	varies
Version Register			
ECC_MULT_DATE_REG	Version control register	0x00FC	R/W

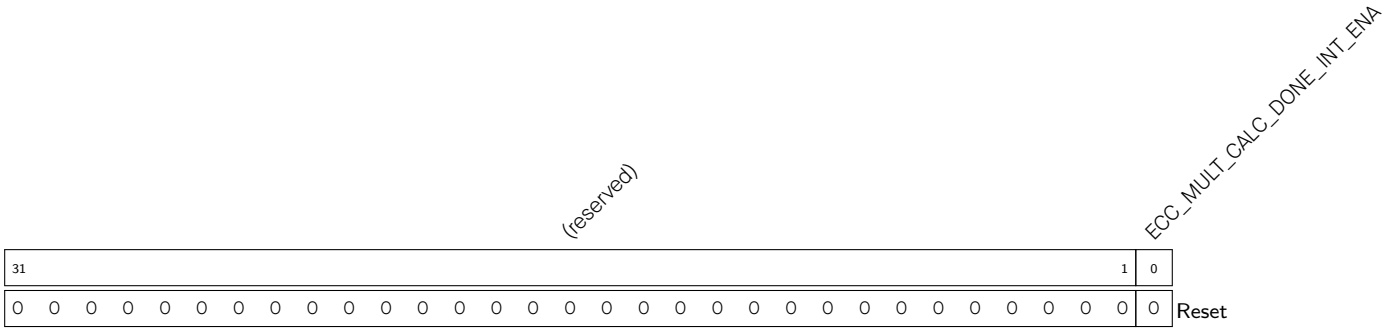
28.9 Registers

The addresses in this section are relative to ECC Accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



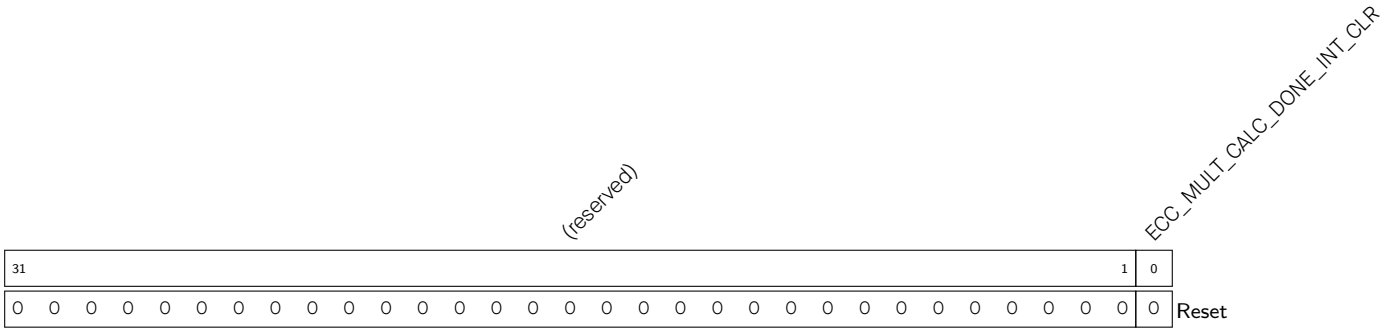
For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 28.1. ECC_MULT_INT_RAW_REG (0x000C)



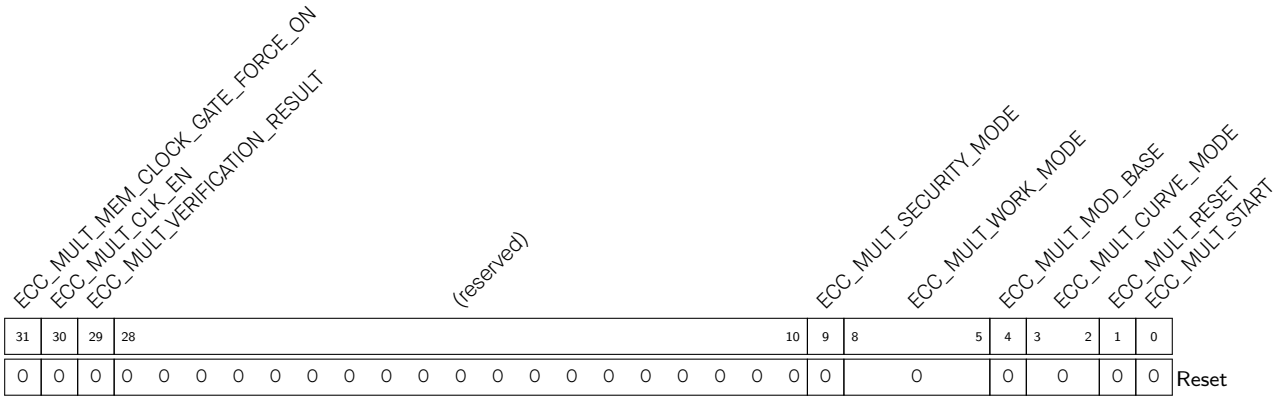
ECC_MULT_CALC_DONE_INT_RAW The raw interrupt status of the ECC_MULT_CALC_DONE_INT interrupt. (R/SS/WTC)

Register 28.2. ECC_MULT_INT_ST_REG (0x0010)



ECC_MULT_CALC_DONE_INT_ST The masked interrupt status of the ECC_MULT_CALC_DONE_INT interrupt. (RO)

Register 28.3. ECC_MULT_INT_ENA_REG (0x0014)



ECC_MULT_CALC_DONE_INT_ENA Write 1 to enable the ECC_MULT_CALC_DONE_INT interrupt. (R/W)

Register 28.4. ECC_MULT_INT_CLR_REG (0x0018)

ECC_MULT_CALC_DONE_INT_CLR Write 1 to clear the ECC_MULT_CALC_DONE_INT interrupt. (WT)

Register 28.5. ECC_MULT_CONF_REG (0x001C)

ECC_MULT_START Configures whether to start the calculation of the ECC accelerator. This bit will be self-cleared when the calculation is done.

0: No effect

1: Start the calculation of the ECC accelerator

(R/W/SC)

ECC_MULT_RESET Configures whether to reset the ECC accelerator.

0: No effect

1: Reset

(WT)

ECC_MULT_CURVE_MODE Configures the curve mode of the ECC accelerator.

0: P-192

1: P-256

2: P-384

3: Invalid

(R/W)

ECC_MULT_MOD_BASE Configures whether to choose using the mod base or order of base point in the mod operation. Only valid in working modes 8-11.

0: n (order of base point)

1: p (mod base of curve)

(R/W)

ECC_MULT_WORK_MODE Configures the working mode of the ECC accelerator.

0: Affine Point Multi mode

1: Reserved

2: Affine Point Verif mode

3: Affine Point Verif + Multi mode

4: Jacobian Point Multi mode

5: Point Add mode

6: Jacobian Point Verif mode

7: Affine Point Verif + Jacobian Point Multi mode

8: Mod Add mode

9. Mod Sub mode

10: Mod Multi mode

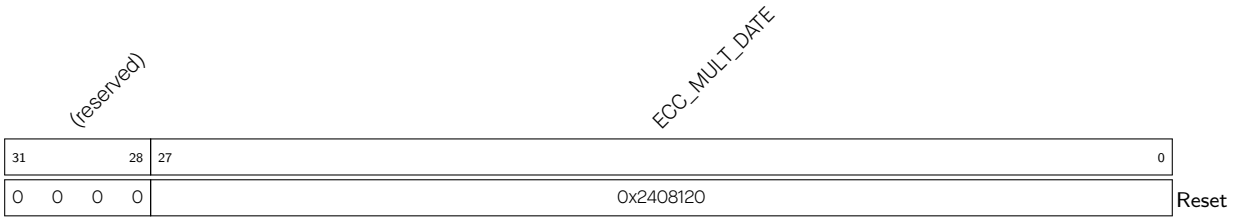
11: Mod Div mode

(R/W)

Continued on the next page...

Register 28.5. ECC_MULT_CONF_REG (0x001C)

Continued from the previous page...



ECC_MULT_SECURITY_MODE Configures whether to enhance the anti-attack performance when calculating point multiplication. Only valid in working modes 0, 3, 4, and 7.
0: Disable
1: Enable
(R/W)

ECC_MULT_VERIFICATION_RESULT Represents the verification result of the ECC accelerator, valid only when the calculation is done.
0: Verification failed
1: Verification passed
(R/SS)

ECC_MULT_CLK_EN Configures whether to force on register clock gate.
0: No effect
1: Force on
(R/W)

ECC_MULT_MEM_CLOCK_GATE_FORCE_ON Configures whether to force on ECC memory clock gate.
0: No effect
1: Force on
(R/W)

Register 28.6. ECC_MULT_DATE_REG (0x00FC)

ECC_MULT_DATE Version control register. (R/W)

Chapter 29

HMAC Accelerator (HMAC)

The Hash-based Message Authentication Code (HMAC) module computes Message Authentication Codes (MACs) using hash algorithm SHA-256 and keys as described in RFC 2104. The 256-bit HMAC key is stored in an eFuse key block and can be set as read-protected, i.e., the key is not accessible from outside the HMAC accelerator.

29.1 Main Features

- Standard HMAC-SHA-256 algorithm
- HMAC-SHA-256 calculation based on key in eFuse,
  - whose result cannot be accessed by software in downstream mode for high security
  - whose result can be accessed by software in upstream mode
- Generates required keys for the RSA Digital Signature Peripheral (RSA_DS) in downstream mode
- Re-enables soft-disabled JTAG in downstream mode

29.2 Functional Description

The HMAC module operates in two modes: upstream mode and downstream mode. In upstream mode, users provide the HMAC message and read back the calculation result. In downstream mode, the HMAC module provides input to two possible other internal hardware modules: On the one hand, an HMAC can be used to enable JTAG after JTAG has been temporarily disabled before. On the other hand, an HMAC can be used as decryption key for Digital Signature parameters stored in flash memory for the RSA_DS peripheral. Furthermore, the calculations happen internally and automatically in downstream mode, so that confidentiality of any key and derived key material is ensured, given correct configuration.

Note:
After the reset signal being released, the HMAC module will check whether the RSA_DS_KEY exists in the eFuse. If the key exists, the HMAC module will enter downstream RSA_DS mode and finish the RSA_DS_KEY calculation automatically. This process is automatically completed by hardware and does not require software participation. When the downstream operation after reset is completed, the HMAC will automatically return to the idle state.

29.2.1 Upstream Mode

To calculate the HMAC value in upstream mode, users should perform the following steps:

1. Initialize the HMAC module and enter upstream mode.

2. Write the correctly padded message to the HMAC, one block at a time.
3. Read back the result from HMAC.

For details of this process, please see Section 29.2.5.

Note:
Common use cases for the upstream mode are challenge-response protocols supporting HMAC-SHA-256. Assume the two entities in the challenge-response protocol are A and B respectively, and the data message they expect to exchange is M. The general authentication process of this protocol is as follows:

- A calculates a unique random number M.
- A sends M to B.
- B calculates the HMAC (through M and KEY) and sends the result to A.
- A calculates the HMAC (through M and KEY) internally.
- A compares the two results. If the results are the same, then the identity of B is authenticated.

29.2.2 Downstream Mode - JTAG Enable Feature

JTAG debugging can be disabled by eFuse in a way which allows later re-enabling using the HMAC module. (For more details, please see Chapter 9.4 *eFuse Controller (EFUSE)*.) The HMAC module will expect the user to supply the HMAC result for one of the eFuse keys. The HMAC module will check whether the supplied HMAC matches the one calculated from the chosen key. If both HMACs are the same, JTAG will be enabled until the user calls the HMAC module to clear the results and consequently disable JTAG again.

To re-enable JTAG, users should perform the following steps:

1. Enable the HMAC module by initializing clock and reset signals of HMAC, and enter downstream JTAG enable mode by configuring HMAC_SET_PARA_PURPOSE_REG. Then, wait for the calculation to complete. Please see Section 29.2.5 for more details.
2. Write 1 to the HMAC_SOFT_JTAG_CTRL_REG register to enter JTAG re-enable mode.
3. Write the 256-bit HMAC value to register HMAC_WR_JTAG_REG. This value is obtained by performing a local HMAC calculation from the 32-byte 0x00 using SHA-256 and the key that has been written to the eFuse. It needs to be written 8 times and 32-bit each time in big-endian word order.
4. If the HMAC result calculated from the key in the eFuse matches the value that users wrote in step 3, then JTAG is re-enabled. Otherwise, JTAG remains disabled.
5. After writing 1 to HMAC_SET_INVALIDATE_JTAG_REG or resetting the chip, JTAG will be disabled. If users want to re-enable JTAG again, they need to repeat the above steps again.

29.2.3 Downstream Mode - RSA_DS Key Derivation Feature

The RSA Digital Signature Peripheral (RSA_DS) encrypts its parameters using the AES-CBC algorithm. The HMAC module is used as a Key Derivation Function (KDF) to derive the AES key to decrypt these parameters (parameter decryption key).

Before starting the RSA_DS peripheral, users need to obtain the parameter decryption key for the RSA_DS peripheral through HMAC calculation. For more information, please see Chapter 32 *RSA Digital Signature*

Peripheral (RSA_DS). After the chip is powered on, the HMAC module will check whether the key required to calculate the parameter decryption key has been burned in the eFuse block. If the key has been burned, HMAC module will automatically enter the downstream RSA_DS algorithm mode and complete the HMAC calculation based on the chosen key.

29.2.4 HMAC eFuse Configuration

Each HMAC key burned into an eFuse block has a key purpose, specifying for which functionality the key can be used. The HMAC module will not accept a key with a non-matching purpose for any functionality. The HMAC module provides three different functionalities: re-enabling JTAG, RSA_DS KDF in downstream mode, and pure HMAC calculation in upstream mode. For each functionality, there exists a corresponding key purpose, listed in Table 29.2-1. Additionally, another purpose specifies a key which may be used for re-enabling JTAG as well as for serving as RSA_DS KDF.

Before enabling HMAC to do calculations, user should make sure the key to be used has been burned in eFuse by reading the registers EFUSE_KEY_PURPOSE_x (We have a total of 6 keys in eFuse, so the value of x is 0 ~ 5. Among which, EFUSE_KEY_PURPOSE_0 ~ EFUSE_KEY_PURPOSE_1 belong to the register EFUSE_RD_REPEAT_DATA1_REG, and EFUSE_KEY_PURPOSE_2 ~ EFUSE_KEY_PURPOSE_5 belong to the register EFUSE_RD_REPEAT_DATA2_REG) from 9.4 *eFuse Controller (EFUSE)*. Take upstream mode as an example, if there is no EFUSE_KEY_PURPOSE_HMAC_UP in EFUSE_KEY_PURPOSE_0 ~ 5, it means there is no key in eFuse that can be used for the HMAC upstream mode. Users can burn a key to eFuse as follows:

1. Prepare a secret 256-bit HMAC key and burn the key to an empty eFuse block y. As there are 6 blocks for storing a key in eFuse and the numbers of those blocks range from 4 to 9, the value of y is 4 ~ 9. Hence, when talking about key0, it means eFuse block4. Then, program the purpose to EFUSE_KEY_PURPOSE_$(y-4)$. Take upstream mode as an example: after programming the key, the user should program EFUSE_KEY_PURPOSE_HMAC_UP (corresponding value is 8) to EFUSE_KEY_PURPOSE_$(y-4)$. Please see Chapter 9.4 *eFuse Controller (EFUSE)* on how to program eFuse keys.
2. If needed, configure this eFuse key block to be read protected, so that users cannot read its value. A copy of this key should be kept by any party who needs to verify this device.

Please note that the key whose purpose is EFUSE_KEY_PURPOSE_HMAC_DOWN_ALL can be used for both re-enabling JTAG or RSA_DS.

Table 29.2-1. HMAC Purposes and Configuration Value

Purpose	Mode	Value	Description
JTAG Re-enable	Downstream	6	EFUSE_KEY_PURPOSE_HMAC_DOWN_JTAG
RSA_DS KDF	Downstream	7	EFUSE_KEY_PURPOSE_HMAC_DOWN_DIGITAL_SIGNATURE
HMAC Calculation	Upstream	8	EFUSE_KEY_PURPOSE_HMAC_UP
Both JTAG Re-enable and RSA_DS KDF	Downstream	5	EFUSE_KEY_PURPOSE_HMAC_DOWN_ALL

Select eFuse Key Blocks and HMAC Purposes

The eFuse controller provides six key blocks, i.e., KEY0 ~ 5. To select a particular KEYn for an HMAC calculation, write the key number n to register HMAC_SET_PARA_KEY_REG.

Write a correct purpose to register HMAC_SET_PARA_PURPOSE_REG (see Section 29.2.5). Note that the purpose of the key has also been programmed to eFuse memory. Only when the configured HMAC purpose matches the defined purpose of KEYn, the HMAC module will execute the configured calculation. Otherwise, it will return a matching error and stop the current calculation.

For example, suppose a user selects KEY3 for HMAC calculation, and the value programmed to EFUSE_KEY_PURPOSE_3 is 6 (EFUSE_KEY_PURPOSE_HMAC_DOWN_JTAG). Based on Table 29.2-1, KEY3 can be used to re-enable JTAG. If the value written to register HMAC_SET_PARA_PURPOSE_REG is also 6, then the HMAC module will start the process to re-enable JTAG.

Select Key from Key Manager

Users can deploy the HMAC key in the Key Manager. For deployment procedures, please refer to Section 36 *Key Manager*. To select this key from the Key Manager, write the key index 7 to the register HMAC_SET_PARA_KEY_REG. When a key is selected from the Key Manager, the intended operation target in the register is automatically set to "HMAC Calculation", and all other configurations will be ignored.

29.2.5 HMAC Process (Detailed)

The process for users to call HMAC in ESP32-P4 is as follows:

29.2.5.1 Enable HMAC Module

1. Set the peripheral clock bits for HMAC and SHA peripherals in register HP_SYS_CLKRST_CRYPTO_HMAC_CLK_EN, and clear the corresponding peripheral reset bits in register HP_SYS_CLKRST_RST_EN_HMAC. For information on those registers, please see Chapter 11 *Reset and Clock*.
2. Write 1 to register HMAC_SET_START_REG.

29.2.5.2 Configure HMAC Keys and Key Purposes

1. Write the key purpose m to register HMAC_SET_PARA_PURPOSE_REG. The possible key purpose values are shown in Table 29.2-1. For more information, please refer to Section 29.2.4.
2. Select KEYn in eFuse memory as the key by writing n (ranges from 0 to 5, and 7) to register HMAC_SET_PARA_KEY_REG. For more information, please refer to Section 29.2.4.
3. Write 1 to register HMAC_SET_PARA_FINISH_REG to complete the configuration.
4. Read register HMAC_QUERY_ERROR_REG. If its value is 1, it means the purpose of the selected block does not match the configured key purpose and the calculation will not proceed. If its value is 0, it means the purpose of the selected block matches the configured key purpose, and then the calculation can proceed.
5. When the value of HMAC_SET_PARA_PURPOSE_REG is not 8, it means the HMAC module is in downstream mode, proceed with 29.2.5.3. When the value is 8, it means the HMAC module is in upstream mode, proceed with 29.2.5.4.

29.2.5.3 Downstream Mode Process

1. Poll Status register HMAC_QUERY_BUSY_REG until it reads 0.

2. To clear the result and make further usage of the dependent hardware (JTAG or RSA_DS) impossible, write 1 to either register HMAC_SET_INVALIDATE_JTAG_REG to clear the result generated by the JTAG key; or to register HMAC_SET_INVALIDATE_DS_REG to clear the result generated by RSA_DS_KEY. Afterwards, the HMAC process needs to be restarted to re-enable any of the dependent peripherals.

29.2.5.4 Upstream Mode Process

1. Write message in upstream mode:
   (a) Poll Status register HMAC_QUERY_BUSY_REG until it reads 0.
   (b) Apply SHA padding to message as described in Section 29.3.1, and get message block: Block_n ($n >= 0$)
   (c) Perform one of the following operations according to the block number n:
   - If there is only one message block in total which has included all padding bits:
     i. Write the 512-bit Block_n to register HMAC_WR_MESSAGE_*n*_REG (*n*: 0-15). Write 1 to register HMAC_SET_MESSAGE_ONE_REG, to trigger the processing of this message block.
     ii. Poll Status register HMAC_QUERY_BUSY_REG until it reads 0.
     iii. Write 1 to register HMAC_ONE_BLOCK_REG, and finish message transmission.
   - If Block_n is the last padded block:
     i. Write the 512-bit Block_0 to register HMAC_WR_MESSAGE_*n*_REG (*n*: 0-15). Write 1 to register HMAC_SET_MESSAGE_ONE_REG, to trigger the processing of this message block.
     ii. Poll Status register HMAC_QUERY_BUSY_REG until it reads 0.
     iii. Message transmission finished automatically.
   - If Block_n is the second last padded block:
     i. Write the 512-bit Block_n to register HMAC_WR_MESSAGE_*n*_REG (*n*: 0-15). Write 1 to register HMAC_SET_MESSAGE_ONE_REG, to trigger the processing of this message block.
     ii. Poll Status register HMAC_QUERY_BUSY_REG until it reads 0.
     iii. Write 1 to register HMAC_SET_MESSAGE_PAD_REG, and continue message transmission (jump back to step (c)).
   - If Block_n is neither the last nor the second last message block:
     i. Write the 512-bit Block_n to register HMAC_WR_MESSAGE_*n*_REG (*n*: 0-15). Write 1 to register HMAC_SET_MESSAGE_ONE_REG, to trigger the processing of this message block.
     ii. Poll Status register HMAC_QUERY_BUSY_REG until it reads 0.
     iii. Write 1 to register HMAC_SET_MESSAGE_ING_REG, and continue message transmission (jump back to step (c)).
2. Read hash result in upstream mode:
   (a) Poll Status register HMAC_QUERY_BUSY_REG until it reads 0.
   (b) Read hash result from register HMAC_RD_RESULT_*n*_REG (*n*: 0-7).

(c) Write 1 to register HMAC_SET_RESULT_FINISH_REG to finish calculation. The result will be cleared at the same time.

(d) Upstream mode operation is completed.

Note:
The SHA accelerator can be called directly, or used internally by the RSA_DS peripheral and the HMAC module. However, they can not share the hardware resources simultaneously. Therefore, the SHA module must not be called neither by the CPU nor by the RSA_DS peripheral when the HMAC module is in use.

29.3 HMAC Algorithm Details

29.3.1 Padding Bits

The HMAC module uses SHA-256 as hash algorithm. If the input message is not a multiple of 512 bits, the user must apply a SHA-256 padding algorithm in software. The SHA-256 padding algorithm is the same as described in Section *Padding the Message* of FIPS PUB 180-4. In downstream mode, users do not need to input any message or apply padding. The HMAC module uses a default 32-byte pattern of 0x00 for re-enabling JTAG and a 32-byte pattern of 0xff for deriving the AES key for the RSA_DS peripheral.

For the convenience of reading, here we will briefly describe the process of message padding. As shown in Figure 29.3-1, suppose the length of the unpadded message is m bits. Padding steps are as follows:

1. Append one bit of value "1" to the end of the unpadded message.
2. Append k bits of value "0", where k is the smallest non-negative number which satisfies $m + 1 + k \equiv 448 (mod 512)$.
3. Append a 64-bit integer value as a binary block. This block consists of the length of the unpadded message as a big-endian binary integer value m.

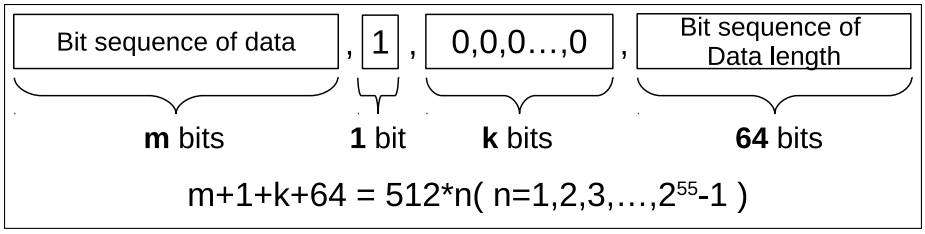


Figure 29.3-1. HMAC SHA-256 Padding Diagram

In upstream mode, if the length of the unpadded message is a multiple of 512 bits, users can configure hardware to apply SHA padding by writing 1 to HMAC_SET_MESSAGE_END_REG or do padding work themselves by writing 1 to HMAC_SET_MESSAGE_PAD_REG. If the length is not a multiple of 512 bits, SHA padding must be manually applied by the user. After the user prepared the padding data, they should complete the subsequent configuration according to the Section 29.2.5.

29.3.2 HMAC Algorithm Structure

The structure of the implemented algorithm in the HMAC module is shown in Figure 29.3-2. This is the standard HMAC algorithm as described in RFC 2104.

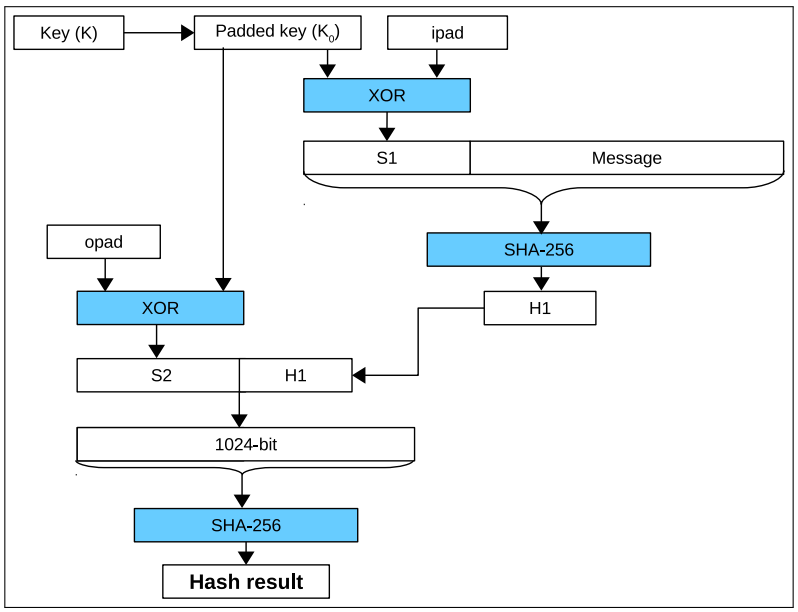

Figure 29.3-2. HMAC Structure Schematic Diagram

In Figure 29.3-2:

1. ipad is a 512-bit message block composed of 64 bytes of 0x36.
2. opad is a 512-bit message block composed of 64 bytes of 0x5c.

The HMAC module appends a 256-bit 0 sequence after the bit sequence of the 256-bit key K in order to get a 512-bit K_0. Then, the HMAC module XORs K_0 with ipad to get the 512-bit S1. Afterwards, the HMAC module appends the input message (multiple of 512 bits) after the 512-bit S1, and exercises the SHA-256 algorithm to get the 256-bit H1.

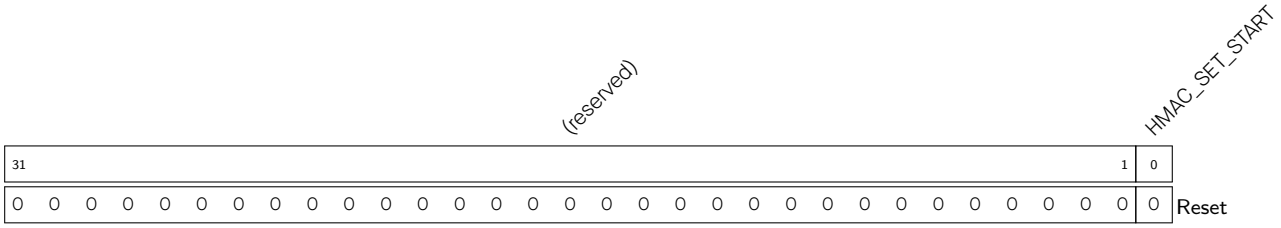
The HMAC module appends the 256-bit SHA-256 hash result H1 to the 512-bit S2 value, which is calculated using the XOR operation of K_0 and opad. A 768-bit sequence will be generated. Then, the HMAC module uses the SHA padding algorithm described in Section 29.3.1 to pad the 768-bit sequence to a 1024-bit sequence, and applies the SHA-256 algorithm to get the final hash result (256-bit).

29.4 Register Summary

The addresses in this section are relative to HMAC Accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Control/Status Registers			
HMAC_SET_START_REG	HMAC start control register	0x0040	WO
HMAC_SET_PARA_FINISH_REG	HMAC configuration completion register	0x004C	WO
HMAC_SET_MESSAGE_ONE_REG	HMAC message control register	0x0050	WO
HMAC_SET_MESSAGE_ING_REG	HMAC message continue register	0x0054	WO
HMAC_SET_MESSAGE_END_REG	HMAC message end register	0x0058	WO
HMAC_SET_RESULT_FINISH_REG	HMAC result reading finish register	0x005C	WO
HMAC_SET_INVALIDATE_JTAG_REG	Invalidate JTAG result register	0x0060	WO
HMAC_SET_INVALIDATE_DS_REG	Invalidate RSA_DS result register	0x0064	WO
HMAC_QUERY_ERROR_REG	Stores matching results between keys generated by users and corresponding purposes	0x0068	RO
HMAC_QUERY_BUSY_REG	Busy state of HMAC module	0x006C	RO
HMAC_SET_MESSAGE_PAD_REG	Software padding register	0x00F0	WO
HMAC_ONE_BLOCK_REG	One block message register	0x00F4	WO
Configuration Registers			
HMAC_SET_PARA_PURPOSE_REG	HMAC parameter configuration register	0x0044	WO
HMAC_SET_PARA_KEY_REG	HMAC parameters configuration register	0x0048	WO
HMAC_SOFT_JTAG_CTRL_REG	Re-enable JTAG register 0	0x00F8	WO
HMAC_WR_JTAG_REG	Re-enable JTAG register 1	0x00FC	WO
HMAC Message Block			
HMAC_WR_MESSAGE_0_REG	Message register 0	0x0080	WO
HMAC_WR_MESSAGE_1_REG	Message register 1	0x0084	WO
HMAC_WR_MESSAGE_2_REG	Message register 2	0x0088	WO
HMAC_WR_MESSAGE_3_REG	Message register 3	0x008C	WO
HMAC_WR_MESSAGE_4_REG	Message register 4	0x0090	WO
HMAC_WR_MESSAGE_5_REG	Message register 5	0x0094	WO
HMAC_WR_MESSAGE_6_REG	Message register 6	0x0098	WO
HMAC_WR_MESSAGE_7_REG	Message register 7	0x009C	WO
HMAC_WR_MESSAGE_8_REG	Message register 8	0x00A0	WO
HMAC_WR_MESSAGE_9_REG	Message register 9	0x00A4	WO
HMAC_WR_MESSAGE_10_REG	Message register 10	0x00A8	WO
HMAC_WR_MESSAGE_11_REG	Message register 11	0x00AC	WO
HMAC_WR_MESSAGE_12_REG	Message register 12	0x00B0	WO
HMAC_WR_MESSAGE_13_REG	Message register 13	0x00B4	WO
HMAC_WR_MESSAGE_14_REG	Message register 14	0x00B8	WO
HMAC_WR_MESSAGE_15_REG	Message register 15	0x00BC	WO
HMAC Upstream Result			



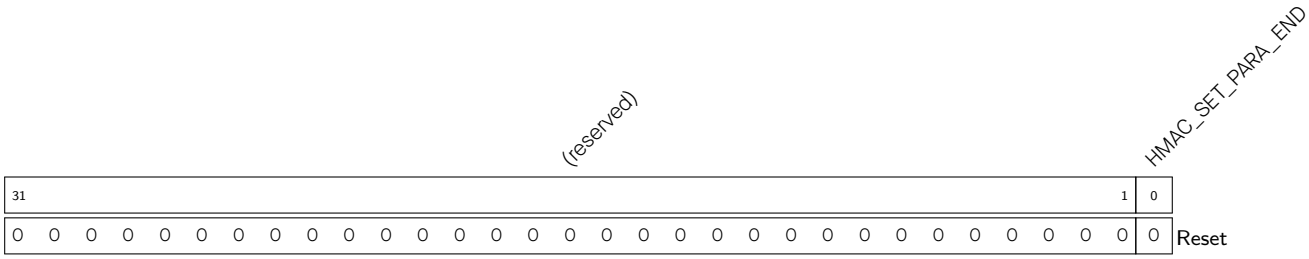
Name	Description	Address	Access
HMAC_RD_RESULT_0_REG	Hash result register 0	0x00C0	RO
HMAC_RD_RESULT_1_REG	Hash result register 1	0x00C4	RO
HMAC_RD_RESULT_2_REG	Hash result register 2	0x00C8	RO
HMAC_RD_RESULT_3_REG	Hash result register 3	0x00CC	RO
HMAC_RD_RESULT_4_REG	Hash result register 4	0x00D0	RO
HMAC_RD_RESULT_5_REG	Hash result register 5	0x00D4	RO
HMAC_RD_RESULT_6_REG	Hash result register 6	0x00D8	RO
HMAC_RD_RESULT_7_REG	Hash result register 7	0x00DC	RO
Version Register			
HMAC_DATE_REG	Version control register	0x01FC	R/W

29.5 Registers

The addresses in this section are relative to HMAC Accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 29.1. HMAC_SET_START_REG (0x0040)



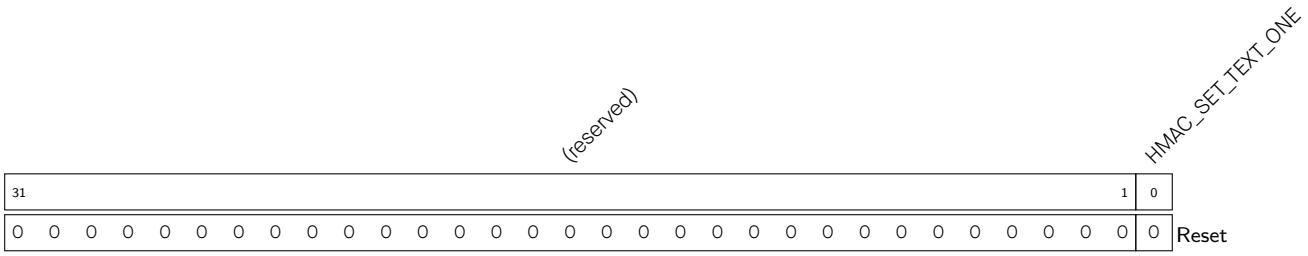
HMAC_SET_START Configures whether or not to enable HMAC.

0: Disable HMAC

1: Enable HMAC

(WO)

Register 29.2. HMAC_SET_PARA_FINISH_REG (0x004C)



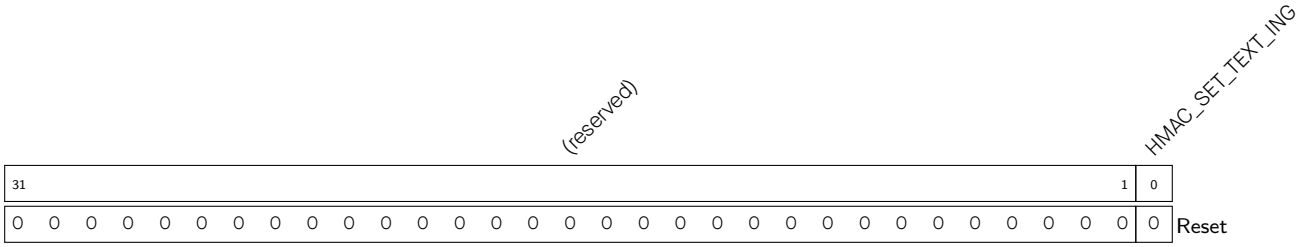
HMAC_SET_PARA_END Configures whether to finish HMAC configuration.

0: No effect

1: Finish configuration

(WO)

Register 29.3. HMAC_SET_MESSAGE_ONE_REG (0x0050)



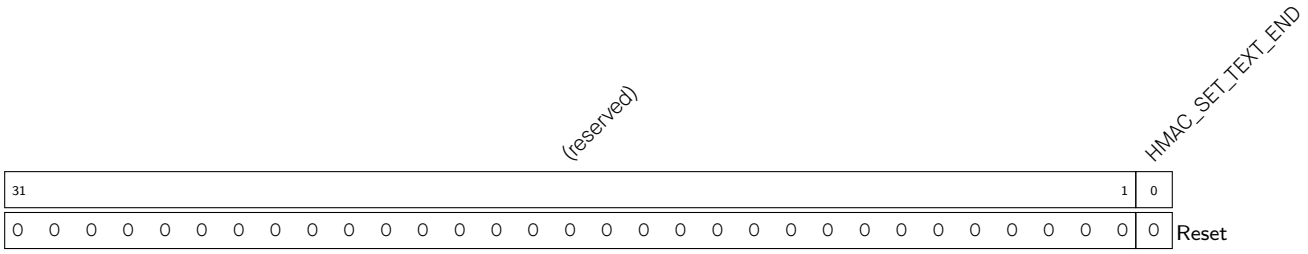
HMAC_SET_TEXT_ONE Calls SHA to calculate one message block.

0: No effect

1: Calls SHA to calculate one message block.

(WO)

Register 29.4. HMAC_SET_MESSAGE_ING_REG (0x0054)



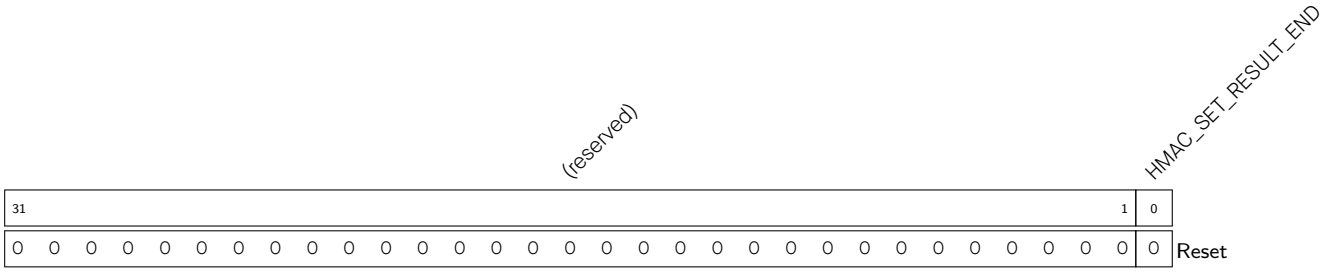
HMAC_SET_TEXT_ING Configures whether or not there are unprocessed message blocks.

0: No unprocessed message block

1: There are still some message blocks to be processed.

(WO)

Register 29.5. HMAC_SET_MESSAGE_END_REG (0x0058)



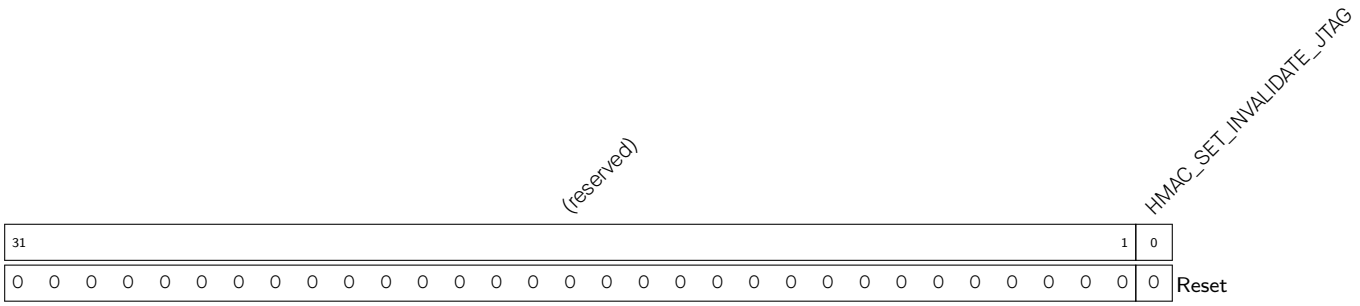
HMAC_SET_TEXT_END Configures whether to start hardware padding.

0: No effect

1: Start hardware padding

(WO)

Register 29.6. HMAC_SET_RESULT_FINISH_REG (0x005C)



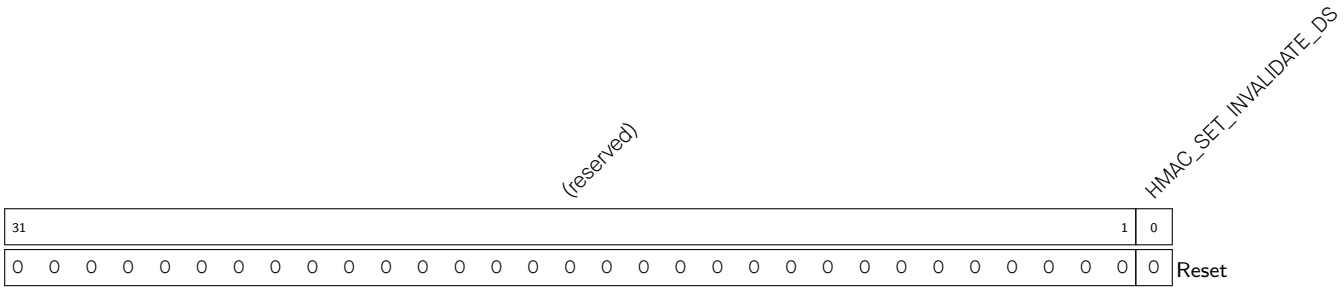
HMAC_SET_RESULT_END Configures whether to exit upstream mode and clear calculation results.

0: Not exit

1: Exit upstream mode and clear calculation results.

(WO)

Register 29.7. HMAC_SET_INVALIDATE_JTAG_REG (0x0060)



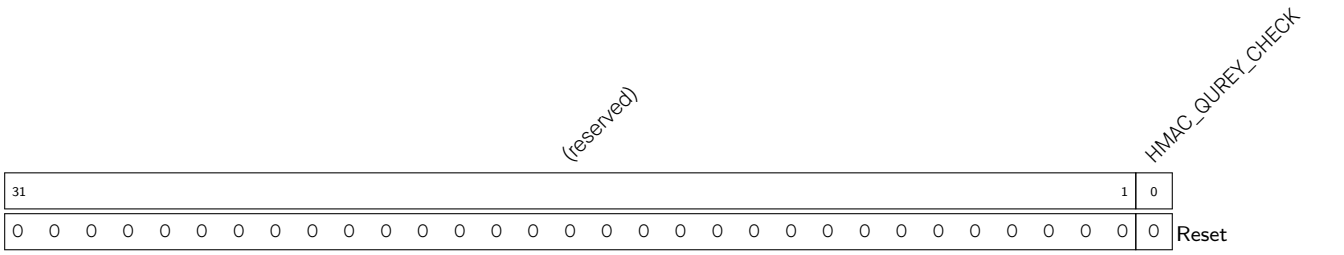
HMAC_SET_INVALIDATE_JTAG Configures whether or not to clear calculation results when re-enabling JTAG in downstream mode.

0: Not clear

1: Clear calculation results

(WO)

Register 29.8. HMAC_SET_INVALIDATE_DS_REG (0x0064)



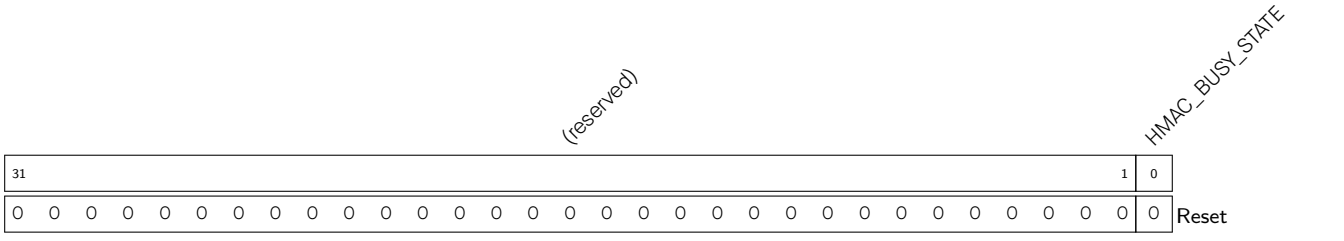
HMAC_SET_INVALIDATE_DS Configures whether or not to clear calculation results of the RSA_DS peripheral in downstream mode.

0: Not clear

1: Clear calculation results

(WO)

Register 29.9. HMAC_QUERY_ERROR_REG (0x0068)



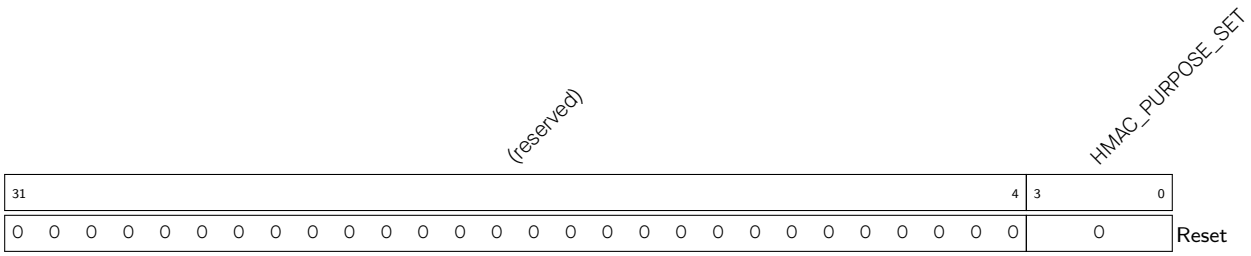
HMAC_QUREY_CHECK Represents whether or not an HMAC key matches the purpose.

0: Match

1: Error

(RO)

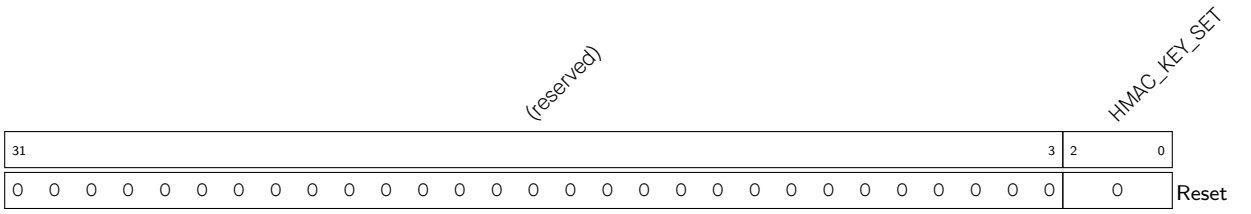
Register 29.10. HMAC_QUERY_BUSY_REG (0x006C)



HMAC_BUSY_STATE Represents whether or not HMAC is in a busy state. Before configuring HMAC, please make sure HMAC is in an IDLE state.

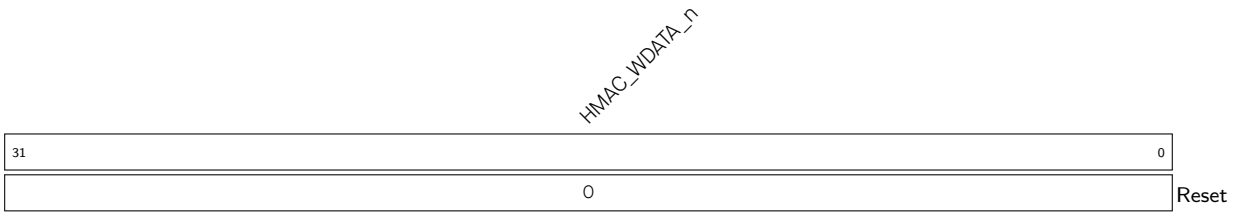
0: Idle

1: HMAC is still working on the calculation



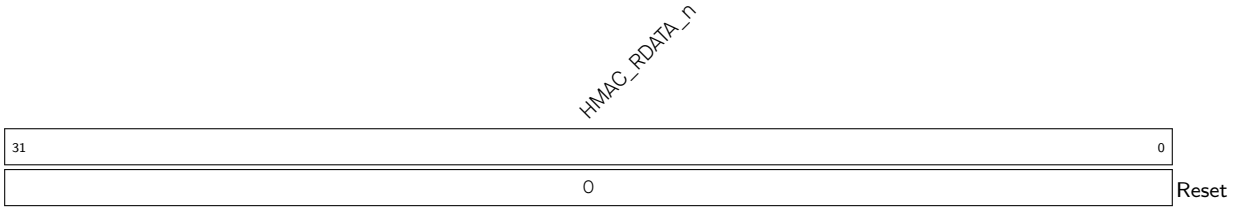
(RO)

Register 29.11. HMAC_SET_PARA_PURPOSE_REG (0x0044)



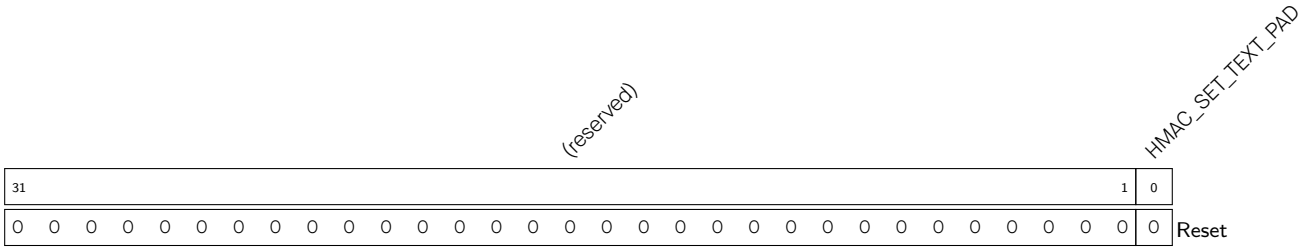
HMAC_PURPOSE_SET Configures the HMAC purpose, refer to the Table 29.2-1. (WO)

Register 29.12. HMAC_SET_PARA_KEY_REG (0x0048)



HMAC_KEY_SET Configures HMAC key. There are seven keys with index 0 ~ 5, and 7. Write the index of the selected key to this field. (WO)

Register 29.13. HMAC_WR_MESSAGE_*n*_REG (*n*: 0-15) (0x0080+4**n*)

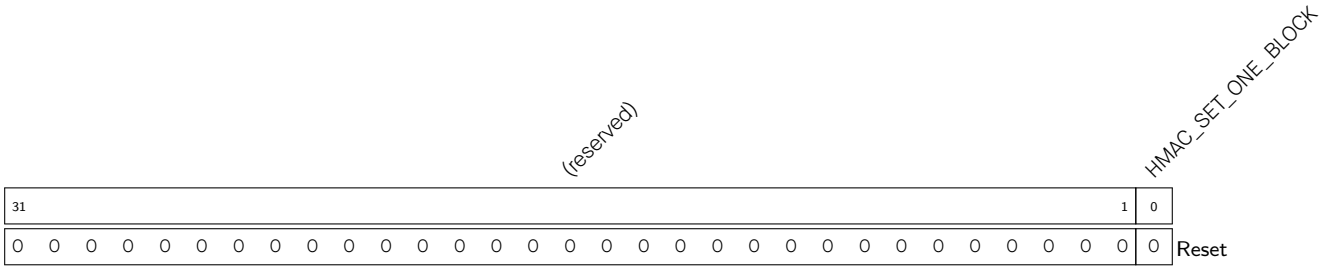


HMAC_WDATA_*n* Represents the *n*th 32-bit of message. (WO)

Register 29.14. HMAC_RD_RESULT_*n*_REG (*n*: 0-7) (0x00C0+4**n*)

HMAC_RDATA_*n* Represents the *n*th 32-bit of hash result. (RO)

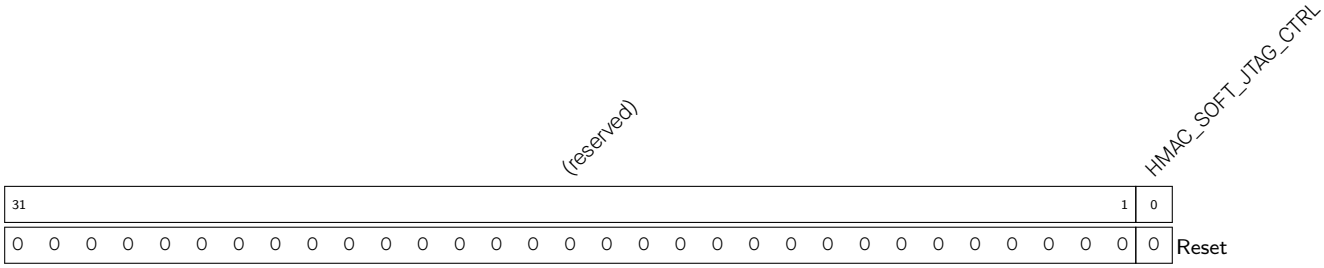
Register 29.15. HMAC_SET_MESSAGE_PAD_REG (0x00F0)



HMAC_SET_TEXT_PAD Configures whether or not the padding is applied by software.

0: Not applied by software

1: Applied by software

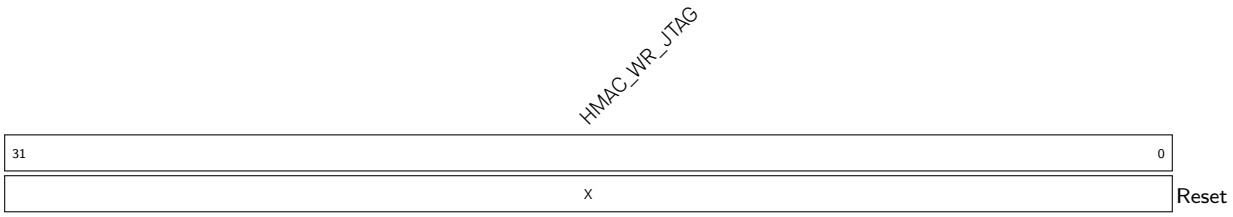


(WO)

Register 29.16. HMAC_ONE_BLOCK_REG (0x00F4)

HMAC_SET_ONE_BLOCK Write 1 to indicate there is only one block which already contains padding bits and there is no need for padding. (WO)

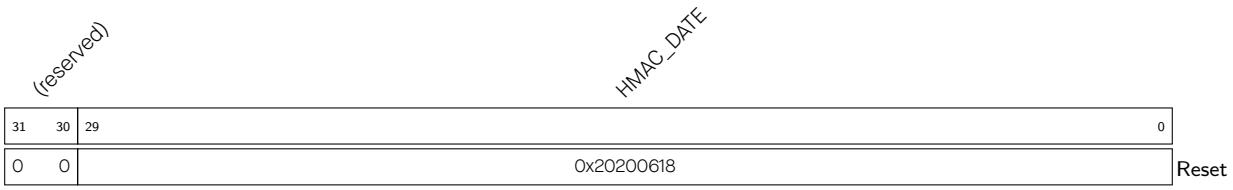
Register 29.17. HMAC_SOFT_JTAG_CTRL_REG (0x00F8)



HMAC_SOFT_JTAG_CTRL Configures whether or not to enable JTAG authentication mode.

0: Disable

1: Enable



(WO)

Register 29.18. HMAC_WR_JTAG_REG (0x00FC)

HMAC_WR_JTAG Writes the comparing input used for re-enabling JTAG. (WO)

Register 29.19. HMAC_DATE_REG (0x01FC)

HMAC_DATE Version control register. (R/W)

Chapter 30

RSA Accelerator (RSA)

30.1 Introduction

The RSA accelerator provides hardware support for high-precision computation used in various RSA asymmetric cipher algorithms, significantly improving their run time and reducing their software complexity compared with RSA algorithms implemented solely in software. The RSA accelerator also supports operands of different lengths, which provides more flexibility during the computation.

30.2 Features

The following functionality is supported:

- Large-number modular exponentiation with two additional acceleration options to further increase the calculation speed
- Large-number modular multiplication
- Large-number multiplication
- Operands of different lengths
- Interrupt on completion of computation

30.3 Functional Description

The RSA accelerator is activated by setting the HP_SYS_CLKRST_CRYPTO_RSA_CLK_EN bit in the HP_SYS_CLKRST_PERI_CLK_CTRL25_REG register and clearing the HP_SYS_CLKRST_RST_EN_RSA bit in the HP_SYS_CLKRST_HP_RST_EN2_REG register. Additionally, users also need to clear HP_SYS_CLKRST_RST_EN_DS and HP_SYS_CLKRST_RST_EN_ECDSA bits to reset the RSA Digital Signature Peripheral (RSA_DS) and the ECDSA Digital Signature Peripheral (ECDSA_DS) accelerators.

The RSA accelerator is only available after the RSA-related memories are initialized. The content of the RSA_QUERY_CLEAN_REG register is 0 during initialization and will become 1 after the initialization is done. Therefore, wait until RSA_QUERY_CLEAN_REG becomes 1 before using the RSA accelerator.

The RSA_INT_ENA_REG register is used to control the interrupt triggered on completion of computation. Write 1 or 0 to this field to enable or disable the interrupt. By default, the interrupt function of the RSA accelerator is enabled.

Notice:

ESP32-P4's RSA Digital Signature Peripheral (RSA_DS) module also calls the RSA accelerator when working. Therefore,

users cannot access the RSA accelerator when the RSA Digital Signature Peripheral (RSA_DS) module is working.

30.3.1 Definitions and Representations

ESP32-P4's RSA accelerator supports operands of different lengths $N = 32 \times n$.

To represent the numbers used as operands, let us define a base-b positional notation, as follows:

$$b = 2^{32}$$

Using this notation, each number is represented by a sequence of base-b digits:

$$n = \frac{N}{32}$$
$$Z = (Z_{n-1}Z_{n-2}\cdots Z_0)_b$$
$$X = (X_{n-1}X_{n-2}\cdots X_0)_b$$
$$Y = (Y_{n-1}Y_{n-2}\cdots Y_0)_b$$
$$M = (M_{n-1}M_{n-2}\cdots M_0)_b$$
$$\overline{r} = (\overline{r}_{n-1}\overline{r}_{n-2}\cdots \overline{r}_0)_b$$

Each of the values in $Z_{n-1}\cdots Z_0$, $X_{n-1}\cdots X_0$, $Y_{n-1}\cdots Y_0$, $M_{n-1}\cdots M_0$, $\overline{r}_{n-1}\cdots \overline{r}_0$ represents one base-b digit (a 32-bit word).

Z_{n-1}, X_{n-1}, Y_{n-1}, M_{n-1} and $\overline{r}_{n-1}$ are the most significant bits of Z, X, Y, M, while Z_0, X_0, Y_0, M_0 and $\overline{r}_0$ are the least significant bits.

If we define $R = b^n$, the additional argument $\overline{r}$ can be calculated as $\overline{r} = R^2 \bmod M$.

Also, argument M' can be calculated using the formula below:

$$M' = -M^{-1} \bmod b$$

where, M^{-1} is the modular multiplicative inverse of M, and it can be calculated with the extended binary GCD algorithm.

30.3.2 Large-Number Modular Exponentiation

Large-number modular exponentiation performs $Z = X^Y \bmod M$. The computation is based on Montgomery multiplication. Therefore, aside from the X, Y, and M arguments, two additional ones are needed — $\overline{r}$ and M', which need to be calculated in advance by software.

The RSA accelerator supports operands of length $N = 32 \times n$, where $n \in \{1, 2, 3, \ldots, 128\}$. The bit lengths of arguments Z, X, Y, M, and $\overline{r}$ can be arbitrary N, but all numbers in a calculation must be of the same length. The bit length of M' must be 32.

Large-number modular exponentiation on the ESP32-P4 can be implemented as follows:

1. Write 1 or 0 to the RSA_INT_ENA field to enable or disable the interrupt function.
2. Configure relevant registers:
   (a) Write $(\frac{N}{32} - 1)$ to the RSA_MODE_REG register.

(b) Write M' to the RSA_M_PRIME_REG register.

(c) Configure registers related to the acceleration options, which are described later in Section 30.3.5.

3. Write X_i, Y_i, M_i and $\overline{r}_i$ for $i \in \{0, 1, \ldots, n-1\}$ to memory blocks RSA_X_MEM, RSA_Y_MEM, RSA_M_MEM and RSA_Z_MEM. The capacity of each memory block is 128 words. Each word of each memory block can store one base-b digit. The memory blocks use the little endian format for storage, i.e., the least significant digit of each number is in the lowest address.

   Users need to write data to each memory block only according to the length of the number; data beyond this length is ignored.

4. Write 1 to the RSA_SET_START_MODEXP field of the RSA_SET_START_MODEXP_REG register to start computation.
5. Wait for the completion of computation, which happens when the content of RSA_QUERY_IDLE becomes 1 or the RSA interrupt occurs, if enabled.
6. Read the result Z_i for $i \in \{0, 1, \ldots, n-1\}$ from RSA_Z_MEM.
7. If you have the interrupt enabled, write 1 to RSA_CLEAR_INTERRUPT to clear the interrupt.

After the computation, the RSA_MODE_REG register, memory blocks RSA_Y_MEM and RSA_M_MEM, as well as the RSA_M_PRIME_REG remain unchanged. However, X_i in RSA_X_MEM and $\overline{r}_i$ in RSA_Z_MEM computation are overwritten, and only these overwritten memory blocks need to be re-initialized before starting another computation.

30.3.3 Large-Number Modular Multiplication

Large-number modular multiplication performs $Z = X \times Y \bmod M$. This computation is based on Montgomery multiplication. Therefore, similar to the large-number modular exponentiation, two additional arguments are needed – $\overline{r}$ and M', which need to be calculated in advance by software.

The RSA accelerator supports large-number modular multiplication with operands of length $N = 32 \times n$, where $n \in \{1, 2, 3, \ldots, 128\}$.

The computation can be executed as follows:

1. Write 1 or 0 to the RSA_INT_ENA_REG register to enable or disable the interrupt function.
2. Configure relevant configuration registers:

   (a) Write $(\frac{N}{32} - 1)$ to the RSA_MODE_REG register.

   (b) Write M' to the RSA_M_PRIME_REG register.

3. Write X_i, Y_i, M_i, and $\overline{r}_i$ for $i \in \{0, 1, \ldots, n-1\}$ to memory blocks RSA_X_MEM, RSA_Y_MEM, RSA_M_MEM, and RSA_Z_MEM, respectively. The capacity of each memory block is 128 words. Each word of each memory block can store one base-b digit. The memory blocks use the little endian format for storage, i.e., the least significant digit of each number is in the lowest address.

   Users need to write data to each memory block only according to the length of the number; data beyond this length are ignored.

4. Write 1 to the RSA_SET_START_MODMULT field.

5. Wait for the completion of computation, which happens when the content of RSA_QUERY_IDLE becomes 1 or the RSA interrupt occurs, if enabled.
6. Read the result Z_i for $i \in \{0, 1, \ldots, n-1\}$ from RSA_Z_MEM.
7. If you have the interrupt enabled, write 1 to RSA_CLEAR_INTERRUPT to clear the interrupt, .

After the computation, the length of operands in RSA_MODE_REG, the X_i in memory RSA_X_MEM, the Y_i in memory RSA_Y_MEM, the M_i in memory RSA_M_MEM, and the M' in memory RSA_M_PRIME_REG remain unchanged. However, the $\overline{r}_i$ in memory RSA_Z_MEM has already been overwritten, and only this overwritten memory block needs to be re-initialized before starting another computation.

30.3.4 Large-Number Multiplication

Large-number multiplication performs $Z = X \times Y$. The length of result Z is twice that of operand X and operand Y. Therefore, the RSA accelerator only supports large-number multiplication with operand length $N = 32 \times n$, where $n \in \{1, 2, 3, \ldots, 64\}$. The length $\hat{N}$ of result Z is $2 \times N$.

The computation can be executed as follows:

1. Write 1 or 0 to the RSA_INT_ENA_REG register to enable or disable the interrupt function.
2. Write $(\frac{\hat{N}}{32} - 1)$, i.e., $(\frac{N}{16} - 1)$ to the RSA_MODE_REG register.
3. Write X_i and Y_i for $\in \{0, 1, \ldots, n-1\}$ to memory blocks RSA_X_MEM and RSA_Z_MEM. Each word of each memory block can store one base-b digit. The memory blocks use the little endian format for storage, i.e., the least significant digit of each number is in the lowest address. n is $\frac{N}{32}$.

   Write X_i for $i \in \{0, 1, \ldots, n-1\}$ to the address of the i words of the RSA_X_MEM memory block. Note that Y_i for $i \in \{0, 1, \ldots, n-1\}$ will not be written to the address of the i words of the RSA_Z_MEM register, but the address of the $n + i$ words, i.e., the base address of the RSA_Z_MEM memory plus the address offset $4 \times (n + i)$.

   Users need to write data to each memory block only according to the length of the number; data beyond this length is ignored.
4. Write 1 to the RSA_SET_START_MULT register.
5. Wait for the completion of computation, which happens when the content of RSA_QUERY_IDLE becomes 1 or the RSA interrupt occurs, if enabled.
6. Read the result Z_i for $i \in \{0, 1, \ldots, \hat{n}-1\}$ from the RSA_Z_MEM register. $\hat{n}$ is $2 \times n$.
7. If you have the interrupt enabled, write 1 to RSA_CLEAR_INTERRUPT to clear the interrupt.

After the computation, the length of operands in RSA_MODE_REG and the X_i in memory RSA_X_MEM remain unchanged. However, the Y_i in memory RSA_Z_MEM has already been overwritten, and only this overwritten memory block needs to be re-initialized before starting another computation.

30.3.5 Options for Additional Acceleration

The ESP32-P4 RSA accelerator also provides SEARCH and CONSTANT_TIME options that can be configured to further accelerate the large-number modular exponentiation. By default, both options are configured as no additional acceleration.

Users can choose to use one or two of these options to further accelerate the computation. Note that, even when none of these two options is configured, using the hardware RSA accelerator is still much faster than implementing the RSA algorithm in software.

To be more specific, when neither of these two options are configured for additional acceleration, the time required to calculate $Z = X^Y \bmod M$ is solely determined by the lengths of operands. When either or both of these two options are configured for additional acceleration, the time required is also correlated with the 0 and 1 bit distribution in Y.

To better illustrate how these two options work, first assume Y is represented in binaries as

$$Y = (\widetilde{Y}_{N-1}\widetilde{Y}_{N-2}\cdots\widetilde{Y}_{t+1}\widetilde{Y}_t\widetilde{Y}_{t-1}\cdots\widetilde{Y}_0)_2$$

where,

- N is the length of Y,
- $\widetilde{Y}_t$ is 1,
- $\widetilde{Y}_{N-1}$, $\widetilde{Y}_{N-2}$, ..., $\widetilde{Y}_{t+1}$ are all equal to 0,
- and $\widetilde{Y}_{t-1}$, $\widetilde{Y}_{t-2}$, ..., $\widetilde{Y}_0$ are either 0 or 1 but exactly m bits should be equal to 0 and t-m bits 1, i.e., the Hamming weight of $\widetilde{Y}_{t-1}\widetilde{Y}_{t-2}, \cdots, \widetilde{Y}_0$ is $t - m$.

When either of these two options is configured for additional acceleration:

- SEARCH Option (Configuring RSA_SEARCH_ENABLE to 1 for additional acceleration)
  - The accelerator ignores the bit positions of $\widetilde{Y}_i$, where $i > \alpha$. Search position α is set by configuring the RSA_SEARCH_POS_REG register. Set α to a number smaller than N-1, which otherwise leads to the same result as if this option is not used for additional acceleration. The best acceleration performance can be achieved by setting α to t, in which case all the $\widetilde{Y}_{N-1}$, $\widetilde{Y}_{N-2}$, ..., $\widetilde{Y}_{t+1}$ of 0 s are ignored during the calculation. Note that if you set α to be less than t, then the result of the modular exponentiation $Z = X^Y \bmod M$ will be incorrect.
  - Note that this option compromises the security because it ignores some bits, which essentially shortens the key length, thus should not be enabled for applications with high security requirement.
- CONSTANT_TIME Option (Configuring RSA_CONSTANT_TIME_REG to 0 for additional acceleration)
  - The accelerator speeds up the calculation by simplifying the calculation concerning the 0 bits of Y. Therefore, the higher the proportion of bits 0 against bits 1, the better is the acceleration performance.
  - Note that this option also compromises the security because its time cost correlates with the 0/1 distribution of the key, which can be used in a Side Channel Attack (SCA), thus should not be enabled for applications with high security requirement.

Below is an example to demonstrate the performance of the RSA accelerator under different combinations of SEARCH and CONSTANT_TIME configuration. In this example:

- We perform $Z = X^Y \bmod M$
- N = 3072

- Y = 65537
- X and M are taken at random
- When the SEARCH option is enabled, α, i.e., the position register RSA_SEARCH_POS_REG, is set to 16.

Table 30.3-1 below demonstrates the time cost in clock cycles under different combinations of SEARCH and CONSTANT_TIME configuration when performing $Z = X^Y \bmod M$ as described above.

Table 30.3-1. Acceleration Performance

SEARCH Option	CONSTANT_TIME Option	Time Cost (clock cycle)
No acceleration	No acceleration	174.7×10^6
Accelerated	No acceleration	1.023×10^6
No acceleration	Acceleration	0.546×10^6
Acceleration	Acceleration	0.540×10^6

As shown in Table 30.3-1:

- The time cost is biggest when none of these two options is configured for additional acceleration.
- The time cost is smallest when both of these two options are configured for additional acceleration.
- The time cost can be dramatically reduced when either or both option(s) are configured for additional acceleration.

30.4 Interrupts

ESP32-P4's RSA accelerator can generate the following interrupt signal that will be sent to the Interrupt Matrix.

- RSA_INTR

There is one internal interrupt source from the RSA accelerator that can generate the above interrupt signal. The interrupt source from the RSA accelerator is listed with its trigger condition and the resulting interrupt signal in Table 30.4-1.

Table 30.4-1. RSA's Internal Interrupt Source

Internal Interrupt Source	Trigger Condition	Interrupt Signal
RSA_CALC_DONE_INT	Completion of an RSA calculation	RSA_INTR

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

30.5 Memory Summary

The addresses in this section are relative to the RSA accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

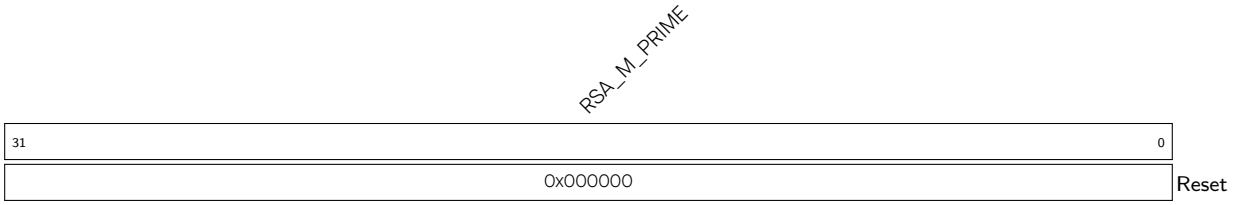
Table 30.5-1. RSA Accelerator Memory Blocks

Name	Description	Size (byte)	Starting Address	Ending Address	Access
RSA_M_MEM	Memory M	512	0x0000	0x01FF	R/W
RSA_Z_MEM	Memory Z	512	0x0200	0x03FF	R/W
RSA_Y_MEM	Memory Y	512	0x0400	0x05FF	R/W
RSA_X_MEM	Memory X	512	0x0600	0x07FF	R/W

30.6 Register Summary

The addresses in this section are relative to the RSA accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

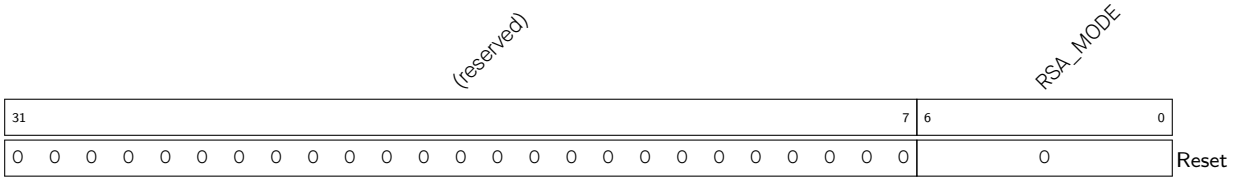
The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Control or Configuration Registers			
RSA_M_PRIME_REG	Represents M'	0x0800	R/W
RSA_MODE_REG	Configures RSA length	0x0804	R/W
RSA_SET_START_MODEXP_REG	Starts modular exponentiation	0x080C	WT
RSA_SET_START_MODMULT_REG	Starts modular multiplication	0x0810	WT
RSA_SET_START_MULT_REG	Starts multiplication	0x0814	WT
RSA_QUERY_IDLE_REG	Represents the RSA status	0x0818	RO
RSA_CONSTANT_TIME_REG	Configures the constant_time option	0x0820	R/W
RSA_SEARCH_ENABLE_REG	Configures the search option	0x0824	R/W
RSA_SEARCH_POS_REG	Configures the search position	0x0828	R/W
Status Register			
RSA_QUERY_CLEAN_REG	RSA initialization status	0x0808	RO
Interrupt Registers			
RSA_INT_CLR_REG	Clears RSA interrupt	0x081C	WT
RSA_INT_ENA_REG	Enables the RSA interrupt	0x082C	R/W
Version Control Register			
RSA_DATE_REG	Version control register	0x0830	R/W

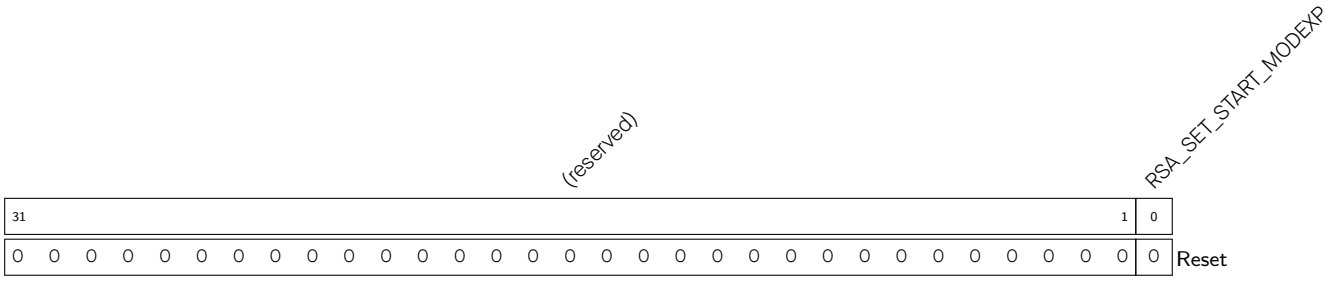
30.7 Registers

The addresses in this section are relative to the RSA accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



For how to program reserved fields, please refer to Section IX .

Register 30.1. RSA_M_PRIME_REG (0x0800)

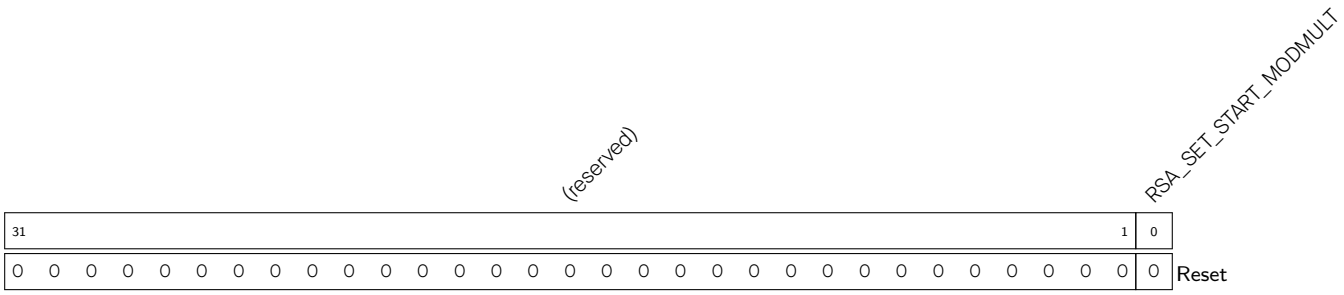


RSA_M_PRIME Represents M'. (R/W)

Register 30.2. RSA_MODE_REG (0x0804)

RSA_MODE Configures the RSA length. (R/W)

Register 30.3. RSA_SET_START_MODEXP_REG (0x080C)



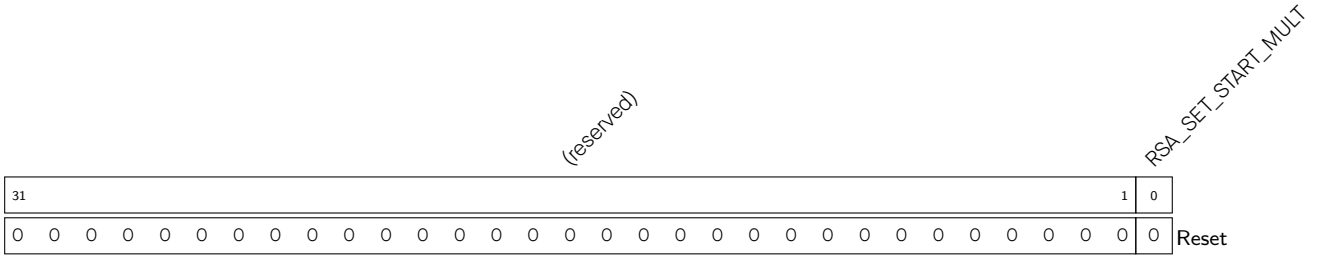
RSA_SET_START_MODEXP Configures whether or not to starts the modular exponentiation.

0: No effect

1: Start

(WT)

Register 30.4. RSA_SET_START_MODMULT_REG (0x0810)



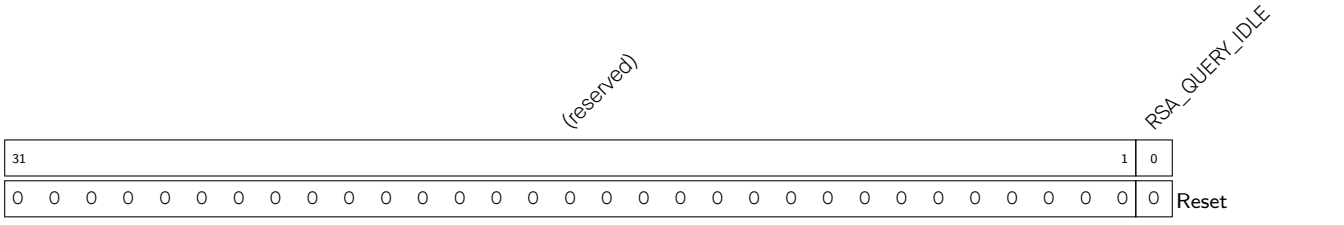
RSA_SET_START_MODMULT Configures whether or not to start the modular multiplication.

0: No effect

1: Start

(WT)

Register 30.5. RSA_SET_START_MULT_REG (0x0814)



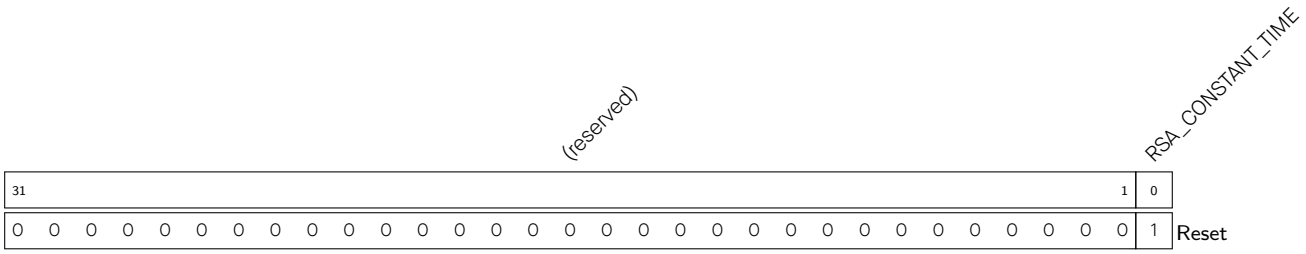
RSA_SET_START_MULT Configures whether or not to start the multiplication.

0: No effect

1: Start

(WT)

Register 30.6. RSA_QUERY_IDLE_REG (0x0818)



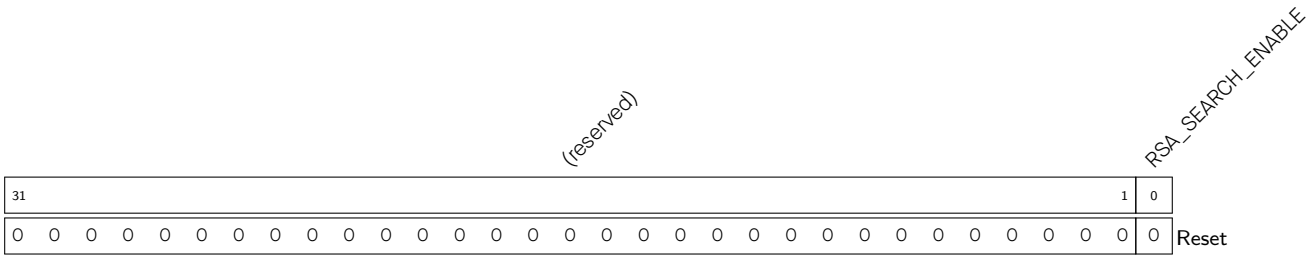
RSA_QUERY_IDLE Represents the RSA status.

0: Busy

1: Idle

(RO)

Register 30.7. RSA_CONSTANT_TIME_REG (0x0820)



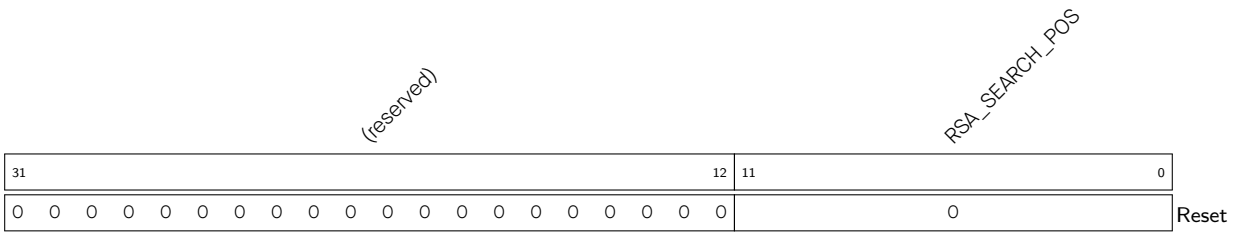
RSA_CONSTANT_TIME Configures the constant_time option.

0: Acceleration

1: No acceleration (default)

(R/W)

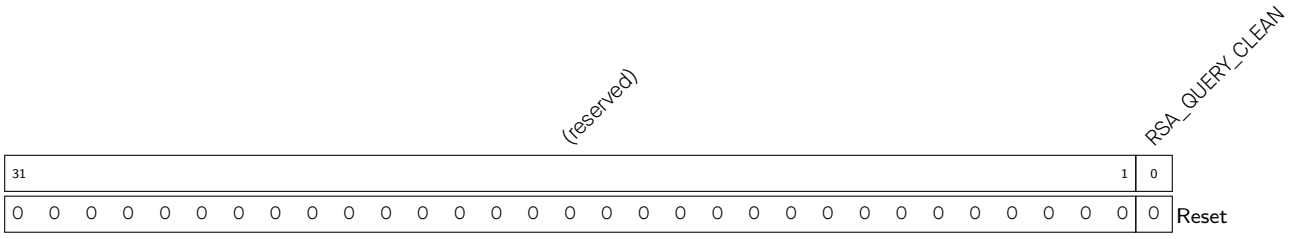
Register 30.8. RSA_SEARCH_ENABLE_REG (0x0824)



RSA_SEARCH_ENABLE Configures the search option.

0: No acceleration (default)

1: Acceleration

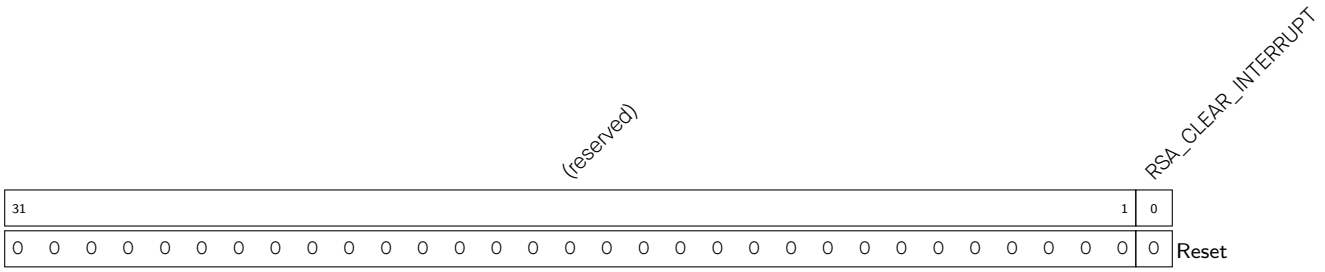


This option should be used together with RSA_SEARCH_POS_REG. (R/W)

Register 30.9. RSA_SEARCH_POS_REG (0x0828)

RSA_SEARCH_POS Configures the starting address to start search. This field should be used together with RSA_SEARCH_ENABLE_REG. The field is only valid when RSA_SEARCH_ENABLE is high. (R/W)

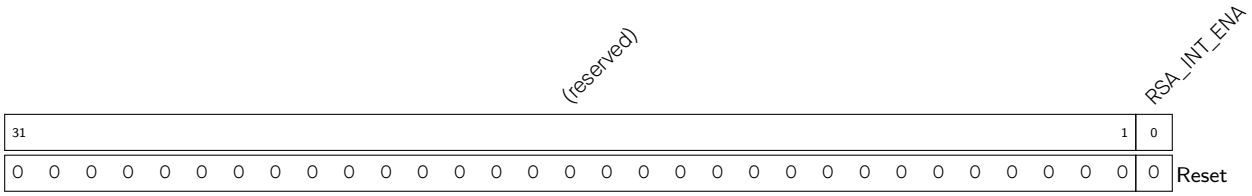
Register 30.10. RSA_QUERY_CLEAN_REG (0x0808)



RSA_QUERY_CLEAN Represents whether or not the RSA memory completes initialization.

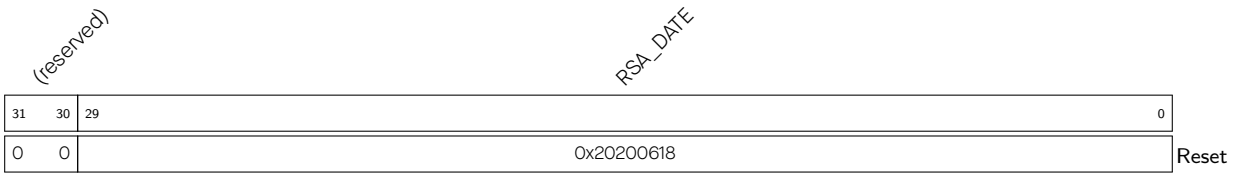
0: Not complete

1: Completed



(RO)

Register 30.11. RSA_INT_CLR_REG (0x081C)



RSA_CLEAR_INTERRUPT Write 1 to clear the RSA interrupt. (WT)

Register 30.12. RSA_INT_ENA_REG (0x082C)

RSA_INT_ENA Write 1 to enable the RSA interrupt. (R/W)

Register 30.13. RSA_DATE_REG (0x0830)

RSA_DATE Version control register. (R/W)

Chapter 31

SHA Accelerator (SHA)

31.1 Introduction

ESP32-P4 integrates an SHA accelerator, which is a hardware device that speeds up the SHA algorithm significantly, compared to an SHA algorithm implemented solely in software. The SHA accelerator integrated in ESP32-P4 has two working modes, which are Typical SHA and DMA-SHA.

31.2 Features

The following functionality is supported:

- The following hash algorithms introduced in FIPS PUB 180-4 Spec.
  - SHA-1
  - SHA-224
  - SHA-256
  - SHA-384
  - SHA-512
  - SHA-512/224
  - SHA-512/256
  - SHA-512/*t*
- Two working modes
  - Typical SHA
  - DMA-SHA
- Interleaved function when working in Typical SHA working mode
- Interrupt function when working in DMA-SHA working mode

31.3 Working Modes

The SHA accelerator integrated in ESP32-P4 has two working modes.

- Typical SHA Working Mode: all the data is written and read via CPU directly.
- DMA-SHA Working Mode: all the data is read via DMA. That is, users can configure the GDMA-AXI controller to read all the data needed for hash operation, thus releasing CPU for completing other tasks.

The SHA accelerator is activated by setting the HP_SYS_CLKRST_CRYPTO_SHA_CLK_EN register field and clearing the HP_SYS_CLKRST_RST_EN_SHA register field. Additionally, due to the hardware reuse relationship between cryptography modules, set the related reset register field of RSA Digital Signature Peripheral (RSA_DS), HMAC Accelerator (HMAC), and ECDSA Digital Signature Peripheral (ECDSA_DS) to 1 can reset the SHA module. Therefore, users also need to clear HP_SYS_CLKRST_RST_EN_DS, HP_SYS_CLKRST_RST_EN_HMAC, and HP_SYS_CLKRST_RST_EN_ECDSA fields.

Users can start the SHA accelerator with different working modes by configuring registers SHA_START_REG and SHA_DMA_START_REG. For details, please see Table 31.3-1.

Table 31.3-1. SHA Accelerator Working Mode

Working Mode	Configuration Method
Typical SHA	Set SHA_START_REG to 1
DMA-SHA	Set SHA_DMA_START_REG to 1

Users can choose hash algorithms by configuring the SHA_MODE_REG register. For details, please see Table 31.3-2.

Table 31.3-2. SHA Hash Algorithm Selection

Hash Algorithm	SHA_MODE_REG Configuration
SHA-1	0
SHA-224	1
SHA-256	2
SHA-384	3
SHA-512	4
SHA-512/224	5
SHA-512/256	6
SHA-512/*t*	7

Notice:

ESP32-P4's RSA Digital Signature Peripheral (RSA_DS) and HMAC Accelerator (HMAC) modules also call the SHA accelerator when working. Therefore, users cannot access the SHA accelerator when these modules are working.

31.4 Function Description

The SHA accelerator generates the message digest via two steps: Preprocessing and Hash operation.

31.4.1 Preprocessing

Preprocessing consists of three steps: padding the message, parsing the message into message blocks and setting the initial hash value.

31.4.1.1 Padding the Message

The SHA accelerator can only process message blocks of 512 or 1024 bits, depending on the algorithm. Thus, all the messages should be padded to a multiple of 512 bits or 1024 bits before the hash operation.

Suppose that the length of the message M is m bits. Then M shall be padded as introduced below:

- **SHA-1**, **SHA-224** and **SHA-256**
  1. First, append the bit "1" to the end of the message;
  2. Second, append k bits of zeros, where k is the smallest, non-negative solution to the equation $m + 1 + k \equiv 448 \ mod \ 512$;
  3. Last, append the 64-bit block of value equal to the number m expressed using a binary representation.
- **SHA-384**, **SHA-512**, **SHA-512/224**, **SHA-512/256** and **SHA-512/t**
  1. First, append the bit "1" to the end of the message;
  2. Second, append k zero bits, where k is the smallest, non-negative solution to the equation $m + 1 + k \equiv 896 \ mod \ 1024$;
  3. Last, append the 128-bit block of value equal to the number m expressed using a binary representation.

For more details, please refer to FIPS PUB 180-4 Spec > Section "Padding the Message".

31.4.1.2 Parsing the Message

The message and its padding must be parsed into N 512-bit or 1024-bit blocks. During the task, all the message blocks should be written into the SHA_M_*n*_REG.

- For **SHA-1**, **SHA-224** and **SHA-256**:

  The message and its padding are parsed into N 512-bit blocks, $M^{(1)}$, $M^{(2)}$, ..., $M^{(N)}$. Since the 512 bits of the input block may be expressed as sixteen 32-bit words, the first 32 bits of message block i are denoted $M_0^{(i)}$, the next 32 bits are $M_1^{(i)}$, and so on up to $M_{15}^{(i)}$.

  During the task, $M_0^{(i)}$ should be stored in SHA_M_0_REG, $M_1^{(i)}$ stored in SHA_M_1_REG, ..., and $M_{15}^{(i)}$ stored in SHA_M_15_REG.

- For **SHA-384**, **SHA-512**, **SHA-512/224**, **SHA-512/256** and **SHA-512/t**:
  The message and its padding are parsed into N 1024-bit blocks. Since the 1024 bits of the input block may be expressed as sixteen 64-bit words, the first 64 bits of message block i are denoted $M_0^{(i)}$, the next 64 bits are $M_1^{(i)}$, and so on up to $M_{15}^{(i)}$.

  During the task, the most significant 32 bits and the least significant 32 bits of $M_0^{(i)}$ should be stored in SHA_M_0_REG and SHA_M_1_REG, respectively, ..., the most significant 32 bits and the least significant 32 bits of $M_{15}^{(i)}$ should be stored in SHA_M_30_REG and SHA_M_31_REG, respectively.

Note:

For more information about "message block", please refer to FIPS PUB 180-4 Spec > Section "Glossary of Terms and Acronyms".

31.4.1.3 Setting the Initial Hash Value

Before hash task begins for each of the secure hash algorithms, the initial Hash value $H^{(0)}$ must be set based on different algorithms, among which the SHA-1, SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, and SHA-512/256 algorithms use the initial Hash values (constant C) stored in the hardware.

However, SHA-512/t requires a distinct initial hash value for each operation for a given value of t. Simply put, SHA-512/t is the generic name for a t-bit hash function based on SHA-512 whose output is truncated to t bits. t is any positive integer without a leading zero such that t<512, and t is not 384. The initial hash value for SHA-512/t for a given value of t can be calculated by performing SHA-512 from hexadecimal representation of the string "SHA-512/t". It's not hard to observe that when determining the initial hash values for SHA-512/t algorithms with different t, the only difference lies in the value of t.

Therefore, we have specially developed the following simplified method to calculate the initial hash value for SHA-512/t:

1. **Generate t_string and t_length**: t_string is a 32-bit data that stores the input message of t. t_length is a 7-bit data that stores the length of the input message. The t_string and t_length are generated in methods described below, depending on the value of t:

   - If $1 <= t <= 9$, then $t_length = 7'h48$ and t_string is padded in the following format:

$8'h30 + 8'ht_0$	$1'b1$	$23'b0$

     where $t_0 = t$.

     For example, if t = 8, then t_0 = 8 and t_string = $32'h38800000$.

   - If $10 <= t <= 99$, then $t_length = 7'h50$ and t_string is padded in the following format:

$8'h30 + 8'ht_1$	$8'h30 + 8'ht_0$	$1'b1$	$15'b0$

     where, $t_0 = t\%10$ and $t_1 = t/10$.

     For example, if t = 56, then t_0 = 6, t_1 = 5, and t_string = $32'h35368000$.

   - If $100 <= t < 512$, then $t_length = 7'h58$ and t_string is padded in the following format:

$8'h30 + 8'ht_2$	$8'h30 + 8'ht_1$	$8'h30 + 8'ht_0$	$1'b1$	$7'b0$

     where, $t_0 = t\%10$, $t_1 = (t/10)\%10$, and $t_2 = t/100$.

     For example, if t = 231, then t_0 = 1, t_1 = 3, t_2 = 2, and t_string = $32'h32333180$.

2. **Initialize relevant registers**: Initialize SHA_T_STRING_REG and SHA_T_LENGTH_REG with the generated t_string and t_length in the previous step.

3. **Obtain initial hash value**: Set the SHA_MODE_REG register to 7. Set the SHA_START_REG register to 1 to start the SHA accelerator. Then poll register SHA_BUSY_REG until the content of this register becomes 0, indicating the calculation of initial hash value is completed.

Please note that the initial value for SHA-512/t can be also calculated according to the Section "5.3.6 SHA-512/t" in FIPS PUB 180-4 Spec, which is performing SHA-512 operation (with its initial hash value set to the result of 8-bitwise XOR operation of C and 0xa5) from the hexadecimal representation of the string "SHA-512/t".

31.4.2 Hash Operation

After the preprocessing, the ESP32-P4 SHA accelerator starts to hash a message M and generates message digest of different lengths, depending on different hash algorithms. As described above, the ESP32-P4 SHA accelerator supports two working modes, which are Typical SHA and DMA-SHA. The operation process for the SHA accelerator under two working modes is described in the following subsections.

31.4.2.1 Typical SHA Mode Process

Usually, the SHA accelerator will process all blocks of a message and produce a message digest before starting the computation of the next message digest.

However, ESP32-P4 SHA also supports optional "interleaved" message digest calculation in Typical SHA mode, which means before SHA completes all blocks of the current message, users are given a chance to insert new computation of another message digest upon the completion of each individual block of the current message.

Specifically, users can read out the message digest from registers SHA_H_*n*_REG after completing part of a message digest calculation, and use the SHA accelerator for a different calculation. After the different calculation completes, users can restore the previous message digest to registers SHA_H_*n*_REG, and resume the accelerator with the previously paused calculation.

Typical SHA Process (except for SHA-512/*t*)

1. Select a hash algorithm.
   - Configure the SHA_MODE_REG register based on Table 31.3-2.
2. Process the current message block.
   - Write the message block in registers SHA_M_*n*_REG.
3. Start the SHA accelerator[1].
   - If this is the first time to execute this step, set the SHA_START_REG register to 1 to start the SHA accelerator. In this case, the accelerator uses the initial hash value stored in hardware for a given algorithm configured in Step 1 to start the calculation;
   - If this is not the first time to execute this step[2], set the SHA_CONTINUE_REG register to 1 to start the SHA accelerator. In this case, the accelerator uses the hash value stored in the SHA_H_*n*_REG register to start calculation.
4. Check the progress of the current message block.
   - Poll register SHA_BUSY_REG until the content of this register becomes 0, indicating the accelerator has completed the calculation for the current message block and now is in the "idle" status [3].
5. Decide if you have more message blocks to process:
   - If yes, please go back to Step 2.
   - Otherwise, please continue.
6. Obtain the message digest.
   - Read the message digest from registers SHA_H_*n*_REG.

Typical SHA Process (SHA-512/t)

1. Select a hash algorithm.
   - Configure the SHA_MODE_REG register to 7 for SHA-512/t.
2. Calculate the initial hash value.
   (a) Calculate t_stiring and t_length and initialize SHA_T_STRING_REG and SHA_T_LENGTH_REG with the generated t_string and t_length. For details, please refer to Section 31.4.1.3.
   (b) Set the SHA_START_REG register to 1 to start the SHA accelerator.
   (c) Poll register SHA_BUSY_REG until the content of this register becomes 0, indicating the calculation of initial hash value is completed.
3. Process the current message block[1].
   - Write the message block in registers SHA_M_n_REG.
4. Start the SHA accelerator
   - Set the SHA_CONTINUE_REG register to 1. In this case, the accelerator uses the hash value stored in the SHA_H_n_REG register to start calculation.
5. Check the progress of the calculation.
   - Poll register SHA_BUSY_REG until the content of this register becomes 0, indicating the accelerator has completed the calculation for the current message block and now is in the "idle" status[3].
6. Decide if you have more message blocks to process:
   - If yes, please go back to Step 3.
   - Otherwise, please continue.
7. Obtain the message digest.
   - Read the message digest from registers SHA_H_n_REG.

Note:

1. In this step, the software can also write the next message block (to be processed) in registers SHA_M_n_REG, if any, while the hardware starts SHA calculation, to save time.
2. You are resuming the SHA accelerator with the previously paused calculation.
3. Here you can decide if you want to insert other calculations. If yes, please go to the process for interleaved calculations for details.

As mentioned above, ESP32-P4 SHA accelerator supports **"interleaving" calculation under the Typical SHA working mode**.

The process to implement interleaved calculation is described below.

1. Prepare to hand the SHA accelerator over for an interleaved calculation by storing the following data of the previous calculation.
   - The selected hash algorithm configured in the SHA_MODE_REG register.
   - The message digest stored in registers SHA_H_n_REG.

2. Perform the interleaved calculation. For the detailed process of the interleaved calculation, please refer to Typical SHA process or DMA-SHA process, depending on the working mode of your interleaved calculation.
3. Prepare to hand the SHA accelerator back to the previously paused calculation by restoring the following data of the previous calculation.
    - Write the previously stored hash algorithm back to register SHA_MODE_REG.
    - Write the previously stored message digest back to registers SHA_H_*n*_REG.
4. Write the next message block from the previous paused calculation in registers SHA_M_*n*_REG, and set the SHA_CONTINUE_REG register to 1 to restart the SHA accelerator with the previously paused calculation.

31.4.2.2 DMA-SHA Mode Process

ESP32-P4 SHA accelerator does not support "interleaving" message digest calculation at the level of individual message blocks when using DMA, which means you cannot insert new calculation before a complete DMA-SHA process (of one or more message blocks) completes. In this case, users who need interleaved operation are recommended to divide the message blocks and perform several DMA-SHA calculations, instead of trying to compute all the messages in one go.

Single DMA-SHA calculation supports up to 63 message blocks.

In contrast to the Typical SHA working mode, when the SHA accelerator is working under the DMA-SHA mode, all data read are completed via GDMA-AXI. Therefore, users are required to configure the GDMA-AXI controller following the description in Chapter 6 *GDMA Controller (GDMA-AHB, GDMA-AXI)*.

DMA-SHA process (except SHA-512/t)

1. Select a hash algorithm.
    - Select a hash algorithm by configuring the SHA_MODE_REG register. For details, please refer to Table 31.3-2.
2. Configure the SHA_INT_ENA_REG register to enable or disable interrupt (Set 1 to enable).
3. Configure the number of message blocks.
    - Write the number of message blocks M to the SHA_DMA_BLOCK_NUM_REG register.
4. Start the DMA-SHA calculation.
    - If the current DMA-SHA calculation follows a previous calculation, firstly write the message digest from the previous calculation to registers SHA_H_*n*_REG, then write 1 to register SHA_DMA_CONTINUE_REG to start SHA accelerator;
    - Otherwise, write 1 to register SHA_DMA_START_REG to start the accelerator.
5. Wait till the completion of the DMA-SHA calculation, which happens when:
    - The content of SHA_BUSY_REG register becomes 0, or
    - An SHA interrupt occurs. In this case, please clear interrupt by writing 1 to the SHA_INT_CLEAR_REG register.

6. Obtain the message digest:
    - Read the message digest from registers SHA_H_*n*_REG.

DMA-SHA process for SHA-512/*t*

1. Select a hash algorithm.
    - Select SHA-512/*t* algorithm by configuring the SHA_MODE_REG register to 7.
2. Configure the SHA_INT_ENA_REG register to enable or disable interrupt (Set 1 to enable).
3. Calculate the initial hash value.
    (a) Calculate t_string and t_length and initialize SHA_T_STRING_REG and SHA_T_LENGTH_REG with the generated t_string and t_length. For details, please refer to Section 31.4.1.3.
    (b) Set the SHA_START_REG register to 1 to start the SHA accelerator.
    (c) Poll register SHA_BUSY_REG until the content of this register becomes 0, indicating the calculation of initial hash value is completed.
4. Configure the number of message blocks.
    - Write the number of message blocks M to the SHA_DMA_BLOCK_NUM_REG register.
5. Start the DMA-SHA calculation.
    - Write 1 to register SHA_DMA_CONTINUE_REG to start the accelerator.
6. Wait till the completion of the DMA-SHA calculation, which happens when:
    - The content of SHA_BUSY_REG register becomes 0, or
    - An SHA interrupt occurs. In this case, please clear interrupt by writing 1 to the SHA_INT_CLEAR_REG register.
7. Obtain the message digest:
    - Read the message digest from registers SHA_H_*n*_REG.

31.4.3 Message Digest

After the hash task completes, the SHA accelerator writes the message digest from the task to registers SHA_H_*n*_REG(*n*: 0 ~ 15). The lengths of the generated message digest are different depending on different hash algorithms. For details, see Table 31.4-4 below:

Table 31.4-4. The Storage and Length of Message Digest from Different Algorithms

Hash Algorithm	Length of Message Digest (in bits)	Storage[1]
SHA-1	160	SHA_H_0_REG ~ SHA_H_4_REG
SHA-224	224	SHA_H_0_REG ~ SHA_H_6_REG
SHA-256	256	SHA_H_0_REG ~ SHA_H_7_REG
SHA-384	384	SHA_H_0_REG ~ SHA_H_11_REG
SHA-512	512	SHA_H_0_REG ~ SHA_H_15_REG
SHA-512/224	224	SHA_H_0_REG ~ SHA_H_6_REG
SHA-512/256	256	SHA_H_0_REG ~ SHA_H_7_REG
SHA-512/*t*[2]	*t*	SHA_H_0_REG ~ SHA_H_*x*_REG

[1] The message digest is stored in registers from most significant bits to the least significant bits, with the first word stored in register SHA_H_0_REG and the second word stored in register SHA_H_1_REG... For details, please see subsection 31.4.1.2.

[2] The registers used for SHA-512/t algorithm depend on the value of t. x+1 indicates the number of 32-bit registers used to store t bits of message digest, so that $x = roundup(t/32)$-1. For example:

- When t = 8, then x = 0, indicating that the 8-bit long message digest is stored in the most significant 8 bits of register SHA_H_0_REG;
- When t = 32, then x = 0, indicating that the 32-bit long message digest is stored in register SHA_H_0_REG;
- When t = 132, then x = 4, indicating that the 132-bit long message digest is stored in registers SHA_H_0_REG, SHA_H_1_REG, SHA_H_2_REG, SHA_H_3_REG, and SHA_H_4_REG.

31.5 Interrupt

ESP32-P4's SHA accelerator can generate the following interrupt signal(s) that will be sent to the Interrupt Matrix.

- SHA_INTR

There are several internal interrupt sources from SHA that can generate the above interrupt signal(s). The interrupt sources from SHA are listed with their trigger conditions and the resulted interrupt signal(s) in Table 31.5-1.

Table 31.5-1. SHA's Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
SHA_CALC_DONE_INT	Completion of an message digest calculation in DMA-SHA mode	SHA_INTR

Note:

- For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13

Interrupt Matrix > Section 13.2 *Interrupt Terminology in ESP32-P4*.

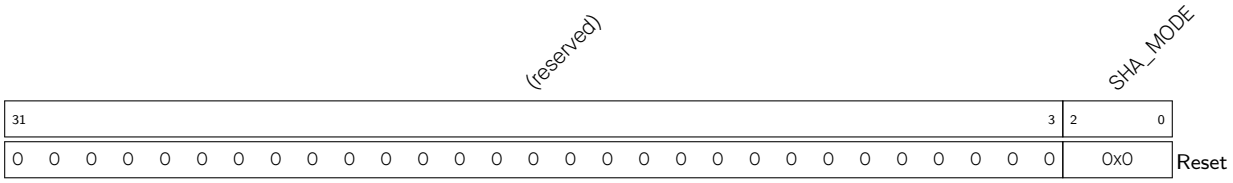
- Different from the standard interrupt register group, the interrupt register group of SHA only contains the INT_ENA (SHA_INT_ENA_REG) and INT_CLR (SHA_INT_CLEAR_REG) fields, and does not support users to read the INT_RAW and INT_ST fields.

31.6 Register Summary

The addresses in this section are relative to SHA accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Control/Configuration Registers			
SHA_MODE_REG	Configures SHA algorithm	0x0000	R/W
SHA_T_STRING_REG	Initial Hash Value calculation factor t_string (for SHA-512/t)	0x0004	R/W
SHA_T_LENGTH_REG	Initial Hash Value calculation factor t_length (for SHA-512/t)	0x0008	R/W
SHA_CONTINUE_REG	Continues SHA operation (only effective in Typical SHA mode)	0x0014	WO
SHA_DMA_START_REG	Starts the SHA accelerator for DMA-SHA operation	0x001C	WO
SHA_START_REG	Starts the SHA accelerator for Typical SHA operation	0x0010	WO
SHA_DMA_CONTINUE_REG	Continues SHA operation (only effective in DMA-SHA mode)	0x0020	WO
SHA_DMA_BLOCK_NUM_REG	Block number register (only effective in DMA-SHA mode)	0x000C	R/W
Status Registers			
SHA_BUSY_REG	Represents if SHA Accelerator is busy or not	0x0018	RO
Interrupt Registers			
SHA_INT_CLEAR_REG	DMA-SHA interrupt clear register	0x0024	WO
SHA_INT_ENA_REG	DMA-SHA interrupt enable register	0x0028	R/W
Data Registers			
SHA_H_0_REG	Hash value	0x0040	R/W
SHA_H_1_REG	Hash value	0x0044	R/W
SHA_H_2_REG	Hash value	0x0048	R/W
SHA_H_3_REG	Hash value	0x004C	R/W
SHA_H_4_REG	Hash value	0x0050	R/W
SHA_H_5_REG	Hash value	0x0054	R/W
SHA_H_6_REG	Hash value	0x0058	R/W
SHA_H_7_REG	Hash value	0x005C	R/W
SHA_H_8_REG	Hash value	0x0060	R/W
SHA_H_9_REG	Hash value	0x0064	R/W
SHA_H_10_REG	Hash value	0x0068	R/W
SHA_H_11_REG	Hash value	0x006C	R/W
SHA_H_12_REG	Hash value	0x0070	R/W
SHA_H_13_REG	Hash value	0x0074	R/W
SHA_H_14_REG	Hash value	0x0078	R/W
SHA_H_15_REG	Hash value	0x007C	R/W
SHA_M_0_REG	Message	0x0080	R/W
SHA_M_1_REG	Message	0x0084	R/W
SHA_M_2_REG	Message	0x0088	R/W
SHA_M_3_REG	Message	0x008C	R/W
SHA_M_4_REG	Message	0x0090	R/W
SHA_M_5_REG	Message	0x0094	R/W

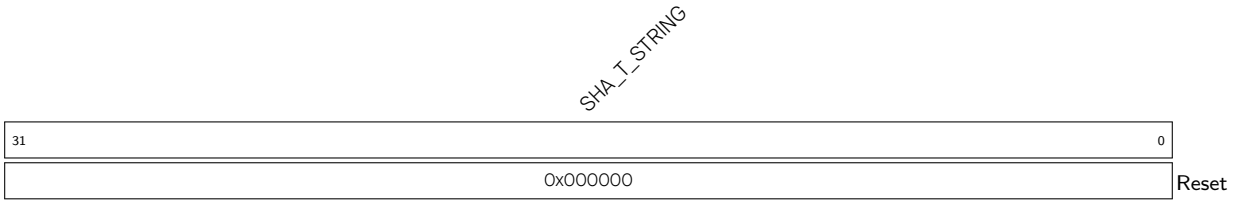


Name	Description	Address	Access
SHA_M_6_REG	Message	0x0098	R/W
SHA_M_7_REG	Message	0x009C	R/W
SHA_M_8_REG	Message	0x00A0	R/W
SHA_M_9_REG	Message	0x00A4	R/W
SHA_M_10_REG	Message	0x00A8	R/W
SHA_M_11_REG	Message	0x00AC	R/W
SHA_M_12_REG	Message	0x00B0	R/W
SHA_M_13_REG	Message	0x00B4	R/W
SHA_M_14_REG	Message	0x00B8	R/W
SHA_M_15_REG	Message	0x00BC	R/W
SHA_M_16_REG	Message	0x00C0	R/W
SHA_M_17_REG	Message	0x00C4	R/W
SHA_M_18_REG	Message	0x00C8	R/W
SHA_M_19_REG	Message	0x00CC	R/W
SHA_M_20_REG	Message	0x00D0	R/W
SHA_M_21_REG	Message	0x00D4	R/W
SHA_M_22_REG	Message	0x00D8	R/W
SHA_M_23_REG	Message	0x00DC	R/W
SHA_M_24_REG	Message	0x00E0	R/W
SHA_M_25_REG	Message	0x00E4	R/W
SHA_M_26_REG	Message	0x00E8	R/W
SHA_M_27_REG	Message	0x00EC	R/W
SHA_M_28_REG	Message	0x00F0	R/W
SHA_M_29_REG	Message	0x00F4	R/W
SHA_M_30_REG	Message	0x00F8	R/W
SHA_M_31_REG	Message	0x00FC	R/W
Version Register			
SHA_DATE_REG	Version control register	0x002C	R/W

31.7 Registers

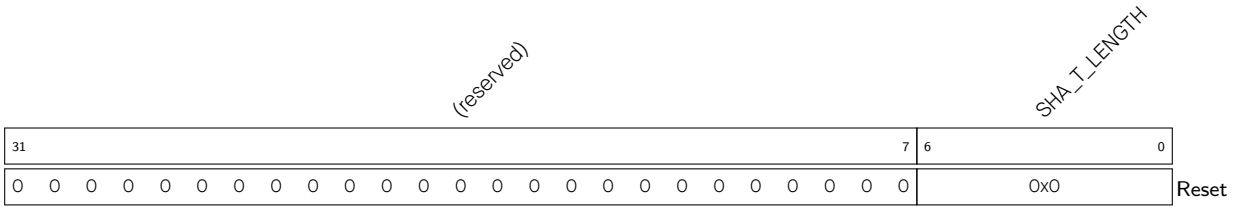
The addresses in this section are relative to SHA accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.



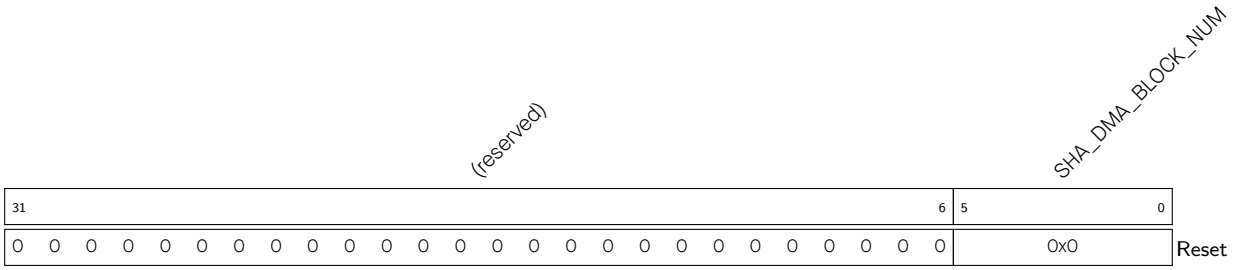
Register 31.1. SHA_MODE_REG (0x0000)

SHA_MODE Configures the SHA algorithm.



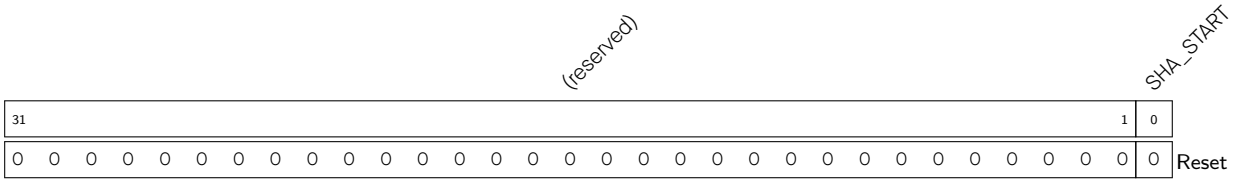
0: SHA-1
1: SHA-224
2: SHA-256
3: SHA-384
4: SHA-512
5: SHA-512/224
6: SHA-512/256
7: SHA-512/t
(R/W)

Register 31.2. SHA_T_STRING_REG (0x0004)



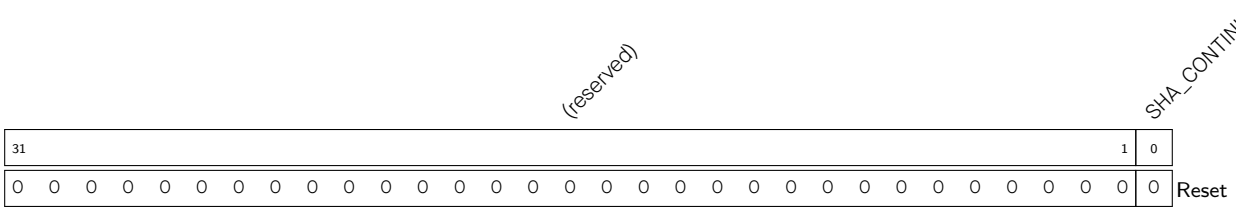
SHA_T_STRING Configures t_string for calculating the initial Hash value for SHA-512/t. (R/W)

Register 31.3. SHA_T_LENGTH_REG (0x0008)



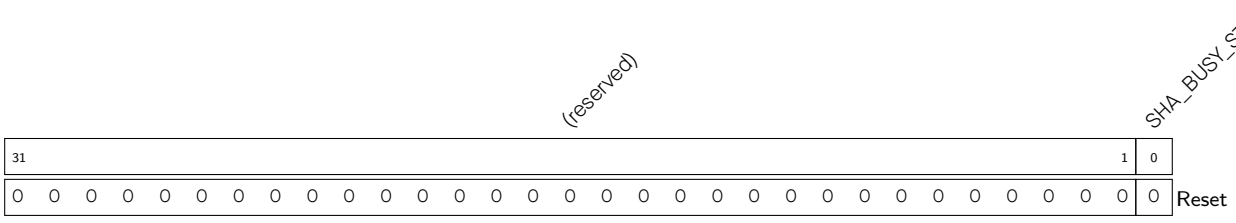
SHA_T_LENGTH Configures t_length for calculating the initial Hash value for SHA-512/t. (R/W)

Register 31.4. SHA_DMA_BLOCK_NUM_REG (0x000C)



SHA_DMA_BLOCK_NUM Configures the DMA-SHA block number. (R/W)

Register 31.5. SHA_START_REG (0x0010)

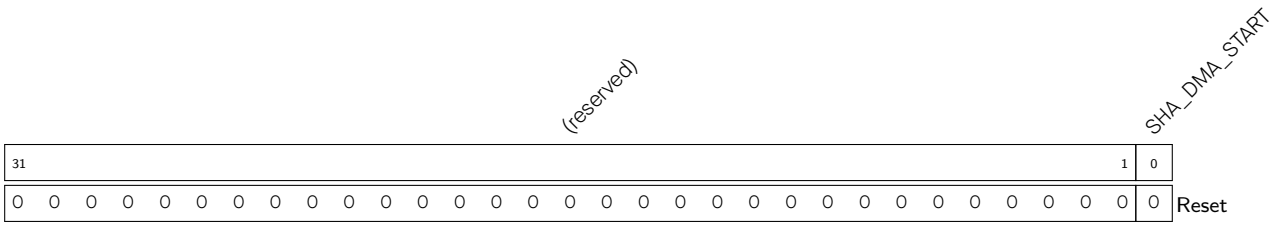


SHA_START Write 1 to start Typical SHA calculation. (WO)

Register 31.6. SHA_CONTINUE_REG (0x0014)

SHA_CONTINUE Write 1 to continue Typical SHA calculation. (WO)

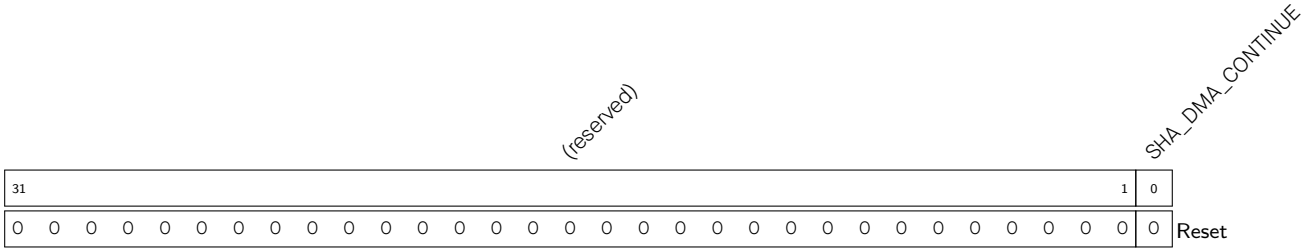
Register 31.7. SHA_BUSY_REG (0x0018)



SHA_BUSY_STATE Represents the states of SHA accelerator.

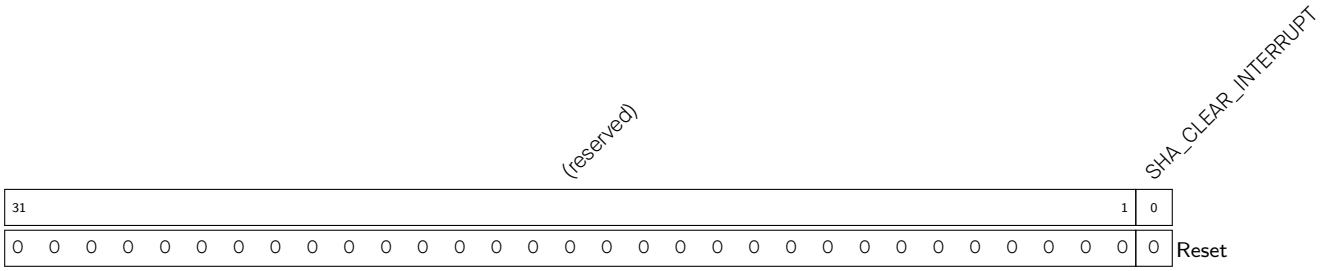
0: idle

1: busy



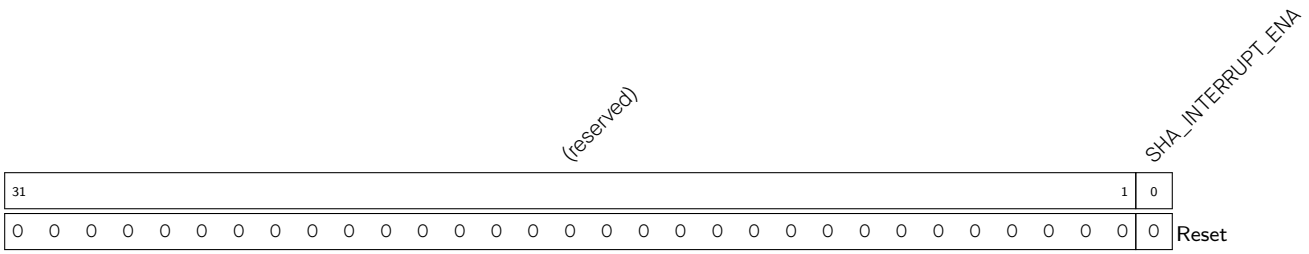
(RO)

Register 31.8. SHA_DMA_START_REG (0x001C)



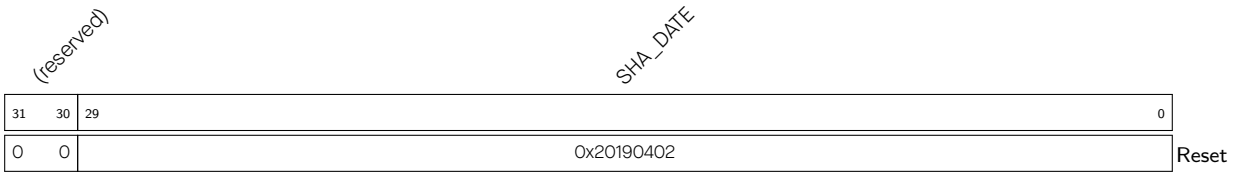
SHA_DMA_START Write 1 to start DMA-SHA calculation. (WO)

Register 31.9. SHA_DMA_CONTINUE_REG (0x0020)



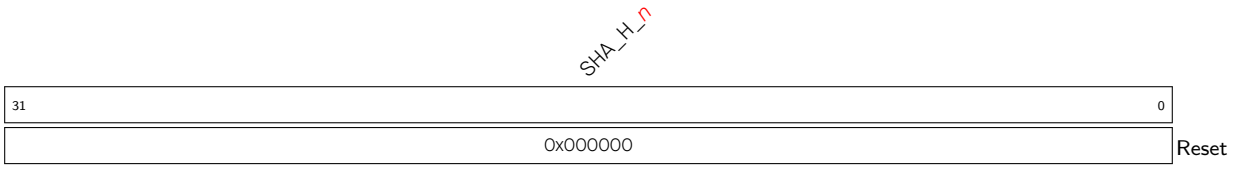
SHA_DMA_CONTINUE Write 1 to continue DMA-SHA calculation. (WO)

Register 31.10. SHA_INT_CLEAR_REG (0x0024)



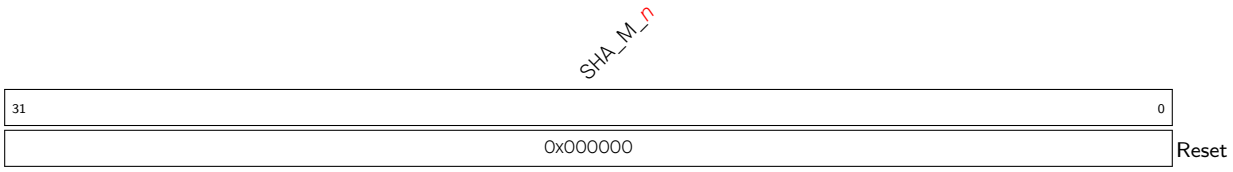
SHA_CLEAR_INTERRUPT Write 1 to clear DMA-SHA interrupt. (WO)

Register 31.11. SHA_INT_ENA_REG (0x0028)



SHA_INTERRUPT_ENA Write 1 to enable DMA-SHA interrupt. (R/W)

Register 31.12. SHA_DATE_REG (0x002C)



SHA_DATE Version control register. (R/W)

Register 31.13. SHA_H_*n*_REG (*n*: 0-15) (0x0040+4**n*)

SHA_H_*n* Represents the *n*th 32-bit piece of the Hash value. (R/W)

Register 31.14. SHA_M_*n*_REG (*n*: 0-31) (0x0080+4**n*)

SHA_M_*n* Represents the *n*th 32-bit piece of the message. (R/W)

Chapter 32

RSA Digital Signature Peripheral (RSA_DS)

32.1 Overview

The RSA Digital Signature Peripheral (RSA_DS) is used to verify the authenticity and integrity of a message using a cryptographic algorithm. This can be used to validate a device's identity to a server or to check the integrity of a message.

ESP32-P4 includes an RSA Digital Signature Peripheral (RSA_DS) providing hardware acceleration of messages' signatures based on RSA. HMAC is used as the key derivation function (KDF) to output the RSA_DS_KEY using a key stored in eFuse or deployed by the Key Manager as the input key. Subsequently, the RSA_DS peripheral uses RSA_DS_KEY to decrypt the pre-encrypted parameters and calculate the signature. The whole process happens in hardware so that all the keys involved during the calculating process cannot be seen by users, guaranteeing the security of the operation.

32.2 Features

- RSA digital signatures with key length up to 4096 bits
- Encrypted private key data, only decryptable by the RSA_DS peripheral
- SHA-256 digest to protect private key data against tampering by an attacker

32.3 Functional Description

32.3.1 Overview

The RSA_DS peripheral calculates RSA signatures as $Z = X^Y \bmod M$, where Z is the signature, X is the input message, and Y and M are the RSA private key parameters.

Private key parameters are stored in flash as ciphertext. They are decrypted using RSA_DS_KEY which can:

- Be calculated by the RSA_DS peripheral via the HMAC peripheral. The required inputs ($HMAC_KEY$) to generate the key are only stored in eFuse and can only be accessed by the HMAC peripheral. That is to say, the RSA_DS peripheral hardware can decrypt the private key, and the private key in plaintext is never accessed by the software. For more detailed information about eFuse and HMAC peripherals, please refer to Chapter 9.4 *eFuse Controller (EFUSE)* and Chapter 29 *HMAC Accelerator (HMAC)*.
- Deploy from Key Manager module. RSA_DS_KEY must be deployed by the Key Manager in a secured way.

The input message X will be sent directly to the RSA_DS peripheral by the software each time a signature is needed. After the RSA signature operation, the signature Z is read back by the software.

For better understanding, we define some symbols and functions here, which are only applicable to this chapter:

- **1**^{s}: A bit string consisting of s bits with the value of "1".
- **[**x**]**$_s$: A bit string of s bits, in which s is an integer multiple of 8 bits. If x is a number ($x < 2^s$), it is represented in little-endian byte order in the bit string. x may be a variable such as $[Y]_{4096}$ or a hexadecimal constant such as $[0x0C]_8$. If necessary, the value $[x]_t$ can be right-padded with $(s-t)$ number of zeros to reach s bits in length, and finally get $[x]_s$. For example, $[0x05]_8 = 00000101$, $[0x05]_{16} = 0000010100000000$, $[0x0005]_{16} = 0000000000000101$, $[0x13]_8 = 00010011$, $[0x13]_{16} = 0001001100000000$, $[0x0013]_{16} = 0000000000010011$.
- ||: A bit string concatenation operator for joining multiple-bit strings into a longer bit string.

32.3.2 Private Key Operands

Private key operands Y (private key exponent) and M (key modulus) are generated by the user. They have a particular RSA key length (up to 4096 bits). Two additional private key operands are needed: $\overline{r}$ and M'. These two operands are derived from Y and M.

Operands Y, M, $\overline{r}$, and M' are encrypted by the user along with an authentication digest and stored as a single ciphertext C. C is input to the RSA_DS peripheral in this encrypted format, decrypted by the hardware, and then used for RSA signature calculation. A detailed description of how to generate C is provided in Section 32.3.3.

The RSA_DS peripheral supports RSA signature calculation $Z = X^Y \bmod M$, in which the length of operands should be $N = 32 \times x$ where $x \in \{1, 2, 3, \ldots, 128\}$. The bit lengths of arguments Z, X, Y, M, and $\overline{r}$ should be an arbitrary value in N, and all of them in a calculation must be of the same length, while the bit length of M' should always be 32. For more detailed information about RSA calculation, please refer to Section 30.3.2 *Large-Number Modular Exponentiation* in Chapter 30 *RSA Accelerator (RSA)*.

32.3.3 Software Prerequisites

If you want to use the RSA_DS peripheral, the software needs a series of preparations, as shown in Figure 32.3-1. The left side lists preparations required by the software before the hardware starts the RSA signature calculation, while the right side lists the hardware workflow during the entire calculation procedure.

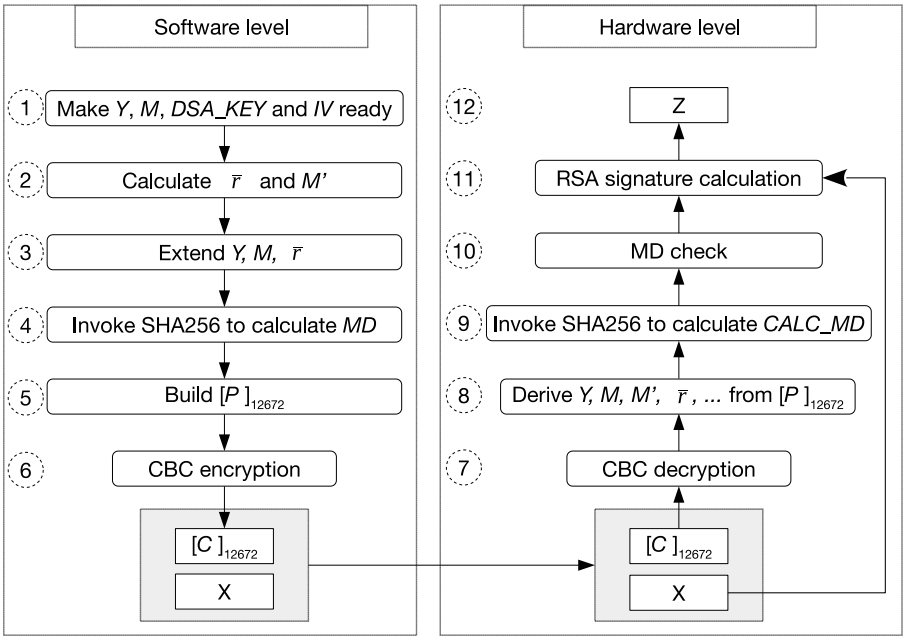


Figure 32.3-1. Software Preparations and Hardware Working Process

Note:

1. The software preparation (left side in Figure 32.3-1) is a one-time operation before any signature is calculated, while the hardware calculation (right side in Figure 32.3-1) repeats for every signature calculation.
2. Software preparation requires configuring the clock reset. For more information, please refer to Chapter 11 *Reset and Clock*.

Users need to follow the steps shown in the left part of Figure 32.3-1 to calculate C. Detailed instructions are as follows:

- **Step 1**: Prepare operands Y and M whose lengths should meet the requirements in Section 32.3.2. Define $[L]_{32} = \frac{N}{32} - 1$ (i.e., for RSA 4096, $[L]_{32}$ == $[0x80\text{-}1]_{32}$). Prepare $[RSA_DS_KEY]_{256}$:
  - when calculated by the RSA_DS peripheral via the HMAC peripheral: RSA_DS_KEY = HMAC-SHA256 ($[HMAC_KEY]_{256}$, 1^{256}).
  - when from Key Manager module: just use the deployed RSA_DS_KEY

  Generate a random $[IV]_{128}$ which should meet the requirements of the AES-CBC block encryption algorithm. For more information on AES, please refer to Chapter 27 *AES Accelerator (AES)*.
- **Step 2**: Calculate $\overline{r}$ and M' based on M.
- **Step 3**: Extend Y, M, and $\overline{r}$ in order to get $[Y]_{4096}$, $[M]_{4096}$, and $[\overline{r}]_{4096}$, respectively. This step is only required for Y, M, and $\overline{r}$ whose length are less than 4096 bits, since their largest length are 4096 bits.
- **Step 4**: Calculate MD authentication code using the SHA-256: $[MD]_{256}$ = SHA256 ($[Y]_{4096}||[M]_{4096}||[\overline{r}]_{4096}||[M']_{32}||[L]_{32}||[IV]_{128}$)
- **Step 5**: Build $[P]_{12672}$ = ($[Y]_{4096}||[M]_{4096}||[\overline{r}]_{4096}||[Box]_{384}$), where $[Box]_{384}$ = ($[MD]_{256}||[M']_{32}||[L]_{32}||[\beta]_{64}$) and $[\beta]_{64}$ is a PKCS#7 padding value, i.e., a $[0x0808080808080808]_{64}$ string composed of 8 bytes (0x80). The purpose of $[\beta]_{64}$ is to make the bit length of P a multiple of 128.

- **Step 6**: Calculate C = $[C]_{12672}$ = AES-CBC-ENC ($[P]_{12672}$, $[RSA_DS_KEY]_{256}$, $[IV]_{128}$), where C is the ciphertext with a length of 1200 bytes. C can also be calculated as C = $[C]_{12672}$ = ($[\widehat{Y}]_{4096}||[\widehat{M}]_{4096}||[\widehat{\overline{r}}]_{4096}||[\widehat{Box}]_{384}$), where $[\widehat{Y}]_{4096}$, $[\widehat{M}]_{4096}$, $[\widehat{\overline{r}}]_{4096}$, $[\widehat{Box}]_{384}$ are the four sub-parameters of C, and correspond to the ciphertext of $[Y]_{4096}$, $[M]_{4096}$, $[\overline{r}]_{4096}$, $[Box]_{384}$ respectively.

32.3.4 RSA_DS Operation at the Hardware Level

The hardware operation is triggered each time a digital signature needs to be calculated. The inputs are the pre-generated private key ciphertext C, a unique message X, and IV.

The RSA_DS operation at the hardware level can be divided into the following three stages:

1. **Decryption: Step 7 and 8 in Figure 32.3-1**

   The decryption process is the inverse of Step 6 in Figure 32.3-1. The RSA_DS peripheral will call the AES accelerator to decrypt C in CBC block mode and get the resulting plaintext. The decryption process can be represented by P = AES-CBC-DEC (C, RSA_DS_KEY, IV), where IV (i.e., $[IV]_{128}$) is defined by the user. $[RSA_DS_KEY]_{256}$ is

   - when calculated by the RSA_DS peripheral via the HMAC peripheral: provided by the HMAC module, derived from $HMAC_KEY$ stored in eFuse, which is not readable by users.
   - when from Key Manager module: RSA_DS_KEY deployed by Key Manager, which is not readable by users.

   With P, the RSA_DS peripheral can derive $[Y]_{4096}$, $[M]_{4096}$, $[\overline{r}]_{4096}$, $[M']_{32}$, $[L]_{32}$, MD authentication code, and the padding value $[\beta]_{64}$. This process is the inverse of Step 5.

2. **Check: Step 9 and 10 in Figure 32.3-1**

   The RSA_DS peripheral will perform two checks: MD check and padding check. The padding check is not shown in Figure 32.3-1, as it happens at the same time as the MD check.

   - MD check: The RSA_DS peripheral calls SHA-256 to calculate the hash value $[CALC_MD]_{256}$ ($[CALC_MD]_{256}$ is calculated the same way and with same parameters as $[MD]_{256}$, see step 4). Then, $[CALC_MD]_{256}$ is compared against the MD authentication code $[MD]_{256}$ from step 4. Only when the two match does the MD check pass.
   - Padding check: The RSA_DS peripheral checks if $[\beta]_{64}$ complies with the aforementioned PKCS#7 format. Only when $[\beta]_{64}$ complies with the format does the padding check pass.

   The RSA_DS peripheral will only perform subsequent operations if MD check passes. If the padding check fails, a warning is generated, but it does not affect the subsequent operations.

3. **Calculation: Step 11 and 12 in Figure 32.3-1**

   The RSA_DS peripheral treats X (input by the user) and Y, M, $\overline{r}$ (decrypted in step 8) as big numbers. With M', all operands to perform X^Y mod M are in place. The operand length is defined by L only. The RSA_DS peripheral will calculate the signed result Z by calling RSA to perform $Z = X^Y$ mod M.

32.3.5 RSA_DS Operation at the Software Level

The software steps below should be followed each time a digital signature needs to be calculated. The inputs are the pre-generated private key ciphertext C, a unique message X, and IV. These software steps trigger

the hardware steps described in Section 32.3.4.

We assume that the software has called the HMAC peripheral and the HMAC peripheral has calculated RSA_DS_KEY based on $HMAC_KEY$.

1. **Prerequisites**: Prepare operands C, X, IV according to Section 32.3.3.
2. **Activate the RSA_DS peripheral**: Write 1 to DSA_SET_START_REG.
3. **Check if RSA_DS_KEY is ready** depending on from where the RSA_DS_KEY comes from:
   - Write 1 to DSA_KEY_SOURCE_REG to select RSA_DS_KEY deployed by the Key Manager. Verify that RSA_DS_KEY has been successfully deployed by checking the register field KEYMNG_KEY_DS_VLD. When its value is 1, it indicates that RSA_DS_KEY has been successfully deployed and is ready.
   - Write 0 to DSA_KEY_SOURCE_REG to select RSA_DS_KEY from HMAC. Poll DSA_QUERY_BUSY_REG until the software reads 0.

   If the software does not read 0 in DSA_QUERY_BUSY_REG after approximately 1 ms, it indicates a problem with HMAC initialization. In such a case, the software can read register DSA_QUERY_KEY_WRONG_REG to get more information:
   - If the software reads 0 in DSA_QUERY_KEY_WRONG_REG, it indicates that the HMAC peripheral has not been called.
   - If the software reads any value from 1 to 15 in DSA_QUERY_KEY_WRONG_REG, it indicates that HMAC was called, but the RSA_DS peripheral did not successfully get RSA_DS_KEY from the HMAC peripheral. This may indicate that the HMAC operation has been interrupted due to a software concurrency problem.
4. **Configure register**: Write the content in the IV block to register DSA_IV_*m*_REG (*m*: 0 ~ 3). For more information on the IV block, please refer to Chapter *27 AES Accelerator (AES)*.
5. **Write X to memory block DSA_X_MEM**: Write X_i ($i \in \{0, 1, \ldots, n-1\}$), where $n = \frac{N}{32}$, to memory block DSA_X_MEM whose capacity is 96 words. Each word can store one base-b digit. The memory block uses the little endian format for storage, i.e., the least significant digit of the operand is in the lowest address. Words in DSA_X_MEM block after the configured length of X (N bits, as described in Section 32.3.2), are ignored.
6. **Write C to corresponding memory blocks**: Write the four sub-parameters of C to corresponding memory blocks:
   - Write $\widehat{Y_i}$ ($i \in \{0, 1, \ldots, 127\}$) to DSA_Y_MEM.
   - Write $\widehat{M_i}$ ($i \in \{0, 1, \ldots, 127\}$) to DSA_M_MEM.
   - Write $\widehat{r}_i$ ($i \in \{0, 1, \ldots, 127\}$) to DSA_RB_MEM.
   - write $\widehat{Box_i}$ ($i \in \{0, 1, \ldots, 11\}$) to DSA_BOX_MEM.

     The capacity of DSA_Y_MEM, DSA_M_MEM, and DSA_RB_MEM is 128 words, whereas the capacity of DSA_BOX_MEM is only 12 words. Each word can store one base-b digit. The memory blocks use the little endian format for storage, i.e., the least significant digit of the operand is in the lowest address.
7. **Start RSA_DS operation**: Write 1 to register DSA_SET_ME_REG.

8. **Wait for the operation to be completed**: Poll register DSA_QUERY_BUSY_REG until the software reads 0.
9. **Query check result**: Read register DSA_QUERY_CHECK_REG and conduct subsequent operations as illustrated below based on the return value:
    - If the value is 0, it indicates that both the padding check and MD check pass. Users can continue to get the signed result Z.
    - If the value is 1, it indicates that the padding check passes but MD check fails. The signed result Z is invalid. The operation will resume directly from Step 11.
    - If the value is 2, it indicates that the padding check fails but the MD check passes. Users can continue to get the signed result Z. But please note that the data does not comply with the aforementioned PKCS#7 padding format, which may not be what you want.
    - If the value is 3, it indicates that both the padding check and MD check fail. In this case, some fatal errors have occurred and the signed result Z is invalid. The operation will resume directly from Step 11.
10. **Read the signed result**: Read the signed result Z_i ($i \in \{0, 1, \ldots, n-1\}$), where $n = \frac{N}{32}$, from memory block DSA_Z_MEM. The memory block stores Z in little-endian byte order.
11. **Exit the operation**: Write 1 to DSA_SET_FINISH_REG, and then poll DSA_QUERY_BUSY_REG until the software reads 0.

After the operation, all the input/output registers and memory blocks are cleared.

32.4 Memory Summary

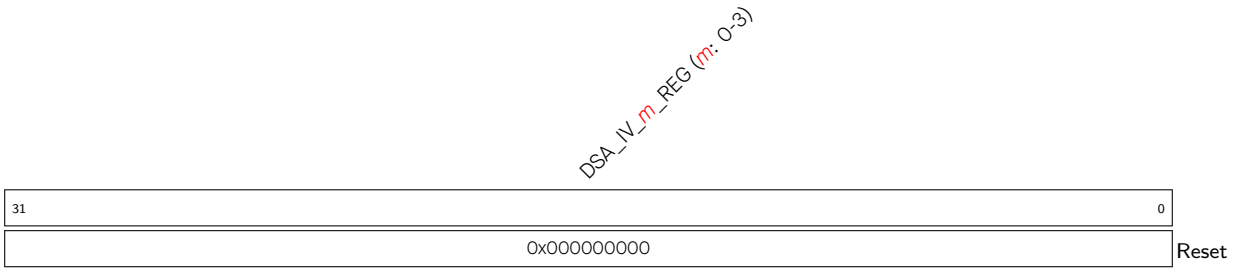
The addresses in this section are relative to the RSA Digital Signature Peripheral (RSA_DS) base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

Name	Description	Size (byte)	Starting Address	Ending Address	Access
DSA_Y_MEM	Memory block Y	512	0x0000	0x01FF	WO
DSA_M_MEM	Memory block M	512	0x0200	0x03FF	WO
DSA_RB_MEM	Memory block $\overline{r}$	512	0x0400	0x05FF	WO
DSA_BOX_MEM	Memory block Box	48	0x0600	0x062F	WO
DSA_X_MEM	Memory block X	512	0x0800	0x09FF	WO
DSA_Z_MEM	Memory block Z	512	0x0A00	0x0BFF	RO

32.5 Register Summary

The addresses in this section are relative to the RSA Digital Signature Peripheral (RSA_DS) base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

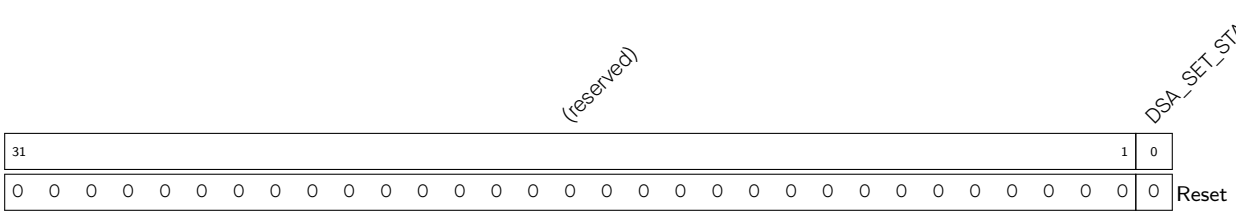
The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Configuration Registers			
DSA_IV_0_REG	IV block data	0x0630	WO
DSA_IV_1_REG	IV block data	0x0634	WO
DSA_IV_2_REG	IV block data	0x0638	WO
DSA_IV_3_REG	IV block data	0x063C	WO
DSA_KEY_SOURCE_REG	Configures RSA_DS_KEY source	0x0E18	R/W
Status/Control Registers			
DSA_SET_START_REG	Activates the RSA_DS peripheral	0x0E00	WO
DSA_SET_ME_REG	Starts RSA_DS operation	0x0E04	WO
DSA_SET_FINISH_REG	Ends RSA_DS operation	0x0E08	WO
DSA_QUERY_BUSY_REG	Status of the RSA_DS peripheral	0x0E0C	RO
DSA_QUERY_KEY_WRONG_REG	Checks the reason why RSA_DS_KEY is not ready	0x0E10	RO
DSA_QUERY_CHECK_REG	Queries DSA check result	0x0E14	RO
Version control register			
DSA_DATE_REG	Version control register	0x0E20	W/R

32.6 Registers

The addresses in this section are relative to the RSA Digital Signature Peripheral (RSA_DS) base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

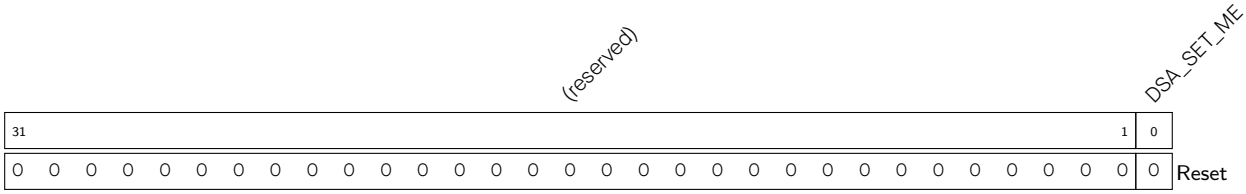


For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 32.1. DSA_IV_*m*_REG (*m*: 0-3) (0x0630+4m*)**

DSA_IV_*m*_REG (*m*: 0-3) Writes IV block data. (WO)

Register 32.2. DSA_SET_START_REG (0x0E00)



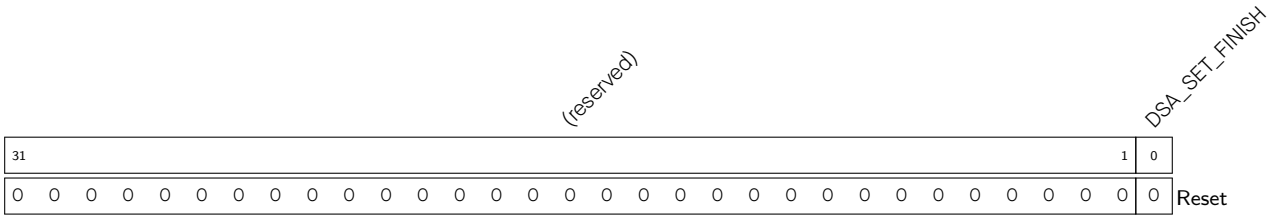
DSA_SET_START Configures whether to activate the RSA_DS peripheral.

0: No effect

1: Activate the RSA_DS peripheral

(WO)

Register 32.3. DSA_SET_ME_REG (0x0E04)



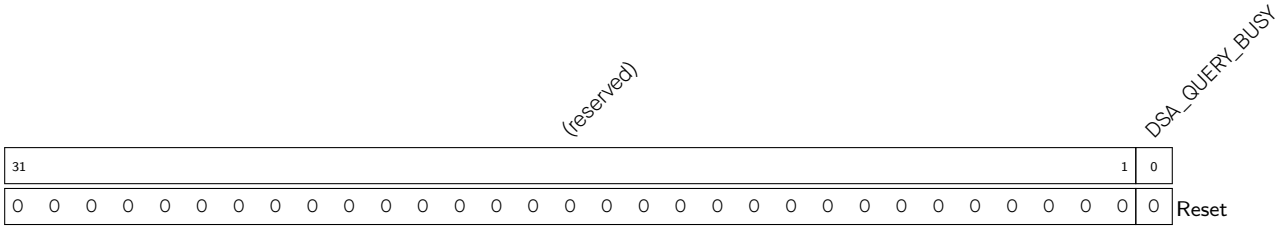
DSA_SET_ME Configures whether to start the RSA_DS operation.

0: No effect

1: Start the RSA_DS operation

(WO)

Register 32.4. DSA_SET_FINISH_REG (0x0E08)



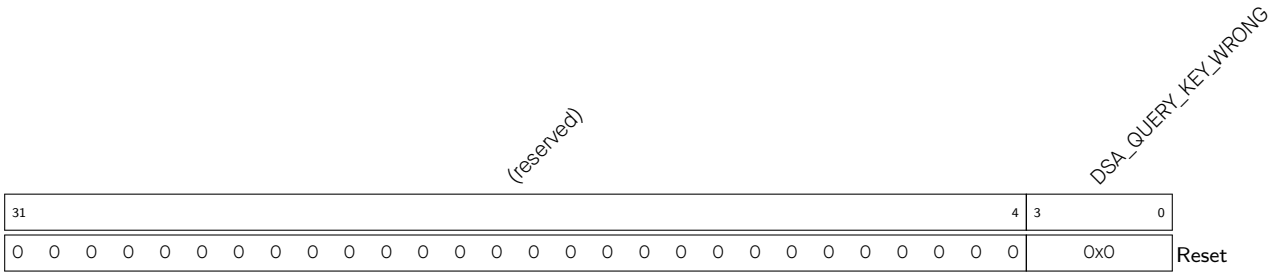
DSA_SET_FINISH Configures whether to end the RSA_DS operation.

0: No effect

1: End the RSA_DS operation

(WO)

Register 32.5. DSA_QUERY_BUSY_REG (0x0E0C)



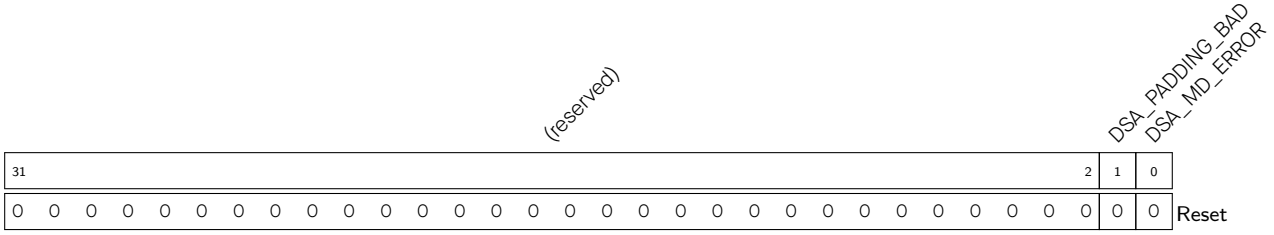
DSA_QUERY_BUSY Represents whether the RSA_DS peripheral is idle.

0: The RSA_DS peripheral is idle.

1: The RSA_DS peripheral is busy.

(RO)

Register 32.6. DSA_QUERY_KEY_WRONG_REG (0x0E10)



DSA_QUERY_KEY_WRONG Represents the specific problem with HMAC initialization.

0: HMAC is not called.

1-15: HMAC was activated, but the RSA_DS peripheral did not successfully receive RSA_DS_KEY from the HMAC peripheral.

(RO)

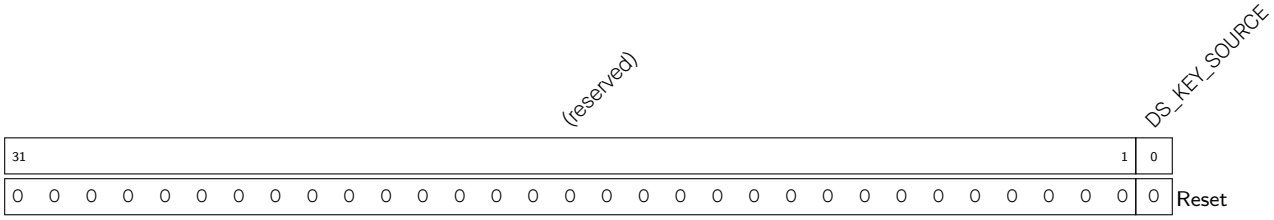
Register 32.7. DSA_QUERY_CHECK_REG (0x0E14)

DSA_PADDING_BAD Represents whether the padding check passes.

0: The padding check passes.

1: The padding check fails.

(RO)



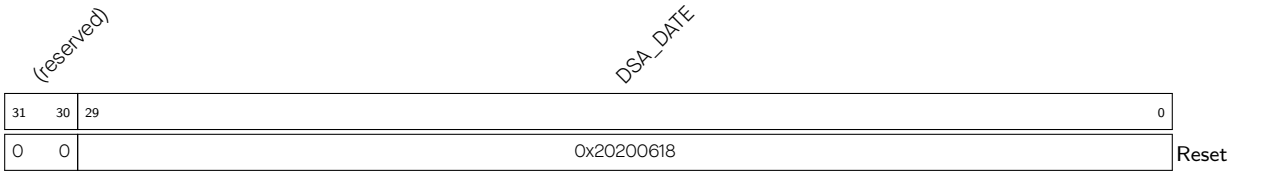
DSA_MD_ERROR Represents whether the MD check passes.

0: The MD check passes.

1: The MD check fails.

(RO)

Register 32.8. DSA_KEY_SOURCE_REG (0x0E18)



DSA_KEY_SOURCE Represents the source of RSA_DS_KEY.

0: HMAC

1: Key Manager

(R/W)

Register 32.9. DSA_DATE_REG (0x0E20)

DSA_DATE Version control register. (R/W)

Chapter 33

ECDSA Digital Signature Peripheral (ECDSA_DS)

33.1 Introduction

In cryptography, the Elliptic Curve Digital Signature Algorithm (ECDSA) offers a variant of the Digital Signature Algorithm (DSA) which uses elliptic-curve cryptography.

ESP32-P4's ECDSA Digital Signature Peripheral (ECDSA_DS) provides a secure and efficient environment for computing ECDSA signatures. It offers fast computations while ensuring the confidentiality of the signing process to prevent information leakage. This makes it a valuable tool for applications that require high-speed cryptographic operations with strong security guarantees. By using ECDSA_DS, users can be confident that their data is protected without sacrificing performance.

33.2 Features

ESP32-P4's ECDSA_DS module supports:

- Digital signature verification
- Three different elliptic curves, namely, P-192, P-256, and P-384 defined in FIPS 186-5
- Multiple hash algorithms for message hash in the ECDSA_DS operation, including SHA-224, SHA-256, SHA-384, SHA-512, SHA-512-224, and SHA-512-256, defined in FIPS PUB 180-4 Spec
- State-dependent register access control in different operation states to ensure information security

33.3 ECDSA Basics

33.3.1 Domain Parameters

ECDSA uses parameters that define the elliptic curve over a finite field, as well as the generator point and the order of the base point. These parameters are usually referred to as domain parameters, and they are required for key generation, signature generation, and signature verification.

The domain parameters used in ECDSA consist of the following:

- The elliptic curve domain parameters, which include:
  - The prime modulus p, which specifies the size of the finite field over which the elliptic curve is defined.
  - The coefficients a and b, which specify the elliptic curve equation.
  - The base point G on the curve, which can be used to generate public keys.

  - The order n of the base point, which is the number of points on the curve that can be generated by repeatedly adding G to itself.
- The parameters for the hash function, which include:
  - The hash algorithm used to generate a fixed-length hash value from the message being signed.
  - The length of the hash value, which determines the size of the signature.

Together, these parameters define the ECDSA domain.

33.3.2 Key Generation

The process of key generation in ECDSA is described below:

1. Select an elliptic curve domain by defining:
   - the prime modulus p
   - the coefficients a and b
   - the base point G and its order n
2. Generate a private key:
   - A private key d is a randomly chosen integer between 1 and n-1. It is essential to use a secure *Random Number Generator (RNG)* to ensure that the private key is truly random and cannot be predicted or reproduced.
   - The private key is used for signature generation. This key must be kept secret and secure.
3. Compute the public key:
   - The public key Q is calculated as $Q = dG$.
4. Export the public key:
   - The public key Q is typically represented as a pair of coordinates (Qx, Qy) that can be shared with others.

33.3.3 Signature Generation

The ECDSA signature generation process is described below:

1. Select a message m to be signed.
2. Calculate the hash of the message e: e is equal to HASH(m), where HASH is a cryptographic hash function, such as SHA-256.
3. Compute the digest of the message hash z: Let z be the L_n leftmost bits of e, where L_n is the bit length of the base point order n.
4. Select a random number k, which is chosen between 1 and n-1, where n is the order of the base point on the elliptic curve.
5. Compute the signature: The signature is calculated as follows:
   (a) Compute the point (x, y) = kG

(b) Calculate r = x mod n. If r is equal to zero, return to the previous step and select a new random value of k.

(c) Calculate s = k^{-1} * $(z + d * r)$ mod n. If s is equal to zero, return to step 4 and select a new random value of k.

(d) The signature is the pair (r, s).

6. Send the message m and signature (r, s) to the recipient.

33.3.4 Signature Verification

The recipient can then use the public key associated with the private key used for signature generation to verify the signature. The verification process involves checking that the signature was generated using the correct private key and that the signature is valid for the given message.

The ECDSA signature verification process is described below:

1. Obtain public key Q and receive the message m and signature (r, s).
2. Calculate the hash of the message e: e is equal to HASH(m), where HASH is a cryptographic hash function, such as SHA-256.
3. Compute the digest of the message z: Let z be the L_n leftmost bits of e, where L_n is the bit length of the base point order n.
4. Verify the signature: The signature is verified as follows:
   (a) Verify that r and s are integers between 1 and n-1, where n is the order of the base point on the elliptic curve. If either r or s is outside of this range, the signature is invalid.
   (b) Calculate $u_1 = z * s^{-1}$ mod n and $u_2 = r * s^{-1}$ mod n.
   (c) Calculate the point $(x_1, y_1) = u_1 * G + u_2 * Q$, where G is the base point on the elliptic curve, and Q is the public key associated with the private key used for signature generation.
   (d) Verify that $r = x_1$ mod n. If r is not equal to x_1 mod n, the signature is invalid.
5. Accept or reject the signature: If the signature is valid, the recipient can be confident that the message was not tampered with and that it came from the expected sender, thus can accept the message as authentic. Otherwise, the recipient rejects the message as invalid.

33.4 Functional Description

This section describes the details of ESP32-P4's ECDSA_DS module.

33.4.1 ECDSA_DS Working Modes

The ECDSA_DS module integrated in the ESP32-P4 supports Signature Verification mode.

Users can select the elliptic curves used by the ECDSA_DS module by configuring ECDSA_ECC_CURVE according to Table 33.4-1.

Table 33.4-1. ECDSA_DS Elliptic Curve Selection

ECDSA_ECC_CURVE	Elliptic Curve
0	P-192
1	P-256
2	P-384

Users can select the SHA algorithms for message hash by configuring ECDSA_SHA_MODE according to Table 33.4-2.

Table 33.4-2. ECDSA_DS SHA Algorithm

ECDSA_SHA_MODE	SHA Algorithm
1	SHA-224
2	SHA-256
3	SHA-384
4	SHA-512
5	SHA-512-224
6	SHA-512-256
Others	Invalid

Additionally, users can check the working states of the ECDSA_DS module by inquiring the ECDSA_STATE_REG register and comparing the return value against the Table 33.4-3 below.

Table 33.4-3. ECDSA_DS Working State

ECDSA_STATE_REG	State	Description
0	IDLE	Idle or completed operation. Corresponding to IDLE Stage.
1	LOAD	Waiting for users to load information into ECDSA_DS. Corresponding to LOAD Stage.
2	Reserved	–
3	BUSY	In the middle of a hardware operation. Corresponding to PREP, PROC & POST Stage.

33.4.2 Data and Data Block

ESP32-P4's ECDSA_DS module can operate on data of 192, 256, 384, or 512 bits. For example, the data ($D[255:0]$) can be divided into 32-bit data blocks.

Take 256-bit long data as an example, $D[n][31:0](n = 0, 1, \cdots, 7)$. Data blocks with the smaller serial number correspond to the lower binary bits. To be specific:

$$D[255:0] = D[7][31:0], D[6][31:0], D[5][31:0], D[4][31:0], D[3][31:0], D[2][31:0], D[1][31:0], D[0][31:0]$$

33.4.2.1 Writing Data

Writing data means writing data to an ECDSA_DS memory block and using this data as the input to ECDSA_DS. To be specific, writing data to an ECDSA_DS memory block means writing $D[n][31:0]$ to the "starting address of this ECDSA_DS memory block + $4 \times n$". For a 256-bit long data:

- write $D[0]$ to "starting address"
- write $D[1]$ to "starting address + 4"
- ...
- write $D[7]$ to "starting address + 28"

Note:
When storing data, write only the data block of the required length. Do not append a 0 to the most significant bit. For example, for 192-bit data, store only the 192 bits without appending 0.

33.4.2.2 Reading Data

Reading data means reading data from the starting address of an ECDSA_DS memory block and using this data as the output from ECDSA_DS. To be specific, reading data from an ECDSA_DS memory block means reading $D[n][31:0]$ from the "starting address of this ECDSA_DS memory block + $4 \times n$". For a 256-bit long data:

- read $D[0]$ from "starting address"
- read $D[1]$ from "starting address + 4"
- ...
- read $D[7]$ from "starting address + 28"

Note:
When reading data, only the data block of the required length needs to be read. For example, to read 192-bit data, simply read the lower 192 bits (i.e., 6 data blocks).

33.4.2.3 Padding the Message

The SHA accelerator can only process message blocks of 512 bits. Thus, all the messages should be padded to a multiple of 512 bits before the hash operation.

Suppose that the length of the message M is L_M bits. Then M shall be padded as introduced below:

1. First, append the bit "1" to the end of the message;
2. Second, append L_A bits of zeros, where L_A is the smallest, non-negative solution to the equation $L_M + 1 + L_A \equiv 448 \ mod \ 512$;
3. Last, append the 64-bit block of value equal to the number L_M expressed using a binary representation.

For more details, please refer to FIPS PUB 180-4 Spec > Section "Padding the Message".

33.4.2.4 Parsing the Message

The message and its padding must be parsed into N 512-bit message blocks: $M^{(1)}$, $M^{(2)}$, ..., $M^{(N)}$.

Note:

1. For more details about "parsing the message", please refer to FIPS PUB 180-4 Spec > Section "Parsing the Message".
2. For more information on "message block", please refer to FIPS PUB 180-4 Spec > Section "Glossary of Terms and Acronyms".

33.4.3 Security Features

To ensure the security of the operation process, the ECDSA_DS module implements a variety of security functions.

33.4.3.1 High Anti-Attack Performance

ESP32-P4's ECDSA_DS module leverages ECC's enhanced anti-attack performance (refer to Section 28.4.3 *Enhancing Anti-Attack Performance*) every time it performs an operation. This means that each time a signature is generated and verified by the ECDSA_DS:

- The execution latency is constant for a given operation.
- Power consumption variations are minimized.

This provides ESP32-P4's ECDSA_DS module strong anti-attack performance.

33.4.3.2 State-Dependent Register Access Control

ESP32-P4's ECDSA_DS module has implemented a state-dependent register access control mechanism to prevent any possibility of key theft by tampering with the configuration or accessing the data during the operation.

By implementing the state-dependent register access control, the accesses for ECDSA_DS registers are designed to vary in different states. For example, ECDSA_CONF_REG is only available for reading and writing when ECDSA_DS is in the IDLE state. In this way, the configuration information is protected from reading or writing when ECDSA_DS is in other states, such as LOAD and BUSY. For details about all ECDSA_DS working states, please refer to Table 33.4-3.

For detailed information on the state-dependent access control of each ECDSA_DS register, please refer to Section Register Summary.

33.4.3.3 Hardware Occupation

During the operation, the following hardware modules will be occupied by ESP32-P4's ECDSA_DS module:

- SHA Accelerator
- ECC Accelerator

Among them, the SHA accelerator will be released when ECDSA_SHA_RELEASE_INT is triggered, while the ECC accelerator will be occupied during the whole ECDSA_DS operation.

Note:

Hardware occupation is a mechanism to protect multiplexed modules and storage space. When a module is hardware occupied, the user will fail to:

- read or write data to the module's registers or memories.
- disable the module clock.
- reset the module.

After hardware occupation is finished, the occupied module will be automatically reset. In addition, when the user performs a software reset to the master module, all the occupied modules will be reset at the same time.

33.5 Programming Procedures

33.5.1 ECDSA_DS Process

The overall ECDSA_DS process consists of the following five stages.

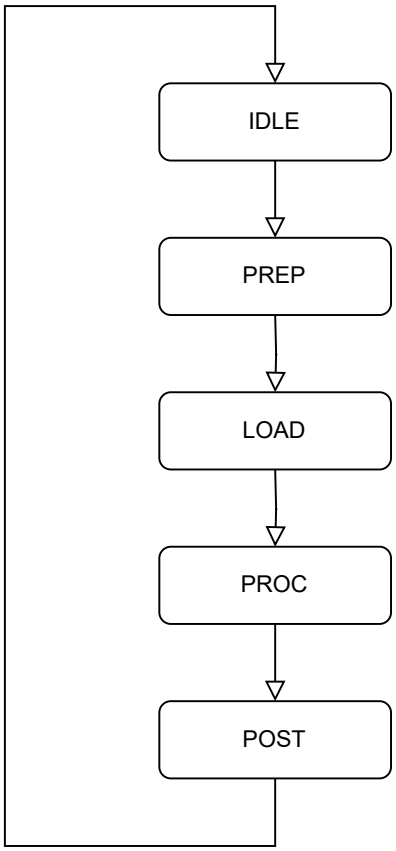


Figure 33.5-1. ECDSA_DS Process

The detailed programming procedures of each stage are described in the following sections.

33.5.1.1 IDLE Stage

In the IDLE stage:

1. Configure the static parameters including eFuse bits ECDSA_KEY, i.e., the value of private key d in ECDSA. To correctly configure the key value in eFuse, user need to write the key value in KEY*n* (n = 0 ~ 5), and set the corresponding EFUSE_KEY_PURPOSE_*n* as ECDSA_KEY. Please refer to Chapter 9.4 *eFuse Controller (EFUSE)* for more detailed configuration steps.
2. Configure the configuration register, including the following fields:
   (a) ECDSA_ECC_CURVE: Choose the elliptic curve of the ECDSA_DS module.
   (b) ECDSA_SOFTWARE_SET_Z: Choose to use direct input z.
3. Configure the register field ECDSA_START to enter the PREP stage.

33.5.1.2 PREP Stage

In the PREP stage, ECDSA_STATE_REG is BUSY, and the ECDSA_DS performs preparation.

Wait till the PREP stage to end by polling ECDSA_BUSY until it is not BUSY. Then the ECDSA_DS will automatically enter the LOAD stage.

33.5.1.3 LOAD Stage

In the LOAD stage:

1. Provide input z into the ECDSA_DS using one of the following options:
   - Direct input z: write z to ECDSA_Z_MEM.
   - ECDSA_DS SHA interface: generate z from the message. For details, please refer to Section 33.5.1.6.
2. Provide signature and public key required by signature verification:
   (a) write signature (r, s) to ECDSA_R_MEM and ECDSA_S_MEM.
   (b) write public key (Qx, Qy) to ECDSA_QX_MEM and ECDSA_QY_MEM.
3. Write 1 to ECDSA_LOAD_DONE, indicating that the configuration is done. Then ECDSA_DS will automatically enter the PROC stage.

33.5.1.4 PROC Stage

In the PROC stage, ECDSA_STATE_REG is BUSY, and the ECDSA_DS performs ECDSA signature verification.

Wait till the PROC stage to end by polling ECDSA_BUSY until it is not BUSY. Then the ECDSA_DS will automatically enter the POST stage.

33.5.1.5 POST Stage

In the POST stage, ECDSA_STATE_REG is BUSY, and the ECDSA_DS performs wrap-up work of the operation.

Wait till the POST stage to end by polling ECDSA_BUSY until it is not BUSY. Then the ECDSA_DS will automatically return to the IDLE stage.

33.5.1.6 ECDSA_DS SHA Interface

ESP32-P4's ECDSA_DS module can automatically execute hash operation and generates z based on a direct input message.

For message hash, the ECDSA_DS module supports SHA algorithms SHA-224 (only valid when P-192 is selected as the elliptic curve) and SHA-256.

To use the ECDSA_DS SHA interface, complete the following steps:

1. Pad the message by following the steps described in Section 33.4.2.3.
2. Parse the message and its padding into message blocks. See details in Section 33.4.2.4.
3. Process the current message block.
   - Write the current message block into ECDSA_MEM_M.
4. Start the ECDSA_DS SHA interface[1].
   - If this is the first time to execute this step, write 1 to ECDSA_SHA_START to start the ECDSA_DS SHA interface;
   - If this is not the first time to execute this step[2], write 1 to ECDSA_SHA_CONTINUE to continue the operation.
5. Check the progress of the current message block processing by polling.
   - Poll register ECDSA_SHA_BUSY until it's IDLE, indicating that the interface has completed the operation for the current message block.
6. Process the next message block:
   - If there is message block to process, go back to Step 3.
   - If there is no more message blocks, exit.

Note:

1. In this step, the software can also write the next message block to be processed, if any, in register ECDSA_MEM_M, while the interface starts SHA operation, to save time.
2. You are resuming the ECDSA_DS SHA interface with the previously paused operation.

33.5.2 Clocks and Resets

ESP32-P4's ECDSA_DS module has one clock module and one reset module. It is activated by setting the HP_SYS_CLKRST_CRYPTO_ECDSA_CLK_EN bit in the HP_SYS_CLKRST_PERI_CLK_CTRL25_REG register and clearing the HP_SYS_CLKRST_RST_EN_ECDSA bit in the HP_SYS_CLKRST_HP_RST_EN2_REG register. For details on how to configure the ECDSA_DS clock and reset, please refer to Chapter 11 *Reset and Clock*.

33.5.3 Interrupts

ESP32-P4's ECDSA_DS module can generate the interrupt signal ECDSA_INTR and send it to Interrupt Matrix.

The ECDSA_DS module has four interrupt sources that can generate the ECDSA_INTR interrupt signal as follows. Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*.

- ECDSA_PREP_DONE_INT: triggered on the completion of the PREP stage. This interrupt source is configured by the following registers:
  - ECDSA_PREP_DONE_INT_RAW: stores the raw interrupt status of ECDSA_PREP_DONE_INT.
  - ECDSA_PREP_DONE_INT_ST: indicates the status of the ECDSA_PREP_DONE_INT interrupt. This field is generated by enabling/disabling the ECDSA_PREP_DONE_INT_RAW field.
  - ECDSA_PREP_DONE_INT_ENA: enables/disables the ECDSA_PREP_DONE_INT interrupt.
  - ECDSA_PREP_DONE_INT_CLR: set this bit to clear the ECDSA_PREP_DONE_INT interrupt status. By setting this bit to 1, fields ECDSA_PREP_DONE_INT_RAW and ECDSA_PREP_DONE_INT_ST will be cleared.
- ECDSA_PROC_DONE_INT: triggered on the completion of the PROC stage. This interrupt source is configured by the following registers:
  - ECDSA_PROC_DONE_INT_RAW: stores the raw interrupt status of ECDSA_PROC_DONE_INT.
  - ECDSA_PROC_DONE_INT_ST: indicates the status of the ECDSA_PROC_DONE_INT interrupt. This field is generated by enabling/disabling the ECDSA_PROC_DONE_INT_RAW field.
  - ECDSA_PROC_DONE_INT_ENA: enables/disables the ECDSA_PROC_DONE_INT interrupt.
  - ECDSA_PROC_DONE_INT_CLR: set this bit to clear the ECDSA_PROC_DONE_INT interrupt status. By setting this bit to 1, fields ECDSA_PROC_DONE_INT_RAW and ECDSA_PROC_DONE_INT_ST will be cleared.
- ECDSA_POST_DONE_INT: triggered on the completion of the POST stage. This interrupt source is configured by the following registers:
  - ECDSA_POST_DONE_INT_RAW: stores the raw interrupt status of ECDSA_POST_DONE_INT.
  - ECDSA_POST_DONE_INT_ST: indicates the status of the ECDSA_POST_DONE_INT interrupt. This field is generated by enabling/disabling the ECDSA_POST_DONE_INT_RAW field.
  - ECDSA_POST_DONE_INT_ENA: enables/disables the ECDSA_POST_DONE_INT interrupt.
  - ECDSA_POST_DONE_INT_CLR: set this bit to clear the ECDSA_POST_DONE_INT interrupt status. By setting this bit to 1, fields ECDSA_POST_DONE_INT_RAW and ECDSA_POST_DONE_INT_ST will be cleared.
- ECDSA_SHA_RELEASE_INT: triggered when SHA is released. This interrupt source is configured by the following registers:
  - ECDSA_SHA_RELEASE_INT_RAW: stores the raw interrupt status of ECDSA_SHA_RELEASE_INT.

- ECDSA_SHA_RELEASE_INT_ST: indicates the status of the ECDSA_SHA_RELEASE_INT interrupt. This field is generated by enabling/disabling the ECDSA_SHA_RELEASE_INT_RAW field via ECDSA_SHA_RELEASE_INT_ENA.
- ECDSA_SHA_RELEASE_INT_ENA: enables/disables the ECDSA_SHA_RELEASE_INT interrupt.
- ECDSA_SHA_RELEASE_INT_CLR: set this bit to clear the ECDSA_SHA_RELEASE_INT interrupt status. By setting this bit to 1, fields ECDSA_SHA_RELEASE_INT_RAW and ECDSA_SHA_RELEASE_INT_ST will be cleared.

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

33.6 Memory Blocks

ECDSA_DS's memory blocks store input data and output data of the operation.

Table 33.6-1. ECDSA_DS Memory Blocks

Memory	Size (byte)	Starting Address*	Ending Address*	Access
ECDSA_MEM_M	64	0x280	0x2BF	R/W
ECDSA_MEM_R	32	0xA00	0xA1F	R/W
ECDSA_MEM_S	32	0xA20	0xA3F	R/W
ECDSA_MEM_Z	32	0xA40	0xA5F	R/W
ECDSA_MEM_Qx	32	0xA60	0xA7F	R/W
ECDSA_MEM_Qy	32	0xA80	0xA9F	R/W

* Address offset related to the ECDSA_DS base address is provided in Table 9.3-2 in Chapter 9 *System and Memory*.

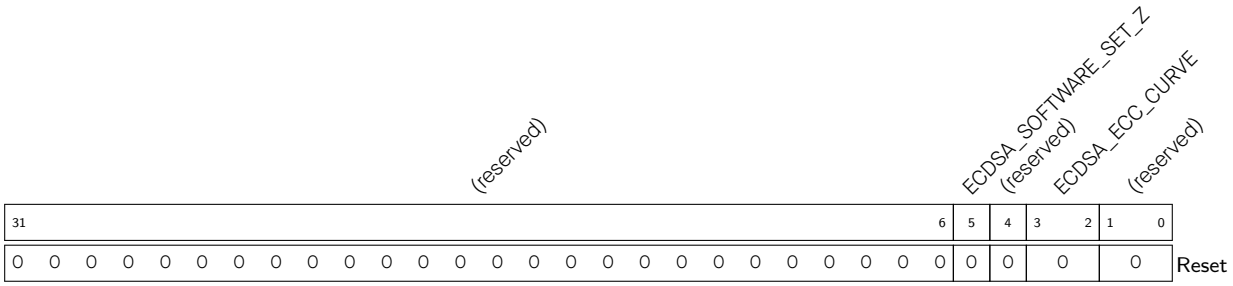
33.7 Register Summary

The addresses in this section are relative to the ECDSA_DS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

To enhance security, ECDSA_DS registers have different read and write permissions in different operating states. The following is the abbreviation and corresponding relationship of each state:

- PI: IDLE state, corresponding to IDLE Stage.
- PL: LOAD state, corresponding to LOAD Stage.
- PB: BUSY state, corresponding to PREP, PROC and POST Stage.

Other abbreviations given in Column **Access** are explained in Section Access Types for Registers.



Name	Description	Address	Access			
			PI	PL	PG	P
Data Memory	See Table 33.6-1.					
Configuration Registers						
ECDSA_CONF_REG	ECDSA_DS configuration register	0x0004	R/W	N/A		
ECDSA_START_REG	ECDSA_DS start register	0x001C	WT			N
Clock and Reset Register						
ECDSA_CLK_REG	ECDSA_DS clock gate register	0x0008	R/W	N/A		
Interrupt Registers						
ECDSA_INT_RAW_REG	ECDSA_DS interrupt raw register	0x000C	RO/WTC/SS			
ECDSA_INT_ST_REG	ECDSA_DS interrupt status register	0x0010	RO			
ECDSA_INT_ENA_REG	ECDSA_DS interrupt enable register	0x0014	R/W

33.8 Registers

The addresses in this section are relative to the ECDSA_DS base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 33.1. ECDSA_CONF_REG (0x0004)

ECDSA_ECC_CURVE Configures the elliptic curve used.

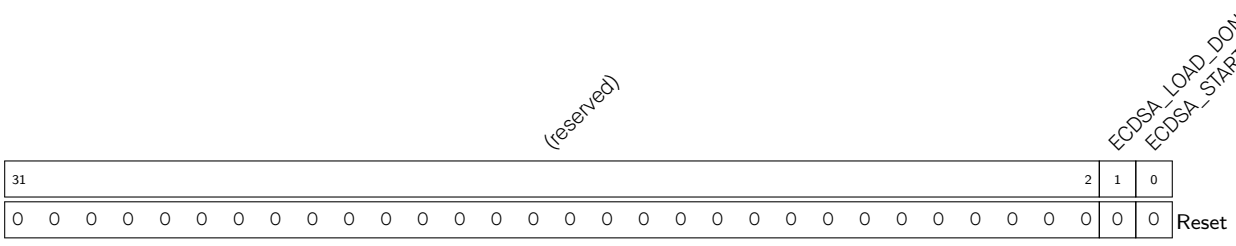
0: P-192

1: P-256

2: P-384

3: Invalid

(R/W)



ECDSA_SOFTWARE_SET_Z Configures how the parameter z is set.

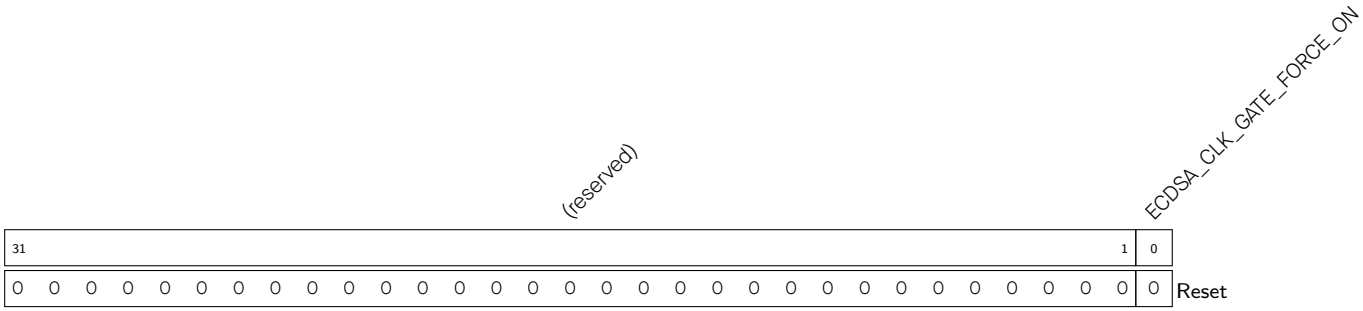
0: Generated from SHA result

1: Written by software

(R/W)

Register 33.2. ECDSA_START_REG (0x001C)

ECDSA_START Configures whether to start the ECDSA_DS operation. This bit will be self-cleared after configuration.



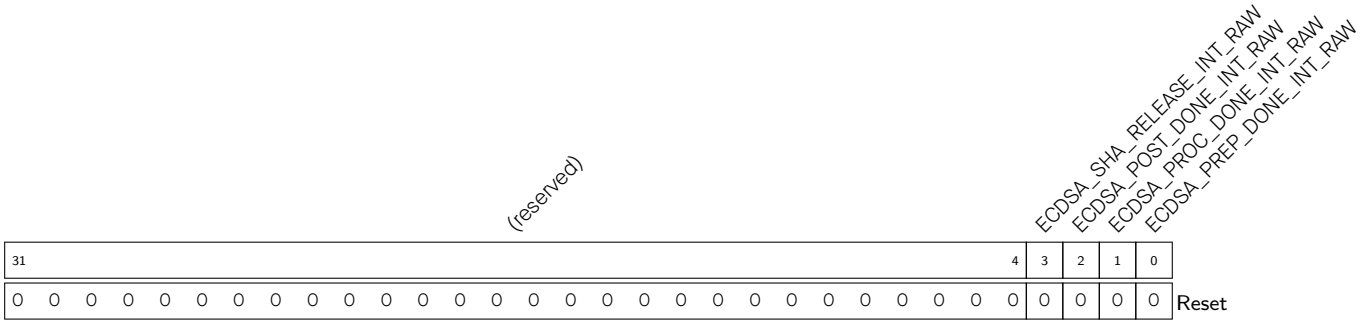
0: No effect

1: Start the ECDSA_DS operation

(WT)

ECDSA_LOAD_DONE Write 1 to generate a signal indicating the ECDSA_DS's LOAD operation is done. This bit will be self-cleared after configuration. (WT)

Register 33.3. ECDSA_CLK_REG (0x0008)



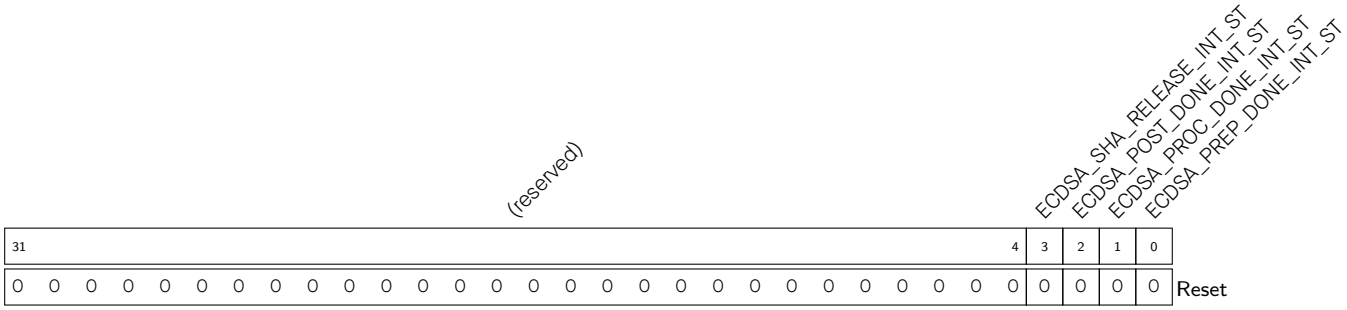
ECDSA_CLK_GATE_FORCE_ON Configures whether to force on ECC memory clock gate.

0: No effect

1: Force on

(R/W)

Register 33.4. ECDSA_INT_RAW_REG (0x000C)



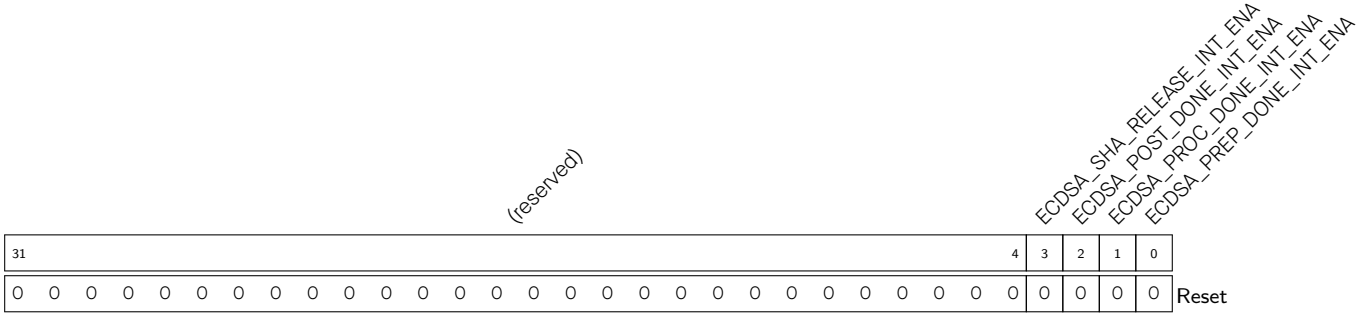
ECDSA_PREP_DONE_INT_RAW The raw interrupt status of the ECDSA_PREP_DONE_INT interrupt. (R/SS/WTC)

ECDSA_PROC_DONE_INT_RAW The raw interrupt status of the ECDSA_PROC_DONE_INT interrupt. (R/SS/WTC)

ECDSA_POST_DONE_INT_RAW The raw interrupt status of the ECDSA_POST_DONE_INT interrupt. (R/SS/WTC)

ECDSA_SHA_RELEASE_INT_RAW The raw interrupt status of the ECDSA_SHA_RELEASE_INT interrupt. (R/SS/WTC)

Register 33.5. ECDSA_INT_ST_REG (0x0010)



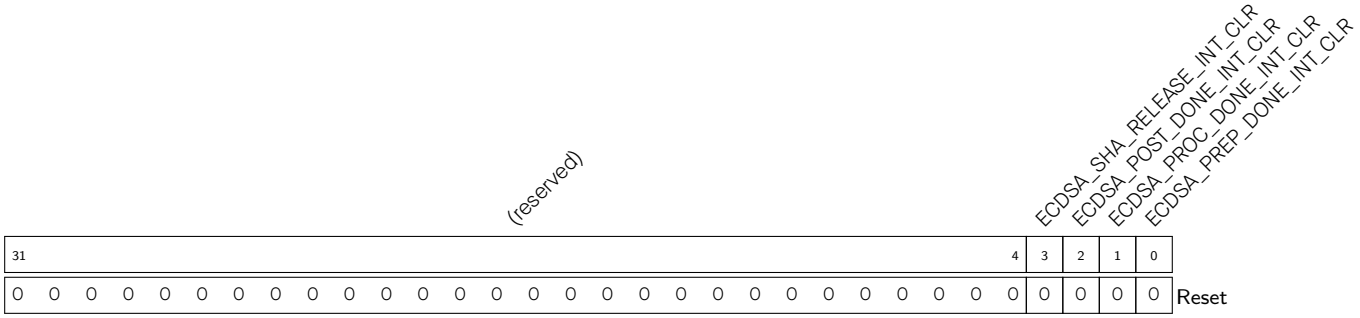
ECDSA_PREP_DONE_INT_ST The masked interrupt status of the ECDSA_PREP_DONE_INT interrupt. (RO)

ECDSA_PROC_DONE_INT_ST The masked interrupt status of the ECDSA_PROC_DONE_INT interrupt. (RO)

ECDSA_POST_DONE_INT_ST The masked interrupt status of the ECDSA_POST_DONE_INT interrupt. (RO)

ECDSA_SHA_RELEASE_INT_ST The masked interrupt status of the ECDSA_SHA_RELEASE_INT interrupt. (RO)

Register 33.6. ECDSA_INT_ENA_REG (0x0014)



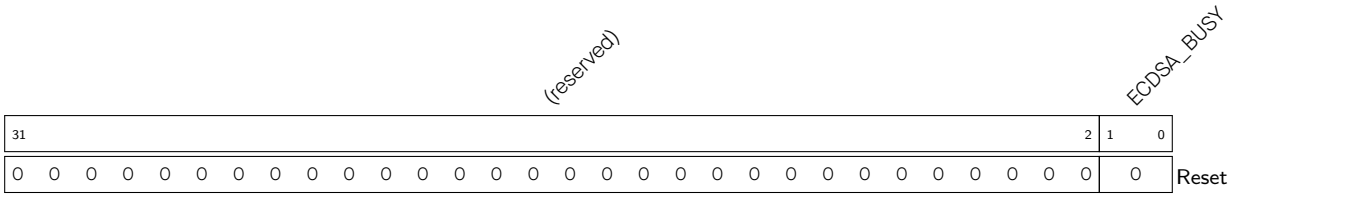
ECDSA_PREP_DONE_INT_ENA Write 1 to enable the ECDSA_PREP_DONE_INT interrupt. (R/W)

ECDSA_PROC_DONE_INT_ENA Write 1 to enable the ECDSA_PROC_DONE_INT interrupt. (R/W)

ECDSA_POST_DONE_INT_ENA Write 1 to enable the ECDSA_POST_DONE_INT interrupt. (R/W)

ECDSA_SHA_RELEASE_INT_ENA Write 1 to enable the ECDSA_SHA_RELEASE_INT interrupt. (R/W)

Register 33.7. ECDSA_INT_CLR_REG (0x0018)



ECDSA_PREP_DONE_INT_CLR Write 1 to clear the ECDSA_PREP_DONE_INT interrupt. (WT)

ECDSA_PROC_DONE_INT_CLR Write 1 to clear the ECDSA_PROC_DONE_INT interrupt. (WT)

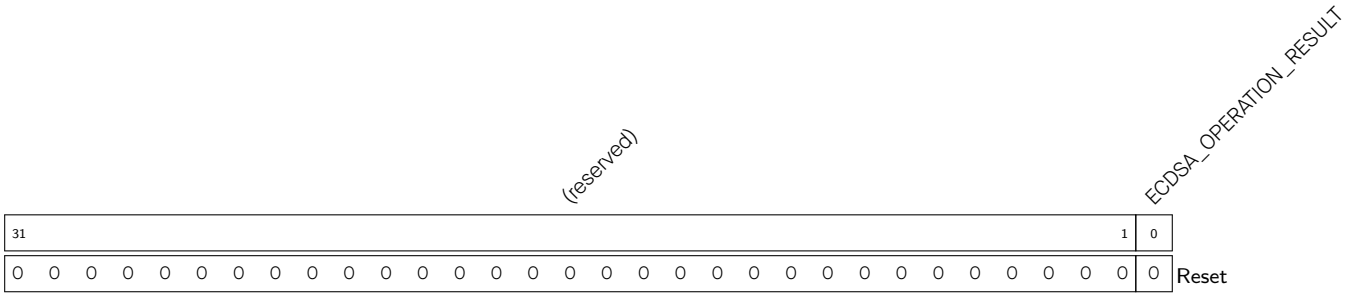
ECDSA_POST_DONE_INT_CLR Write 1 to clear the ECDSA_POST_DONE_INT interrupt. (WT)

ECDSA_SHA_RELEASE_INT_CLR Write 1 to clear the ECDSA_SHA_RELEASE_INT interrupt. (WT)

Register 33.8. ECDSA_STATE_REG (0x0020)

ECDSA_BUSY Represents the working state of the ECDSA_DS module.

0: IDLE



1: LOAD

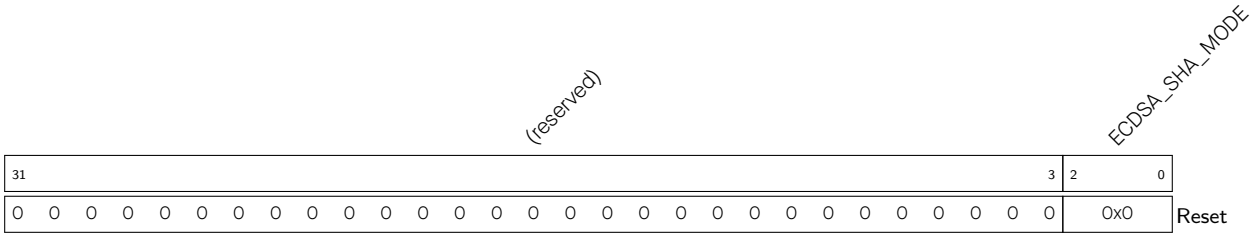
2: Reserved

3: BUSY

(RO)

Register 33.9. ECDSA_RESULT_REG (0x0024)

ECDSA_OPERATION_RESULT Indicates if the ECDSA_DS operation is successful.



0: Not successful

1: Successful

Only valid when the ECDSA_DS operation is done.

(RO/SS)

Register 33.10. ECDSA_SHA_MODE_REG (0x0200)

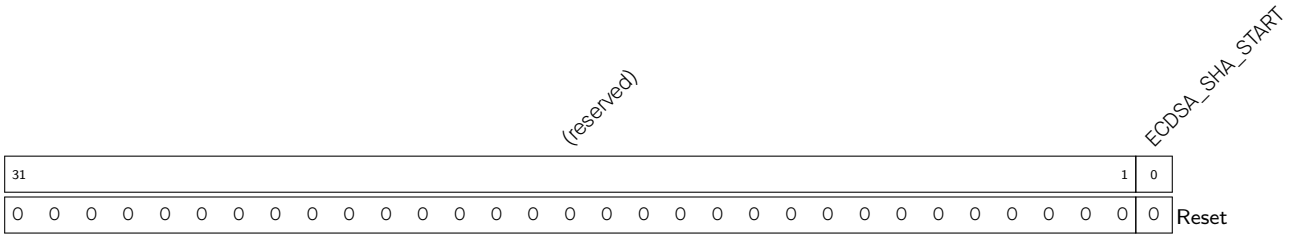
ECDSA_SHA_MODE Configures SHA algorithms for message hash.

1: SHA-224

2: SHA-256

3: SHA-384

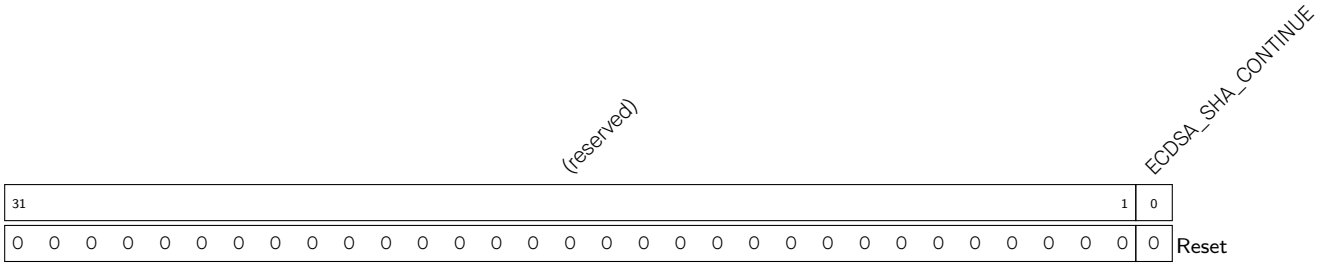
4: SHA-512



5: SHA-512-224

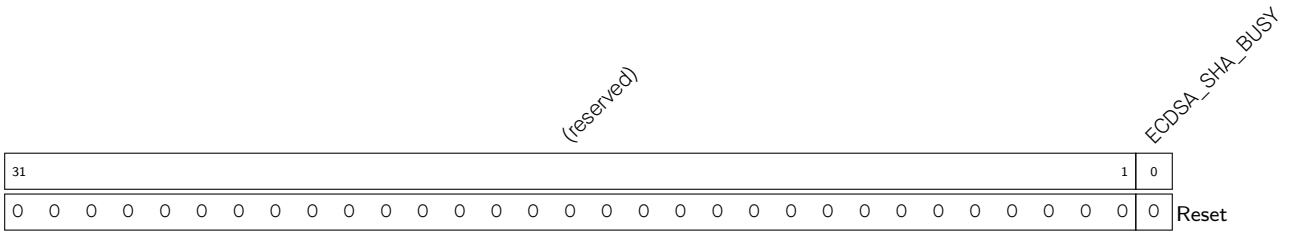
6: SHA-512-256

Others: invalid



(R/W)

Register 33.11. ECDSA_SHA_START_REG (0x0210)

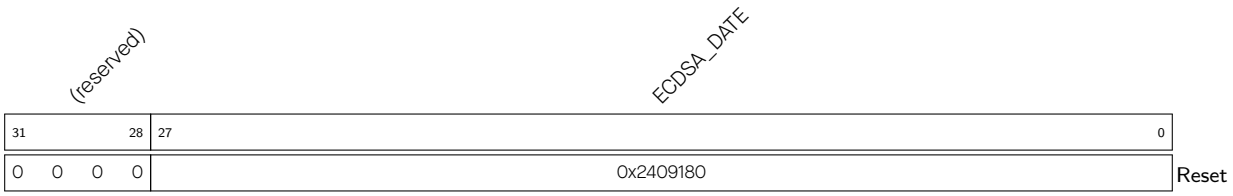


ECDSA_SHA_START Write 1 to start the first SHA operation in the ECDSA_DS process. This bit will be self-cleared after configuration. (WT)

Register 33.12. ECDSA_SHA_CONTINUE_REG (0x0214)

ECDSA_SHA_CONTINUE Write 1 to start the latter SHA operation in the ECDSA_DS process. This bit will be self-cleared after configuration. (WT)

Register 33.13. ECDSA_SHA_BUSY_REG (0x0218)



ECDSA_SHA_BUSY Represents the working state of the SHA accelerator in the ECDSA_DS process.

0: IDLE

1: BUSY

(RO)

Register 33.14. ECDSA_DATE_REG (0x00FC)

ECDSA_DATE The ECDSA_DS version control register. (R/W)

Chapter 34

External Memory Encryption and Decryption (XTS_AES)

34.1 Overview

The ESP32-P4 integrates an External Memory Encryption and Decryption module that complies with the XTS-AES standard algorithm specified in IEEE Std 1619-2007, providing security for users' application code and data stored in the external memory (flash and RAM). Users can store proprietary firmware and sensitive data (e.g., credentials for gaining access to a private network) in the external flash, or store general data in the external RAM.

34.2 Features

- General XTS-AES algorithm, compliant with IEEE Std 1619-2007
- Software-based manual encryption
- High-speed auto encryption and decryption without software's participation
- Encryption and decryption functions jointly enabled/disabled by registers configuration, eFuse parameters, and boot mode
- Configurable Anti-DPA

34.3 Module Structure

The External Memory Encryption and Decryption module consists of three blocks, namely the Manual Encryption block, Auto Encryption block, and Auto Decryption block. The module architecture is shown in Figure 34.3-1.

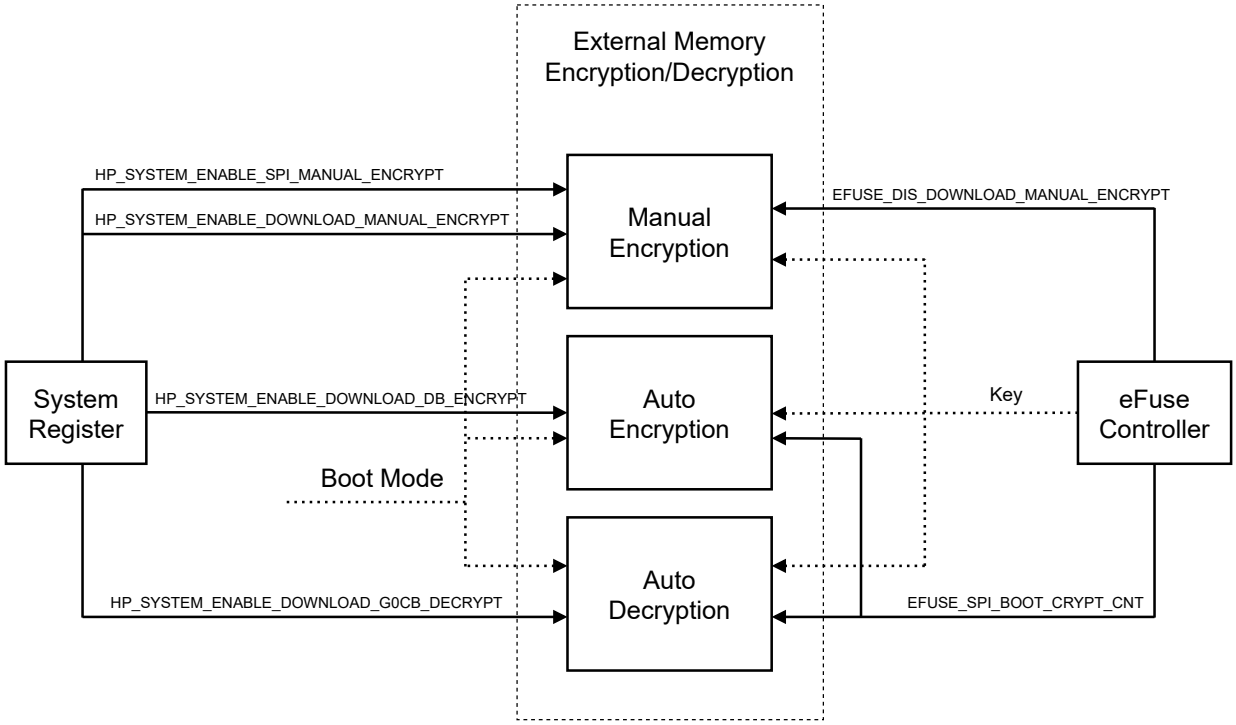


Figure 34.3-1. Architecture of the External Memory Encryption and Decryption

The Manual Encryption block can encrypt instructions and data, which will then be written to the external flash as ciphertext via SPI1.

When the CPU writes data to the external RAM through cache, the Auto Encryption block will automatically encrypt the data first, then the data will be written to the external RAM as ciphertext.

When the CPU reads from the external flash or external RAM through cache, the Auto Decryption block will automatically decrypt the ciphertext to retrieve instructions and data.

In the System Registers peripheral (see *21 System Registers (SYSREG)*), the following four bits in register HP_SYSTEM_CRYPTO_CTRL_REG are relevant to the external memory encryption and decryption:

- HP_SYSTEM_ENABLE_DOWNLOAD_MANUAL_ENCRYPT
- HP_SYSTEM_ENABLE_DOWNLOAD_G0CB_DECRYPT
- HP_SYSTEM_ENABLE_DOWNLOAD_DB_ENCRYPT
- HP_SYSTEM_ENABLE_SPI_MANUAL_ENCRYPT

The XTS_AES module also fetches two parameters from the peripheral eFuse Controller, which are: EFUSE_DIS_DOWNLOAD_MANUAL_ENCRYPT and EFUSE_SPI_BOOT_CRYPT_CNT. For detailed information, please see Chapter 9.4 *eFuse Controller (EFUSE)*.

34.4 Functional Description

34.4.1 XTS Algorithm

The manual encryption and auto encryption/decryption all use the same algorithm. During implementation, the XTS algorithm is characterized by a "data unit" of 1024 bits, defined in the Section *XTS-AES encryption procedure* of
XTS-AES Tweakable Block Cipher Standard. For more information about the XTS-AES algorithm, please refer to IEEE Std 1619-2007.

34.4.2 Key

The Manual Encryption block, Auto Encryption block, and Auto Decryption block share the same Key when implementing the XTS algorithm. The Key is provided by the eFuse hardware or the Key Manager and cannot be accessed by users.

The Key can be either 256-bit or 512-bit long. The value and length of the Key are determined by the content in the eFuse blocks from Block4 ~ Block9 and corresponding eFuse parameters. For easier description, we define:

- Block$_A$: the block whose key purpose is EFUSE_KEY_PURPOSE_XTS_AES_256_KEY_1 (please refer to Table 9.4-2 *Secure Key Purpose Values*). If Block$_A$ exists, a 256-bit Key_A is stored in it.
- Block$_B$: the block whose key purpose is EFUSE_KEY_PURPOSE_XTS_AES_256_KEY_2 (please refer to Table 9.4-2 *Secure Key Purpose Values*). If Block$_B$ exists, a 256-bit Key_B is stored in it.
- Block$_C$: the block whose key purpose is EFUSE_KEY_PURPOSE_XTS_AES_128_KEY (please refer to Table 9.4-2 *Secure Key Purpose Values*). If Block$_C$ exists, a 256-bit Key_C is stored in it.

There are five possibilities of how the Key is generated depending on whether Block$_A$, Block$_B$, and Block$_C$ exist or not, as shown in Table 34.4-1. In each case, the Key can be uniquely determined by Block$_A$, Block$_B$ or Block$_C$.

Table 34.4-1. Key generated based on Key_A, Key_B, and Key_C

Block$_A$	Block$_B$	Block$_C$	Key	Key Length (bit)
Yes	Yes	Don't care	$Key_A \| \| Key_B$	512
Yes	No	Don't care	$Key_A \| \| 0^{256}$	512
No	Yes	Don't care	$0^{256} \| \| Key_B$	512
No	No	Yes	Key_C	256
No	No	No	0^{256}	256

Notes:

- "YES" indicates that the block exists
- "NO" indicates that the block does not exist
- "0^{256}" indicates a bit string that consists of 256-bit zeros
- "||" is a bonding operator for joining one-bit string to another

For more information on key purposes, please refer to Table 9.4-2 *Secure Key Purpose Values* in Chapter 9.4 *eFuse Controller (EFUSE)*.

34.4.3 Target Memory Space

The target memory space refers to a continuous address space in the external memory where the first encrypted ciphertext is stored. The target memory space can be uniquely determined by three relevant parameters: type, size, and base address, whose definitions are listed below.

- Type: the $type$ of the target memory space, either external flash or external RAM. Value 0 indicates external flash, while 1 indicates external RAM.
- Size: the $size$ of the target memory space, indicating the number of bytes encrypted in one encryption operation, which supports 16, 32, or 64 bytes.
- Base address: the $base_addr$ of the target memory space. It is a 30-bit physical address, with a range of 0x0000_0000 ~ 0x3FFF_FFFF. It should be aligned to $size$, i.e., $base_addr\%size == 0$.

For example, if there are 16 bytes of instruction data that need to be encrypted and written to address 0x130 ~ 0x13F in the external flash, then the target space is 0x130 ~ 0x13F, type is 0 (external flash), size is 16 (bytes), and the base address is 0x130.

The encryption of any length (must be multiples of 16 bytes) of plaintext instruction/data can be completed separately in multiple operations, and each operation has individual target memory space and relevant parameters.

For Auto Encryption/Decryption blocks, these parameters are automatically defined by hardware. For the Manual Encryption block, these parameters should be configured manually by users.

Note:

The "tweak" defined in Chapter *5.1 Data units and tweaks* of IEEE Std 1619-2007 is a 128-bit non-negative integer ($tweak$), which can be generated according to $tweak$ = $type * 2^{30}$ + ($base_addr$ & 0x3FFFFF80). The lowest 7 bits and the highest 97 bits in $tweak$ are always zero.

34.4.4 Data Writing

For Auto Encryption/Decryption blocks, data writing is automatically applied in hardware. For Manual Encryption blocks, data writing should be applied by users. The Manual Encryption block has a register block which consists of 16 registers, i.e., XTS_AES_PLAIN_*n*_REG (*n*: 0 ~ 15), that are dedicated to data writing and can store up to 512 bits of plaintext at a time.

Actually, the Manual Encryption block does not care where the plaintext comes from, but only where the ciphertext will be stored. Because of the strict correspondence between plaintext and ciphertext, in order to better describe how the plaintext is stored in the register block, we assume that the plaintext is stored in the target memory space in the first place and replaced by ciphertext after encryption. Therefore, the following description in this section no longer has the concept of "plaintext", but uses "target memory space" instead.

How mapping between target memory space and registers works:

Assume a word in the target memory space is stored in $address$, define $offset$ = $address\%64$, n = $offset/4$, then the word will be stored in register XTS_AES_PLAIN_n_REG.

For example, when the $size$ is 64, all registers in the register block will be used. The mapping between $offset$ and registers now is shown in Table 34.4-2.

Table 34.4-2. Mapping Between Offsets and Registers

offset	Register	*offset*	Register
0x00	XTS_AES_PLAIN_0_REG	0x20	XTS_AES_PLAIN_8_REG
0x04	XTS_AES_PLAIN_1_REG	0x24	XTS_AES_PLAIN_9_REG
0x08	XTS_AES_PLAIN_2_REG	0x28	XTS_AES_PLAIN_10_REG
0x0C	XTS_AES_PLAIN_3_REG	0x2C	XTS_AES_PLAIN_11_REG
0x10	XTS_AES_PLAIN_4_REG	0x30	XTS_AES_PLAIN_12_REG
0x14	XTS_AES_PLAIN_5_REG	0x34	XTS_AES_PLAIN_13_REG
0x18	XTS_AES_PLAIN_6_REG	0x38	XTS_AES_PLAIN_14_REG
0x1C	XTS_AES_PLAIN_7_REG	0x3C	XTS_AES_PLAIN_15_REG

34.4.5 Manual Encryption Block

The Manual Encryption block is a peripheral module. It is equipped with registers and can be accessed by the CPU directly. Registers embedded in this block, the System Registers peripheral, eFuse parameters, and boot mode jointly configure and use this module. Please note that the Manual Encryption block can only encrypt for storage in the external flash.

The Manual Encryption block is operational only under certain conditions:

- In SPI Boot mode:

  If bit HP_SYSTEM_ENABLE_SPI_MANUAL_ENCRYPT in register HP_SYSTEM_CRYPTO_CTRL_REG is 1, the Manual Encryption block can be enabled. Otherwise, it is not operational.

- In Joint Download Boot mode:

  If bit HP_SYSTEM_ENABLE_DOWNLOAD_MANUAL_ENCRYPT in register HP_SYSTEM_CRYPTO_CTRL_REG is 1 and the eFuse parameter EFUSE_DIS_DOWNLOAD_MANUAL_ENCRYPT is 0, the Manual Encryption block can be enabled. Otherwise, it is not operational.

Note:

Even though the CPU can skip cache and get the encrypted instruction/data directly by reading the external memory, users can by no means access Key.

34.4.6 Auto Encryption Block

The Auto Encryption block is not a conventional peripheral, so it does not have any registers and cannot be accessed by the CPU directly. The System Registers peripheral, eFuse parameters, and boot mode jointly configure and use this block.

The Auto Encryption block is operational only under certain conditions:

- In SPI Boot mode:

  when EFUSE_SPI_BOOT_CRYPT_CNT (3 bits) is set to 1, 2, 4 or 7 (i.e., there is an odd number of 1s in its binary representation), then the Auto Encryption block can be enabled. Otherwise, it is not operational.

- In Joint Download Boot mode:

  when bit HP_SYSTEM_ENABLE_DOWNLOAD_DB_ENCRYPT in register HP_SYSTEM_CRYPTO_CTRL_REG is 1, the Auto Encryption block can be enabled. Otherwise, it is not operational.

Note:

- When the Auto Encryption block is enabled, it will automatically encrypt data if the CPU writes data to the external RAM, and then the encrypted ciphertext will be written to the external RAM. The entire encryption process does not need software participation and is transparent to the cache. Users can by no means obtain the encryption Key during the process.
- When the Auto Encryption block is disabled, it will ignore the CPU's access request to the cache and not process the data. Therefore, the data will be written to the external RAM as plaintext directly.

34.4.7 Auto Decryption Block

The Auto Decryption block is not a conventional peripheral, so it does not have any registers and cannot be accessed by the CPU directly. The System Registers peripheral, eFuse parameters, and boot mode jointly configure and use this block.

The Auto Decryption block is operational only under certain conditions:

- In SPI Boot mode:

  when EFUSE_SPI_BOOT_CRYPT_CNT (3 bits in total) is set to 1, 2,4 or 7 (i.e., there is an odd number of 1s in its binary representation), then the Auto Decryption block can be enabled. Otherwise, it is not operational.

- In Joint Download Boot mode:

  when bit HP_SYSTEM_ENABLE_DOWNLOAD_GOCB_DECRYPT in register HP_SYSTEM_CRYPTO_CTRL_REG is 1, the Auto Decryption block can be enabled. Otherwise, it is not operational.

Note:

- When the Auto Decryption block is enabled, it will automatically decrypt the ciphertext if the CPU reads instructions/data from the external memory via cache to retrieve the instructions/data. The entire decryption process does not need software participation and is transparent to the cache. The software can by no means obtain the decryption Key during the process.
- When the Auto Decryption block is disabled, it does not have any effect on the contents stored in the external memory, no matter if they are encrypted or not. Therefore, what the CPU reads via cache is the original information stored in the external memory.

34.5 Software Process

When the Manual Encryption block operates, software needs to be involved in the process. The steps are as follows:

1. Configure XTS_AES:
   - Set register XTS_AES_DESTINATION_REG to $type$ = 0.
   - Set register XTS_AES_PHYSICAL_ADDRESS_REG to $base_addr$.
   - Set register XTS_AES_LINESIZE_REG to $\frac{size}{32}$.

   For definitions of $base_addr$ and $size$, please refer to Section 34.4.3.
2. Write plaintext instructions/data to the registers block XTS_AES_PLAIN_*n*_REG (*n*: 0-15). For detailed information, please refer to Section 34.4.4.
   Please write data to registers according to your actual needs, and the unused ones could be set to arbitrary values.
3. Wait for Manual Encryption block to be idle. Poll register XTS_AES_STATE_REG until it reads 0 which indicates the Manual Encryption block is idle.
4. Trigger manual encryption by writing 1 to register XTS_AES_TRIGGER_REG.
5. Wait for the encryption process completion. Poll register XTS_AES_STATE_REG until it reads 2.
   Step 1 to 5 are the steps of encrypting plaintext instructions/data with the Manual Encryption block using the Key.
6. Write 1 to register XTS_AES_RELEASE_REG to grant SPI1 the access to the encrypted ciphertext. After this, the value of register XTS_AES_STATE_REG will become 3.
7. Call SPI1 to write the ciphertext in the external flash (see Section API Reference - Flash Encrypt in ESP-IDF Programming Guide).
8. Write 1 to register XTS_AES_DESTROY_REG to destroy the ciphertext. After this, the value of register XTS_AES_STATE_REG will become 0.

Repeat the above steps according to the amount of plaintext instructions/data that need to be encrypted.

34.6 Anti-DPA

DPA (Differential Power Analysis) is a side-channel attack method in cryptography, through which an attacker can statistically analyze data collected from multiple encryption operations to calculate intermediate values in the encryption computation. ESP32-P4 XTS_AES supports Anti-DPA to defend against external DPA attacks.
The XTS-AES algorithm can be divided into two steps, according to IEEE Std 1619-2007:

- Step 1: Calculating T value. In this section, we define this step as "calculating T".
- Step 2: Calculating Cipher/Plain text. In this section, we define this step as "calculating D".

Different security levels can be configured through registers:

- First we define the below parameters for a better description:
  - $select_reg$ = XTS_AES_CRYPT_DPA_SELECT_REGISTER
  - $reg_d_dpa_en$ = XTS_AES_CRYPT_CALC_D_DPA_EN
  - $efuse_dpa_en$ = EFUSE_CRYPT_DPA_ENABLE

  - $reg_anti_dpa_level =$ XTS_AES_CRYPT_SECURITY_LEVEL
  - $efuse_anti_dpa_level = 3$

- Configure the security level of Anti-DPA for the XTS_AES module:

$$Anti_DPA_level = select_reg\ ?\ (reg_anti_dpa_level) : (efuse_dpa_en * efuse_anti_dpa_level)$$

  When $Anti_DPA_level$ equals 0, Anti-DPA is disabled. The higher the value of $Anti_DPA_level$ is, the stronger the Anti-DPA ability is.

- Configure whether to enable Anti-DPA when the XTS-AES algorithm is calculating D:

$$Anti_DPA_enabled_in_calc_D = select_reg\ ?\ reg_d_dpa_en : efuse_dpa_en$$

  If $Anti_DPA_level$ is not 0, when $Anti_DPA_enabled_in_calc_D$ equals to 1, Anti-DPA is enabled when XTS-AES algorithm is calculating D.
  If $Anti_DPA_level$ is not 0, Anti-DPA is always enabled when the XTS-AES algorithm is calculating T.

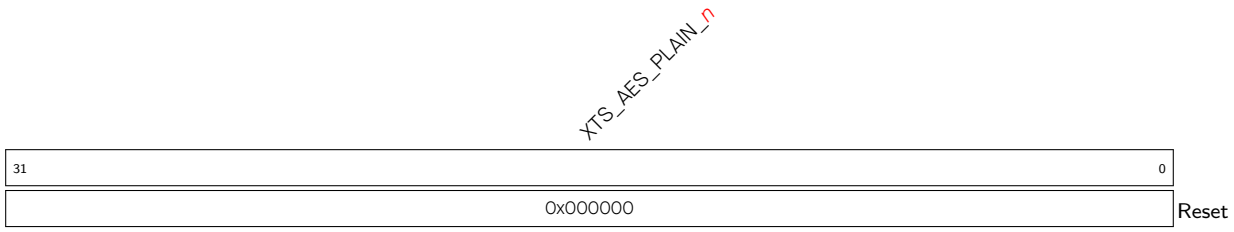
Note:

- Even if efuse_dpa_en is set to 1, you can still disable anti-DPA by configuring $select_reg$ = 1 and $reg_anti_dpa_level$ = 0.
- Configuring whether or not to enable Anti-DPA will have an impact on the external storage access bandwidth:
  - When Anti-DPA is enabled during the calculation of D, the read and write bandwidth will be reduced by more than 50% when the Anti-DPA level >= 4.
  - When Anti-DPA is disabled during the calculation of D, the read and write bandwidth will be reduced by more than 50% when the Anti-DPA level >= 6.

34.7 Register Summary

The addresses in this section are relative to the External Memory Encryption and Decryption base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

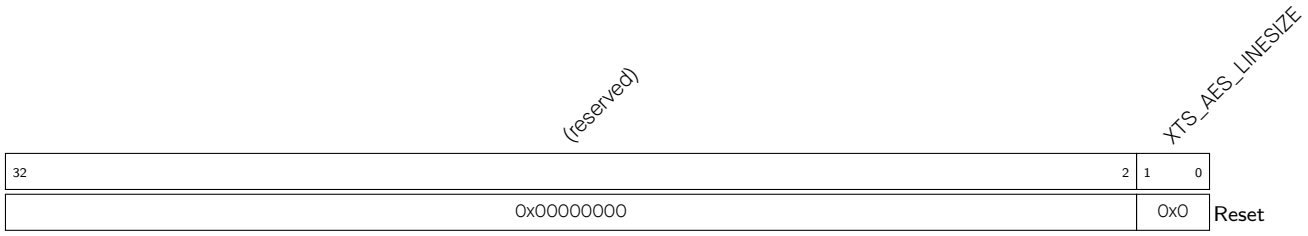
The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Plaintext Register Heap			
XTS_AES_PLAIN_0_REG	Plaintext register 0	0x0300	R/W
XTS_AES_PLAIN_1_REG	Plaintext register 1	0x0304	R/W
XTS_AES_PLAIN_2_REG	Plaintext register 2	0x0308	R/W
XTS_AES_PLAIN_3_REG	Plaintext register 3	0x030C	R/W
XTS_AES_PLAIN_4_REG	Plaintext register 4	0x0310	R/W
XTS_AES_PLAIN_5_REG	Plaintext register 5	0x0314	R/W
XTS_AES_PLAIN_6_REG	Plaintext register 6	0x0318	R/W
XTS_AES_PLAIN_7_REG	Plaintext register 7	0x031C	R/W
XTS_AES_PLAIN_8_REG	Plaintext register 8	0x0320	R/W
XTS_AES_PLAIN_9_REG	Plaintext register 9	0x0324	R/W
XTS_AES_PLAIN_10_REG	Plaintext register 10	0x0328	R/W
XTS_AES_PLAIN_11_REG	Plaintext register 11	0x032C	R/W
XTS_AES_PLAIN_12_REG	Plaintext register 12	0x0330	R/W
XTS_AES_PLAIN_13_REG	Plaintext register 13	0x0334	R/W
XTS_AES_PLAIN_14_REG	Plaintext register 14	0x0338	R/W
XTS_AES_PLAIN_15_REG	Plaintext register 15	0x033C	R/W
Configuration Registers			
XTS_AES_LINESIZE_REG	Configures the size of target memory space	0x0340	R/W
XTS_AES_DESTINATION_REG	Configures the type of the external memory	0x0344	R/W
XTS_AES_PHYSICAL_ADDRESS_REG	Physical address	0x0348	R/W
XTS_AES_DPA_CTRL_REG	Configures the Anti-DPA function	0x0388	R/W
Control/Status Registers			
XTS_AES_TRIGGER_REG	Activates AES algorithm	0x034C	WO
XTS_AES_RELEASE_REG	Release control	0x0350	WO
XTS_AES_DESTROY_REG	Destroy control	0x0354	WO
XTS_AES_STATE_REG	Status register	0x0358	RO
Version Register			
XTS_AES_DATE_REG	Version control register	0x035C	R/W

34.8 Registers

The addresses in this section are relative to the External Memory Encryption and Decryption base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



For how to program reserved fields, please refer to Section Programming Reserved Register Field.

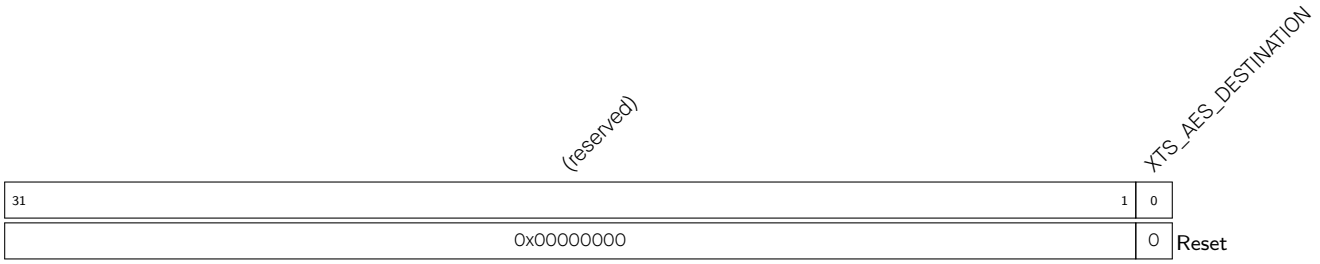
Register 34.1. XTS_AES_PLAIN_*n*_REG (*n*: 0-15) (0x0300+4n*)**

XTS_AES_PLAIN_*n* Configures the *n*th 32-bit piece of plain text. (R/W)

Register 34.2. XTS_AES_LINESIZE_REG (0x0340)

XTS_AES_LINESIZE Configures the data size of one encryption operation.

0: 16 bytes



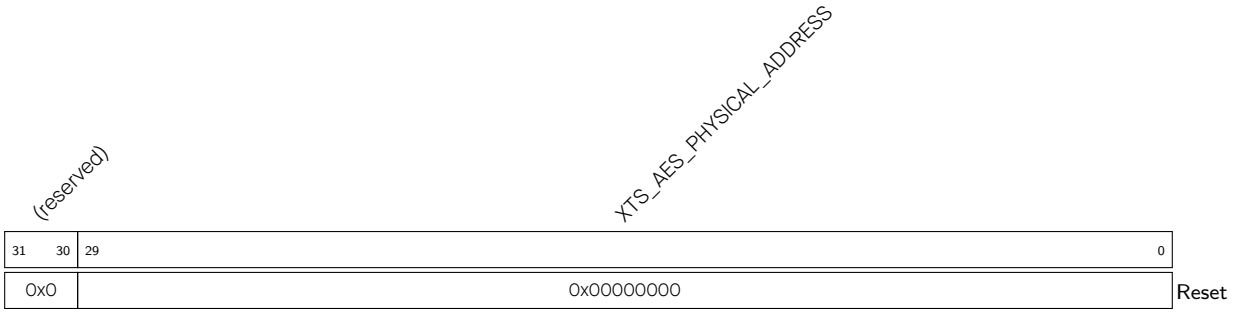
1: 32 bytes

2: 64 bytes

3: Invalid

(R/W)

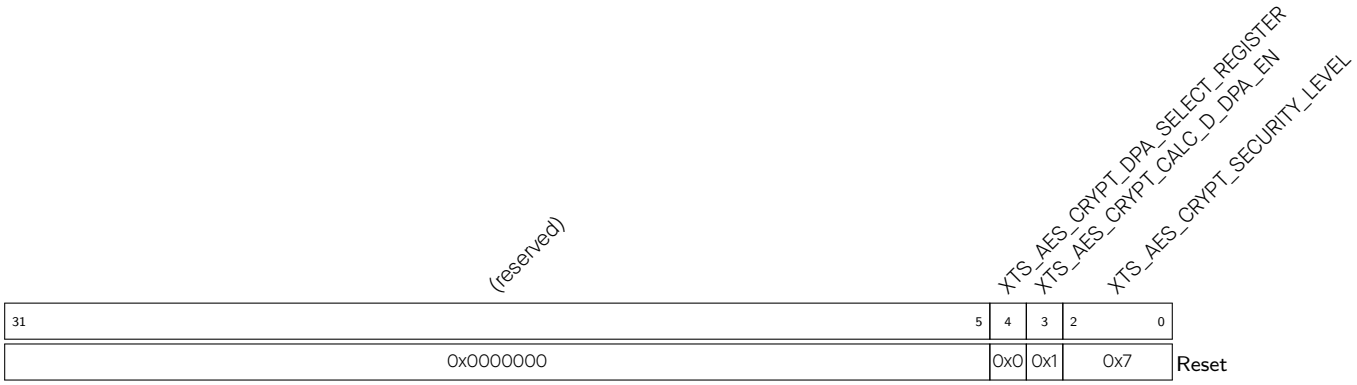
Register 34.3. XTS_AES_DESTINATION_REG (0x0344)



XTS_AES_DESTINATION Configures the type of external memory for Manual Encryption. Currently, it must be set to 0, as the Manual Encryption block only supports flash encryption. Set this bit to 1 may cause an error.

0: flash

1: external RAM



(R/W)

Register 34.4. XTS_AES_PHYSICAL_ADDRESS_REG (0x0348)

XTS_AES_PHYSICAL_ADDRESS Configures physical address. Note that its value should be within the range between 0x0000_0000 and 0x00FF_FFFF. (R/W)

Register 34.5. XTS_AES_DPA_CTRL_REG (0x0388)

XTS_AES_CRYPT_DPA_SELECT_REGISTER Configures whether the Anti-DPA function is controlled by eFuse or register.

0: The Anti-DPA function is configured by register.

1: The Anti-DPA function is configured by eFuse.

(R/W)

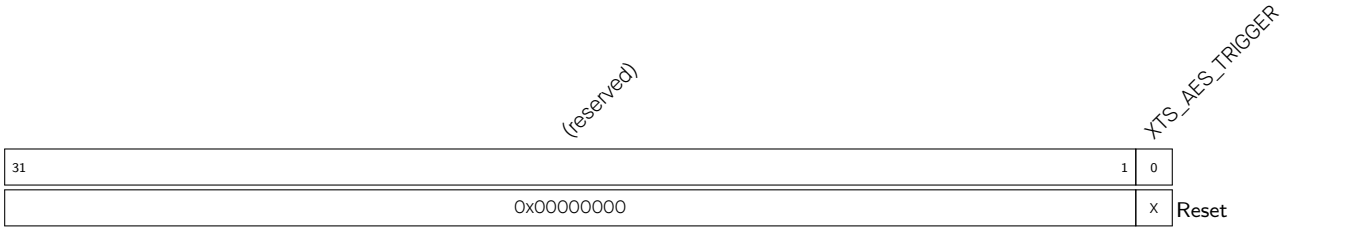
XTS_AES_CRYPT_CALC_D_DPA_EN Configures whether to enable Anti-DPA in the XTS_AES algorithm.

0: Enable Anti-DPA only when calculating T

1: Enable Anti-DPA both when calculating T and D

Note that this field is only effective when XTS_AES_CRYPT_SECURITY_LEVEL is not 0.

(R/W)



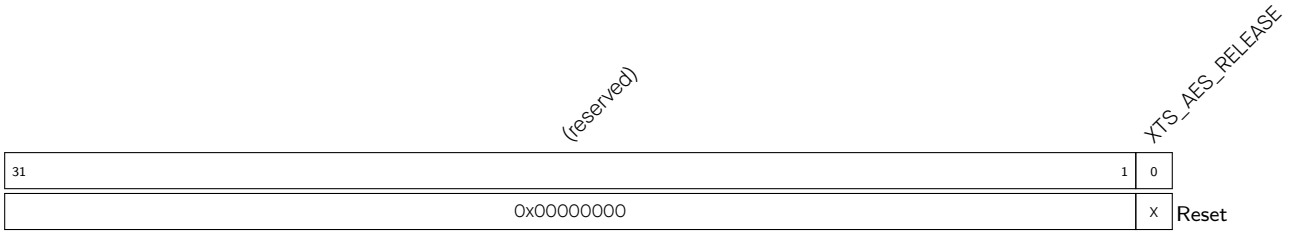
XTS_AES_CRYPT_SECURITY_LEVEL Configures the security level of external memory encryption and decryption.

0: Disable the Anti-DPA function

1-7: The bigger the number is, the more secure the encryption and decryption are

(R/W)

Register 34.6. XTS_AES_TRIGGER_REG (0x034C)



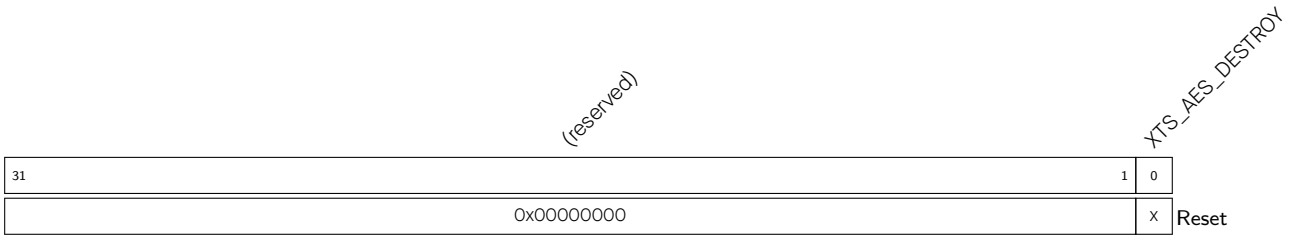
XTS_AES_TRIGGER Configures whether or not to enable manual encryption.

0: Disable manual encryption

1: Enable manual encryption

(WO)

Register 34.7. XTS_AES_RELEASE_REG (0x0350)



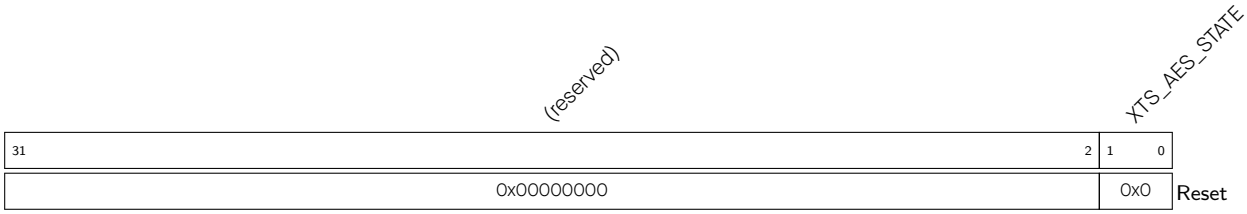
XTS_AES_RELEASE Configures whether to grant SPI1 access to the encrypted result.

0: No effect

1: Grant SPI1 access

(WO)

Register 34.8. XTS_AES_DESTROY_REG (0x0354)



XTS_AES_DESTROY Configures whether to destroy the encrypted result.

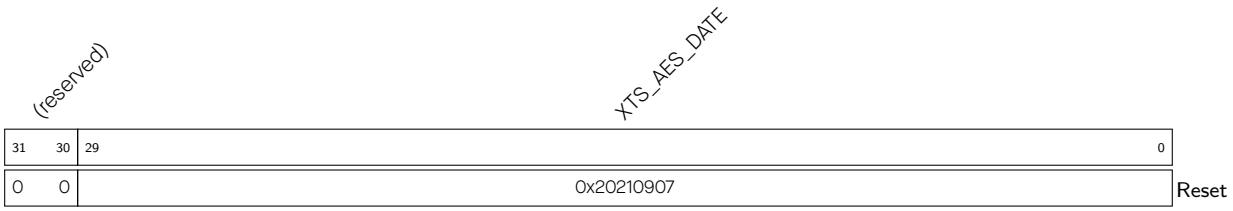
0: No effect

1: Destroy encrypted result

(WO)

Register 34.9. XTS_AES_STATE_REG (0x0358)

XTS_AES_STATE Represents the status of the Manual Encryption block. 0 (XTS_AES_IDLE): Idle



1 (XTS_AES_BUSY): Busy with encryption

2 (XTS_AES_DONE): Encryption completed, but the encrypted result is not accessible to SPI

3 (XTS_AES_RELEASE): Encrypted result is accessible to SPI

(RO)

Register 34.10. XTS_AES_DATE_REG (0x035C)

XTS_AES_DATE Version control register. (R/W)

Chapter 35

Random Number Generator (RNG)

35.1 Introduction

The ESP32-P4 contains a true random number generator, which generates 32-bit random numbers that can be used for cryptographical operations, among other things.

35.2 Feature List

The random number generator in ESP32-P4 generates true random numbers, which means random numbers generated from a physical process, rather than by means of an algorithm. No number generated within the specified range is more or less likely to appear than any other number.

35.3 Functional Description

Every 32-bit value that the system reads from the LPSYSREG_RNG_DATA_REG register of the random number generator is a true random number. These true random numbers are generated based on the system's **thermal noise**, the **asynchronous clock mismatch** and the **BUF_CHAIN**.

- **Thermal noise** comes from the SAR ADC. Whenever the SAR ADC is enabled, bit streams will be generated and fed into the random number generator through an XOR logic gate as random seeds.
- RC_FAST_CLK is an **asynchronous clock** source and it increases the RNG entropy by introducing circuit metastability. Please refer to the Note about the RC_FAST_CLK.
- The count value generated by the **BUF_CHAIN**, implemented using BUF_CELL, is used as a random seed for the random number generator.

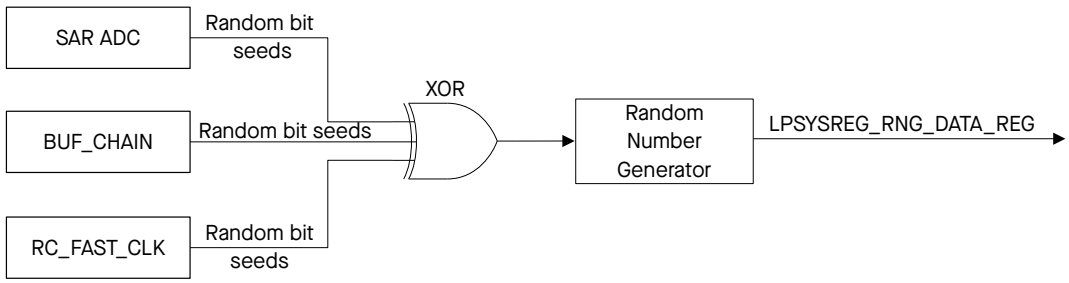


Figure 35.3-1. Noise Source

When there is noise coming from the SAR ADC, the random number generator is fed with a 1-bit entropy in one clock cycle of RC_FAST_CLK, which is generated from an internal RC oscillator (see Chapter 11 *Reset and Clock* for details). Thus, it is advisable to read the LPSYSREG_RNG_DATA_REG register at a maximum rate of 1 MHz to obtain the maximum entropy.

35.4 Programming Procedure

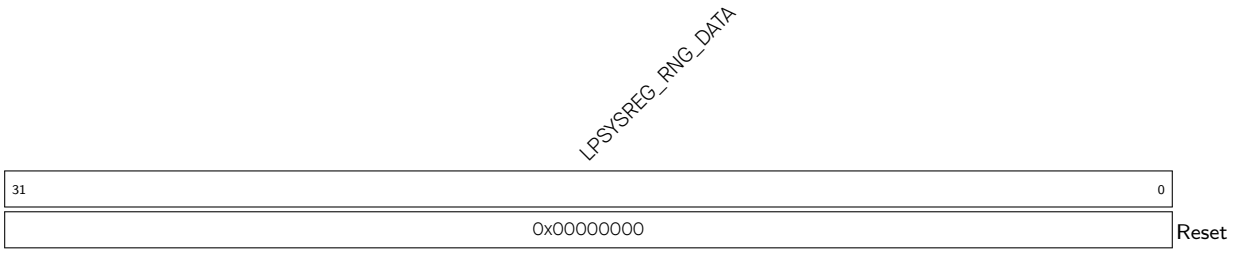
When using the random number generator, make sure at least either the SAR ADC or RC_FAST_CLK is enabled. Otherwise, pseudo-random numbers will be returned.

- For SAR ADC, please refer to Chapter 65 *ADC Controller (ADC)*.
- RC_FAST_CLK is enabled by setting the PMU_HP_SLEEP_XPD_FOSC_CLK bit in the PMU_HP_SLEEP_LP_CK_POWER_REG register. Please refer to the Note about the RC_FAST_CLK.
- RC_FAST_CLK is gated by setting the LPPERI_CK_EN_RNG bit in the LPPERI_CLK_EN_REG register.
- The BUF_CHAIN can be enabled by setting the RNG_CFG_REG register's RNG_SAMPLE_ENABLE bit.

Note:
Enabling RC_FAST_CLK increases the RNG entropy. However, to ensure maximum entropy, it's recommended to always enable an ADC source as well.

When using the random number generator, read the LPSYSREG_RNG_DATA_REG register multiple times until sufficient random numbers have been generated. Ensure the rate at which the register is read does not exceed the frequencies described in section 35.3 above.

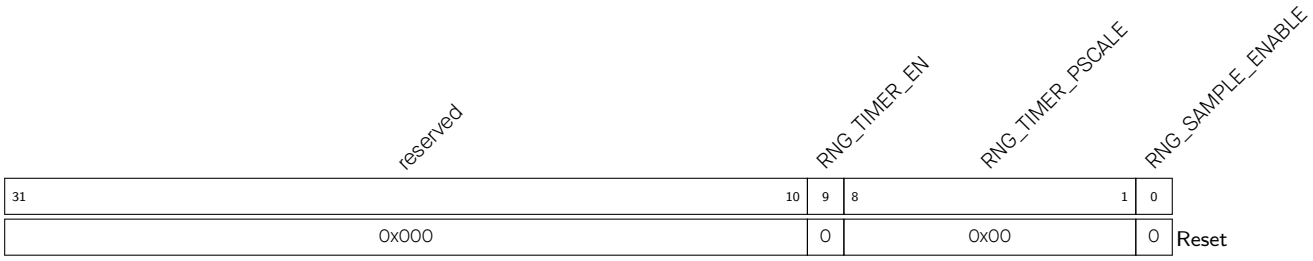
35.5 Register Summary



The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
LPSYSREG_RNG_DATA_REG	Random source data	0x5011_01A4	RO
LPPERI_CLK_EN_REG	Integrated clock gating enable signal of RC_FAST_CLK	0x5012_0000	R/W
RNG_CFG_REG	Configuration register of RNG	0x5012_6000	R/W

35.6 Registers



For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 35.1. LPSYSREG_RNG_DATA_REG (0x5011_01A4)

LPSYSREG_RNG_DATA Random number source. (RO)

Register 35.2. RNG_CFG_REG (0x5012_6000)

RNG_SAMPLE_ENABLE Configures whether to enable the RNG asynchronous clock noise source.

1: Enable

0: Disable

(R/W)

RNG_TIMER_PSCALE Represents the prescale factor of the RNG internal timer.(R/W)

RNG_RTC_TIMER_EN Configures whether to enable the RNG internal timer.

1: Enable and use the counter value of this timer when generating random numbers.

0: Disable the timer.

(R/W)

Chapter 36

Key Manager

36.1 Overview

This Key Management module is the security core of the system. It has a Key Manager and a Hardware Unique Key (HUK) Generator. They can store and deploy keys securely. By utilizing the HUK as the root of trust for each chip, the system ensures that no plaintext keys are ever stored on the chip, enhancing its overall security.

Compared with using eFuse to store keys, the Key Manager and HUK Generator can improve the system in the following ways:

- Environmental adaptability: It supports secure key deployment and can complete key deployment safely, even if the external environment is untrusted.
- Anti-attack ability: Each chip's SRAM has a unique default value that software cannot access. The chip stores no plaintext key. It resists slice and copy attacks. For example, observing the keys in eFuse directly by slicing will fail.
- Key management flexibility: The Key Manager enables users to store key information (non-plaintext) in external memory. Unlike eFuse, which has limitations on the number of keys it can store, Key Manager allows users to create an unlimited number of keys, perform dynamic key changes, key replacements, and etc.

36.2 Background Knowledge

An SRAM PUF (Physical Unclonable Function) uses the natural power-up state of SRAM cells as a kind of silicon "fingerprint." When a chip powers on, each uninitialized SRAM bit tends to fall into 0 or 1 based on tiny manufacturing differences in its transistors, and because those differences are unique for every chip, the resulting bit pattern is device-unique.

We use this behavior to create a Hardware Unique Key (HUK) without ever storing that key anywhere on chip: the chip can regenerate its secret from physics on each boot instead of reading it from flash or fuses. The HUK then acts as the root of trust for secure boot, device identity and attestation, encryption keys, and wrapping other keys.

The raw SRAM PUF bits are not perfectly stable, though: most bits come up the same way on every power cycle, but some are noisy and occasionally flip due to temperature, voltage, or noise. In order to generate a stable HUK, the chip generates auxiliary data (huk_info) with error correction capabilities during the HUK generation stage to recover the HUK. Users need to store this auxiliary data in flash memory.

On every later boot, hardware reads the new (noisy) PUF response, uses the helper data to correct any flipped bits back to the reference pattern, and reconstructs exactly the same HUK as during enrollment. That HUK is

loaded into hidden key slots inside crypto hardware (never into normal RAM), giving the device a repeatable, per-chip unique secret key derived from SRAM PUF, even though the underlying bits are not 100% identical at every power-up.

36.3 Glossary

To better illustrate the functions of the HUK Generator and Key Manager, the following terms and parameters are used in this chapter.

Terms

HUK	Hardware Unique Key (HUK), a hardware-generated key derived from the default power-on value using SRAM PUF.
SRAM PUF	Physical Unclonable Function (PUF), based on SRAM, a security technology that leverages the unique, unpredictable power-up behavior of SRAM to generate a unique fingerprint or cryptographic key for a device.
HUK Generation Mode	In this mode, the HUK Generator creates a new HUK.
HUK Recovery Mode	In this mode, the HUK Generator recovers a previously deployed HUK.
Random Deploy Mode	In this mode, the Key Manager deploys a random private key generated by the Random Number Generator.
AES Deploy Mode	In this mode, the Key Manager deploys a specified private key ($k1$) onto the chip.
ECDH0 Deploy Mode	In this mode, the Key Manager deploys a negotiated private key ($k1 * k2 * G$) onto the chip. $k1 * k2 * G$ is generated using $k1$ and $k2 * G$.
ECDH1 Deploy Mode	In this mode, the Key Manager deploys a negotiated private key ($k1 * k2 * G$) onto the chip. $k1 * k2 * G$ is generated using $k1$, $k2 * G$, and $k2_info$.
Private Key Recovery Mode	In this mode, the Key Manager recovers a previously deployed private key.
key_info **Export Mode**	In this mode, the Key Manager regenerates the key_info. Users can export this key_info from the internal memory of the Key Manager.

Parameters

huk_info	Contains fuzzy extraction information and error-correcting code information after RS coding of HUK, but does not contain any information of HUK itself. This huk_info later can be used to recover the deployed HUK.
key_info	In any working mode of the Key Manager, this key_info is generated by calculating AES{AES{key,rand_num}||rand_num,HUK}.
$AES\{a, b\}$	Encrypt plaintext a with b as the key, using AES_ECB algorithm, which is the typical mode of the AES module.
$rand_num$	A random number
$a\|\|b$	Concatenates two pieces of data into one.
$k1$	A specified private key

$k2$	Auxiliary key used to assist with key deployment, applicable in both AES Deploy Mode and ECDH1 Deploy Mode. In AES Deployment Mode, its value does not affect the deployed key. In ECDH1 deployment mode, its value affects the negotiated deployment key.
$k1_encrypted$	A key generated by encrypting $k1$ with $k2$. In AES Deploy Mode or ECDH1 Deploy Mode: $k1_encrypted$ = AES{k1,k2}
$k2_info$	The recovery information of $k2$. In AES Deploy Mode or ECDH1 Deploy Mode: $k2_info$ = AES{AES{k2,rand_num}||rand_num,init_key}.
$init_key$	Used in the generation of $k2_info$ as well as in the recovery process from $k2_info$ to $k2$. Its value can be stored in the eFuse block whose purpose is EFUSE_KM_INIT_KEY or provided through software configuration.
sw_init_key	Software configured $init_key$
$k1 * k2 * G$	A negotiated key generated by calculating $k2 * G$ through ECC.
$k1 * G$	A key generated by calculating $k1$ through ECC.
$k2 * G$	An auxiliary public key generated by calculating $k2 * G$ through ECC. This key is used later to generate $k1 * k2 * G$.
$key_purpose$	The intended usage of the key.

36.4 Features

The HUK Generator has the following features:

- HUK Generation Mode:
  - Generates a new HUK and its recovery information
- HUK Recovery Mode:
  - Recovers a deployed HUK with its recovery information
- Prompt for HUK recovery error
- Prompt for HUK risk level

The Key Manager has the following features:

- Unlimited number of keys
- Specified private key deployment (AES Deploy Mode):
  - Users specify the value of the key
- Negotiated private key deployment (ECDH0 Deploy Mode):
  - Highest security mode: there is no need to worry about the leaks of data in external channels
  - Requires chip initiation to obtain the private key
  - Negotiates the key value between each chip and the user
- Negotiated private key deployment (ECDH1 Deploy Mode):

  - Deploy the negotiated private key using the auxiliary key
  - No need to boot the chip to obtain the private key
- Random key deployment (Random Deploy Mode):
  - Deploys a hardware-generated random key with nobody knowing the exact value
- Private key recovery deployment (Private Key Recovery Mode):
  - Recovers exactly the same key by entering the key information generated during deployment
- Key information export (key_info Export Mode):
  - Generates unique key information for the same key each time

36.5 Architectural Overview

The top-level architecture of the Key Manager and HUK Generator is shown in the figure below.

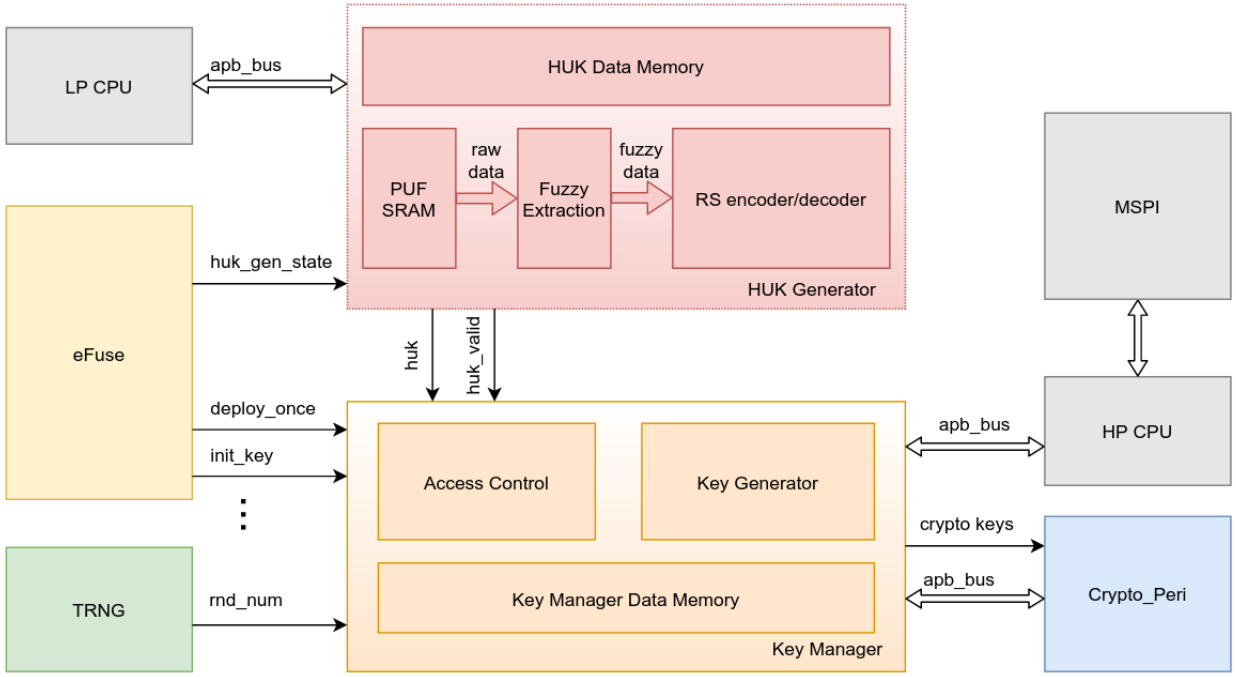


Figure 36.5-1. Architecture of Key Manager and HUK Generator

The Key Manager has the following interaction paths with external modules:

- **eFuse path:** Controls the configuration of Key Manager with the help of eFuse bits.
- **HP APB path:** Configures registers and transmits memory data via HP APB bus.
- **HUK path:** Receives HUK from HUK Generator.
- **Crypto path:** Controls cryptographic accelerators such as ECC/AES to complete cryptographic operations via Crypto APB bus.
- **TRNG path:** Receives true random data from the TRNG.

The HUK Generator has the following interaction paths with external modules.

- **eFuse path:** Controls the configuration of HUK Generator with the help of eFuse bits.
- **LP APB path:** Configures registers and transmits memory data via LP APB bus.
- **Key Manager path:** Sends HUK to Key Manager.

36.6 Functional Description

36.6.1 HUK Generator

HUK Generator generates unique HUKs for each chip based on SRAM Physical Unclonable Function (PUF). This HUK is completely inaccessible by software, ensuring robust security for the Key Manager, which relies on this HUK for secure operations later on.

36.6.1.1 HUK Generation Process

The HUK Generator has the following modes:

- **HUK Generation Mode:** Creates a new HUK and generates corresponding HUK recovery information (huk_info).
- **HUK Recovery Mode:** Recovers HUK according to huk_info.

The modes above are jointly controlled by the eFuse field EFUSE_KM_HUK_GEN_STATE, and the register HUK_MODE, as shown in the following table.

Table 36.6-1. HUK Generator Working Mode

HUK_MODE	eFuse *	Mode
1	Total number of bits set to 1 is even	HUK Generation Mode
	Total number of bits set to 1 is odd	HUK Recovery Mode
0	—	HUK Recovery Mode

* Total number of bits set to 1 in EFUSE_KM_HUK_GEN_STATE.

Note:

- Once the process is completed in HUK Generation Mode, it is recommended to write a 1 to EFUSE_KM_HUK_GEN_STATE field, ensuring that the total number of bits set to 1 in EFUSE_KM_HUK_GEN_STATE is an odd number. With this, when the chip starts next time, the HUK Generator can only enter HUK Recovery Mode. The HUK restored in HUK Recovery Mode will be the same as the one generated this time in HUK Generation Mode.
- If you do not update the eFuse bits EFUSE_KM_HUK_GEN_STATE field after completing the HUK Generation Mode and before powering off the chip, the HUK Generator can still be configured to enter HUK Generation Mode again when the chip is powered on next time. The newly generated HUK this time will have a different value from the previous one that is used in private keys. By this way, you can generate multiple HUKs and restore the one you need with its huk_info.
- huk_info can only be used with the same chip; that is, an huk_info generated on chip A can not be used to recover the HUK on chip B.

36.6.1.2 HUK Status Check

Users can read the register HUK_STATUS_REG to check the current status of the HUK and decide whether to regenerate the HUK. HUK_STATUS_REG has the following fields:

- HUK_STATUS: Indicates the current status of the HUK.
  - 0: The HUK has not been generated
  - 1: The HUK has been successfully generated and is valid
  - 2: The HUK has been generated but is invalid
  - 3: Reserved
- HUK_RISK_LEVEL: Indicates the current risk level of the HUK. The value ranges from 0 to 7, with higher values indicating greater risk. When the value is 7, the HUK is no longer available. At this point, the HUK_STATUS will be set to 2.

Note:

- HUK Generator uses the default value of SRAM PUF to generate HUK. The HUK risk level refers to the difference between the current default value of SRAM PUF and the default value of SRAM PUF at the time when the HUK was created.
- In certain special applications, such as when users want to discard a key and invalidate the corresponding key_info, they can select to update the HUK. Once the HUK is changed, the previously deployed key, as well as its key_info, both become invalid, i.e., the new huk_info together with the previous key_info can not be used to recover the key.
- It is strongly recommended that software monitor the risk level and regenerate the HUK at the value 4-6.

36.6.2 Key Manager

Note:
Each time before using the Key Manager for key deployment, please ensure that the HUK is valid by checking the register HUK_STATUS_REG.

Key Manager provides the following modes:

- **Key Deployment Modes:**
  - Random Deploy Mode: Deploys a random private key.
  - AES Deploy Mode: Deploys a specified private key.
  - ECDH0 Deploy Mode: Deploys a negotiated private key.
  - ECDH1 Deploy Mode: Deploys a negotiated private key.

  These four deployment modes allow users to select the most convenient deployment process in environments with different security levels according to their own needs.
- **Key Recovery Mode:**
  - Private Key Recovery Mode: Recovers the deployed private key.

This recovery mode allows users to freely select the key they want to recover from any number of the deployed keys.

- **Export Mode:**
  - key_info Export Mode: Generates and outputs key_info of the deployed private key.

  This export mode allows users to regenerate key_info for already deployed keys.

36.6.2.1 Random Deploy Mode

Users can use this mode to deploy a random key generated with the help of the Random Number Generator.

Note:
The Random Deploy Mode is highly convenient and well-suited for application scenarios where the exact value of the private key does not need to be known.

36.6.2.2 AES Deploy Mode

Users can use this mode to deploy a specified private key.

This mode requires the following keys and parameters:

- HUK: generated by the HUK Generator and passed to the Key Manager.
- $k1$: the specified private key to be deployed.
- $k2$: Auxiliary key used to encrypt $k1$, ensuring that $k1$ is not transmitted in plaintext over the communication link, thereby enhancing data security.
- $init_key$: Initial auxiliary key used for generating and decrypting the $k2_info$ key.
- $k2_info$: Generated from $k2$ and $init_key$, and used to recover $k2$. The calculation formula is: $k2_info = AES\{AES\{k2, rand_num\}||rand_num, init_key\}$.

The deployment flow chart is as follows.

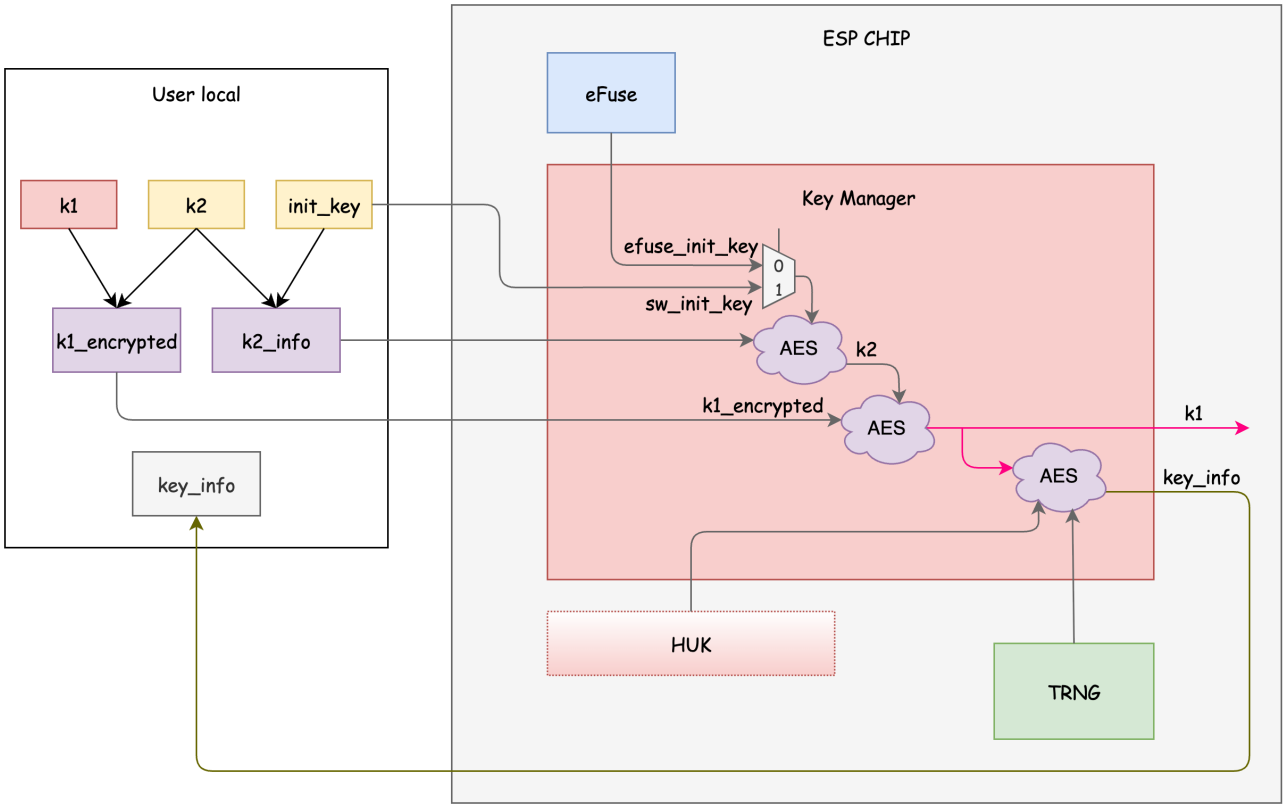

Figure 36.6-1. AES Deploy Mode

Detailed Process

1. Generate locally $k1$, $k2$, and $init_key$.
2. Calculate locally $k1_encrypted$ and $k2_info$.
3. Then complete the key deployment in Key Manager:
   (a) Write $init_key$ into the eFuse block whose purpose is EFUSE_KM_INIT_KEY, or to sw_init_key, depending on your need.
   (b) Write $k2_info$ and $k1_encrypted$ into internal memory of the Key Manager.
   (c) Wait for the Key Manager to complete the deployment.
   (d) Read key_info from the internal memory of the Key Manager by specifying the address.

Notes:

- Due to the necessity of re-deploying the key each time when the chip powers up, if key_info is to be used for key recovery upon the next power-up, ensure that key_info must persist after the chip powers off. A common method is to store it in the flash.
- AES Deploy Mode is suitable for factory production: the manufacturer provides the factory with $init_key$ and the firmware encrypted with $k1$, and store $k2_info$ and $k1_encrypted$ in the firmware.
  - In this case, it is recommended to include a private key first-time deployment process in the firmware, to store key_info. In the subsequent chip power-ups, use the recovery deployment mode, instead of deploying via AES mode each time. This helps effectively defend against eFuse slice attacks.

  - Note that this deployment method requires a trusted factory, as the factory will have access to the plaintext $init_key$ (used to be burned into eFuse key block). If the factory is untrusted and knows how to use $init_key$ to decrypt $k2_info$ into $k2$, it may result in a potential leakage of $k1$.

- When using AES Deploy Mode to deploy the key each time, it is essential to ensure that the values of $init_key$, $k2_info$, and $k1_encrypted$ are not leaked simultaneously.
  - If using $init_key$ stored in the EFUSE_KM_INIT_KEY eFuse block, $k2_info$ and $k1_encrypted$ may be transmitted in an untrusted environment. However, this requires to locally retain the $init_key$ that was written to EFUSE_KM_INIT_KEY eFuse block at the first time.
  - If using sw_init_key, the transmission of sw_init_key, $k2_info$, and $k1_encrypted$ must occur in a trusted environment.

36.6.2.3 ECDH0 Deploy Mode

Users can use this mode to deploy a negotiated private key.

This mode requires the following keys and parameters:

- HUK, generated by the HUK Generator and passed to the Key Manager.
- $k1$: root key, a private key from users.
- $k1 * G$: obtained by calculating $k1 * G$ using ECC.
- $k2 * G$: a public auxiliary key, generated by calculating $k2 * G$ using ECC.
- $k1 * k2 * G$: the negotiated private key to be deployed, generated by Key Manager using $k1 * G$ and $k2$ or by the user locally using $k1$ and $k2 * G$.
- key_info: the recovery information of $k1 * k2 * G$.

Any information disclosure during this deployment, occurring outside the users' local environment or the chip, will not affect the generation of $k1 * k2 * G$ or pose a risk of exposure. The deployment flow chart is as follows.

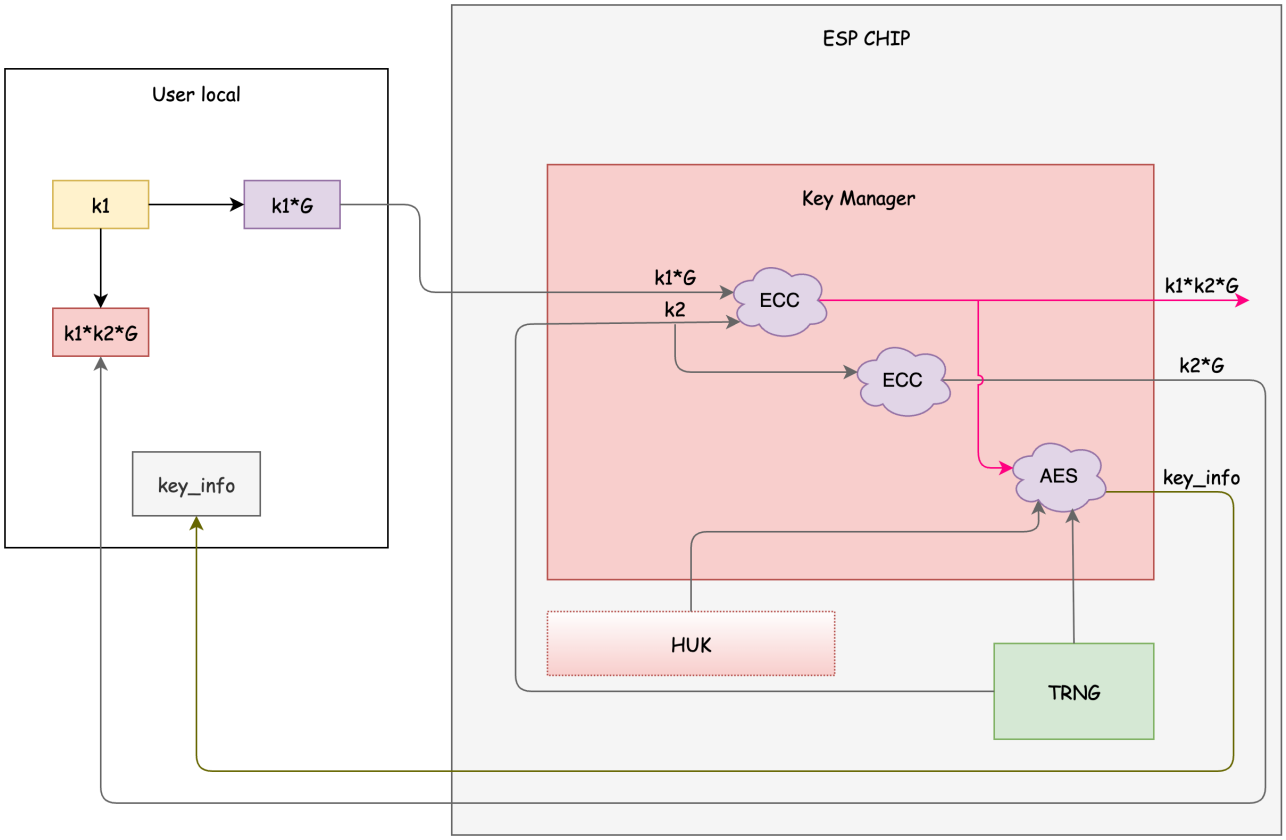

Figure 36.6-2. ECDH0 Deploy Mode

Detailed Process

1. Generate locally $k1$ and calculate $k1 * G$.
2. Complete the key deployment in Key Manager:
   (a) Write $k1 * G$ to the internal memory of the Key Manager.
   (b) Wait for the Key Manager to complete the deployment.
   (c) Read $k2 * G$ and key_info (corresponding to the negotiated private key $k1 * k2 * G$) from the internal memory of the Key Manager by specifying the address.
3. Generate the negotiated key $k1 * k2 * G$ by using $k2 * G$ together with the local private key $k1$.

Note:

- NIST-P256 curve is used in the ECDH0 mode, all the ECC point multiplication is calculated on NIST-P256 curve.
- The ECDH0 Deploy Mode ensures that the negotiated private key is generated only locally by the user and internally by the Key Manager. Any data leakage during the deployment process will not result in the leakage of the negotiated private key. Therefore, data transmission in this mode can occur in an untrusted environment.
- In ECDH0 Deploy Mode, the negotiated private key can only be obtained after running the Key Manager. This mode is not suitable for scenarios where the exact value of the private key needs to be known in advance.

36.6.2.4 ECDH1 Deploy Mode

Users can use this mode to deploy a negotiated private key.

This mode requires the following keys and parameters:

- HUK, generated by the HUK Generator and passed to the Key Manager.
- $k1$: root key, a private key from users.
- $k1 * G$: obtained by calculating $k1$ using ECC.
- $k2$: an auxiliary private key, in ECDH1 Deploy Mode only existing locally or inside Key Manager.
- $k2 * G$: an auxiliary public key, generated by using the chip supplier's software or script.
- $k2_info$: generated by using $k2$ and $init_key$, and used to recover $k2$. The calculation formula is: $k2_info = AES\{AES\{k2, rand_num\}||rand_num, init_key\}$.
- $k1 * k2 * G$: the negotiated private key to be deployed. The chip generates the negotiated private key using $k1 * G$ and $k2_info$, while the user generates the negotiated private key using $k1$ and $k2 * G$.
- key_info: the recovery information of $k1 * k2 * G$.

The deployment flow chart is as follows.

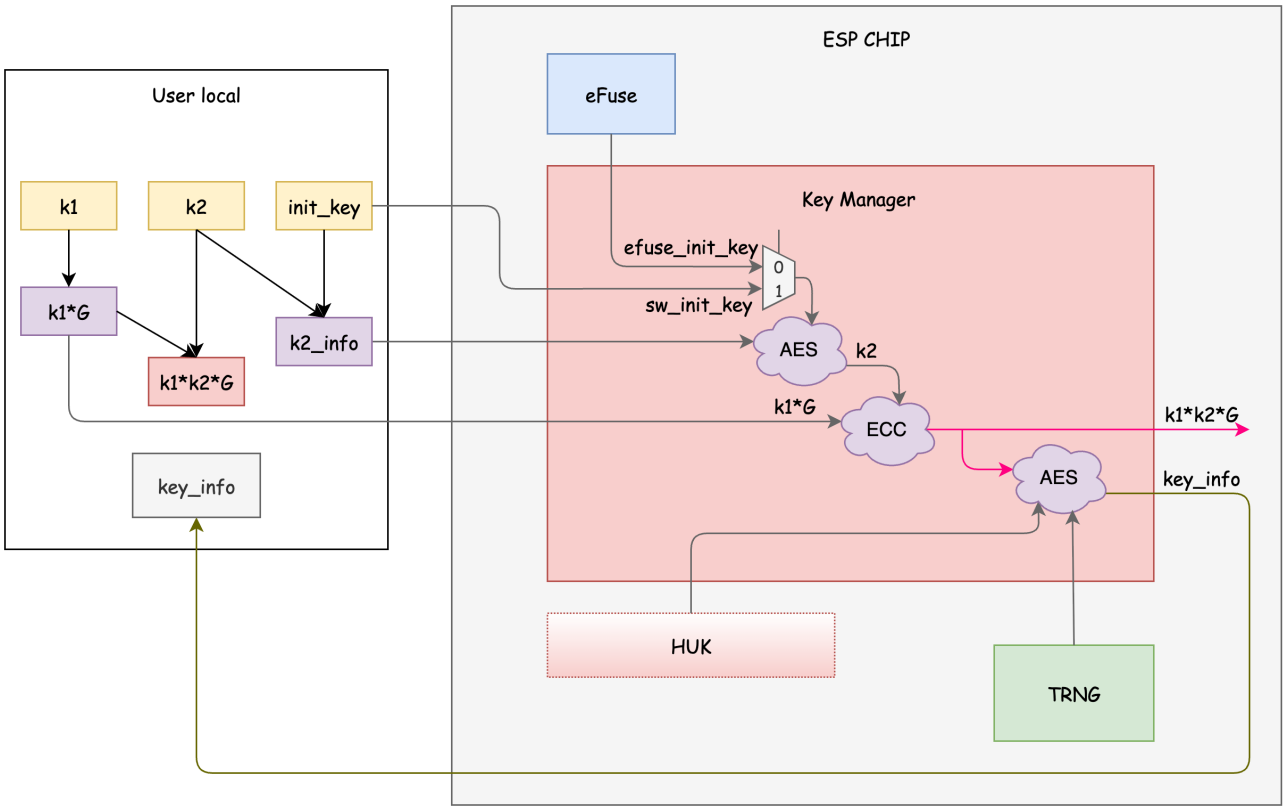

Figure 36.6-3. ECDH1 Deploy Mode

Detailed Process

1. Generate locally $k1$, $k2$ and $init_key$.
2. Calculate locally $k1 * G$, $k2 * G$, $k2_info$, and $k1 * k2 * G$.
3. Complete the key deployment in Key Manager:
   (a) Write $init_key$ into EFUSE_KM_INIT_KEY eFuse block or into sw_init_key, depending on your needs. See the notes below.

(b) Write $k1 * G$ and $k2_info$ to the internal memory of the Key Manager.

(c) Wait for the Key Manager to complete the deployment.

(d) Read $k2 * G$ and key_info (corresponding to the negotiated private key $k1 * k2 * G$) from the internal memory of the Key Manager by specifying the address.

Notes:

- NIST-P256 curve is used in the ECDH1 mode, all the ECC point multiplication is calculated on NIST-P256 curve.
- ECDH1 Deploy Mode is suitable for factory production: the manufacturer provides the factory with $init_key$ and the firmware encrypted with $k1 * k2 * G$, and store $k2_info$ and $k1 * G$ in the firmware.
  - In this case, it is recommended to include a private key first-time deployment process in the firmware, to store key_info. In the subsequent chip power-ups, use the recovery deployment mode, instead of deploying via ECDH1 mode each time. This helps effectively defend against eFuse slice attacks.
  - Note that this deployment method requires a trusted factory, as the factory will have access to the plaintext $init_key$ (used to be burned into eFuse). If the factory is untrusted and knows how to use $init_key$ to decrypt $k2_info$ into $k2$, it may result in a potential leakage of $k1 * k2 * G$.
- Similar to AES Deploy Mode, when using ECDH1 Deploy Mode to deploy the key each time, it is essential to ensure that the values of $init_key$, $k2_info$, and $k1 * G$ are not leaked simultaneously.
  - If using $init_key$ stored in EFUSE_KM_INIT_KEY eFuse block, $k2_info$ and $k1 * G$ may be transmitted in an untrusted environment. However, this requires to locally retain the $init_key$ that was written to EFUSE_KM_INIT_KEY eFuse block at the first time.
  - If using sw_init_key, the transmission of sw_init_key, $k2_info$, and $k1 * G$ must occur in a trusted environment.
- When updating keys using the ECDH1 Deploy Mode, it provides higher security performance compared to the AES Deploy Mode. Since the value of $k1 * G$ is independent of $k2$ and $init_key$, you can update the negotiated key in ECDH1 mode by updating only $k2_info$ without changing k1*G. Users can:
  - Write $k1 * G$ into the firmware in a trusted environment.
  - When updating the key using the ECDH1 Deploy Mode, transmit only $init_key$ and $k2_info$. In this case, users can deploy the key in ECDH1 mode using sw_init_key even in an untrusted environment.

36.6.2.5 Private Key Recovery Mode

After deploying the private key, users can restore it using the key_info generated during deployment. The specific process is as follows.

1. Read the key_info from the external memory and store it to the fixed address in the internal memory of Key Manager.
2. Wait for the Key Manager to complete the deployment.
3. Repeat Step 1 $\sim$ Step 2 above until all required private keys are restored.

Note that if two or more private keys with the same $key_purpose$ are restored, only the last one will take effect. For more information about $key_purpose$, see Section 4.

36.6.2.6 key_info Export Mode

After successfully deploying the private key, users can regenerate key_info and obtain it with the help of this mode.
The specific process is as follows.

1. Select the successfully deployed $key_purpose$ to enter the key_info export mode.
2. Wait for the Key Manager process to complete.
3. Read key_info from the internal memory of the Key Manager.

Note:

- This mode can be used to output different key_info for the same key.
- This mode can also only update HUK without updating the private key. The detailed operation is:
  - Update the HUK using the HUK Generation Mode.
  - Update the key_info through the key_info Export Mode.

  By such way, the chip in the next startup can use the new key_info to restore the same private key under the new HUK.

36.7 Programming Procedures

36.7.1 HUK Generator

The HUK generation process is divided into six phases:

1. **IDLE**: In this phase, users configure the mode and static parameters.
2. **PREP**: In this phase, HUK_STATE is BUSY. The HUK Generator prepares for HUK generation. Users need to wait for this phase to complete. The HUK Generator will automatically proceed to the LOAD phase.
3. **LOAD**: In this phase, users store the HUK information into the internal memory of the HUK Generator based on the selected mode.
4. **PROC**: In this phase, HUK_STATE is BUSY. The HUK Generator performs the HUK generation process. Users need to wait for the phase to complete. The HUK Generator will automatically proceed to the GAIN phase.
5. **GAIN**: In this phase, users read the required HUK information from the internal memory of the HUK Generator based on the selected mode.
6. **POST**: In this phase, HUK_STATE is BUSY. The HUK Generator completes the follow-up tasks for HUK generation. Users need to wait for this phase to complete. The HUK Generator will automatically return to the IDLE phase.

36.7.1.1 IDLE Phase

Users check HUK_STATE to confirm that the HUK Generator is in the IDLE phase. In the IDLE phase, users need to perform the following configurations.

1. **Set the Working Mode:** Configure the working mode of the HUK Generator as specified in Table 36.6-1.
2. **Transition to PREP Phase:** Set HUK_START to complete the IDLE phase and enter the PREP phase.

36.7.1.2 PREP Phase

Users need to wait for the PREP phase to complete. This can be accomplished using one of the following methods:

- **Monitor HUK_STATE:** Continuously check HUK_STATE until it is no longer BUSY.
- **Use Interrupts:** Enable the interrupt HUK_PREP_DONE_INT and handle the completion in the interrupt service routine.

36.7.1.3 LOAD Phase

Users check HUK_STATE to confirm that the HUK Generator is in the LOAD phase. In the LOAD phase, users need to perform the following configurations.

1. **Configure Based on Mode**: Depending on the mode of the HUK Generator, configure as follows:
   - **HUK Generation Mode:** No additional configuration is required.
   - **HUK Recovery Mode:** Write the HUK recovery information (huk_info, 165 words) into HUK_INFO_MEM.

   Note:
   If multiple huk_info have been generated and stored in external memory previously, using any huk_info in the HUK Recovery Mode will restore its corresponding HUK.

2. **Transition to PROC Phase:** Set the bit HUK_CONTINUE to 1 to complete the LOAD phase and enter the PROC phase.

36.7.1.4 PROC Phase

Users need to wait for the PROC phase to complete. This can be done using one of the following methods.

- **Monitor HUK_STATE:** Continuously check HUK_STATE until it is no longer BUSY.
- **Use Interrupts:** Enable the interrupt HUK_PROC_DONE_INT and handle the completion in the interrupt service routine.

36.7.1.5 GAIN Phase

Users check HUK_STATE to confirm that the HUK Generator is in the GAIN phase. In the GAIN phase, users extract the required key information based on the selected mode of the HUK Generator.

1. **Extract Key Information:**

- **HUK Generation Mode:** Read huk_info (165 words) from HUK_INFO_MEM.
- **HUK Recovery Mode:** Update huk_info (165 words), depending on HUK_UPDATE_REQ:
  - 0: Do not need to update huk_info, or read any information.
  - 1: Must update huk_info by reading a new value (165 words) from HUK_INFO_MEM.

2. **Transition to POST Phase:** Set the bit HUK_CONTINUE to complete the GAIN phase and enter the POST phase.

36.7.1.6 POST Phase

Users need to wait for the POST phase to complete. This can be done using one of the following methods.

- **Monitor HUK_STATE:** Continuously check HUK_STATE until it is no longer BUSY.
- **Use Interrupts:** Enable the interrupt HUK_POST_DONE_INT and handle the completion in the interrupt service routine.

36.7.2 Key Manager

The key deployment process of the Key Manager is divided into six phases:

1. **IDLE**: In this phase, users configure the mode, key usage, and static parameters.
2. **PREP**: In this phase, KEYMNG_STATE is BUSY. The Key Manager performs the necessary preparations for key deployment. Users need to wait for this phase to complete. The Key Manager will automatically proceed to the LOAD phase.
3. **LOAD**: In this phase, users store the key information into the internal memory of the Key Manager based on the selected mode.
4. **PROC**: In this phase, KEYMNG_STATE is BUSY. The Key Manager performs the key deployment process. Users need to wait for this phase to complete. The Key Manager will automatically proceed to the GAIN phase.
5. **GAIN**: In this phase, users read the required key information from the internal memory of the Key Manager based on the selected mode.
6. **POST**: In this phase, KEYMNG_STATE is BUSY. The Key Manager completes the follow-up tasks for key deployment. Users need to wait for this phase to complete. The Key Manager will automatically return to the IDLE phase.

36.7.2.1 IDLE Phase

Users check KEYMNG_STATE to confirm that the Key Manager is in the IDLE phase. In the IDLE phase, users need to perform the following configurations.

1. **Complete HUK Generation Process:**
   (a) Select one of the following two processes, depending on whether the HUK has been generated or not:
   - **If HUK has not been generated:** Follow the HUK generation process described in Section 36.7.1.

- **If HUK has already been generated:** Skip this HUK generation process.

(b) **Verify HUK Validity:** Check KEYMNG_HUK_VALID:

- 0: the HUK is invalid. Return to Step 1a until its value is 1.
- 1: the HUK is valid.

2. **Initialize TRNG correctly:** The user needs to make sure the TRNG is working correctly.
3. **Configure Static Parameters:** Set the following parameters, including eFuse bits, registers and their corresponding locks:
   - **EFUSE_KM_INIT_KEY eFuse block:** 256-bit initial key used by the Key Manager in AES Deploy Mode and ECDH1 Deploy Mode.
   - **EFUSE_KM_DEPLOY_ONLY_ONCE:** Controls whether the corresponding private key can only be deployed once after a power-on.
     - **Bit[0]:** Configures whether ECDSA Digital Signature Peripheral (ECDSA_DS) key can be deployed only once.
       * 0: ECDSA_DS key can be deployed more than once.
       * 1: ECDSA_DS key can be deployed only once.
     - **Bit[1]**: Configures whether XTS key can be deployed only once.
       * 0: XTS key can be deployed more than once.
       * 1: XTS key can be deployed only once.
   - **EFUSE_FORCE_USE_KEY_MANAGER_KEY:** Controls whether the corresponding private key must come from the Key Manager.
     - **Bit[0]:** Configures whether ECDSA_DS key must come from the Key Manager.
       * 0: ECDSA_DS key does not have to come from the Key Manager.
       * 1: ECDSA_DS key must come from the Key Manager.
     - **Bit[1]:** Configures whether flash encryption key must come from the Key Manager.
       * 0: Flash key does not have to come from the Key Manager.
       * 1: Flash key must come from the Key Manager.
     - **Bit[2]**: Configures whether HMAC key must come from the Key Manager.
       * 0: HMAC key does not have to come from the Key Manager.
       * 1: HMAC key must come from the Key Manager.
     - **Bit[3]**: Configures whether RSA Digital Signature Peripheral (RSA_DS) key must come from the Key Manager.
       * 0: RSA_DS key does not have to come from the Key Manager.
       * 1: RSA_DS key must come from the Key Manager.
     - **Bit[4]**: Configures whether PSRAM key must come from the Key Manager.
       * 0: PSRAM key does not have to come from the Key Manager.

    * 1: PSRAM key must come from the Key Manager.

- **KEYMNG_USE_EFUSE_KEY:** Configures whether the key bit comes from eFuse block, valid only when the corresponding bit in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
  - **Bit[0]:** Configures whether ECDSA_DS key comes from eFuse block.
    * 0: No effect.
    * 1: ECDSA_DS key comes from eFuse block, valid only when bit[0] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
  - **Bit[1]:** Configures whether flash encryption key comes from eFuse block.
    * 0: No effect.
    * 1: Flash key comes from eFuse block, valid only when bit[1] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
  - **Bit[2]:** Configures whether HMAC key comes from eFuse block.
    * 0: No effect.
    * 1: Flash key comes from eFuse block, valid only when bit[2] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
  - **Bit[3]:** Configures whether RSA Digital Signature Peripheral (RSA_DS) key comes from eFuse block.
    * 0: No effect.
    * 1: RSA_DS key comes from eFuse block, valid only when bit[3] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
  - **Bit[4]:** Configures whether PSRAM key comes from eFuse block.
    * 0: No effect.
    * 1: PSRAM key comes from eFuse block, valid only when bit[4] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
- **EFUSE_FORCE_DISABLE_SW_INIT_KEY:** Controls whether the use of software-source $init_key$ (sw_init_key) is permanently disabled.
  - 0: Not disabled.
  - 1: Permanently disabled.
- **KEYMNG_USE_SW_INIT_KEY:** Configures whether or not to use the software configured sw_init_key instead of the eFuse block whose purpose is EFUSE_KM_INIT_KEY, valid only when EFUSE_FORCE_DISABLE_SW_INIT_KEY is 0.
  - 0: Use the eFuse block whose purpose is EFUSE_KM_INIT_KEY.
  - 1: Use the software configured sw_init_key.
- **EFUSE_KM_RND_SWITCH_CYCLE:** Configures the interval for the Key Manager to switch random numbers. It is recommended to set this switch cycle to the number of Key Manager clock cycles corresponding to the TRNG module clock cycles.
  - 0: Switch cycle is controlled by KEYMNG_RND_SWITCH_CYCLE.

  - 1: 8 cycles of Key Manager clock.
  - 2: 16 cycles of Key Manager clock.
  - 3: 32 cycles of Key Manager clock.

- **KEYMNG_RND_SWITCH_CYCLE:** Configures the interval for the Key Manager to switch random numbers, valid only when EFUSE_KM_RND_SWITCH_CYCLE is 0. It is recommended to set this switch cycle to the number of Key Manager clock cycles corresponding to the TRNG module clock cycles.

4. **Configure Working Mode:** Configure KEYMNG_KGEN_MODE to complete the working mode configuration of the Key Manager as described in Section 36.6.2.
   - 0: Random Deploy Mode
   - 1: AES Deploy Mode
   - 2: ECDH0 Deploy Mode
   - 3: ECDH1 Deploy Mode
   - 4: Private Key Recovery mode
   - 5: key_info Export Mode
   - Others: Not valid
5. **Configure Target Key:** Configure KEYMNG_KEY_PURPOSE to the target $key_purpose$:
   - 1: ecdsa_key_192
   - 2: ecdsa_key_256
   - 3: flash_256_1_key
   - 4: flash_256_2_key
   - 5: flash_128_key
   - 6: hmac_key
   - 7: ds_key
   - 8: psram_256_1_key
   - 9: psram_256_2_key
   - 10: psram_128_key
   - 11: ecdsa_key_384_l
   - 12: ecdsa_key_384_h
   - Other values: Not valid
6. **Transition to PREP Phase:** Configure KEYMNG_START to complete the IDLE phase and enter the PREP phase.

36.7.2.2 PREP Phase

Users need to wait for the PREP phase to complete. This can be done using one of the following methods:

- **Monitor KEYMNG_STATE:** Continuously check KEYMNG_STATE until it is no longer BUSY.
- **Use Interrupt:** Enable the interrupt KEYMNG_PREP_DONE_INT and handle the completion in the interrupt service routine.

36.7.2.3 LOAD Phase

Users check KEYMNG_STATE to confirm that the Key Manager is in the LOAD phase. In the LOAD phase, users need to perform the following configurations.

1. **Configure Based on Mode**: Depending on the mode of the Key Manager, configure as follows:
   - **Random Deploy Mode:** No additional configuration is required.
   - **AES Deploy Mode:**
     (a) If using software to configure $init_key$: write sw_init_key (256 bits) into KEYMNG_SW_INIT_KEY_MEM.
     (b) Write $k2_info$ (512 bits) into KEYMNG_ASSIST_INFO_MEM.
     (c) Write $k1_encrypted$ (256 bits) into KEYMNG_PUBLIC_INFO_MEM.
   - **ECDH0 Deploy Mode:**
     (a) Write $k1 * G$ (512 bits) into KEYMNG_PUBLIC_INFO_MEM.
   - **ECDH1 Deploy Mode:**
     (a) If the software configured init_key is used: write sw_init_key (256 bits) into KEYMNG_SW_INIT_KEY_MEM.
     (b) Write $k2_info$ (512 bits) into KEYMNG_ASSIST_INFO_MEM.
     (c) Write $k1 * G$ (512 bits) into KEYMNG_PUBLIC_INFO_MEM.
   - **Private Key Recovery Mode:**
     (a) Write key_info (512 bits) into KEYMNG_ASSIST_INFO_MEM.
   - key_info **Export Mode:** No additional configuration is required.
2. **Transition to PROC Phase:** Configure KEYMNG_CONTINUE to complete the LOAD phase and enter the PROC phase.

36.7.2.4 PROC Phase

Users need to wait for the PROC phase to complete. This can be done using one of the following methods.

- **Monitor KEYMNG_STATE:** Continuously check KEYMNG_STATE until it is no longer BUSY.
- **Use Interrupt:** Enable the interrupt KEYMNG_PROC_DONE_INT and handle the completion in the interrupt service routine.

36.7.2.5 GAIN Phase

Users check KEYMNG_STATE to confirm that the Key Manager is in the GAIN phase. In the GAIN phase, users extract the required key information based on the selected mode of the Key Manager.

1. **Extract Key Information:**
   - **Random Deploy Mode:**
     (a) Read key_info (512 bits) from KEYMNG_PUBLIC_INFO_MEM.
   - **AES Deploy Mode:**
     (a) Read key_info (512 bits) from KEYMNG_PUBLIC_INFO_MEM.
   - **ECDH0 Deploy Mode:**
     (a) Read key_info (512 bits) from KEYMNG_PUBLIC_INFO_MEM.
     (b) Read $k2 * G$ (512 bits) from KEYMNG_ASSIST_INFO_MEM.
   - **ECDH1 Deploy Mode:**
     (a) Read key_info (512 bits) from KEYMNG_PUBLIC_INFO_MEM.
   - **Private Key Recovery Mode:** no need to read any information.
   - key_info **Export Mode:**
     (a) Read key_info (512 bits) from KEYMNG_PUBLIC_INFO_MEM.
2. **Transition to POST Phase:** Configure KEYMNG_CONTINUE to complete the GAIN phase and enter the POST phase.

36.7.2.6 POST Phase

Users need to wait for the POST phase to complete. This can be done using one of the following methods.

- **Monitor KEYMNG_STATE:** Continuously check KEYMNG_STATE until it is no longer BUSY.
- **Use Interrupt:** Enable the interrupt KEYMNG_POST_DONE_INT and handle the completion in the interrupt service routine.

36.8 Programming Examples

Based on the previous sections, we can outline a comprehensive chip deployment process. This section explains the operation procedures for the HUK Generator and Key Manager during two typical chip startup scenarios.

Note:
In this section, all configuration processes are described in a simplified manner. For detailed instructions, please refer to Section 36.7.

36.8.1 Software Process in Chip Private Key Deploy Phase

The following steps outline the process for booting up the chip for the first time and deploying the private key for encrypting and decrypting external memory.

1. **Enter Download Mode:** The chip enters the download mode.
2. **Configure HUK Generator:** Since it is the first time to start the chip, configure the HUK Generator to enter the HUK Generation Mode.
   (a) Configure the IDLE phase and set the working mode as HUK Generation Mode as specified in Table 36.6-1, then configure HUK_START.
   (b) After entering the LOAD phase, configure HUK_CONTINUE.
   (c) After entering GAIN phase, read out huk_info, then configure HUK_CONTINUE.
   (d) Wait for the HUK Generator to return to the IDLE phase.
3. **Set HUK Generation State:** Write EFUSE_KM_HUK_GEN_STATE to make the total number of bits set to 1 is odd, so that the HUK Generator will work only in HUK Recovery Mode during subsequent startups.
4. **Configure Key Deployment:** Take the key deployment in ECDHO Deploy Mode as an example.
   (a) Configure the IDLE phase, set KEYMNG_KEY_PURPOSE as XTS, and configure KEYMNG_START.
   (b) After entering the LOAD phase, write the locally generated $k1 * G$ to the Key Manager, then configure KEYMNG_CONTINUE.
   (c) After entering the GAIN phase, read out key_info and $k2 * G$, then configure KEYMNG_CONTINUE.
   (d) Wait for the Key Manager to return to the IDLE phase.
5. **Upload Key:** Upload $k2 * G$ to the user through the communication interface.
6. **Generate and Encrypt Data:**
   - Generate the negotiated private key $k1 * k2 * G$ based on the obtained $k2 * G$ and the local $k1$.
   - Encrypt data locally and write the ciphertext to flash.

36.8.2 Software Process in Chip Normal Startup Phase

Once the chip has been deployed, the complete process for a normal startup is as follows.

1. **Start in SPI Boot Mode:**

   The chip begins in SPI boot mode and first enters the unencrypted program segment.
2. **Configure HUK Recovery Mode:**

   Since the HUK has been generated, configure the HUK Recovery Mode as follows:
   (a) Configure the IDLE phase and set the working mode as HUK Recovery Mode as specified in Table 36.6-1, then configure HUK_START.
   (b) After entering the LOAD phase, write huk_info into the HUK Generator, then configure HUK_CONTINUE.
   (c) After entering GAIN phase, configure HUK_CONTINUE.

(d) Wait for the HUK Generator to return to the IDLE phase.

3. **Configure Key Manager for Private Key Recovery Mode:**

   (a) Configure the IDLE phase and set KEYMNG_KEY_PURPOSE as flash_128_key, then configure KEYMNG_START.

   (b) After entering the LOAD phase, write key_info into the Key Manager, then configure KEYMNG_CONTINUE.

   (c) After entering the GAIN phase, configure KEYMNG_CONTINUE.

   (d) Wait for the Key Manager to return to the IDLE phase.

4. **Enter Encrypted Program Segment:**

   At this point, the encryption/decryption private key in the external memory has taken effect, and the system enters the encrypted program segment.

36.9 Interrupts

ESP32-P4's Key Manager and HUK Generator can generate the following interrupt signals that will be sent to the Interrupt Matrix.

- KEYMNG_INTR
- HUK_INTR

There are several internal interrupt sources from Key Manager and HUK Generator that can generate the above interrupt signals. The interrupt sources from Key Manager and HUK Generator are listed with their trigger conditions and the resulted interrupt signals in Table 36.9-1.

Table 36.9-1. Key Manager and HUK Generator's Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal
KEYMNG_PREP_DONE_INT	Completion of Key Manager's PREP phase	KEYMNG_INTR
KEYMNG_PROC_DONE_INT	Completion of Key Manager's PROC phase	KEYMNG_INTR
KEYMNG_POST_DONE_INT	Completion of Key Manager's POST phase	KEYMNG_INTR
HUK_PREP_DONE_INT	Completion of HUK Generator's PREP phase	HUK_INTR
HUK_PROC_DONE_INT	Completion of HUK Generator's PROC phase	HUK_INTR
HUK_POST_DONE_INT	Completion of HUK Generator's POST phase	HUK_INTR

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

36.10 Memory Blocks

The addresses in this section are relative to Key Manager or HUK Generator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

Table 36.10-1. Key Manager Memory Blocks

Name	Description	Size (byte)	Starting Address	Ending Address	Access
KEYMNG_ASSIST_INFO_MEM	Stores assistant information	64	0x0100	0x013F	Varies
KEYMNG_PUBLIC_INFO_MEM	Stores public information	64	0x0140	0x017F	Varies
KEYMNG_SW_INIT_KEY_MEM	Stores sw_init_key	32	0x0180	0x019F	Varies

Table 36.10-2. HUK Generator Memory Blocks

Name	Description	Size (byte)	Starting Address	Ending Address	Access
HUK_INFO_MEM	Stores huk_info	660	0x0100	0x0393	Varies

36.11 Register Summary

36.11.1 HUK Register Summary

The addresses in this section are relative to HUK Generator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Clock Gate Register			
HUK_CLK_REG	Clock gate control register	0x0004	R/W
Interrupt Registers			
HUK_INT_RAW_REG	Interrupt raw register (valid in level)	0x0008	RO/WTC/SS
HUK_INT_ST_REG	Interrupt status register	0x000C	RO
HUK_INT_ENA_REG	Interrupt enable register	0x0010	R/W
HUK_INT_CLR_REG	Interrupt clear register	0x0014	WT
Configuration Register			
HUK_CONF_REG	Configuration register	0x0020	R/W
Control Register			
HUK_START_REG	Control register	0x0024	WT
State Register			
HUK_STATE_REG	HUK Generator state register	0x0028	RO
Result Register			
HUK_STATUS_REG	HUK status register	0x0034	RO
Version Register			
HUK_DATE_REG	Version control register	0x00FC	R/W

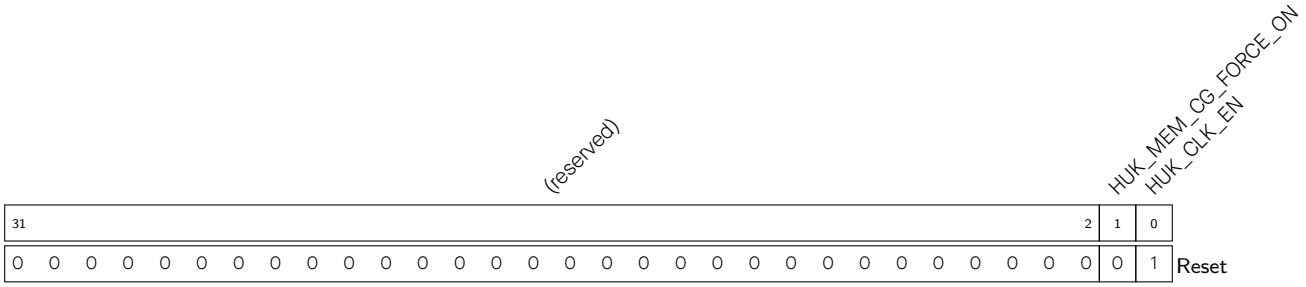
36.11.2 Key Manager Register Summary

The addresses in this section are relative to Key Manager base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Clock Gate Register			
KEYMNG_CLK_REG	Clock gate control register	0x0004	R/W
Interrupt Registers			
KEYMNG_INT_RAW_REG	Interrupt raw register (valid in level)	0x0008	RO/WTC/SS
KEYMNG_INT_ST_REG	Interrupt status register	0x000C	RO
KEYMNG_INT_ENA_REG	Interrupt enable register	0x0010	R/W
KEYMNG_INT_CLR_REG	Interrupt clear register	0x0014	WT
Static Configuration Registers			
KEYMNG_STATIC_REG	Static configuration register	0x0018	R/W
KEYMNG_LOCK_REG	Static configuration lock register	0x001C	R/W1

Name	Description	Address	Access
Configuration register			
KEYMNG_CONF_REG	Configuration register	0x0020	R/W
Control Register			
KEYMNG_START_REG	Control register	0x0024	WT
State Register			
KEYMNG_STATE_REG	State register	0x0028	RO
Result Registers			
KEYMNG_RESULT_REG	Operation result register	0x002C	RO/SS
KEYMNG_KEY_VLD_REG	Key status register	0x0030	RO
KEYMNG_HUK_VLD_REG	HUK status register	0x0034	RO
Version Register			
KEYMNG_DATE_REG	Version control register	0x00FC	R/W



36.12 Registers

36.12.1 HUK Registers

The addresses in this section are relative to HUK base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section IX .

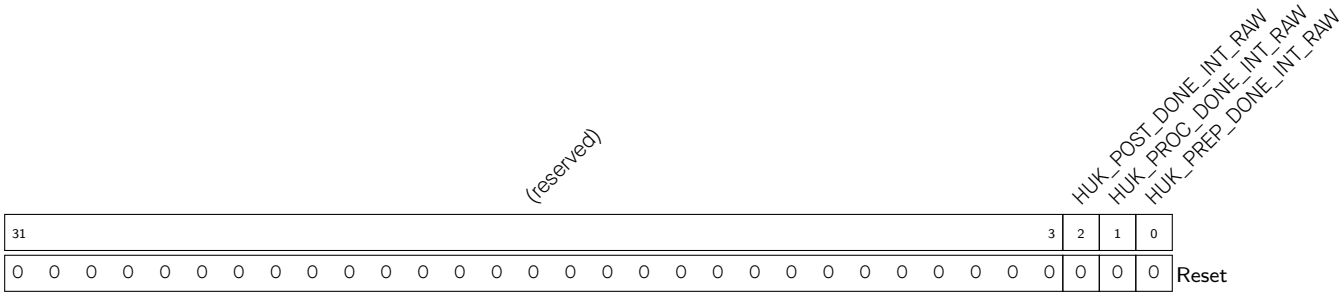
Register 36.1. HUK_CLK_REG (0x0004)

HUK_CLK_EN Configures whether or not to force on register clock gate.

0: Not force on

1: Force on

(R/W)



HUK_MEM_CG_FORCE_ON Configures whether or not to force on memory clock gate.

0: Not force on

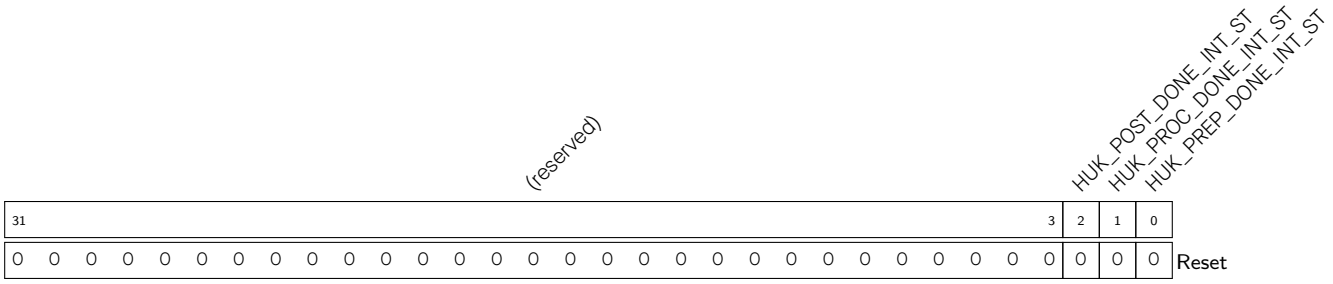
1: Force on

(R/W)

Register 36.2. HUK_INT_RAW_REG (0x0008)

HUK_PREP_DONE_INT_RAW The raw interrupt status of HUK_PREP_DONE_INT interrupt.

(RO/WTC/SS)



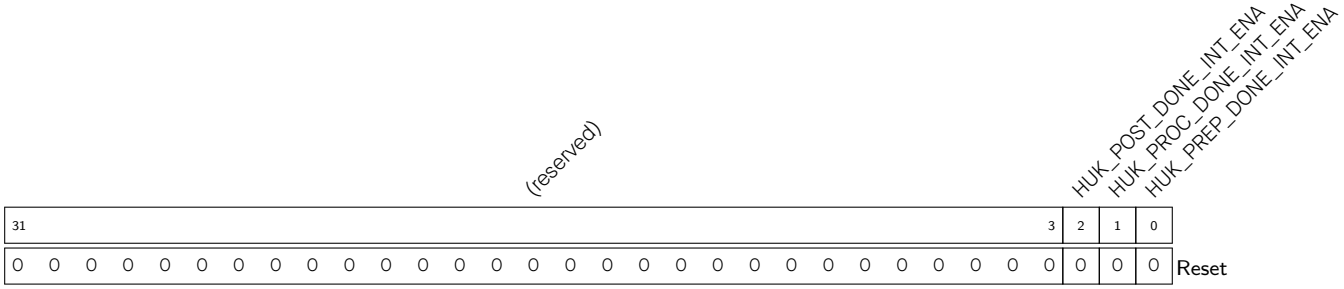
HUK_PROC_DONE_INT_RAW The raw interrupt status of HUK_PROC_DONE_INT interrupt.

(RO/WTC/SS)

HUK_POST_DONE_INT_RAW The raw interrupt status of HUK_POST_DONE_INT interrupt.

(RO/WTC/SS)

Register 36.3. HUK_INT_ST_REG (0x000C)

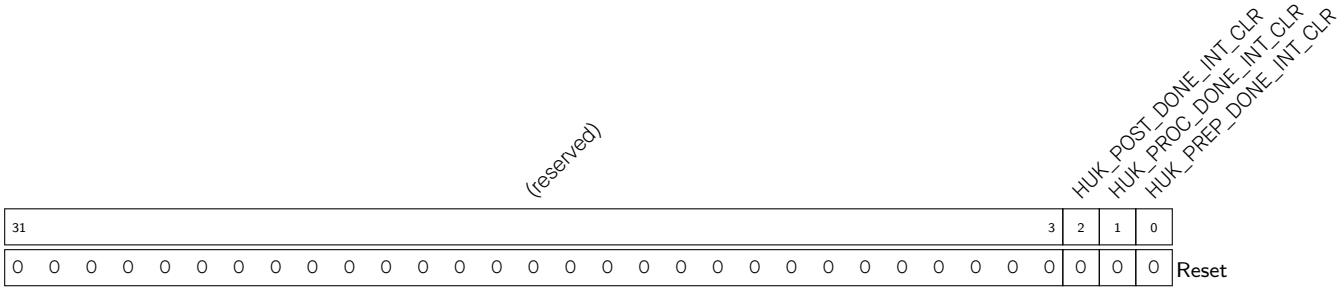


HUK_PREP_DONE_INT_ST The masked interrupt status of HUK_PREP_DONE_INT interrupt. (RO)

HUK_PROC_DONE_INT_ST The masked interrupt status of HUK_PROC_DONE_INT interrupt. (RO)

HUK_POST_DONE_INT_ST The masked interrupt status of HUK_POST_DONE_INT interrupt. (RO)

Register 36.4. HUK_INT_ENA_REG (0x0010)

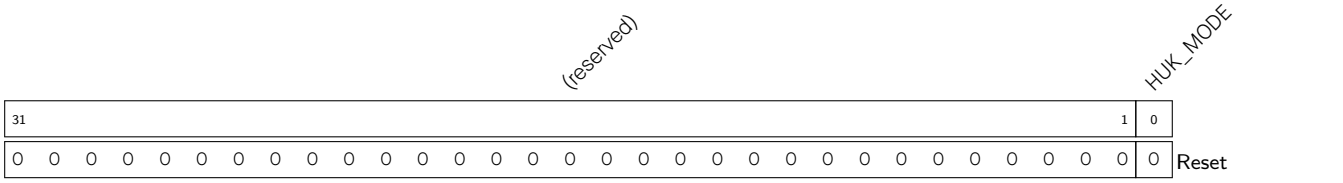


HUK_PREP_DONE_INT_ENA Write 1 to enable the HUK_PREP_DONE_INT interrupt. (R/W)

HUK_PROC_DONE_INT_ENA Write 1 to enable the HUK_PROC_DONE_INT interrupt. (R/W)

HUK_POST_DONE_INT_ENA Write 1 to enable the HUK_POST_DONE_INT interrupt. (R/W)

Register 36.5. HUK_INT_CLR_REG (0x0014)

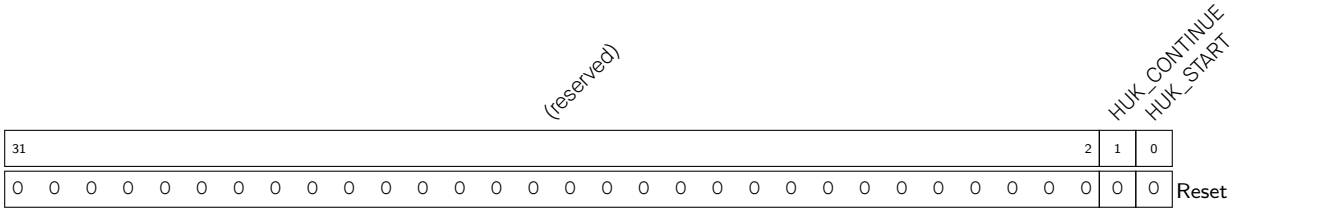


HUK_PREP_DONE_INT_CLR Write 1 to clear the HUK_PREP_DONE_INT interrupt. (WT)

HUK_PROC_DONE_INT_CLR Write 1 to clear the HUK_PROC_DONE_INT interrupt. (WT)

HUK_POST_DONE_INT_CLR Write 1 to clear the HUK_POST_DONE_INT interrupt. (WT)

Register 36.6. HUK_CONF_REG (0x0020)

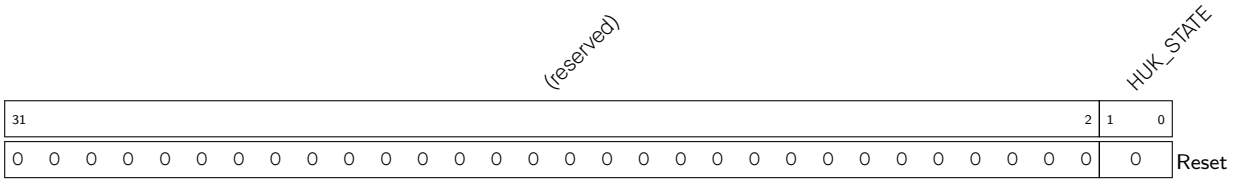


HUK_MODE Configures HUK mode.

0: HUK Recovery Mode

1: HUK Generation Mode

(R/W)



Register 36.7. HUK_START_REG (0x0024)

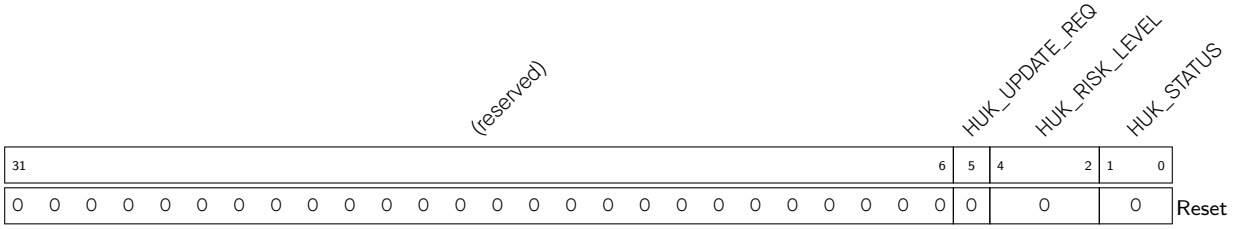
HUK_START Write 1 to start HUK Generator at IDLE phase. (WT)

HUK_CONTINUE Write 1 to continue HUK Generator operation at LOAD/GAIN phase. (WT)

Register 36.8. HUK_STATE_REG (0x0028)

HUK_STATE Represents the state of HUK Generator.

0: IDLE



1: LOAD

2: GAIN

3: BUSY

(RO)

Register 36.9. HUK_STATUS_REG (0x0034)

HUK_STATUS Represents the HUK generation status.

0: HUK is not generated.

1: HUK is generated and valid.

2: HUK is generated but invalid.

3: Reserved.

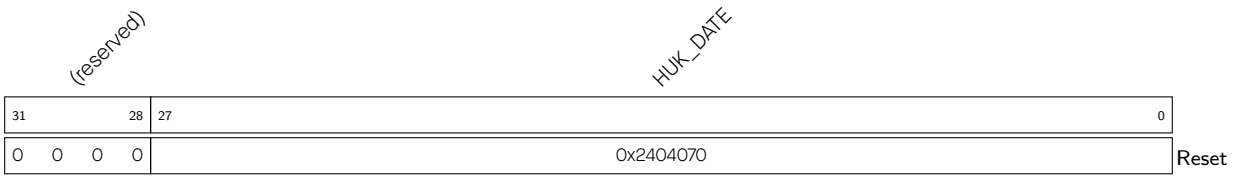
(RO)

HUK_RISK_LEVEL Represents the risk level of HUK.

0∼6: The higher the risk level is, the more error bits there are in the PUF SRAM.

7: Error Level, HUK is invalid.

(RO)



HUK_UPDATE_REQ Represents the update request of huk_info.

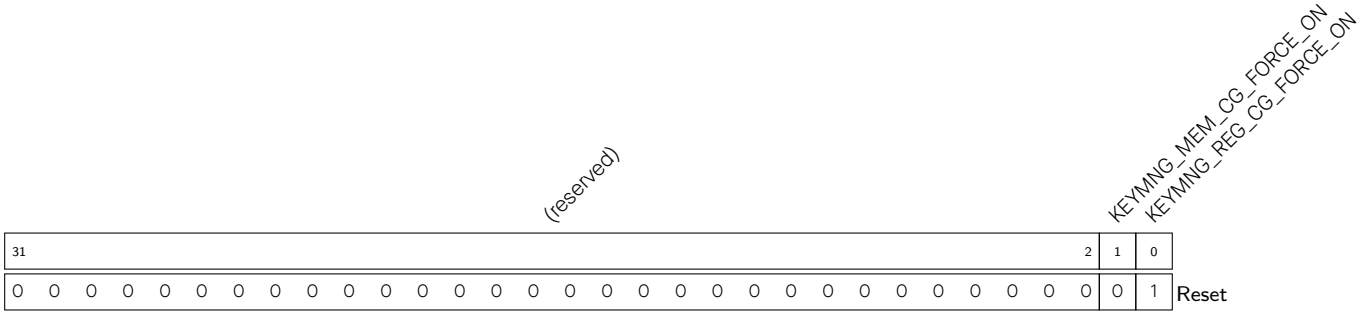
0: User can update huk_info according to the risk level.

1: The huk_info is expired, and user need to update it.

(RO)

Register 36.10. HUK_DATE_REG (0x00FC)

HUK_DATE Version control register.



(R/W)

36.12.2 Key Manager Registers

The addresses in this section are relative to Key Manager base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section IX .

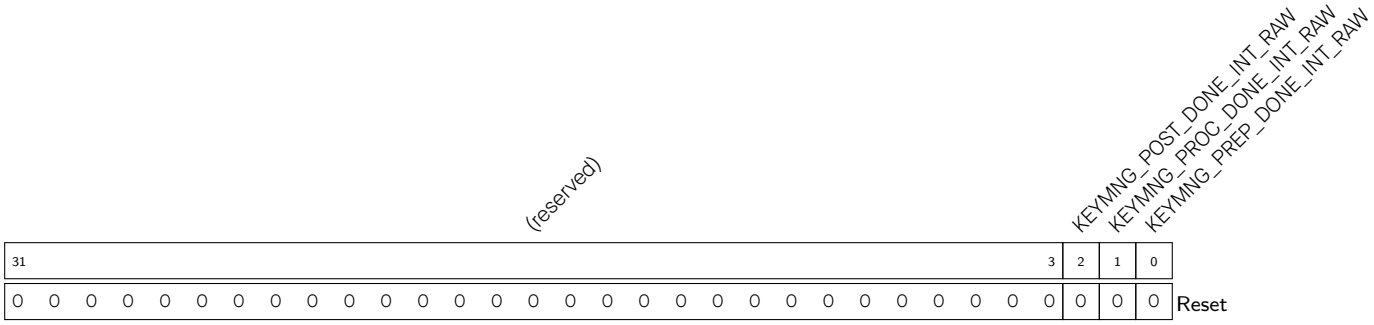
Register 36.11. KEYMNG_CLK_REG (0x0004)

KEYMNG_REG_CG_FORCE_ON Configures whether or not to force on register clock gate.

0: Not force on

1: Force on

(R/W)



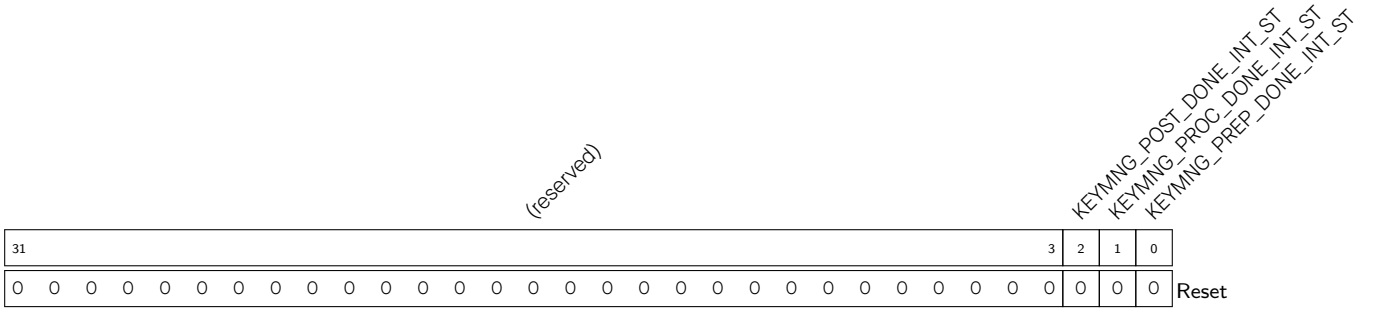
KEYMNG_MEM_CG_FORCE_ON Configures whether or not to force on memory clock gate.

0: Not force on

1: Force on

(R/W)

Register 36.12. KEYMNG_INT_RAW_REG (0x0008)

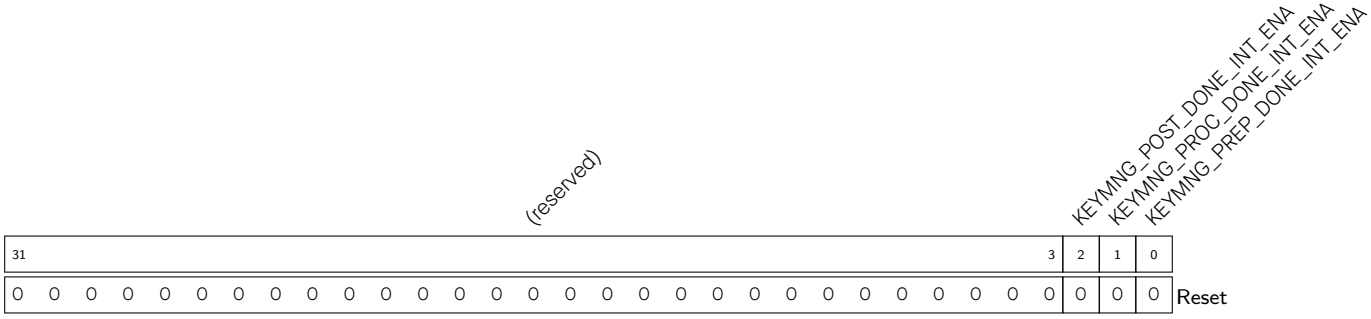


KEYMNG_PREP_DONE_INT_RAW The raw interrupt status of KEYMNG_PREP_DONE_INT interrupt. (RO/WTC/SS)

KEYMNG_PROC_DONE_INT_RAW The raw interrupt status of KEYMNG_PROC_DONE_INT interrupt. (RO/WTC/SS)

KEYMNG_POST_DONE_INT_RAW The raw interrupt status of KEYMNG_POST_DONE_INT interrupt. (RO/WTC/SS)

Register 36.13. KEYMNG_INT_ST_REG (0x000C)

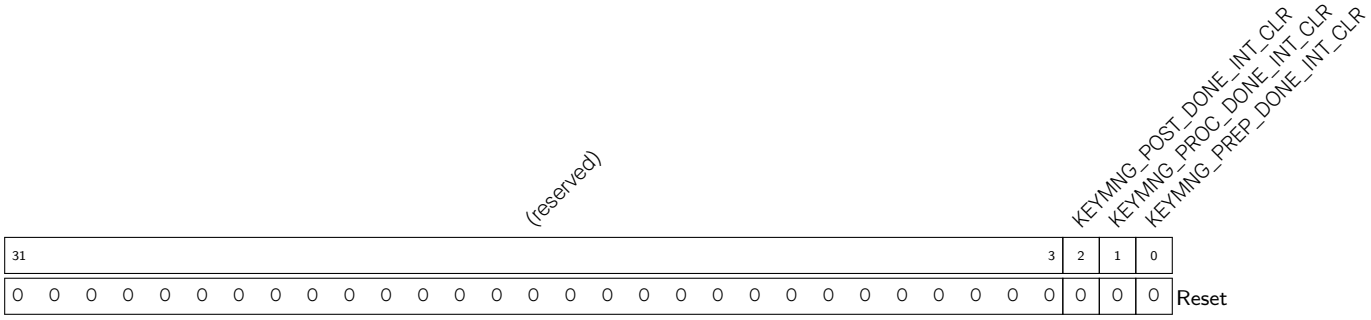


KEYMNG_PREP_DONE_INT_ST The masked interrupt status of KEYMNG_PREP_DONE_INT interrupt.
(RO)

KEYMNG_PROC_DONE_INT_ST The masked interrupt status of KEYMNG_PROC_DONE_INT interrupt.
(RO)

KEYMNG_POST_DONE_INT_ST The masked interrupt status of KEYMNG_POST_DONE_INT interrupt.
(RO)

Register 36.14. KEYMNG_INT_ENA_REG (0x0010)

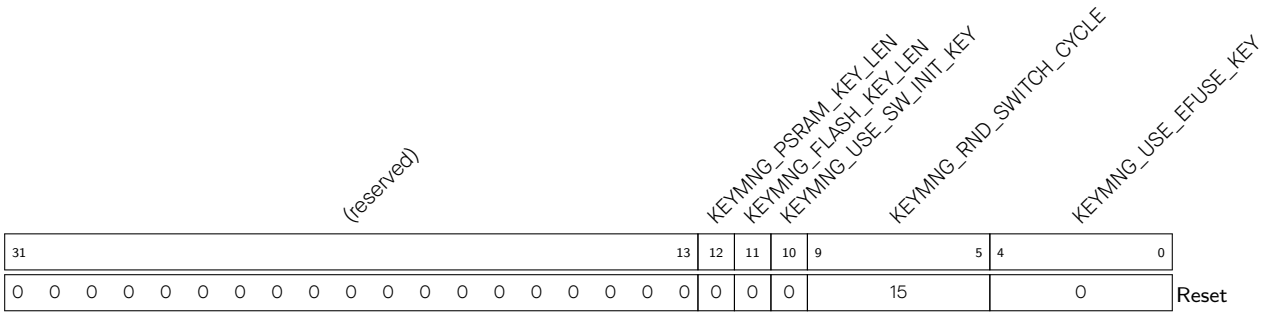


KEYMNG_PREP_DONE_INT_ENA Write 1 to enable the KEYMNG_PREP_DONE_INT interrupt. (R/W)

KEYMNG_PROC_DONE_INT_ENA Write 1 to enable the KEYMNG_PROC_DONE_INT interrupt. (R/W)

KEYMNG_POST_DONE_INT_ENA Write 1 to enable the KEYMNG_POST_DONE_INT interrupt. (R/W)

Register 36.15. KEYMNG_INT_CLR_REG (0x0014)



KEYMNG_PREP_DONE_INT_CLR Write 1 to clear the KEYMNG_PREP_DONE_INT interrupt. (WT)

KEYMNG_PROC_DONE_INT_CLR Write 1 to clear the KEYMNG_PROC_DONE_INT interrupt. (WT)

KEYMNG_POST_DONE_INT_CLR Write 1 to clear the KEYMNG_POST_DONE_INT interrupt. (WT)

Register 36.16. KEYMNG_STATIC_REG (0x0018)

KEYMNG_USE_EFUSE_KEY Configures whether or not to use eFuse key instead of Key Manager deployed key.

- Bit[0]: configures whether to use eFuse key for ECDSA_DS key.
  0: No effect
  1: Use eFuse Key, valid only when bit[0] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
- Bit[1] configures whether to use eFuse key for flash key.
  0: No effect
  1: Use eFuse Key, valid only when bit[1] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
- Bit[2] configures whether to use eFuse key for HMAC key.
  0: No effect
  1: Use eFuse Key, valid only when bit[2] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
- Bit[3] configures whether to use eFuse key for RSA_DS_KEY.
  0: No effect
  1: Use eFuse Key, valid only when bit[3] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.
- Bit[4] configures whether to use eFuse key for PSRAM key.
  0: No effect
  1: Use eFuse Key, valid only when bit[4] in EFUSE_FORCE_USE_KEY_MANAGER_KEY is 0.

(R/W)

KEYMNG_RND_SWITCH_CYCLE Configures cycles of the Key Manager to switch random numbers.
Measurement: Key Manager clock cycle.
This field is valid only when EFUSE_KM_RND_SWITCH_CYCLE is set to 0.
It is recommended to set this switch cycle to the number of Key Manager clock cycles corresponding to the TRNG module's clock cycle.
(R/W)

KEYMNG_USE_SW_INIT_KEY Configures whether or not to use sw_init_key, instead of EFUSE_KM_INIT_KEY, valid only when EFUSE_FORCE_DISABLE_SW_INIT_KEY is 0.
0: Use EFUSE_KM_INIT_KEY
1: Use software written sw_init_key
(R/W)

Register 36.16. KEYMNG_STATIC_REG (0x0018)

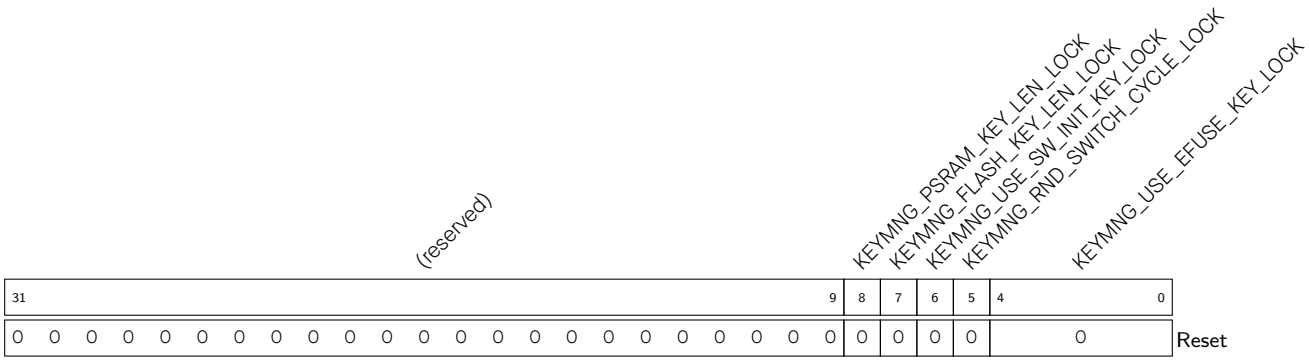
Continued from the previous page...

KEYMNG_FLASH_KEY_LEN Configures the key length for flash crypt.

0: Use xts-aes-128

1: Use xts-aes-256

(R/W)



KEYMNG_PSRAM_KEY_LEN Configures the key length for PSRAM crypt.

0: Use xts-aes-128

1: Use xts-aes-256

(R/W)

Register 36.17. KEYMNG_LOCK_REG (0x001C)

KEYMNG_USE_EFUSE_KEY_LOCK Write 1 to lock KEYMNG_USE_EFUSE_KEY.

Each bit locks the corresponding bit of KEYMNG_USE_EFUSE_KEY.

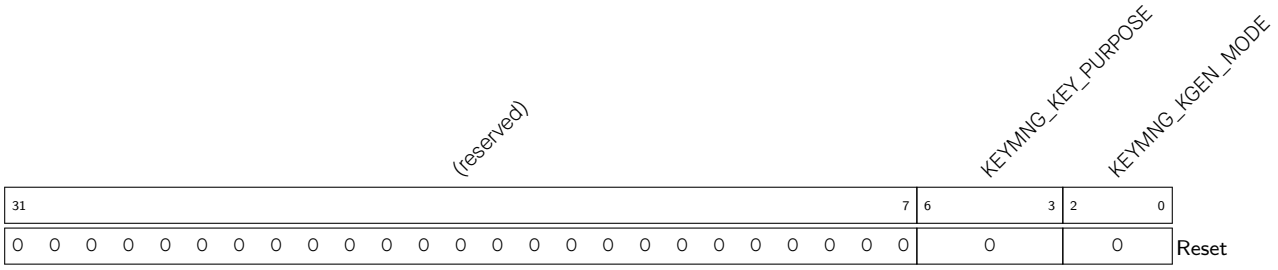
(R/W1)

KEYMNG_RND_SWITCH_CYCLE_LOCK Write 1 to lock KEYMNG_RND_SWITCH_CYCLE.

(R/W1)

KEYMNG_USE_SW_INIT_KEY_LOCK Write 1 to lock KEYMNG_USE_SW_INIT_KEY.

(R/W1)



KEYMNG_FLASH_KEY_LEN_LOCK Write 1 to lock KEYMNG_FLASH_KEY_LEN.

(R/W1)

KEYMNG_PSRAM_KEY_LEN_LOCK Write 1 to lock KEYMNG_PSRAM_KEY_LEN.

(R/W1)

Register 36.18. KEYMNG_CONF_REG (0x0020)

KEYMNG_KGEN_MODE Configures deployment mode.

0: Random Deploy Mode

1: AES Deploy Mode

2: ECDH0 Deploy Mode

3: ECDH1 Deploy Mode

4: Private Key Recovery Mode

5: key_info Export Mode

6∼7: Reserved

(R/W)

KEYMNG_KEY_PURPOSE Configures key purpose.

1: ecdsa_key_192

2: ecdsa_key_256

3: flash_256_1_key

4: flash_256_2_key

5: flash_128_key

6: hmac_key

7: ds_key

8: psram_256_1_key

9: psram_256_2_key

10: psram_128_key

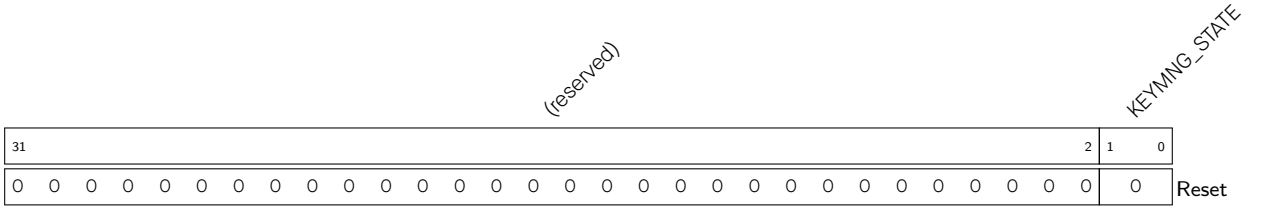
12: ecdsa_key_384_h

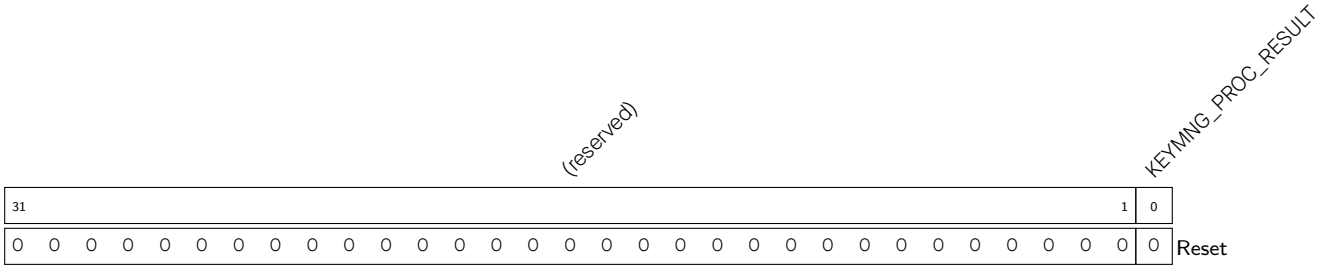
Others: Reserved

(R/W)



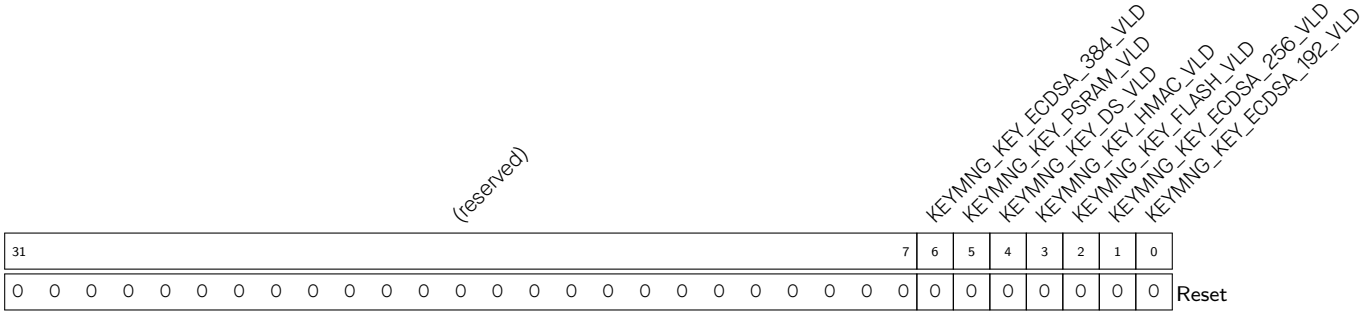
Register 36.19. KEYMNG_START_REG (0x0024)

KEYMNG_START Write 1 to start Key Manager operation at IDLE phase.
(WT)



KEYMNG_CONTINUE Write 1 to continue the operation of Key Manager at LOAD/GAIN phase.
(WT)

Register 36.20. KEYMNG_STATE_REG (0x0028)



KEYMNG_STATE Represents the state of Key Manager.
0: IDLE
1: LOAD
2: GAIN
3: BUSY
(RO)

Register 36.21. KEYMNG_RESULT_REG (0x002C)

KEYMNG_PROC_RESULT Represents the procedure result of Key Manager, valid only when Key Manager procedure is done.
0: Key Manager procedure failed.
1: Key Manager procedure succeeded.
(RO/SS)

Register 36.22. KEYMNG_KEY_VLD_REG (0x0030)

KEYMNG_KEY_ECDSA_192_VLD Represents the status of key_ecdsa_192.

0: The key has not been deployed yet.

1: The key has been deployed correctly.

(RO)

KEYMNG_KEY_ECDSA_256_VLD Represents the status of key_ecdsa_256.

0: The key has not been deployed yet.

1: The key has been deployed correctly.

(RO)

KEYMNG_KEY_FLASH_VLD Represents the status of key_flash.

0: The key has not been deployed yet.

1: The key has been deployed correctly.

(RO)

KEYMNG_KEY_HMAC_VLD Represents the status of key_hmac.

0: The key has not been deployed yet.

1: The key has been deployed correctly.

(RO)

KEYMNG_KEY_DS_VLD Represents the status of key_ds.

0: The key has not been deployed yet.

1: The key has been deployed correctly.

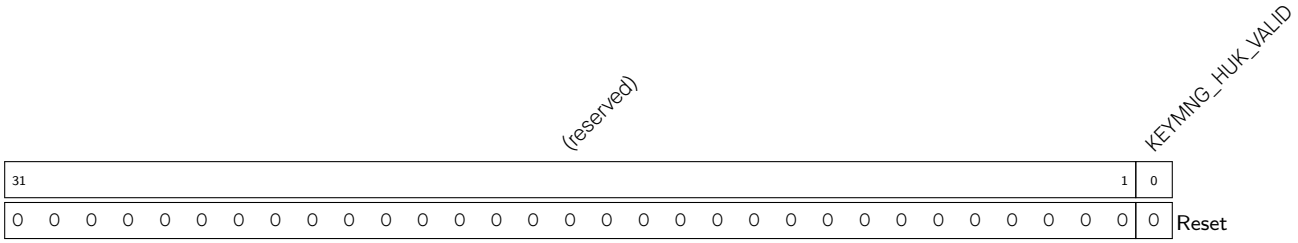
(RO)

KEYMNG_KEY_PSRAM_VLD Represents the status of key_psram.

0: The key has not been deployed yet.

1: The key has been deployed correctly.

(RO)



KEYMNG_KEY_ECDSA_384_VLD Represents the status of key_ecdsa_384.

0: The key has not been deployed yet.

1: The key has been deployed correctly.

Part VI

Image and Voice Processing

Focusing on multimedia processing, this part classifies components related to image and voice processing, including camera controllers, video encoders, image signal processors, and voice activity detection.

Chapter 37

JPEG Codec

ESP32-P4's JPEG codec is an image codec, which is based on the JPEG baseline standard, for compressing (encoding) and decompressing (decoding) images to reduce the bandwidth required to transmit images or the space required to store images, making it possible to process large-resolution images. The image encoding process mainly includes discrete cosine transform (DCT), zigzag scanning, quantization, and Huffman coding. The image decoding process, which is the inverse operation of the encoding process, mainly includes Huffman decoding, inverse quantization, inverse zigzag scanning, and inverse discrete cosine transform (IDCT).

37.1 Terminology

MCU	Minimum coded unit. The basic unit of codec processing
baseline	A particular sequential DCT-based encoding and decoding process specified in the standard, which is required for all DCT-based decoding processes
image	A set of two-dimensional arrays of integer data
component	One of the two-dimensional arrays that comprise an image
data unit	An 8 × 8 block of pixels of one component
marker	A two-byte code in which the first byte is hexadecimal FF (0xFF) and the second byte is a value between 1 and hexadecimal FE (0xFE). It is served to identify the various structural parts of the compressed data formats
restart marker	Used to isolate coded data segments and for application-specific uses, such as decoder re-synchronization and error recovery
restart interval	The integer number of MCUs processed between two restart markers
scan	A single pass through the data for one or more of the components in an image

Figure 37.1-1 shows the schematic diagram of JPEG bitstream format. In this diagram, the dashed lines mark the structural composition of the corresponding parts of the bitstream, and the orange blocks indicate the marker codes.

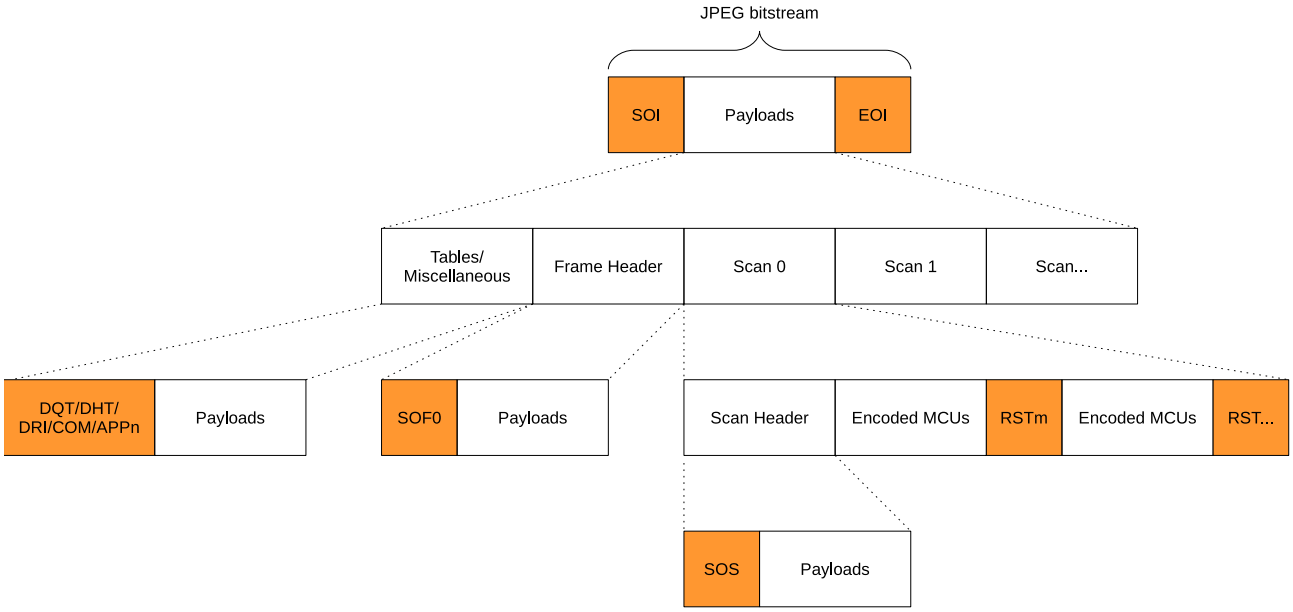

Figure 37.1-1. JPEG Bitstream Format

The marker code assignments are shown in Table 37.1-2.

Table 37.1-2. Marker Code Assignments

Code Assignment	Marker	Description
0xFFC0	SOF0	Start of frame (Baseline DCT)
0xFFC4	DHT	Define Huffman table(s)
0xFFDm	RSTm	Restart with modulo 8 count “m”
0xFFD8	SOI	Start of image
0xFFD9	EOI	End of image
0xFFDA	SOS	Start of scan
0xFFDB	DQT	Define quantization table(s)
0xFFDD	DRI	Define restart interval
0xFFEn	APPn	Reserved for application segments, “n” is 0 to F
0xFFFE	COM	Comment

37.2 Introduction

The JPEG codec is based on the JPEG baseline standard, which specifies that an encoding process is completed through one or more scans. An scan contains one or more MCUs. MCU is the sequence of data units defined by the sampling factors of the image components in the scan, which means MCU of different image formats contains different sequence of data units, as shown in Table 37.2-1.

Table 37.2-1. The Number of Data Units in the MCU of Different Image Format

Image Format	MCU[1]		
	Luminance Component Y	Chrominance Component U	Chrominance Component V
YUV444	1 x 1	1 x 1	1 x 1

YUV422	2 x 1	1 x 1	1 x 1
YUV420	2 x 2	1 x 1	1 x 1
GRAY	1 x 1	none	none

[1] The MCU of each image format is represented by the number of data units in the horizontal direction x the number of data units in the vertical direction of each component.

At a time, the JPEG codec can only be configured as an encoder or a decoder, that is, it cannot work as an encoder and a decoder at the same time.

- When used as an encoder, it obtains the image to be compressed through 2D DMA and sends the encoded bitstream to the 2D DMA.
- When used as a decoder, it obtains the coded bitstream through 2D DMA and sends the decoded image to 2D DMA.

The workflow of JPEG codec is shown in Figure 37.2-1.

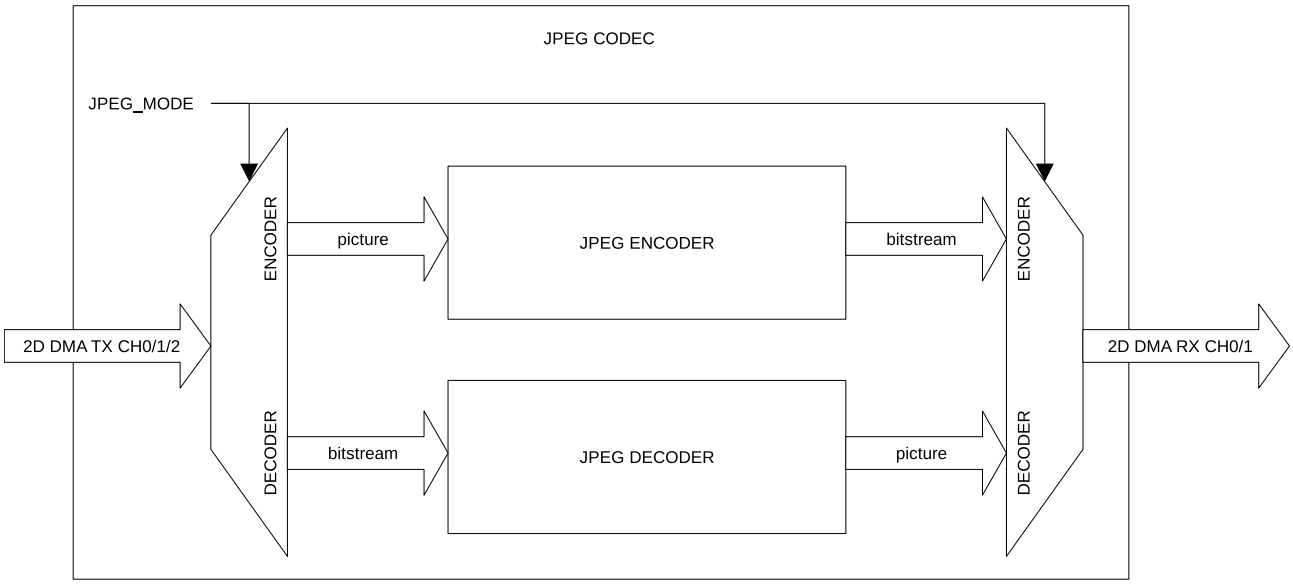

Figure 37.2-1. JPEG codec system connection block diagram

The function clock of the JPEG codec is SYS_CLK.

37.3 Features

When used as an encoder, the JPEG codec has the following features:

- integrated discrete cosine transform algorithm
- integrated canonical Huffman coding
- RGB888, RGB565, YUV422 and GRAY as original input image formats
- conversion of RGB888 and RGB565 into YUV444, YUV422 or YUV420 (the only formats supported by impression) for image compression

- 4 x configurable quantization coefficient tables with 8-bit or 16-bit precision
- performance:
  - still image compression: up to 4K resolution
  - dynamic image compression: up to 1080P@40fps,720P@70fps (excluding header encoding time)
- automatically added stuffed zero byte
- automatically added EOI marker

When used as a decoder, the JPEG codec has the following features:

- integrated inverse discrete cosine transform algorithm
- integrated Huffman decoding
- supported image formats for compressed bitstream decoding: YUV444, YUV422, YUV420, and GRAY.
- 4 x configurable quantization coefficient tables with 8-bit or 16-bit precision
- 2 x DC and 2 x AC Huffman tables
- supports image decoding of any resolution. However, the resolution of output decoded image differs from the format of the input image:
  - YUV444, GRAY: both the horizontal and vertical resolutions of the output decoded image are multiples of 8, i.e., 150 × 150 images with an output resolution of 152 × 152
  - YUV422: the horizontal resolution of the output decoded image is the multiples of 16 and the vertical resolution is multiples of 8, i.e., 150 × 150 images with an output resolution of 160 × 152
  - YUV420: both the horizontal and vertical resolutions of the output decoded image are multiples of 16, i.e., 150 × 150 images with an output resolution of 160 × 160
- performance:
  - still image decoding: up to 4K resolution
  - dynamic image decoding: up to 1080P@40fps,720P@70fps (excluding header parsing time)

37.4 Architectural Overview

When the JPEG codec is configured as an encoder, its architecture is shown in Figure 37.4-1.

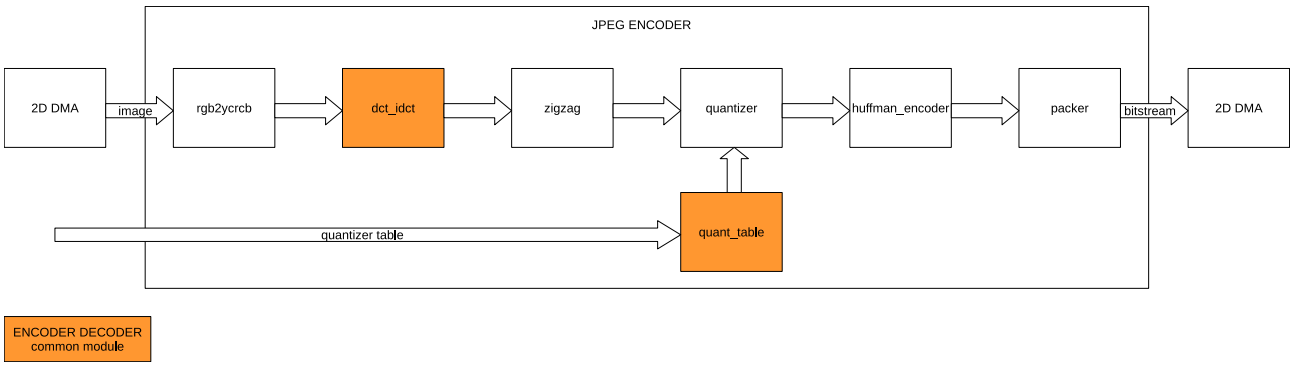

Figure 37.4-1. JPEG encoder architecture

- **rgb2ycrcb** implements the color space conversion, and converts the original image into an image format supported by the codec for compressing.
- **dct_idct** implements two-dimensional DCT transformation of data units.
- **zigzag** performs zigzag scanning and sorting on the DCT transformed data units.
- **quant_table** stores the quantization coefficient table delivered by the software.
- **quantizer** quantifies the zigzag sorted data units based on the quantization coefficient table stored in **quant_table**.
- **huffman_encoder** performs Huffman encoding on the quantized result of the data units.
- **packer** packs the Huffman-encoded data into groups of 32 bits, and outputs the final encoded bitstream.

When the JPEG codec is configured as a decoder, its architecture is shown in figure 37.4-2.

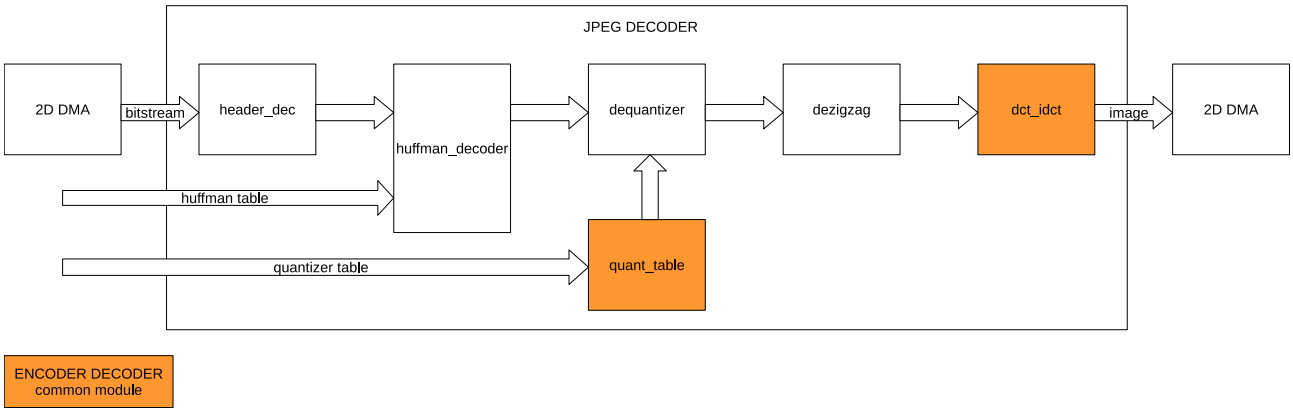

Figure 37.4-2. JPEG decoder architecture

- **header_dec** implements bitstream extraction and marker SOS and EOI parsing, and controls the decoding process.
- **huffman_decoder** stores the Huffman table delivered by the software, and implements Huffman decoding of the bitstream.
- **quant_table** stores the quantization coefficient table delivered by the software.
- **dequantizer** dequantizes the Huffman decoded data based on the quantization coefficient table stored in **quant_table**.
- **dezigzag** implements reverse zigzag scanning and sorting on the dequantized data units, and combines them into dequantized data units
- **dct_idct** implements the two-dimensional inverse DCT transformation of the dequantized data units, and outputs the final decoded data units.

Since the JPEG codec cannot be used as an encoder and decoder at the same time, the encoder and decoder share the **quant_table** and **dct_idct** modules to save hardware resources.

37.5 Functional Description

The JPEG Codec can be configured to work as an encoder or a decoder.

37.5.1 JPEG Encoder

37.5.1.1 Pause

The JPEG encoder can be paused during the operation for other higher priority tasks. This feature is controlled by register field JPEG_PAUSE_EN.

- Set JPEG_PAUSE_EN to 1, the JPEG encoder will no longer output the bitstream to the 2D DMA RX channel.
- Set JPEG_PAUSE_EN back to 0, the JPEG encoder will be resumed, and output the bitstream normally.

37.5.1.2 Color Space Conversion

According to the standard, the image formats supported by the JPEG encoder are YUV444, YUV422, YUV420, and GRAY. However, ESP32-P4's JPEG encoder has integrated a color space conversion function to convert RGB888 and RGB565 formats into the above-mentioned image formats supported by the encoder before encoding. In this way, the range of supported image formats is expanded.

The color space conversion formulas for converting RGB to YUV are:

$$
\begin{aligned}
Y &= (0.299 * R) + (0.587 * G) + (0.114 * B) \\
U &= (-0.1687 * R) + (-0.3313 * G) + (0.5 * B) + 128 \\
V &= (0.5 * R) + (-0.4187 * G) + (-0.0813 * B) + 128
\end{aligned}
$$

YUV formats only support downsampling. For example, YUV444 can remain unchanged or be downsampled to YUV422 or YUV420, and YUV422 can remain unchanged or be downsampled to YUV420.

The image format before conversion is represented by its format as well as pixel order. Table 37.5-1 demonstrates the representations of the supported image formats for color space conversion:

Table 37.5-1. Supported Image Formats for Color Space Conversion

JPEG_EXTD_ COLOR_SPACE_EN	JPEG_ COLOR_SPACE	JPEG_EXTD_ COLOR_SPACE	Format[1]	JPEG_ PIXEL_REV	Pixel Order
0	0	N/A	RGB888	0	RGB
				1	BGR
	1		YUV422[2]	0	YUYV
				1	UYVY
	2		RGB565	0	RGB
				1	BGR
	3		GRAY[2]	N/A	YYY
1	N/A	0	YUV444	0	YUV
				1	VUY
		1	YUV420[2]	N/A	YYU/YYV[3]

[1] The image formats can be converted into other formats supported by the encoder via configuring register field JPEG_SAMPLE_SEL:

- 0: YUV444
- 1: YUV422
- 2: YUV420

[2] Image format conversion is limited:

- YUV422: can only remain unchanged or be downsampled to YUV420. Setting JPEG_SAMPLE_SEL to 0 has no effect.
- YUV420 or GRAY: will not be converted, regardless of the value of JPEG_SAMPLE_SEL.

[3] The pixel arrangement alternates between rows: odd-numbered rows use the YYU pattern, and even-numbered rows use the YYV pattern.

37.5.1.3 Configurable Quantization Coefficient Table

ESP32-P4 JEPG encoder has implemented four 8 x 8 quantization coefficient tables in its hardware, which allows 64 software-configurable coefficient values per table.

The precision of each quantization table is configurable via JPEG_QNR_PRECISION:

- 0: low 8-bit effective
- 1: low 16-bit effective

The coefficient values for each table can be configured in FIFO mode or non-FIFO mode depending on the value of JPEG_QNR_FIFO_EN:

- 0: non-FIFO mode, in which each coefficient is written to a specific address
- 1: FIFO mode, in which all coefficients are written to the same address

Table 37.5-2. Position Number of Coefficients in a Quantization Coefficient Table (Example)

0	1	2	3	4	5	6	7
8	9	10	11	12	13	14	15
...							

56	57	58	59	60	61	62	63

In different modes, the configuration of the quantization coefficient table is different. Note, *n* (*n* = 0, 1, 2, 3) indicates the number of each quantization coefficient table:

- non-FIFO mode: each quantization coefficient in a specific position of a quantization coefficient table *n* must be written to a specific address, which is (JPEG codec base address + *n* * 0x100 + *quantization coefficient position number* * 0x4), in which the *quantization coefficient position number* can be 0, 1, 2, ..., 63 (see Table 37.5-2). In this mode, since each coefficient is written to a specific address, configuring the 64 quantization coefficients in sequence is not required.
- FIFO mode: all 64 quantization coefficients of the quantization table *n* are written to the same address, which is JPEG_T*n*QNR_REG. In this mode, since all coefficients are written to the same address, configuring the 64 quantization coefficients one by one in sequence is required. Afterwards, the hardware will automatically store these 64 quantization coefficients in sequence as shown in Table 37.5-2.

If there are less than 4 quantization tables, the corresponding quantization table will not be written.

To use a specific quantization coefficient table *n* for the luminance component or the chrominance component, just set the corresponding register fields to *n*:

- luminance component: JPEG_LQNR_TBL_SEL
- chrominance component: JPEG_CQNR_TBL_SEL

The JPEG baseline standard recommended 8-bit precision quantization coefficient tables for the luminance component and the chrominance component are shown in Table 37.5-3 and Table 37.5-4.

Table 37.5-3. Recommended 8-bit Precision Quantization Coefficient Table for the Luminance Component

16	11	10	16	24	40	51	61
12	12	14	19	26	58	60	55
14	13	16	24	40	57	69	56
14	17	22	29	51	87	80	62
18	22	37	56	68	109	103	77
24	35	55	64	81	104	113	92
49	64	78	87	103	121	120	101
72	92	95	98	112	100	103	99

Table 37.5-4. Recommended 8-bit Precision Quantization Coefficient Table for the Chrominance Component

17	18	24	47	99	99	99	99
18	21	26	66	99	99	99	99
24	26	56	99	99	99	99	99
47	66	99	99	99	99	99	99
99	99	99	99	99	99	99	99
99	99	99	99	99	99	99	99
99	99	99	99	99	99	99	99
99	99	99	99	99	99	99	99

More information can be found in ITU T.81 Recommendation. Adjusting the quantization table can change the compression ratio (the ratio between the uncompressed image size and compressed image size) and the quality of encoded images (the larger the quantization coefficient, the greater the compression ratio and the worse the image quality).

37.5.1.4 Stuffed Zero Byte

As required in the JPEG baseline standard to avoid any marker within a Huffman-coded segment, any 0xFF byte generated by the Huffman coding should be followed by a "stuffed" zero byte.

JPEG encoder has implemented a mechanism to automatically add this "stuffed" 0x00 byte after each 0xFF byte in the Huffman-coded segment of bitstream.

Users can configure whether to add 0x00 byte after each 0xFF byte via JPEG_FF_CHECK_EN:

- 0: not add
- 1: add (by default)

37.5.1.5 EOI Marker

The end of Image (EOI) marker is used to mark the end of the bitstream of a compressed image. The EOI marker code is 0xFFD9.

JPEG encoder has implemented a mechanism to automatically add the EOI marker at the end of the bitstream.

Users can configure whether to add EOF marker via JPEG_TAILER_EN:

- 0: not add
- 1: add

37.5.2 JPEG Decoder

The information in the bitstream must be parsed by the software, then sent to the hardware through the APB configuration bus. Note that the hardware does not support parsing any marker segments, except the SOS, RST and EOI marker segments.

37.5.2.1 Multiple Chrominance Components

The frame header contains information about the number of chrominance components of the image, the ID of each component, and the sampling factors in the horizontal and vertical directions of each component.

JPEG decoder's software must parse such information and pass it to respective registers JPEG_COMPONENT_NUM, JPEG_C*n*_ID, JPEG_C*n*_X_FACTOR, and JPEG_C*n*_Y_FACTOR. Here, *n* can be 0, 1, 2, indicating that up to 3 chrominance components are supported by hardware. Note that if less than 3 components are involved, just do not configure the rest of the registers.

According to the value of register JPEG_C*n*_ID of each chrominance component, the hardware will check whether it is consistent with the ID in the scan header information. The sampling factor indicates the number of data units of this component that an MCU contains in both the horizontal and vertical directions. So

according to the value of register JPEG_COMPONENT_NUM, JPEG_C*n*_X_FACTOR and JPEG_C*n*_Y_FACTOR, the hardware can obtain the proportional relationship of chrominance components, that is, the format of the image to be decoded. See Table 37.5-5.

Table 37.5-5. Sampling Factor and Image Format

JPEG_COMPONENT_NUM	JPEG_C*n*_X/Y_FACTOR	Format of the Image to be Decoded
0	-	invalid
1	C0_X_FACTOR is 1 C0_Y_FACTOR is 1	GRAY
2	-	invalid
3	C0_X_FACTOR is 1 C0_Y_FACTOR is 1 C1_X_FACTOR is 1 C1_Y_FACTOR is 1 C2_X_FACTOR is 1 C2_Y_FACTOR is 1	YUV444
	C0_X_FACTOR is 2 C0_Y_FACTOR is 1 C1_X_FACTOR is 1 C1_Y_FACTOR is 1 C2_X_FACTOR is 1 C2_Y_FACTOR is 1	YUV422
	C0_X_FACTOR is 2 C0_Y_FACTOR is 2 C1_X_FACTOR is 1 C1_Y_FACTOR is 1 C2_X_FACTOR is 1 C2_Y_FACTOR is 1	YUV420

Regardless of the format of the image to be decoded, the decoder only supports one scan, which contains all components. After decoding, the image will be sent to 2D DMA, so please refer to Chapter 8 *2D-DMA Controller (2D-DMA)* for the layout of the decoded image in each format.

37.5.2.2 Parsing RST Marker

The bitstream may have a restart (RST) marker in the scan segment. The RST marker code is 0xFFD*x* (*x* = 0, 1, ..., 7).

JPEG decoder's hardware can parse RST markers and check whether the actual number of MCUs between two RST markers is the same as the restart interval defined in the DRI segment of the Tables/Miscellaneous segment.

Firstly, the software parses the DRI segment and pass the defined restart interval to register JPEG_RESTART_INTERVAL. Then, the hardware will check whether the subsequent bitstream has an RST marker every time JPEG_RESTART_INTERVAL MCUs are decoded.

Configuring JPEG_RESTART_INTERVAL to 0 indicates the bitstream does not contain any RST marker. In this case, the hardware will not check RST markers.

37.5.2.3 Configurable Quantization Coefficient Table

ESP32-P4 JPEG decoder also supports 4 configurable quantization coefficient tables. Since the JPEG codec cannot be used as an encoder and decoder at the same time, decoder can share the same four configurable quantization coefficient tables with the encoder to save hardware resources.

Therefore, the configuration of decoder's quantization coefficient tables is similar to that of the encoder (see Section 37.5.1.3) with some exceptions described below:

- The software needs to parse the DQT segment in the Tables/Miscellaneous segment to obtain the quantization coefficient tables of the decoder. The recommended quantization coefficient tables are the same as the encoder shown in Table 37.5-3 and Table 37.5-4.
- The precision of the quantization table*n* is configured via higher 4 bits of register JPEG_T*n*_DQT_INFO:
  - 0: low 8-bit effective
  - 1: low 16-bit effective

  The precision is also obtained from the DQT segment in the Tables/Miscellaneous segment.
- For each chrominance component, a different quantization coefficient table can be selected. The lower 4 bits of register JPEG_T*n*_DQT_INFO specify the ID of each quantization coefficient table, and each chrominance component selects the quantization coefficient table whose ID is the value of register JPEG_C*n*_DQT_TBL_SEL. The ID of each quantization coefficient table is also obtained from the DQT segment in the Tables/Miscellaneous segment.

37.5.2.4 Configurable Huffman Table

ESP32-P4 supports up to 2 DC Huffman tables and 2 AC Huffman tables. Users can configure as many Huffman tables as needed within the limits.

Each Huffman table can be established with three types of information, which can be obtained from the DHT segment in the Tables/Miscellaneous segment:

- the number of codeword with a codeword length of 1 to 16 bits,
- the symbols corresponding to the decoded codeword
  - DC table: up to 16 symbols
  - AC table: up to 256 symbols
- the minimum codeword with a codeword length of 1 to 16 bits.

Both of the DC and AC Huffman tables can be configured in a FIFO fashion or a non-FIFO fashion depending on the value of JPEG_DHT_FIFO_EN:

- 0: non-FIFO mode
- 1: FIFO mode

In different modes, the configuration of the Huffman table is different. Here is the configuration of DC table*n* (*n* = 0, 1):

- non-FIFO mode: each piece in different type of information used to establish the DC*n* Huffman table must be written to a specific address.

  - the number of codeword with a codeword length of 1 to 16 bits: JPEG codec base address + 0x500 + *n* * 0x80 + (*codeword length* - 1) * 0x4, in which *codeword length* = 1, 2, ..., 16.
  - the symbols corresponding to the decoded codeword: JPEG codec base address + 0x600 + *n* * 0x40 + *symbol number* * 0x4, in which *symbol number* = 0, 1, ..., 15.
  - the minimum codeword with a codeword length of 1 to 16 bits: JPEG codec base address + 0xF00 + *n* * 0x80 + (*codeword length* - 1) * 0x4, in which *codeword length* = 1, 2, ..., 16.

  In this mode, since each piece of different type of information is written to a specific address, configuring each piece of information in sequence is not required.

- FIFO mode: all pieces of the same type of information used to establish the DC*n* Huffman table must be written to the same address, respectively.
  - the number of codeword with a codeword length of 1 to 16 bits: JPEG_DHT_TOTLEN_DC*n*_REG.
  - all symbols corresponding to the decoded codeword (DC table has up to 16 symbols): JPEG_DHT_VAL_DC*n*_REG.
  - the minimum codeword with a codeword length of 1 to 16 bits: JPEG_DHT_CODEMIN_DC*n*_REG.

  In this mode, since all pieces of the same type of information are written to the same address, configuring each piece of same type of information one by one in sequence is required. Afterwards, the hardware will automatically store such information in sequence.

The configuration of AC*n* (*n* = 0, 1) tables is very similar to that of the DC*n* (*n* = 0, 1) tables. Here below is the configuration of AC*n* (*n* = 0, 1) tables:

- non-FIFO mode: each piece in different type of information used to establish the AC*n* Huffman table must be written to a specific address.
  - the number of codeword with a codeword length of 1 to 16 bits: JPEG codec base address + 0x540 + *n* * 0x80 + (*codeword length* - 1) * 0x4, in which *codeword length* = 1, 2, ..., 16.
  - the symbols corresponding to the decoded codeword: JPEG codec base address + 0x680 + *n* * 0x400 + *symbol number* * 0x4, in which *symbol number* = 0, 1, ..., 256.
  - the minimum codeword with a codeword length of 1 to 16 bits: JPEG codec base address + 0xF40 + *n* * 0x80 + (*codeword length* - 1) * 0x4, in which *codeword length* = 1, 2, ..., 16.

  In this mode, since each piece of different type of information is written to a specific address, configuring each piece of information in sequence is not required.

- FIFO mode: all pieces of the same type of information used to establish the AC*n* Huffman table must be written to the same address, respectively.
  - the number of codeword with a codeword length of 1 to 16 bits: JPEG_DHT_TOTLEN_AC*n*_REG.
  - all symbols corresponding to the decoded codeword (AC table has up to 256 symbols): JPEG_DHT_VAL_AC*n*_REG.
  - the minimum codeword with a codeword length of 1 to 16 bits: JPEG_DHT_CODEMIN_AC*n*_REG.

  In this mode, since all pieces of the same type of information are written to the same address, configuring each piece of same type of information one by one in sequence is required. Afterwards, the hardware will automatically store such information in sequence.

For the minimum codeword with a codeword length of 1 to 16 bits, it should be moved left to the high bit of the 16-bit configuration data. If a codeword length does not exist, the configuration value is 0xFFFF. For example, if a minimum codeword is 0x7C, the 16-bit configuration data should be 0x7C00.

The JPEG baseline standard recommended DC and AC Huffman tables can be found in ITU T.81 Recommendation.

The software can obtain the IDs of DC*n* and AC*n* Huffman tables by parsing the DHT segment in the Tables/Miscellaneous segment, then pass these ID to the corresponding register JPEG_DC*n*_DHT_ID and JPEG_AC*n*_DHT_ID.

The hardware will automatically use the DC*n* and AC*n* Huffman tables with the same ID from JPEG_DC*n*_DHT_ID and JPEG_AC*n*_DHT_ID.

37.5.2.5 Timeout Detection

Additionally, timeout detection is supported when the JPEG codec is working as a decoder. The hardware triggers the timeout interrupt JPEG_DECODE_TIMEOUT_INT:

- when the decoder stops reading the bitstream for more than $(2^{JPEG_DECODE_TIMEOUT_THRES} - 1)$ clock cycles,
- or when the number of clock cycles consumed for decoding an image exceeds the value of $(2^{JPEG_DECODE_TIMEOUT_THRES} - 1)$

In this case, the decoder will be reset depending on the configuration of JPEG_DECODE_TIMEOUT_TASK_SEL:

- 0: the hardware will not perform any operation, and the software is required to configure the JPEG_SOFT_RST or JPEG_FSM_RST to perform a reset operation.
- 1: the hardware will automatically reset the decoder to exit the timeout state and enter the initial state.

37.6 Interrupts

ESP32-P4's JPEG Codec can generate the JPEG_INTR interrupt signal that will be sent to the Interrupt Matrix.

Interrupt signal JPEG_INTR can be generated by the following internal interrupt sources:

- JPEG_DONE_INT: Triggered when a frame of image encoding or decoding ends.
- JPEG_RLE_PARALLEL_ERR_INT: Triggered when a run-length encoding error occurs.
- JPEG_CID_ERR_INT: Triggered when the decoded component ID is different from the component ID configured by the software.
- JPEG_C_DHT_DC_ID_ERR_INT: Triggered when the decoded DC Huffman table ID of each component is not the software configured DC0 Huffman table ID or DC1 Huffman table ID.
- JPEG_C_DHT_AC_ID_ERR_INT: Triggered when the decoded AC Huffman table ID of each component is not the software configured AC0 Huffman table ID or AC1 Huffman table ID.
- JPEG_C_DQT_ID_ERR_INT: Triggered when the decoded quantization table ID of each component is different from the software configured quantization table ID.

- JPEG_RST_UXP_ERR_INT: Triggered when the JPEG_RESTART_INTERVAL configured by the software is 0 but the RST marker is parsed by the decoder.
- JPEG_RST_CHECK_NONE_ERR_INT: Triggered when the JPEG_RESTART_INTERVAL configured by the software is non-0 but the RST marker cannot be parsed by the decoder.
- JPEG_RST_CHECK_POS_ERR_INT: Triggered when the MCU number between two parsed RST markers is not equal to the JPEG_RESTART_INTERVAL configured by the software.
- JPEG_OUT_EOF_INT: Triggered when the EOF marker is read from the TX channel of 2D DMA.
- JPEG_SR_COLOR_MODE_ERR_INT: This interrupt is invalid.
- JPEG_DCT_DONE_INT: Triggered when the DCT or IDCT calculation of one data unit is completed.
- JPEG_BS_LAST_BLOCK_EOF_INT: Triggered when the encoding of the last data unit is completed.
- JPEG_SCAN_CHECK_NONE_ERR_INT: Triggered when an image frame has multiple scans to be decoded and the SOS marker is not parsed within (JPEG_SOS_CHECK_BYTE_NUM + 1) bytes in any scan header information.
- JPEG_SCAN_CHECK_POS_ERR_INT: Triggered when the position of the scan header information parsed by the decoder is wrong.
- JPEG_UXP_DET_INT: Triggered when the marker parsed by the decoder is not supported by the hardware.
- JPEG_EN_FRAME_EOF_ERR_INT: Triggered when the number of data units to be encoded read from 2D DMA is less than the number of data units calculated based on the image resolution configured by the software.
- JPEG_EN_FRAME_EOF_LACK_INT: Triggered when a frame of image to be encoded is completely read from 2D DMA but the EOF marker is not read.
- JPEG_DE_FRAME_EOF_ERR_INT: Triggered when the number of data units obtained after decoding a frame of image is different from the number of data units calculated based on the image resolution configured by the software.
- JPEG_DE_FRAME_EOF_LACK_INT: Triggered when the bitstream of a image is completely read from 2D DMA but the EOF marker or EOI marker is not read.
- JPEG_SOS_UNMATCH_ERR_INT: Triggered when the number of components in the scan header information parsed by the decoder is 0 or the header length in the scan header information parsed by the decoder does not match the actual header length.
- JPEG_MARKER_ERR_FST_SCAN_INT: Triggered when there is an error in the first scan header information parsed by the decoder. The errors include errors triggering JPEG_CID_ERR_INT, errors triggering JPEG_C_DHT_DC_ID_ERR_INT, errors triggering JPEG_C_DHT_AC_ID_ERR_INT, errors triggering JPEG_C_DQT_ID_ERR_INT and errors triggering JPEG_SOS_UNMATCH_ERR_INT.
- JPEG_MARKER_ERR_OTHER_SCAN_INT: Triggered when there is an error in the non-first scan header information parsed by the decoder. The error type is the same as the errors that trigger JPEG_MARKER_ERR_FST_SCAN_INT.
- JPEG_UNDET_INT: Triggered when the bitstream of an image is completely read from 2D DMA but the SOS marker is not read.

- JPEG_DECODE_TIMEOUT_INT: Triggered when the decoder is timeout. Section 37.7.2 describes how this interrupt will occur.

The above interrupt sources can only be triggered when the interrupt enable register *interrupt_source_name*_ENA is set to 1. Write 1 to *interrupt_source_name*_CLR will clear the interrupt.

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 37.8 *Register Summary*.

37.7 Programming Procedures

37.7.1 JPEG Encoder

When the JPEG codec is working as an encoder, the configuration process is:

1. Activate the JPEG codec:
   - Set HP_SYS_CLKRST_JPEG_SYS_CLK_EN to 1 to enable the JPEG codec clock;
   - Set HP_SYS_CLKRST_RST_EN_JPEG to 0 to release the JPEG codec system level reset.
2. Configure the JPEG codec:
   - Set JPEG_SOFT_RST to 1 to reset the JPEG codec, and then set JPEG_SOFT_RST to 0 to release the JPEG codec reset.
   - Set JPEG_MODE to 0 to configure the JPEG codec to be used as an encoder.
   - Select the original image format by configuring the following registers:
     - Format:
       * JPEG_COLOR_SPACE
       * JPEG_EXTD_COLOR_SPACE_EN
       * JPEG_EXTD_COLOR_SPACE
     - Pixel order: JPEG_PIXEL_REV

     See details in Table 37.5-1.
   - Select whether to add the EOI marker (0xFFD9) at the end of the bitstream by configuring JPEG_TAILER_EN:
     - 0: disable
     - 1: enable
   - Select the image format to be compressed by configuring JPEG_SAMPLE_SEL:
     - 0: YUV444

  - 1: YUV422
  - 2: YUV420

  Note that this register is valid only when the original image format is RGB, YUV444, or YUV422. See details in Table 37.5-1.

- Configure JPEG_HA as the original image width and JPEG_VA as the original image height.
- Configure the quantization coefficient table by following the instructions in Section 37.5.1.3.

3. Configure 2D DMA (For detailed instructions or introduction to related concepts, please refer to Chapter *8 2D-DMA Controller (2D-DMA)*.)

   (a) Configure the linked list of 2D DMA TX channel.

   - Set 2DEN to 1 to enable 2D function.
   - Configure the Buffer address pointer as the starting address where the original image is stored.
   - Configure pbyte to select the number of bytes of one pixel of the original image.
   - Configure HA as the width of the original image and VA as the height of the original image.
   - Configure hb as the number of pixels in the horizontal direction of an image block and vb as the number of pixels in the vertical direction of an image block.
   - Configure mod as 1, which means continuous reading of image blocks of hb × vb size.
   - Configure (X, Y) as the coordinate of the first pixel in the starting image block. Among them, according to the original image format and the format of the image to be compressed, there are restrictions on hb and vb, as shown in the table 37.7-1:

Table 37.7-1. JPEG Encoder hb and vb Configuration

Format of Original Image	Format of the Image to be Compressed	hb	vb
RGB/YUV444	YUV444	Multiples of 8	Multiples of 8
	YUV422	Multiples of 16	Multiples of 8
	YUV420	Multiples of 16	Multiples of 16
YUV422	YUV422	Multiples of 16	Multiples of 8
	YUV420	Multiples of 16	16
YUV420	YUV420	Multiples of 16	16
GRAY	GRAY	Multiples of 8	Multiples of 8

   (b) Configure the linked list of the 2D DMA RX channel:

   - Set 2DEN to 0 to enable 1D function.
   - Configure the Buffer address pointer as the starting address where the encoded bitstream will be stored.
   - Configure size as the number of bytes in the space to store the encoded bitstream.
   - configure mod as 0, which means one-time reading of image blocks of hb × vb size.

   (c) Connect 2D DMA channels to JPEG codec:

- Connect the TX channel*n* to the JPEG codec by configuring DMA2D_OUT_PERI_SEL_CH*n* to 0;
- Connect the RX channel*n* to the JPEG codec by configuring DMA2D_IN_PERI_SEL_CH*n* to 0.

(d) Reset 2D DMA channels:

- 2D DMA TX channel*n*: Set DMA2D_OUT_RST_CH*n* to 1 to reset 2D DMA TX channel*n*, then set DMA2D_OUT_RST_CH*n* to 0 to release the reset of 2D DMA TX channel*n*.
- 2D DMA RX channel*n*: Set DMA2D_IN_RST_CH*n* to 1 to reset 2D DMA RX channel*n*, then set DMA2D_IN_RST_CH*n* to 0 to release the reset of 2D DMA RX channel*n*.

(e) Select the burst length of 2D DMA channels:

- Configure DMA2D_OUT_MEM_BURST_LENGTH_CH*n* to select the burst length of 2D DMA TX channel*n*.
- Configure DMA2D_IN_MEM_BURST_LENGTH_CH*n* to select the burst length of 2D DMA RX channel*n*.

(f) Select the 2D DMA output image block size by configuring DMA2D_OUT_MACRO_BLOCK_SIZE_CH*n* according to the format of original image and the format of the image to be compressed. See details in Table 37.7-2:

- 0: 8x8
- 1: 16x8
- 2: 16x16

Table 37.7-2. DMA2D_OUT_MACRO_BLOCK_SIZE_CH*n* Configuration

Format of Original Image	Format of the Image to be Compressed	DMA2D_OUT_MACRO_BLOCK_SIZE_CH*n*
RGB/YUV444	YUV444	0
	YUV422	1
	YUV420	2
YUV422	YUV422	1
	YUV420	2
YUV420	YUV420	2
GRAY	GRAY	0

(g) Enable the reorder function to improve bandwidth utilization by setting DMA2D_OUT_REORDER_EN_CH0 to 1. Note that, this function is only available for 2D DMA TX channel0, not for any other TX channels.

(h) Configure 2D DMA channel linked list address:

- 2D DMA TX channel: DMA2D_OUTLINK_ADDR_CH*n*
- 2D DMA RX channel: DMA2D_INLINK_ADDR_CH*n*

4. Enable interrupt sources:

- DMA2D_OUT_INT_ENA_CH*n*_REG
- DMA2D_IN_INT_ENA_CH*n*_REG

- JPEG_INT_ENA_REG

5. Start the transmission of 2D DMA channels:
   - 2D DMA TX channel: set DMA2D_OUTLINK_START_CH*n* to 1 and then to 0
   - 2D DMA RX channel: set DMA2D_INLINK_START_CH*n* to 1 and then to 0
6. Start the JPEG codec encoding by setting the JPEG_JPEG_START field.
7. Wait till DMA2D_IN_SUC_EOF_CH*n*_INT becomes 1, indicating that the encoded bitstream has been completely written to the memory.

37.7.2 JPEG Decoder

When the JPEG codec is working as a decoder, the configuration process is:

1. Activate the JPEG codec:
   - Set HP_SYS_CLKRST_JPEG_SYS_CLK_EN to 1 to enable the JPEG codec clock
   - Set HP_SYS_CLKRST_RST_EN_JPEG to 0 to release the JPEG codec system level reset.
2. Configure the JPEG codec:
   - Set JPEG_SOFT_RST to 1 to reset the JPEG codec, and then set JPEG_SOFT_RST to 0 to release the JPEG codec reset.
   - Set JPEG_MODE to 1 to configure the JPEG codec to be used as a decoder.
   - Enable the RST marker check following the instructions in Section 37.5.2.2, if required.
   - Configure the quantization coefficient tables by following the instructions in Section 37.5.2.3.
   - Configure the Huffman tables by following the instructions in Section 37.5.2.4.
   - Configure the width and height of the decoded image:
     - Width: write width of the decoded image to JPEG_HA.
     - Height: write the height of the decoded image to JPEG_VA.
     - According to different decoded image formats, JPEG_HA and JPEG_VA must meet the requirements of Table 37.7-3.

Table 37.7-3. JPEG Decoder JPEG_HA and JPEG_VA Configuration

Format of Decoded Image	JPEG_HA	JPEG_VA
YUV444	Multiples of 8	8
YUV422	Multiples of 16	8
YUV420	Multiples of 16	16
GRAY	Multiples of 8	8

3. Configure 2D DMA (For detailed instructions or introduction to related concepts, please refer to Chapter 8 *2D-DMA Controller (2D-DMA)*.)
   (a) Configure the linked list of the 2D DMA TX channel.

- Set 2DEN to 0 to enable the 1D function.
- Configure the Buffer address pointer as the starting address where the bitstream to be decoded is stored.
- Configure the length and size as the number of bytes in the space to store the bitstream to be decoded.
- configure mod as 0, which means one-time reading of image blocks of hb x vb size.

(b) Configure the linked list of 2D DMA RX channel.

- Set 2DEN to 1 to enable 2D function.
- Configure the Buffer address pointer as the starting address where the decoded image will be stored.
- Configure pbyte to select the number of bytes of one pixel of the image which is decoded and has undergone 2D DMA color space conversion.
- Configure HA as the width of the output decoded image, configure VA as the height of the output decoded image, configure hb as the number of pixels in the horizontal direction of an image block, configure vb as the number of pixels in the vertical direction of an image block.
- Configure mod as 1, which means continuous reading of image blocks of hb × vb size.
- Configure (X, Y) as the coordinates of the first pixel in the starting image block. Among them, according to the decoded image format, there are restrictions on hb and vb, as shown in the table 37.7-4:

Table 37.7-4. JPEG Decoder hb and vb Configuration

Decoded image format	hb	vb
YUV444	Multiples of 8	Multiples of 8
YUV422	Multiples of 16	Multiples of 8
YUV420	Multiples of 16	Multiples of 16
GRAY	Multiples of 8	Multiples of 8

(c) Connect 2D DMA channels to JPEG codec:

- Connect the TX channel*n* to the JPEG codec by configuring DMA2D_OUT_PERI_SEL_CH*n* to 0;
- Connect the RX channel*n* to the JPEG codec by configuring DMA2D_IN_PERI_SEL_CH*n* to 0.

(d) Reset 2D DMA channels:

- 2D DMA TX channel*n*: set DMA2D_OUT_RST_CH*n* to 1 to reset 2D DMA TX channel*n*, then set DMA2D_OUT_RST_CH*n* to 0 to release the reset of 2D DMA TX channel*n*.
- 2D DMA RX channel*n*: set DMA2D_IN_RST_CH*n* to 1 to reset 2D DMA RX channel*n*, then set DMA2D_IN_RST_CH*n* to 0 to release the reset of 2D DMA RX channel*n*.

(e) Select the burst length of 2D DMA channels:

- Configure DMA2D_OUT_MEM_BURST_LENGTH_CH*n* to select the burst length of 2D DMA TX channel*n*

- Configure DMA2D_IN_MEM_BURST_LENGTH_CH*n* to select the burst length of 2D DMA RX channel*n*

(f) Select 2D DMA receive image block size by configuring DMA2D_IN_MACRO_BLOCK_SIZE_CH*n* according to the format of the decoded image. See details in Table 37.7-5:

- 0: 8x8
- 1: 16x8
- 2: 16x16

Table 37.7-5. DMA2D_IN_MACRO_BLOCK_SIZE_CH*n* Configuration

Format of Decoded Image	DMA2D_IN_MACRO_BLOCK_SIZE_CH*n*
YUV444	0
YUV422	1
YUV420	2
GRAY	0

(g) Enable the reorder function to improve bandwidth utilization by setting set DMA2D_IN_REORDER_EN_CH0 to 1. Note that, this function is only available for 2D DMA RX channel0, not for any other RX channels.

(h) Select whether to scramble the pixel order of the decoded image before 2D DMA color space conversion by configuring DMA2D_IN_SCRAMBLE_SEL_PRE_CH0:

- 0: BYTE2-1-0
- 1: BYTE2-0-1
- 2: BYTE1-0-2
- 3: BYTE1-2-0
- 4: BYTE0-2-1
- 5: BYTE0-1-2

Configuring DMA2D_IN_SCRAMBLE_SEL_PRE_CH0 to 5 means swapping the pixel order, for example, swapping YUV444 output by the JPEG decoder to VUY444. Note that, this function is only available for 2D DMA RX channel0, not for any other RX channels.

(i) Select the color conversion methods by configuring DMA2D_IN_COLOR_INPUT_SEL_CH0, DMA2D_IN_COLOR_3B_PROC_EN_CH0, and DMA2D_IN_COLOR_OUTPUT_SEL_CH0. See details in Table 37.7-6:

Table 37.7-6. 2D DMA Color Space Conversion Configuration

Color Space Conversion Method	INPUT_SEL_CH0	3B_PROC_EN_CH0	OUTPUT_SEL_CH0
YUV420 → RGB	0	1	1
YUV422 → RGB	0	1	1
YUV444 → RGB	2	1	1
YUV444 (only reverse the pixel order)	2	0	1
No color space conversion	7	N/A	N/A

Note that, this function is only available for 2D DMA RX channel0, not for any other RX channels.

(j) Configure parameters required for the color space conversion formula, including DMA2D_IN_COLOR_PARAM_H0_CH0, DMA2D_IN_COLOR_PARAM_H1_CH0, DMA2D_IN_COLOR_PARAM_M0_CH0, DMA2D_IN_COLOR_PARAM_M1_CH0, DMA2D_IN_COLOR_PARAM_L0_CH0, and DMA2D_IN_COLOR_PARAM_L1_CH0. Note that, this function is only available for 2D DMA RX channel0, not for any other RX channels.

(k) Select whether to reverse the pixel order of the image after 2D DMA color space conversion by configuring DMA2D_IN_SCRAMBLE_SEL_POST_CH0:

- 0: BYTE2-1-0
- 1: BYTE2-0-1
- 2: BYTE1-0-2
- 3: BYTE1-2-0
- 4: BYTE0-2-1
- 5: BYTE0-1-2

Configuration of 5 means reversing the pixel order, for example, reversing the RGB after 2D DMA color space conversion to BGR. Note that, this function is only available for 2D DMA RX channel0, not for any other RX channels.

(l) Configure DMA2D_OUTLINK_ADDR_CH*n* as the 2D DMA TX channel linked list address, configure DMA2D_INLINK_ADDR_CH*n* as the 2D DMA RX channel linked list address.

4. Enable interrupt sources:
   - DMA2D_OUT_INT_ENA_CH*n*_REG
   - DMA2D_IN_INT_ENA_CH*n*_REG
   - JPEG_INT_ENA_REG
5. Start the transmission of 2D DMA channels:
   - 2D DMA TX channel*n*: set DMA2D_OUTLINK_START_CH*n* to 1 and then to 0
   - 2D DMA RX channel*n*: set DMA2D_INLINK_START_CH*n* to 1 and then to 0
6. Start JPEG codec decoding by setting the JPEG_JPEG_START field.
7. Wait till DMA2D_IN_SUC_EOF_CH*n*_INT becomes 1, indicating that the decoded image has been completely written to the memory.

37.7.3 Reset

Users can **reset** JPEG codec entirely or partially, depending on the actual scenarios, at any time during the encoding or decoding process:

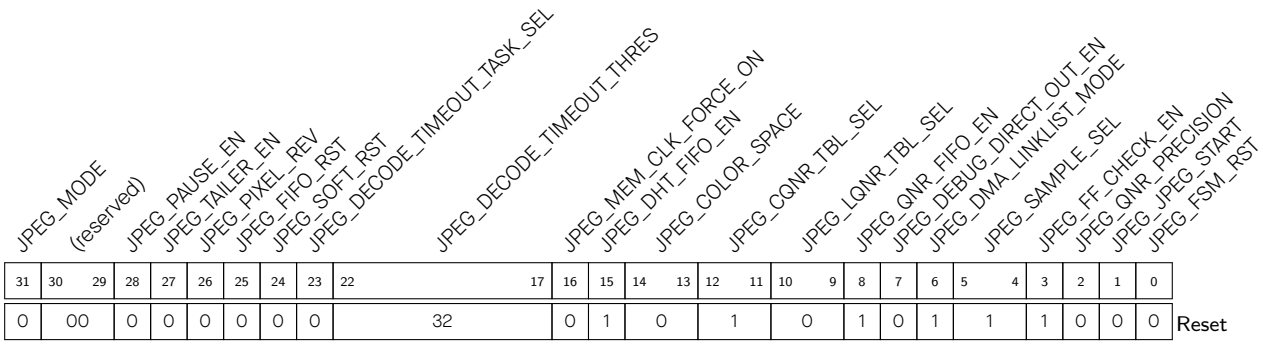
- The entire JPEG codec, including all the RAMs and FIFOs as well as all the state machines: set JPEG_SOFT_RST to 1. In this case, the register configuration value will not be reset.

- Only all the RAMs and FIFOs inside the JPEG codec, for example, changing the quantization coefficient tables or Huffman tables: set JPEG_FIFO_RST to 1.
- Only all the state machines inside the JPEG codec, for example, only stop the current encoding or decoding process: set JPEG_FSM_RST to 1.

37.8 Register Summary

The addresses in this section are relative to JEPG Codec base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
Control and Configuration registers			
JPEG_CONFIG_REG	System level control and configuration register	0x0000	varies
JPEG_DQT_INFO_REG	Quantization coefficient table information register	0x0004	R/W
JPEG_PIC_SIZE_REG	Image size register	0x0008	R/W
JPEG_EXTD_CONFIG_REG	Extended color space conversion configuration register	0x000C	R/W
JPEG_T0QNR_REG	Quantization coefficient table0 register	0x0010	HRO
JPEG_T1QNR_REG	Quantization coefficient table1 register	0x0014	HRO
JPEG_T2QNR_REG	Quantization coefficient table2 register	0x0018	HRO
JPEG_T3QNR_REG	Quantization coefficient table3 register	0x001C	HRO
JPEG_DECODE_CONF_REG	Decoder configuration register	0x0020	varies
JPEG_C0_REG	Color component0 register	0x0024	R/W
JPEG_C1_REG	Color component1 register	0x0028	R/W
JPEG_C2_REG	Color component2 register	0x002C	R/W
JPEG_C3_REG	Color component3 register	0x0030	R/W
JPEG_DHT_INFO_REG	Huffman table information register	0x0034	R/W
JPEG_DHT_TOTLEN_DC0_REG	DC0 Huffman table codeword length register	0x0058	HRO
JPEG_DHT_VAL_DC0_REG	DC0 Huffman table symbol register	0x005C	HRO
JPEG_DHT_TOTLEN_AC0_REG	AC0 Huffman table codeword length register	0x0060	HRO
JPEG_DHT_VAL_AC0_REG	AC0 Huffman table symbol register	0x0064	HRO
JPEG_DHT_TOTLEN_DC1_REG	DC1 Huffman table codeword length register	0x0068	HRO
JPEG_DHT_VAL_DC1_REG	DC1 Huffman table symbol register	0x006C	HRO
JPEG_DHT_TOTLEN_AC1_REG	AC1 Huffman table codeword length register	0x0070	HRO
JPEG_DHT_VAL_AC1_REG	AC1 Huffman table symbol register	0x0074	HRO
JPEG_DHT_CODEMIN_DC0_REG	DC0 Huffman table minimum codeword register	0x0078	HRO
JPEG_DHT_CODEMIN_AC0_REG	AC0 Huffman table minimum codeword register	0x007C	HRO
JPEG_DHT_CODEMIN_DC1_REG	DC1 Huffman table minimum codeword register	0x0080	HRO
JPEG_DHT_CODEMIN_AC1_REG	AC1 Huffman table minimum codeword register	0x0084	HRO
JPEG_SYS_REG	System configuration register	0x00F8	R/W
Interrupt registers			
JPEG_INT_RAW_REG	Interrupt raw status register	0x0038	R/WTC/SS
JPEG_INT_ENA_REG	Interrupt enable register	0x003C	R/W
JPEG_INT_ST_REG	Interrupt masked status register	0x0040	RO
JPEG_INT_CLR_REG	Interrupt clear register	0x0044	WT
Version Register			
JPEG_VERSION_REG	Version control register	0x00FC	R/W

37.9 Registers

The addresses in this section are relative to the JEPG Codec base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 37.1. JPEG_CONFIG_REG (0x0000)

JPEG_FSM_RST Configures whether or not to reset the state machine of JPEG Codec.

0: Invalid. No effect

1: Reset the state machine

(WT)

JPEG_JPEG_START Configures whether or not to start compressing a new image.

0: Invalid. No effect

1: Start compressing a new image

(WT)

JPEG_QNR_PRECISION Configures the quantization coefficient table precision for the encoder.

0: 8-bit precision

1: 16-bit precision

(R/W)

JPEG_FF_CHECK_EN Configures whether or not to add “0x00” after “0xFF”.

0: Not add

1: Add

(R/W)

JPEG_SAMPLE_SEL Configures the format of the image to be compressed.

0: YUV444

1: YUV422

2: YUV420

3: Invalid. No effect

(R/W)

Continued on the next page...

Register 37.1. JPEG_CONFIG_REG (0x0000)

Continued from the previous page...

JPEG_DMA_LINKLIST_MODE Represents 2D DMA linked list mode.
0: Invalid. No effect
1: 2D DMA uses linked lists to configure
(RO)

JPEG_DEBUG_DIRECT_OUT_EN Configures whether out not to enable debug mode for encoder.
0: Disable debug mode, the encoder will work in normal mode
1: Enable debug mode, the input image will be directly output by the encoder
(R/W)

JPEG_QNR_FIFO_EN Configures whether or not to enable FIFO mode when configuring quantization coefficient tables.
0: Disable. Use non-FIFO mode
1: Enable
(R/W)

JPEG_LQNR_TBL_SEL Configures the luminance quantization table ID for the encoder. (R/W)

JPEG_CQNR_TBL_SEL Configures the chrominance quantization table ID for the encoder. (R/W)

JPEG_COLOR_SPACE Configures the original image's color space.
0: RGB888
1: YUV422
2: RGB565
3: GRAY
(R/W)

JPEG_DHT_FIFO_EN Configures whether or not to enable FIFO mode when configuring Huffman tables.
0: Disable. Use non-FIFO mode
1: Enable
Note that to read Huffman tables only non-FIFO mode is supported.
(R/W)

JPEG_MEM_CLK_FORCE_ON Configures whether or not to force on memory's clock gate.
0: Not force on
1: Force on
(R/W)

JPEG_DECODE_TIMEOUT_THRES Configures decode timeout period to trigger JPEG_DECODE_TIMEOUT_INT_RAW. The clock cycles of timeout period = $2^{JPEG_DECODE_TIMEOUT_THRES} - 1$. (R/W)

Continued on the next page...

Register 37.1. JPEG_CONFIG_REG (0x0000)

Continued from the previous page...

JPEG_DECODE_TIMEOUT_TASK_SEL Configures the reset mode upon the decoder timeout.

0: Software uses reset to abort the decoding process

1: Hardware automatically aborts decoding process

(R/W)

JPEG_SOFT_RST Configures whether or not to apply soft reset to the JPEG Codec.

0: Release the soft reset

1: Apply soft reset to the JPEG Codec (the register configuration value will not be reset)

(R/W)

JPEG_FIFO_RST Configures whether or not to apply FIFO reset to the JPEG Codec.

0: Release the FIFO reset

1: Apply FIFO reset to the JPEG Codec

(R/W)

JPEG_PIXEL_REV Configures whether or not to reverse the original image's pixel order.

0: Not reverse

1: Reverse

(R/W)

JPEG_TAILER_EN Configures whether or not to add EOI marker "0xFFD9" at the end of bitstream.

0: Not add

1: Add

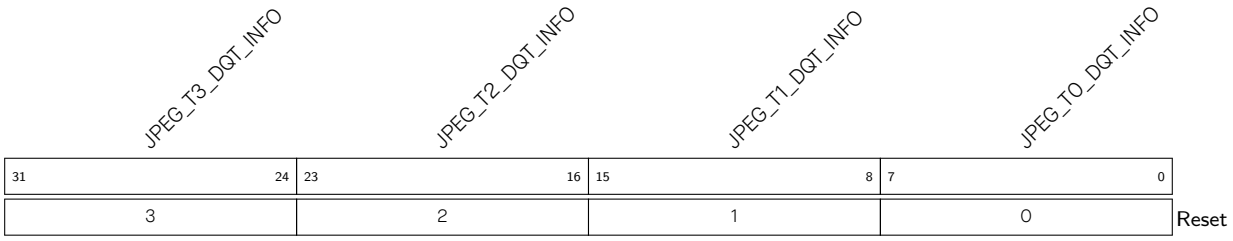
(R/W)

JPEG_PAUSE_EN Configures whether or not to pause the JPEG Codec.

0: Not pause

1: Pause

(R/W)



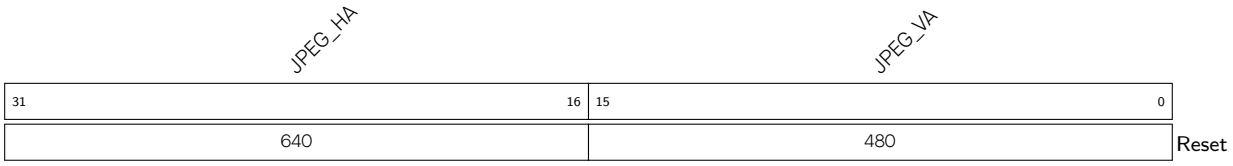
JPEG_MODE Configures if the JPEG Codec is working as an encoder or a decoder.

0: Encoder

1: Decoder

(R/W)

Register 37.2. JPEG_DQT_INFO_REG (0x0004)

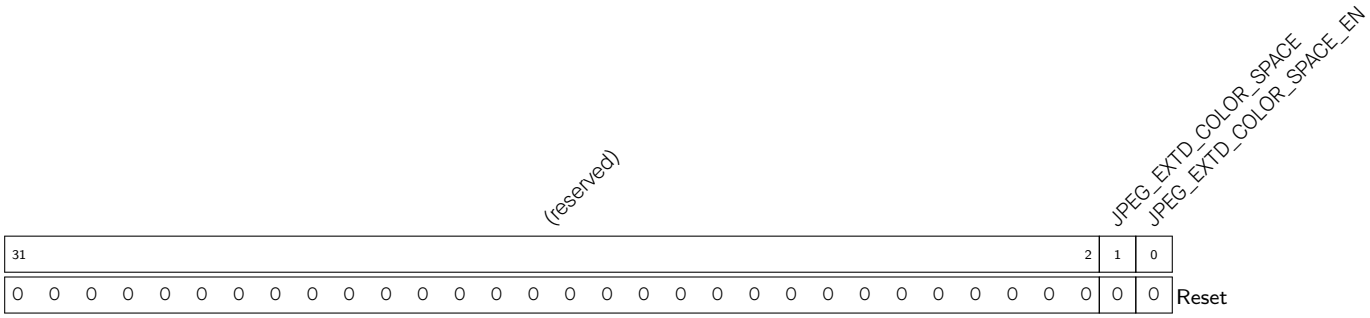


JPEG_T0_DQT_INFO Configures quantization coefficient table0's precision and ID for decoder.
Bit[7:4]: Configures precision
Bit[3:0]: Configures ID
(R/W)

JPEG_T1_DQT_INFO Configures quantization coefficient table1's precision and ID for decoder. See details in JPEG_T0_DQT_INFO. (R/W)

JPEG_T2_DQT_INFO Configures quantization coefficient table2's precision and ID for decoder. See details in JPEG_T0_DQT_INFO. (R/W)

JPEG_T3_DQT_INFO Configures quantization coefficient table3's precision and ID for decoder. See details in JPEG_T0_DQT_INFO. (R/W)



Register 37.3. JPEG_PIC_SIZE_REG (0x0008)

JPEG_VA Configures the image's height.
When JPEG Codec works as an encoder, the maximum configurable bits is 14.
When JPEG Codec works as a decoder, the maximum configurable bits is 16.
(R/W)

JPEG_HA Configures the image's width.
When JPEG Codec works as an encoder, the maximum configurable bits is 14.
When JPEG Codec works as a decoder, the maximum configurable bits is 16.
(R/W)

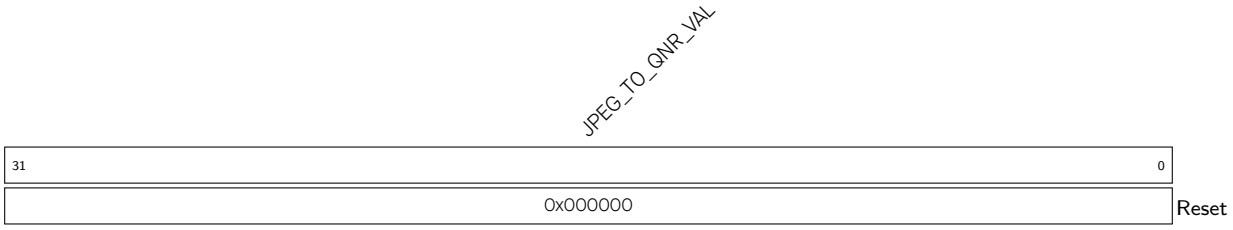
Register 37.4. JPEG_EXTD_CONFIG_REG (0x000C)

JPEG_EXTD_COLOR_SPACE_EN Configure whether to enable extended color space conversion options.

0: Disable

1: Enable

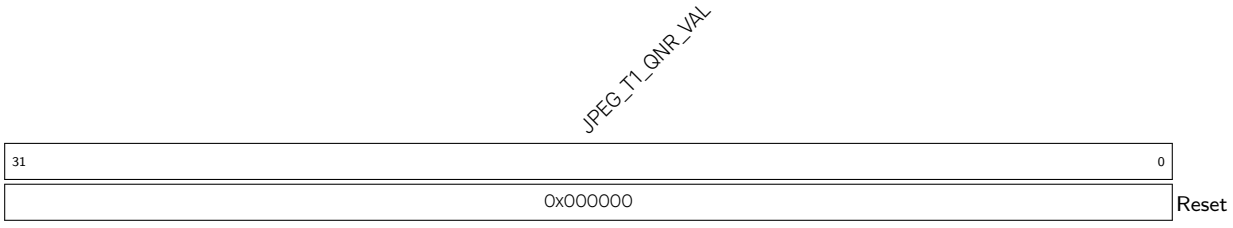
(R/W)



JPEG_EXTD_COLOR_SPACE Configure the extended color space format to be converted. Valid when JPEG_EXTD_COLOR_SPACE_EN configured to 1.

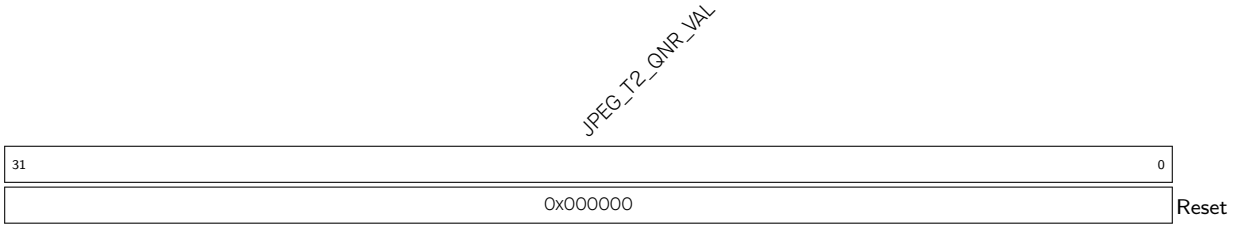
0: YUV444

1: YUV420



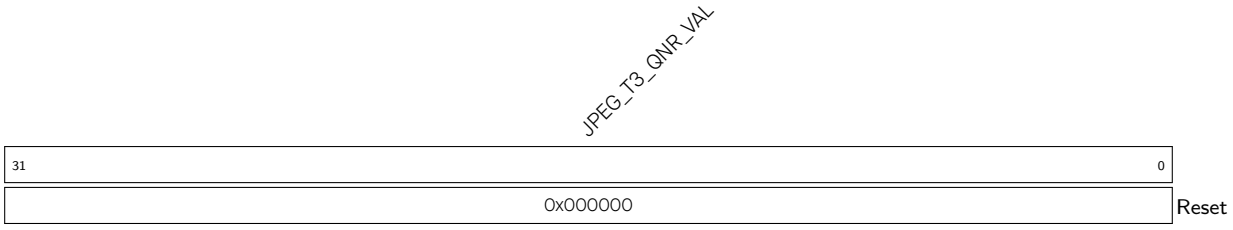
(R/W)

Register 37.5. JPEG_T0QNR_REG (0x0010)



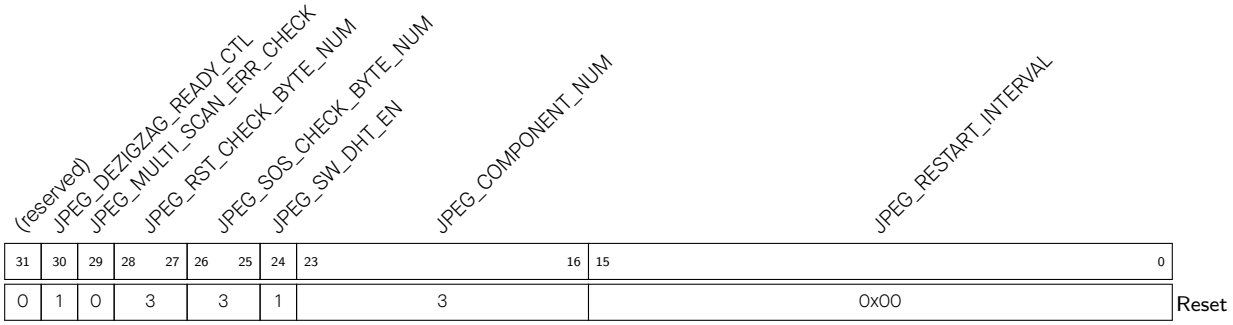
JPEG_T0_QNR_VAL Configures the quantization coefficients of the quantization table 0 in FIFO mode. (HRO)

Register 37.6. JPEG_T1QNR_REG (0x0014)



JPEG_T1_QNR_VAL Configures the quantization coefficients of the quantization table 1 in FIFO mode. (HRO)

Register 37.7. JPEG_T2QNR_REG (0x0018)



JPEG_T2_QNR_VAL Configures the quantization coefficients of the quantization table 2 in FIFO mode. (HRO)

Register 37.8. JPEG_T3QNR_REG (0x001C)

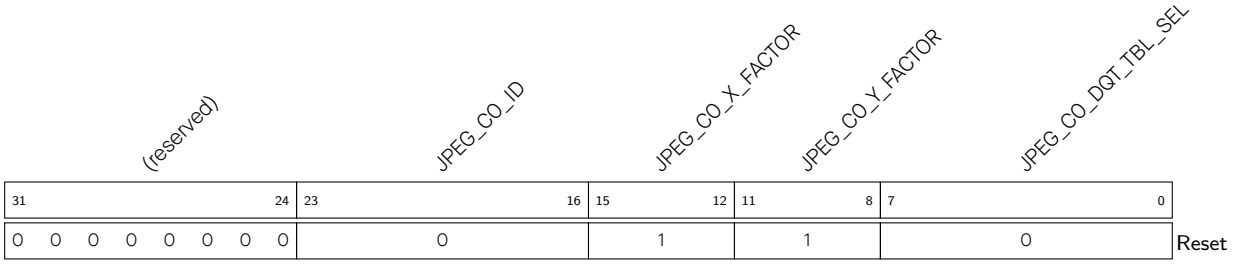
JPEG_T3_QNR_VAL Configures the quantization coefficients of the quantization table 3 in FIFO mode. (HRO)

Register 37.9. JPEG_DECODE_CONF_REG (0x0020)

JPEG_RESTART_INTERVAL Configures the RST interval in DRI segment when decoding. (R/W)

JPEG_COMPONENT_NUM Configures the number of chrominance components in the image when decoding. (R/W)

JPEG_SW_DHT_EN Represents the Huffman table configured by the software for the decoder. The value is always 1. (RO)



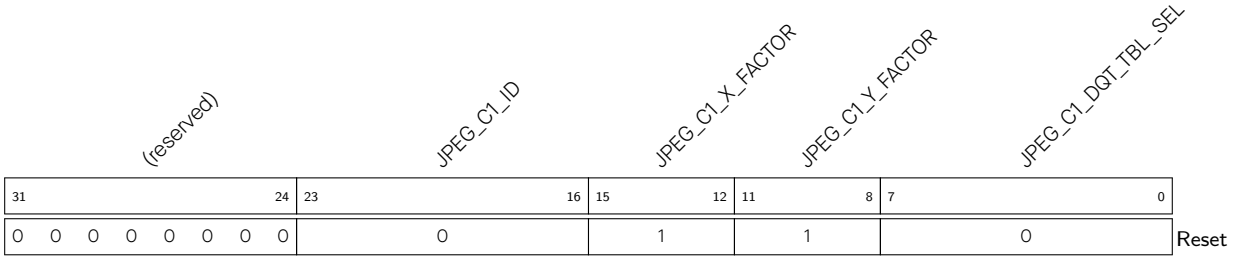
JPEG_SOS_CHECK_BYTE_NUM Configures the byte number to check the next SOS marker in the multi-scan image after one scan is decoded down. The actual check number is JPEG_SOS_CHECK_BYTE_NUM + 1 (R/W)

JPEG_RST_CHECK_BYTE_NUM Configures the byte number to check the next RST marker after one RST interval is decoded down. The actual check number is JPEG_RST_CHECK_BYTE_NUM + 1. (R/W)

JPEG_MULTI_SCAN_ERR_CHECK Reserved for decoder and should not be configured. (R/W)

JPEG_DEZIGZAG_READY_CTL Reserved for decoder and should not be configured. (R/W)

Register 37.10. JPEG_C0_REG (0x0024)



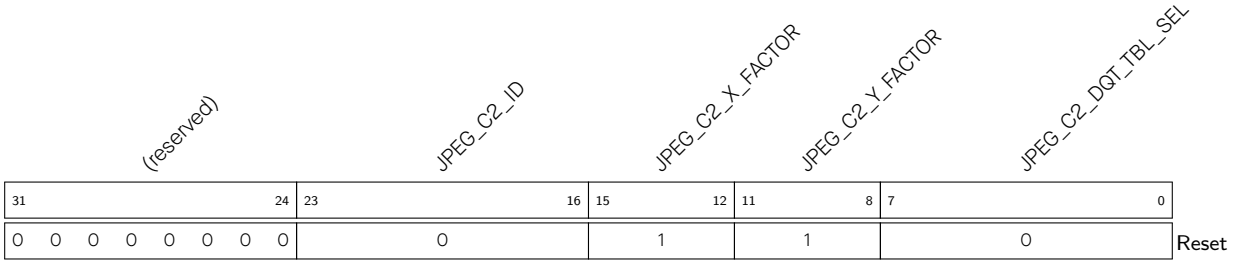
JPEG_C0_DQT_TBL_SEL Configures the selected quantization coefficient table ID for component0 in decoder mode. (R/W)

JPEG_C0_Y_FACTOR Configures the vertical sampling factor of component0 in decoder mode. (R/W)

JPEG_C0_X_FACTOR Configures the horizontal sampling factor of component0 in decoder mode. (R/W)

JPEG_C0_ID Configures the ID of component0 in decoder mode. (R/W)

Register 37.11. JPEG_C1_REG (0x0028)



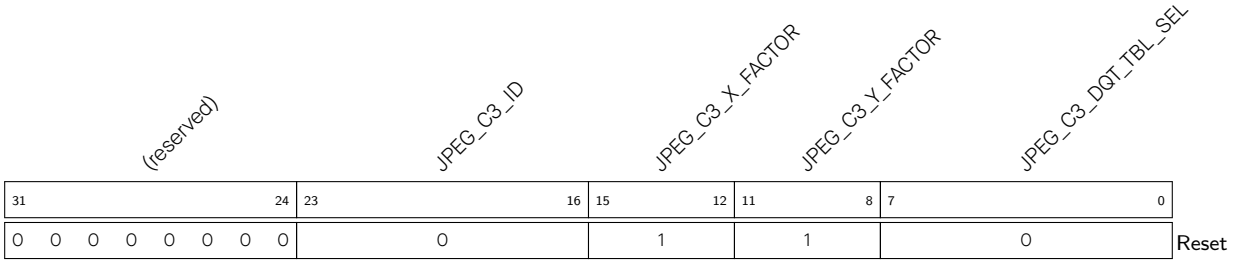
JPEG_C1_DQT_TBL_SEL Configures the selected quantization coefficient table ID for component1 in decoder mode. (R/W)

JPEG_C1_Y_FACTOR Configures the vertical sampling factor of component1 in decoder mode. (R/W)

JPEG_C1_X_FACTOR Configures the horizontal sampling factor of component1 in decoder mode. (R/W)

JPEG_C1_ID Configures the ID of component1 in decoder mode. (R/W)

Register 37.12. JPEG_C2_REG (0x002C)



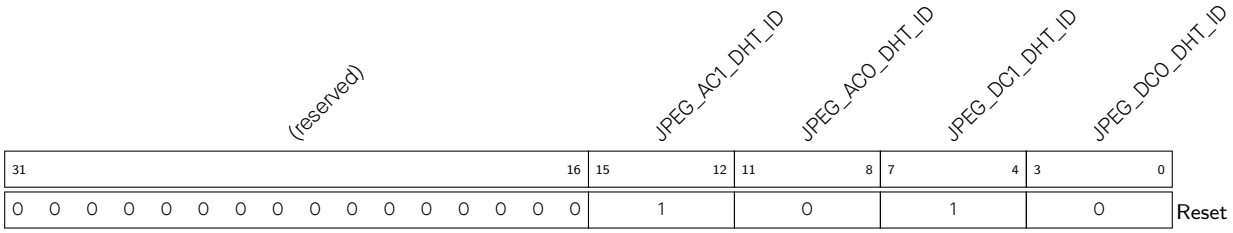
JPEG_C2_DQT_TBL_SEL Configures the selected quantization coefficient table ID for component2 in decoder mode. (R/W)

JPEG_C2_Y_FACTOR Configures the vertical sampling factor of component2 in decoder mode. (R/W)

JPEG_C2_X_FACTOR Configures the horizontal sampling factor of component2 in decoder mode. (R/W)

JPEG_C2_ID Configures the ID of component2 in decoder mode. (R/W)

Register 37.13. JPEG_C3_REG (0x0030)



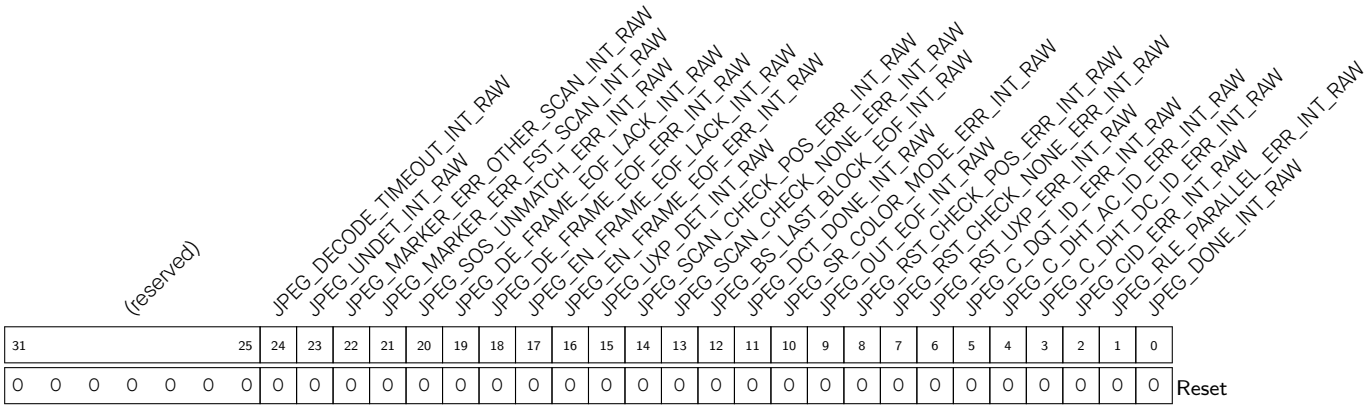
JPEG_C3_DQT_TBL_SEL Configures the selected quantization coefficient table ID for component3 in decoder mode. (R/W)

JPEG_C3_Y_FACTOR Configures the vertical sampling factor of component3 in decoder mode. (R/W)

JPEG_C3_X_FACTOR Configures the horizontal sampling factor of component3 in decoder mode. (R/W)

JPEG_C3_ID Configures the ID of component3 in decoder mode. (R/W)

Register 37.14. JPEG_DHT_INFO_REG (0x0034)



JPEG_DC0_DHT_ID Configures the ID of DC0 Huffman table in decoder mode. (R/W)

JPEG_DC1_DHT_ID Configures the ID of DC1 Huffman table in decoder mode. (R/W)

JPEG_AC0_DHT_ID Configures the ID of AC0 Huffman table in decoder mode. (R/W)

JPEG_AC1_DHT_ID Configures the ID of AC1 Huffman table in decoder mode. (R/W)

Register 37.15. JPEG_INT_RAW_REG (0x0038)

JPEG_DONE_INT_RAW The raw status of JPEG_DONE_INT. (R/WTC/SS)

JPEG_RLE_PARALLEL_ERR_INT_RAW The raw status of JPEG_RLE_PARALLEL_ERR_INT. (R/WTC/SS)

JPEG_CID_ERR_INT_RAW The raw status of JPEG_CID_ERR_INT. (R/WTC/SS)

JPEG_C_DHT_DC_ID_ERR_INT_RAW The raw status of JPEG_C_DHT_DC_ID_ERR_INT. (R/WTC/SS)

JPEG_C_DHT_AC_ID_ERR_INT_RAW The raw status of JPEG_C_DHT_AC_ID_ERR_INT. (R/WTC/SS)

JPEG_C_DQT_ID_ERR_INT_RAW The raw status of JPEG_C_DQT_ID_ERR_INT. (R/WTC/SS)

JPEG_RST_UXP_ERR_INT_RAW The raw status of JPEG_RST_UXP_ERR_INT. (R/WTC/SS)

JPEG_RST_CHECK_NONE_ERR_INT_RAW The raw status of JPEG_RST_CHECK_NONE_ERR_INT. (R/WTC/SS)

Continued on the next page...

Register 37.15. JPEG_INT_RAW_REG (0x0038)

Continued from the previous page...

JPEG_RST_CHECK_POS_ERR_INT_RAW The raw status of JPEG_RST_CHECK_POS_ERR_INT. (R/WTC/SS)

JPEG_OUT_EOF_INT_RAW The raw status of JPEG_OUT_EOF_INT. (R/WTC/SS)

JPEG_SR_COLOR_MODE_ERR_INT_RAW The raw status of JPEG_SR_COLOR_MODE_ERR_INT. This interrupt is invalid. (R/WTC/SS)

JPEG_DCT_DONE_INT_RAW The raw status of JPEG_DCT_DONE_INT. (R/WTC/SS)

JPEG_BS_LAST_BLOCK_EOF_INT_RAW The raw status of JPEG_BS_LAST_BLOCK_EOF_INT. (R/WTC/SS)

JPEG_SCAN_CHECK_NONE_ERR_INT_RAW The raw status of JPEG_SCAN_CHECK_NONE_ERR_INT. (R/WTC/SS)

JPEG_SCAN_CHECK_POS_ERR_INT_RAW The raw status of JPEG_SCAN_CHECK_POS_ERR_INT. (R/WTC/SS)

JPEG_UXP_DET_INT_RAW The raw status of JPEG_UXP_DET_INT. (R/WTC/SS)

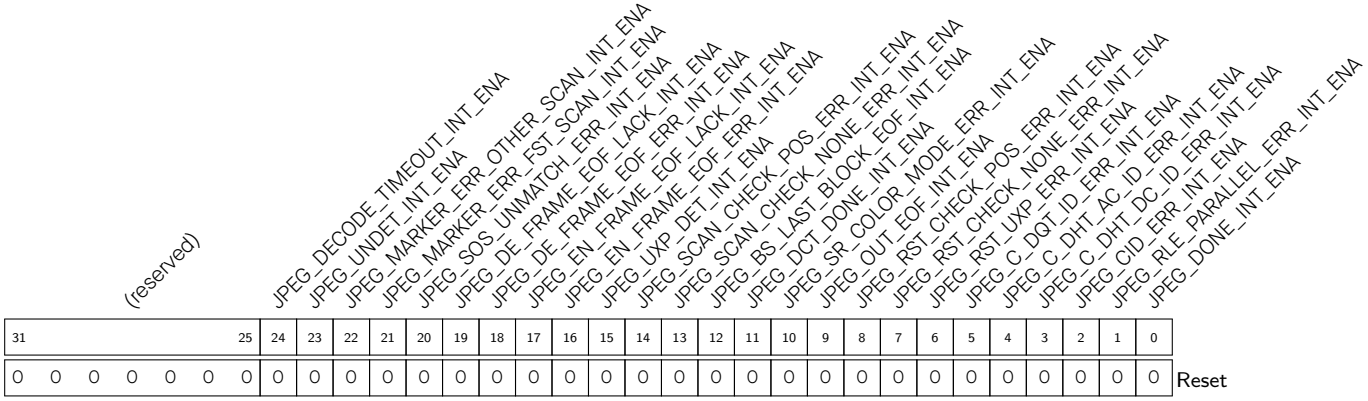
JPEG_EN_FRAME_EOF_ERR_INT_RAW The raw status of JPEG_EN_FRAME_EOF_ERR_INT. (R/WTC/SS)

JPEG_EN_FRAME_EOF_LACK_INT_RAW The raw status of JPEG_EN_FRAME_EOF_LACK_INT. (R/WTC/SS)

JPEG_DE_FRAME_EOF_ERR_INT_RAW The raw status of JPEG_DE_FRAME_EOF_ERR_INT. (R/WTC/SS)

JPEG_DE_FRAME_EOF_LACK_INT_RAW The raw status of JPEG_DE_FRAME_EOF_LACK_INT. (R/WTC/SS)

JPEG_SOS_UNMATCH_ERR_INT_RAW The raw status of JPEG_SOS_UNMATCH_ERR_INT. (R/WTC/SS)



JPEG_MARKER_ERR_FST_SCAN_INT_RAW The raw status of JPEG_MARKER_ERR_FST_SCAN_INT. (R/WTC/SS)

JPEG_MARKER_ERR_OTHER_SCAN_INT_RAW The raw status of JPEG_MARKER_ERR_OTHER_SCAN_INT. (R/WTC/SS)

JPEG_UNDET_INT_RAW The raw status of JPEG_UNDET_INT. (R/WTC/SS)

JPEG_DECODE_TIMEOUT_INT_RAW The raw status of JPEG_DECODE_TIMEOUT_INT. (R/WTC/SS)

Register 37.16. JPEG_INT_ENA_REG (0x003C)

JPEG_DONE_INT_ENA Write 1 to enable JPEG_DONE_INT_ENA. (R/W)

JPEG_RLE_PARALLEL_ERR_INT_ENA Write 1 to enable JPEG_RLE_PARALLEL_ERR_INT. (R/W)

JPEG_CID_ERR_INT_ENA Write 1 to enable JPEG_CID_ERR_INT. (R/W)

JPEG_C_DHT_DC_ID_ERR_INT_ENA Write 1 to enable JPEG_C_DHT_DC_ID_ERR_INT. (R/W)

JPEG_C_DHT_AC_ID_ERR_INT_ENA Write 1 to enable JPEG_C_DHT_AC_ID_ERR_INT. (R/W)

JPEG_C_DQT_ID_ERR_INT_ENA Write 1 to enable JPEG_C_DQT_ID_ERR_INT. (R/W)

JPEG_RST_UXP_ERR_INT_ENA Write 1 to enable JPEG_RST_UXP_ERR_INT. (R/W)

JPEG_RST_CHECK_NONE_ERR_INT_ENA Write 1 to enable JPEG_RST_CHECK_NONE_ERR_INT. (R/W)

JPEG_RST_CHECK_POS_ERR_INT_ENA Write 1 to enable JPEG_RST_CHECK_POS_ERR_INT. (R/W)

JPEG_OUT_EOF_INT_ENA Write 1 to enable JPEG_OUT_EOF_INT. (R/W)

JPEG_SR_COLOR_MODE_ERR_INT_ENA Write 1 to enable JPEG_SR_COLOR_MODE_ERR_INT. (R/W)

JPEG_DCT_DONE_INT_ENA Write 1 to enable JPEG_DCT_DONE_INT. (R/W)

JPEG_BS_LAST_BLOCK_EOF_INT_ENA Write 1 to enable JPEG_BS_LAST_BLOCK_EOF_INT. (R/W)

JPEG_SCAN_CHECK_NONE_ERR_INT_ENA Write 1 to enable JPEG_SCAN_CHECK_NONE_ERR_INT. (R/W)

JPEG_SCAN_CHECK_POS_ERR_INT_ENA Write 1 to enable JPEG_SCAN_CHECK_POS_ERR_INT. (R/W)

JPEG_UXP_DET_INT_ENA Write 1 to enable JPEG_UXP_DET_INT. (R/W)

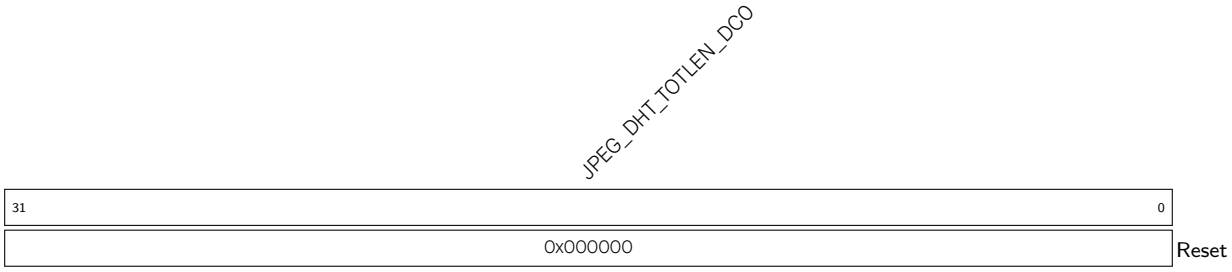
JPEG_EN_FRAME_EOF_LACK_INT_CLR Write 1 to clear JPEG_EN_FRAME_EOF_LACK_INT. (WT)

JPEG_DE_FRAME_EOF_ERR_INT_CLR Write 1 to clear JPEG_DE_FRAME_EOF_ERR_INT. (WT)

JPEG_DE_FRAME_EOF_LACK_INT_CLR Write 1 to clear JPEG_DE_FRAME_EOF_LACK_INT. (WT)

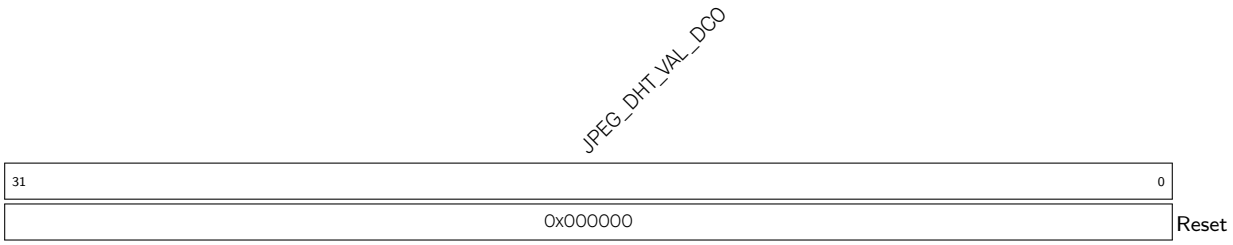
JPEG_SOS_UNMATCH_ERR_INT_CLR Write 1 to clear JPEG_SOS_UNMATCH_ERR_INT. (WT)



JPEG_MARKER_ERR_FST_SCAN_INT_CLR Write 1 to clear JPEG_MARKER_ERR_FST_SCAN_INT. (WT)

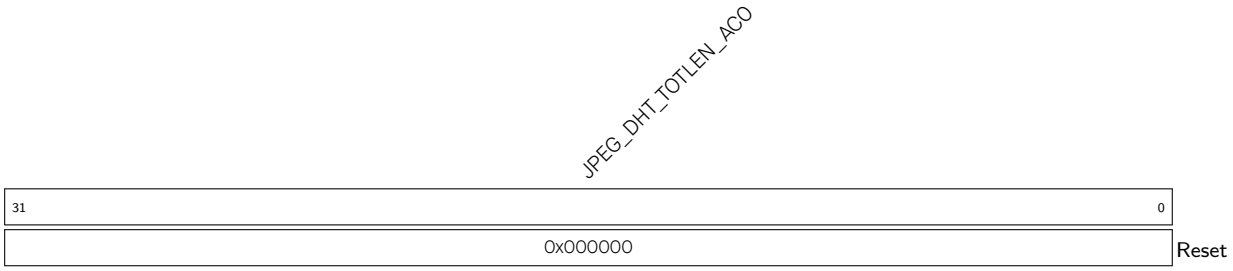
JPEG_MARKER_ERR_OTHER_SCAN_INT_CLR Write 1 to clear JPEG_MARKER_ERR_OTHER_SCAN_INT. (WT)

JPEG_UNDET_INT_CLR Write 1 to clear JPEG_UNDET_INT. (WT)



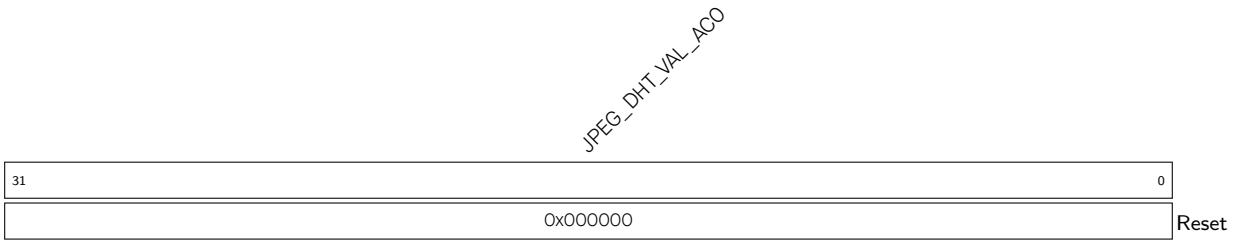
JPEG_DECODE_TIMEOUT_INT_CLR Write 1 to clear JPEG_DECODE_TIMEOUT_INT. (WT)

Register 37.19. JPEG_DHT_TOTLEN_DC0_REG (0x0058)



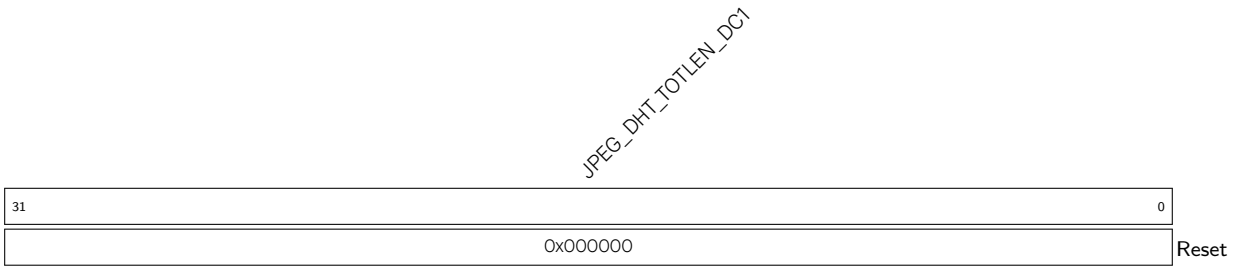
JPEG_DHT_TOTLEN_DC0 Configures the number of codeword with a codeword length of 1 to 16 bits for DC0 Huffman table in FIFO mode. (HRO)

Register 37.20. JPEG_DHT_VAl_DC0_REG (0x005C)



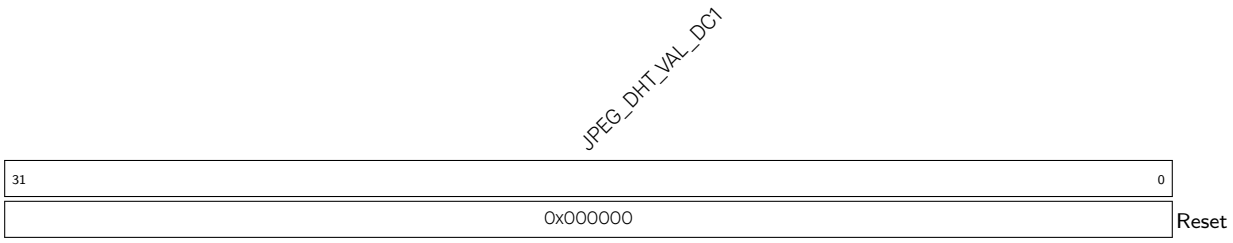
JPEG_DHT_VAL_DC0 Configures the symbols corresponding to the decoded codeword for DC0 Huffman table in FIFO mode. (HRO)

Register 37.21. JPEG_DHT_TOTLEN_AC0_REG (0x0060)



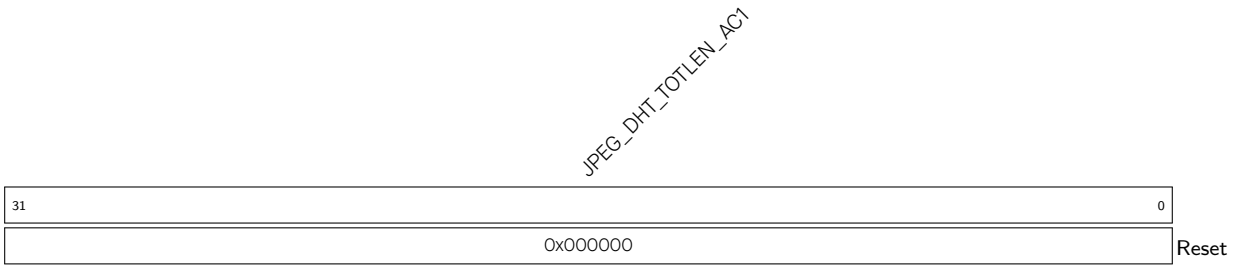
JPEG_DHT_TOTLEN_AC0 Configures the number of codeword with a codeword length of 1 to 16 bits for AC0 Huffman table in FIFO mode. (HRO)

Register 37.22. JPEG_DHT_VAl_AC0_REG (0x0064)



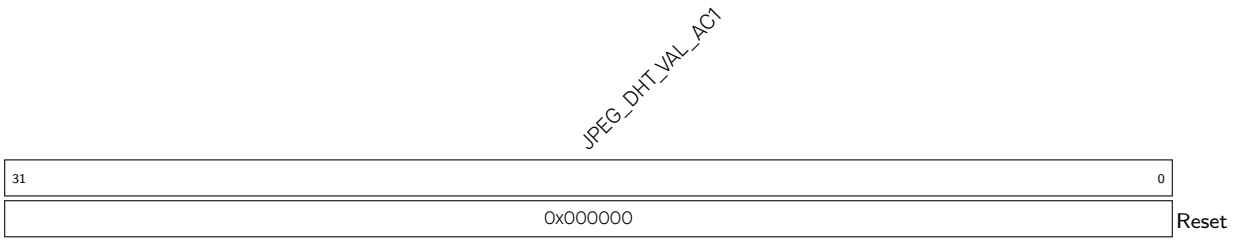
JPEG_DHT_VAL_AC0 Configures the symbols corresponding to the decoded codeword for AC0 Huffman table in FIFO mode. (HRO)

Register 37.23. JPEG_DHT_TOTLEN_DC1_REG (0x0068)



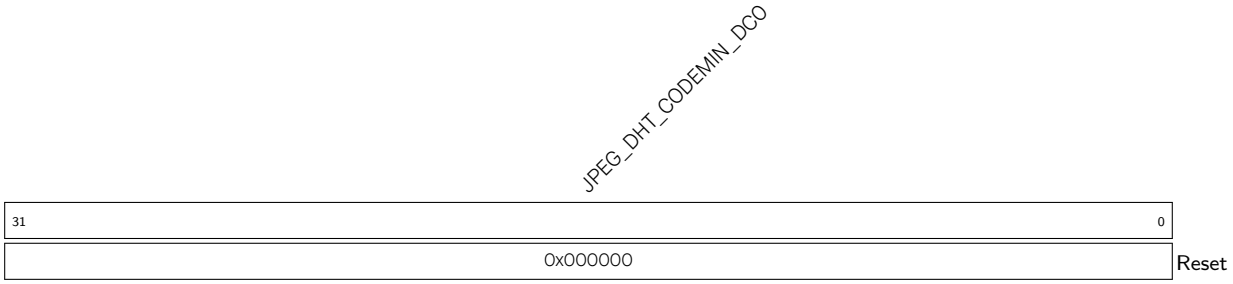
JPEG_DHT_TOTLEN_DC1 Configures the number of codeword with a codeword length of 1 to 16 bits for DC1 Huffman table in FIFO mode. (HRO)

Register 37.24. JPEG_DHT_VAl_DC1_REG (0x006C)



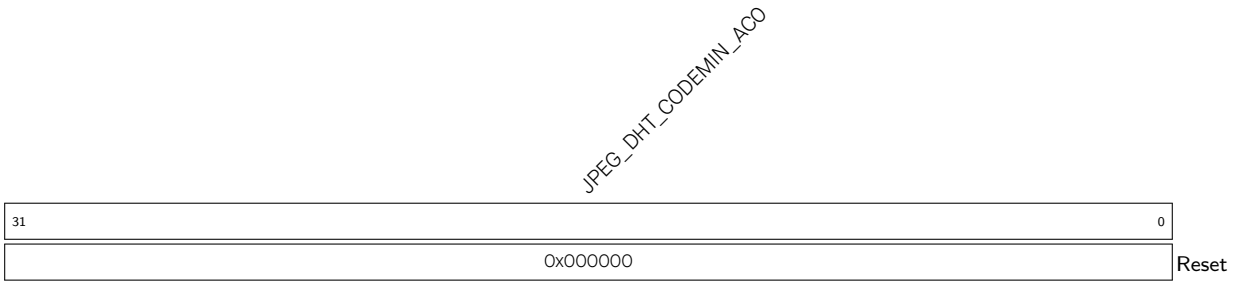
JPEG_DHT_VAL_DC1 Configures the symbols corresponding to the decoded codeword for DC1 Huffman table in FIFO mode. (HRO)

Register 37.25. JPEG_DHT_TOTLEN_AC1_REG (0x0070)



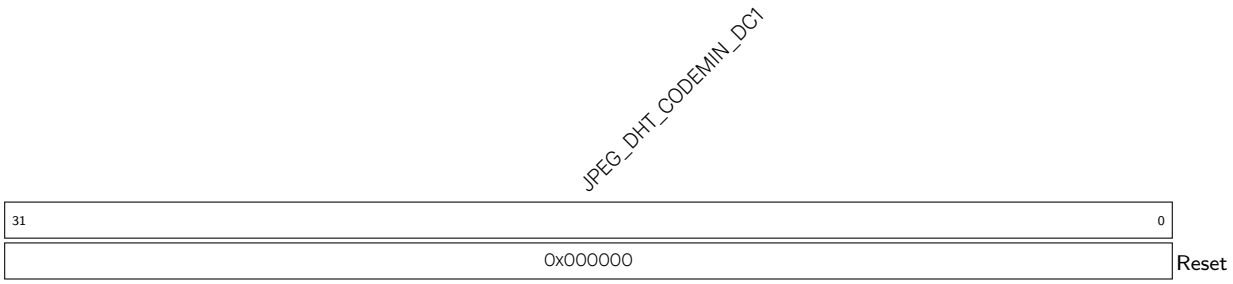
JPEG_DHT_TOTLEN_AC1 Configures the number of codeword with a codeword length of 1 to 16 bits for AC1 Huffman table in FIFO mode. (HRO)

Register 37.26. JPEG_DHT_VAl_AC1_REG (0x0074)



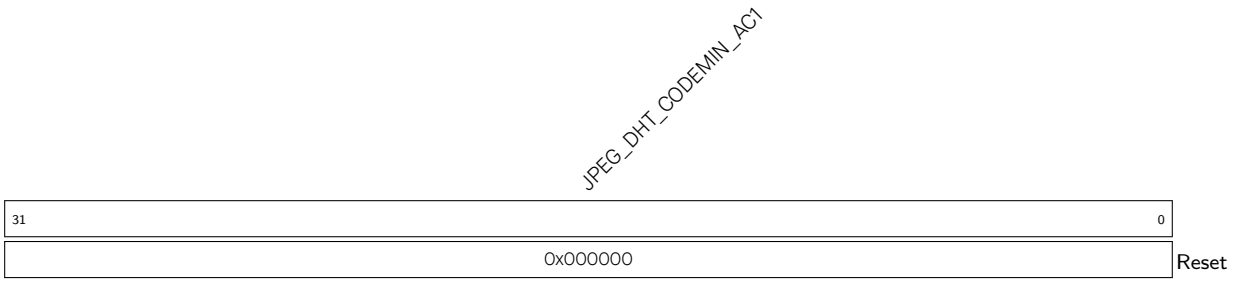
JPEG_DHT_VAL_AC1 Configures the symbols corresponding to the decoded codeword for AC1 Huffman table in FIFO mode. (HRO)

Register 37.27. JPEG_DHT_CODEMIN_DC0_REG (0x0078)



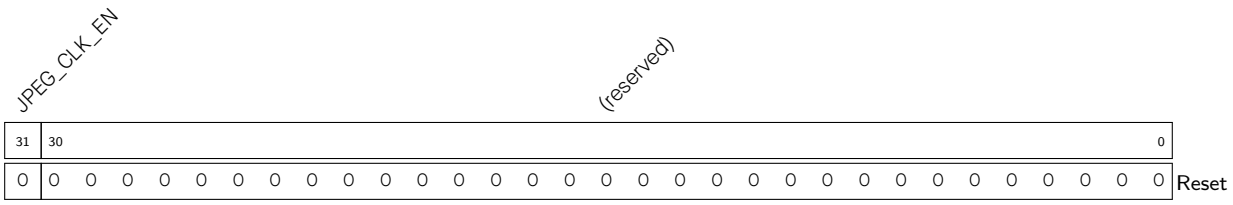
JPEG_DHT_CODEMIN_DC0 Configures the minimum codeword with a codeword length of 1 to 16 bits for DC0 Huffman table in FIFO mode. The codeword should be left shifted to the MSB position of a 16-bit word. (HRO)

Register 37.28. JPEG_DHT_CODEMIN_AC0_REG (0x007C)



JPEG_DHT_CODEMIN_AC0 Configures the minimum codeword with a codeword length of 1 to 16 bits for AC0 Huffman table in FIFO mode. The codeword should be left shifted to the MSB position of a 16-bit word. (HRO)

Register 37.29. JPEG_DHT_CODEMIN_DC1_REG (0x0080)

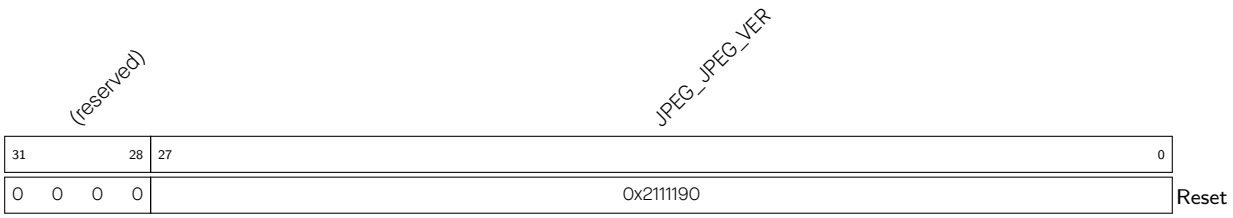


JPEG_DHT_CODEMIN_DC1 Configures the minimum codeword with a codeword length of 1 to 16 bits for DC1 Huffman table in FIFO mode. The codeword should be left shifted to the MSB position of a 16-bit word. (HRO)

Register 37.30. JPEG_DHT_CODEMIN_AC1_REG (0x0084)

JPEG_DHT_CODEMIN_AC1 Configures the minimum codeword with a codeword length of 1 to 16 bits for AC1 Huffman table in FIFO mode. The codeword should be left shifted to the MSB position of a 16-bit word. (HRO)

Register 37.31. JPEG_SYS_REG (0x00F8)



JPEG_CLK_EN Configures whether or not to force open register clock gate.

0: Open the clock gate only when the application writes registers

1: Force open the clock gate for register

(R/W)

Register 37.32. JPEG_VERSION_REG (0x00FC)

JPEG_JPEG_VER Version control. (R/W)

Chapter 38

Image Signal Processor (ISP)

38.1 Introduction

ESP32-P4 includes an image signal processor (ISP), which is a pipeline composed of various image processing algorithms.

ISP reads image data from the DVP or MIPI-CSI camera interface, or from the system memory directly, and writes the processed image data to the system memory through VDMA.

The SoC architecture of ISP is shown in Figure 38.1-1. ISP must work with other modules to read and write data and can not work alone.

- When outputting images, ISP uses CSI_Bridge to convert data to AXI interface and stores the images to system memory through the VDMA controller. For more information about VDMA, see Chapter 7 *VDMA Controller (VDMA)*
- When the input image comes from the system memory, ISP must acquire the image data through VDMA
- When the input image comes from the MIPI-CSI camera interface,
  - ISP must acquire the image data through CSI HOST. For details, see Chapter 42 *MIPI CSI*
  - CSI_CM can preprocess it to perform 8-bit or 16-bit bit-swapping, color-channel reordering for RGB888, RGB565, or YUV422, downsample RGB888 to RGB565, or downsample YUV422 to YUV420
- When the input image comes from the DVP camera interface, ISP acquire the image data through the DVP IO. For details, see Chapter 10 *GPIO Matrix and IO MUX*

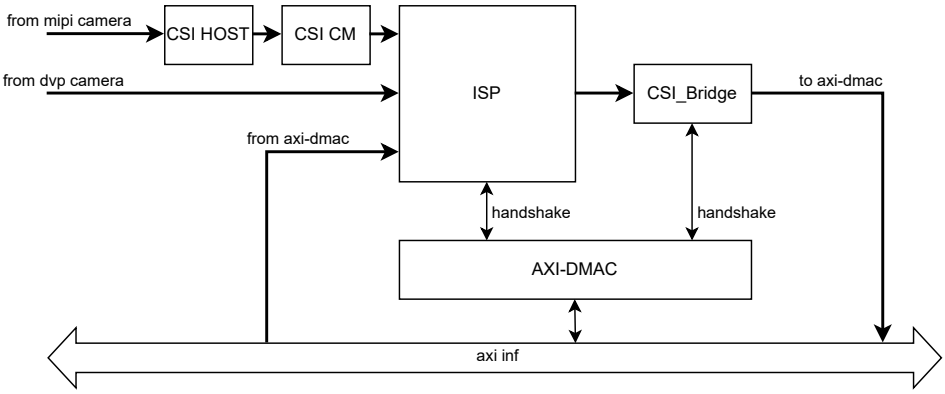


Figure 38.1-1. ESP32-P4 ISP SoC Architecture

38.2 Terminology

MIPI-CSI	Camera serial interface, a high-speed serial interface for cameras complaint with MIPI specifications
Image Interface	Image data interface, the output interface of CSI HOST Classified into Image Interface 32 and Image Interface 64 based on bit width
DVP	Digital video parallel interface, generally composed of vsync, hsync, de, and data signals
RAW	Unprocessed data directly output from an image sensor, typically divided into R, Gr, Gb, and B channels Classified into RAW8, RAW10, RAW12, etc., based on bit width
RGB	Colored image format composed of red, green, and blue colors Classified into RGB888, RGB565, etc., based on the bit width of each color
YUV	Colored image format composed of luminance and chrominance Classified into YUV444, YUV422, YUV420, etc., based on the data arrangement

38.3 Feature List

ISP supports the following features:

- maximum resolution: 1920 x 1080
- three input channels: MIPI-CSI, DVP, and VDMA
- input formats: RAW8, RAW10, and RAW12
- output formats: RAW8, RGB888, RGB565, YUV422, and YUV420
- pipeline features:
  - Black level correction (BLC)
  - Defect pixel correction (DPC)
  - Bayer filter (BF)
  - Lens shading correction (LSC)
  - Demosaic
  - White balance gain (WBG)
  - Color correction matrix (CCM)
  - Gamma correction
  - RGB2YUV
  - Sharpen
  - Contrast/hue/saturation/luminance adjustment (COLOR)
  - YUV_limit
  - YUV2RGB
  - Crop

38.4 Architectural Overview

ISP architecture is shown in Figure 38.4-1, consisting of ISP_Header, ISP_Pipeline, ISP_Tail, and CSI_Bridge.

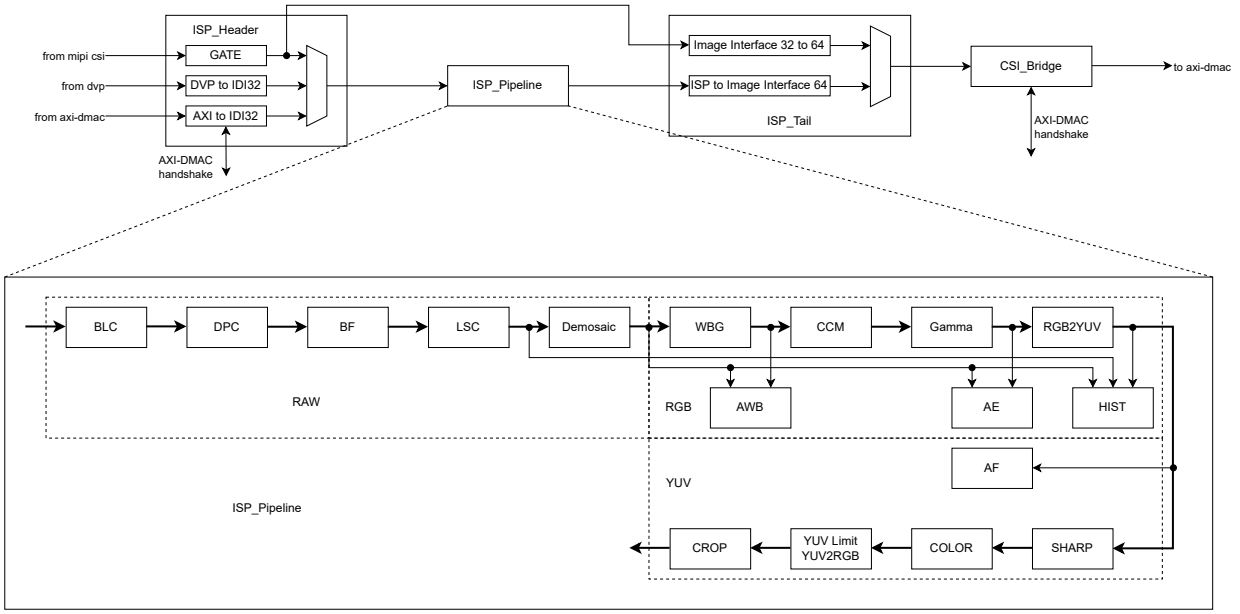

Figure 38.4-1. ISP IP Architecture

- ISP_Header selects data from various input sources based on the configuration and buffers it. Then it transmits the buffered data to ISP_Pipeline in a standardized format.
- ISP_Pipeline serves as the core module of the ISP, containing all the algorithms for image processing.
- ISP_Tail has two input sources, MIPI-CSI and ISP_Pipeline. When ISP is disabled, Image Interface 32 data from MIPI-CSI is converted into Image Interface 64 format by ISP_Tail and transmitted to CSI_Bridge. When ISP is enabled, the output of ISP_Pipeline is cropped and converted into Image Interface 64 format by ISP_Tail, and then transmitted to CSI_Bridge.
- As the output of the ISP, CSI_Bridge transmits the images from ISP to the system memory through VDMA.

38.5 Functional Description

38.5.1 ISP_Header

ISP_Header serves as the input of ISP. The main features are:

- Select image data as input source based on the configuration of ISP_IN_SRC
- Buffer image data, and convert images to the format required by ISP_Pipeline based on the configured type and size of image data

- When MIPI-CSI is the input, set the input type via ISP_DATA_TYPE
- When DVP is the input, set ISP_DATA_TYPE to 0, then set the data type via ISP_CAM_DATA_TYPE
- When VDMA is the input, set the input type via ISP_DATA_TYPE, and configure ISP_DMA_DATA_TYPE accordingly

38.5.2 ISP_Pipeline

ISP_Pipeline is the core of ISP, housing all the image processing algorithms. Each algorithm module can be enabled or disabled via the corresponding bit of ISP_CNTL_REG. Except for modules related to color space conversion (demosaic, RGB2YUV, and YUV2RGB), other modules can be enabled or disabled dynamically without the need to shut down the ISP for reconfiguration. Moreover, once enabled, each algorithm module generates an end-of-frame interrupt, capable of triggering an interrupt after processing each image frame.

38.5.2.1 Black Level Correction (BLC)

This module is used to subtract the black level offset of the sensor. The black level offset to be subtracted for each Bayer channel is configured via ISP_BLC_Rx_VALUE. With the black level offset subtracted, the pixel range will be reduced, which can be stretched back to 0-255 via ISP_BLC_Rx_STRETCH.

There are four Bayer channels in total. The mapping between channel and index is as follows:

- R0 refers to the top-left channel
- R1 refers to the top-right channel
- R2 refers to the bottom-left channel
- R3 refers to to the bottom-right channel

38.5.2.2 Defective Pixel Correction (DPC)

This module removes defective pixels from the input image. DPC supports both dynamic correction and static correction, which are controlled by ISP_STA_EN and ISP_DYN_EN, respectively. The two correction modes can be enabled simultaneously.

Dynamic correction automatically detects defective pixels based on the input pixel values and replaces them with the median value. Two defective pixel detection algorithms are supported:

- **Algorithm 0:** Compute the minimum value *min8* and the maximum value *max8* among the eight neighboring pixels of the current pixel. If the current pixel value is greater than max8 + ISP_DPC_THRESHOLD_H, or less than min8 - ISP_DPC_THRESHOLD_L, the pixel is classified as defective.
- **Algorithm 1:** Let the current pixel value be *pix*. Compute the mean value *est* of the eight neighboring pixels, and the absolute difference *dif* = $|est - pix|$. Define *avg* = (sum of the eight neighbors + $8 \times pix$) / 16. Detection is performed in two steps:
  - **Step 1:** Determine the maximum value *max8* among the eight neighboring pixels. If $pix < max8 \times$ ISP_DPC_THRESHOLD_H and $pix > max8 \times$ ISP_DPC_THRESHOLD_L, the pixel is considered non-defective; otherwise, proceed to Step 2.
  - **Step 2:** The pixel is classified as defective if either of the following conditions is met:

    * $dif > avg \times$ ISP_DPC_FACTOR_DARK and $est \geq pix$
    * $dif > (255 - avg) \times$ ISP_DPC_FACTOR_BRIG and $est < pix$

Static correction is implemented using a defective pixel coordinate lookup table (LUT). Pixels whose coordinates are stored in the LUT are replaced with the median value. The defective pixel coordinates must be obtained through static calibration. During calibration, neither static nor dynamic correction can be enabled.

The calibration procedure is as follows:

- Black image defective pixel calibration
  - Set ISP_DPC_BLACK_EN = 1
  - Set ISP_DPC_CHECK_EN = 1
  - Set ISP_DPC_EN = 1
  - Input a black image and wait for the calibration to complete
  - Set ISP_DPC_CHECK_EN = 0
  - Software reads all defective pixel coordinates for the black image from the LUT registers
- White image defective pixel calibration
  - Set ISP_DPC_BLACK_EN = 0
  - Set ISP_DPC_CHECK_EN = 1
  - Set ISP_DPC_EN = 1
  - Input a white image and wait for the calibration to complete
  - Set ISP_DPC_CHECK_EN = 0
  - Software reads all defective pixel coordinates for the white image from the LUT registers
- Software merges the defective pixel coordinates obtained from the black and white images, removes duplicates, and writes the final list back to the LUT

The LUT read and write procedure is described in Section 38.5.2.4. By setting ISP_LUT_NUM = 1, the defective pixel coordinate LUT for DPC is selected. This LUT has a depth of 512, allowing up to 512 defective pixel coordinates to be stored.

38.5.2.3 Bayer Filter (BF)

This module is designed for denoising input images in the Bayer domain. The denoising strength can be adjusted using ISP_SIGMA, and the denoising template can be fine-tuned using ISP_GAU_TEMPLATExx.

38.5.2.4 Lens Shading Correction (LSC)

This module is utilized for lens shading correction in the Bayer domain. It corrects the R, Gr, Gb, and B channels independently by dividing each channel into a 32 x 32 grid (equivalent to a 64 x 64 division for the entire image) and stores the correction coefficients for each channel in a lookup table (LUT).

Before using this module, calibration is necessary to obtain the LUT correction coefficients. Specifically, first we capture a white image in a scene with uniform ambient lighting. Divide the image into a 32 x 32 grid for

each channel, and use the luminance at the center of the image as a reference. Calculate the luminance gain at each grid vertex based on this reference luminance. For grids extending beyond the image boundaries on the right or bottom, calculate the gain at the image boundary points. Then, use a linear relationship based on the gain of the previous point to calculate the gain at the next grid boundary. Finally, store these gains in the LUT in a left-to-right, top-to-bottom order to complete the initialization.

In the context of a 1920 x 1080 resolution image, each channel operates at 960 x 540 resolution and is divided into a 32 x 32 grid, consisting of 30 grids horizontally and 17 grids vertically. Assuming the image's luminance center aligns with its geometric center, we derive the reference luminance ref_lum from the average luminance of pixels around coordinates (480, 270). Moving methodically from left to right and top to bottom, derive the actual pixel luminance act_lum for each grid vertex. Using the formula $gain = ref_lum/act_lum$, we compute the correction coefficient, which is then stored sequentially in the LUT.

In cases where grids extend beyond the image boundaries, such as the vertical coordinate of the last grid reaching 543 (beyond the maximum vertical coordinate of 539), we leverage the correction coefficients gain_0 at coordinate 511 and gain_1 at coordinate 539. Then the gain for coordinate 543 can be calculated based on $gain = gain_0 + (gain_1 - gain_0)/(539 - 511) * (543 - 511)$.

LSC employs two LUTs for storing gains related to specific color channels: Gb and B are stored in one LUT, while R and Gr are stored in the other. Each LUT has a depth of 560. The number of gain coefficients per channel, determined by the image resolution, must not exceed this value. The gain values are represented as 10-bit fixed-point numbers, with the high 2 bits representing the integer part and the low 8 bits the fractional part. The storage order within the LUTs is detailed in Table 38.5-1. The LUTs can be accessed through specific registers:

- A write operation writes the data from ISP_LUT_WDATA_REG into the LUT.
- A read operation stores the data read from the LUT into ISP_LUT_RDATA_REG.
- Trigger LUT operations via ISP_LUT_CMD_REG. Each write to this register initiates a read or write operation on the LUT. It is required to write to all the fields within this register at the same time.
  - ISP_LUT_CMD: Set to 0 for a read operation and 1 for a write operation
  - ISP_LUT_NUM: Set to 0 to select the LSC LUT
  - ISP_LUT_ADDR: Specifies the LUT address to access. If bits [11:10] are 0, LUT_Gb_B is selected; if bits [11:10] are 1, LUT_R_Gr is selected

Table 38.5-1. Gain Storage Sequence in LSC LUTs

LUT sel	bit [19:10]	bit [9:0]
LUT_Gb_B	Gb	B
LUT_R_Gr	R	Gr

Before enabling LSC, ISP_LSC_XTABLESIZE should be configured to set the number of horizontal correction coefficients. The number is determined by $ISP_LSC_XTABLESIZE = fix((line_width - 1)/2/32) + 2$, where $fix()$ denotes rounding down. For example, if the input RAW image has a horizontal width of 1920 pixels, then $ISP_LSC_XTABLESIZE = fix((1920 - 1)/2/32) + 2 = 29 + 2 = 31$.

38.5.2.5 Demosaic

The demosaicing process converts Bayer images to RGB888 images. The conversion effect can be fine-tuned using ISP_DEMOSAIC_GRAD_RATIO. This register field comprises 2 integer bits and 4 fractional bits, with a default value of 1.0.

38.5.2.6 White Balance Gain (WBG)

This module performs white balance adjustment on the input image. The adjustment is achieved by multiplying the pixel value of each color channel by its corresponding ISP_WBG_R/B/G gain coefficient. Each gain coefficient consists of a 4-bit integer part and an 8-bit fractional part.

38.5.2.7 Color Correction Matrix (CCM)

CCM is a correction matrix for image pixels that can adjust RGB888 pixels, including white balance adjustments. The relationship between the output R', G', B' and the input R, G, B is described by the following matrix. The parameters RR, RG, RB, GR, GG, GB, BR, BG, and BB can be configured with ISP_CCM_xx. Each parameter is a 13-bit fixed-point number, where bit [12] is the sign bit, bits [11:0] represent the absolute value of the number, bits [11:8] the integer part, and bits [7:0] the fractional part.

$$\begin{bmatrix} R' \\ G' \\ B' \end{bmatrix} = \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} \times \begin{bmatrix} R \\ G \\ B \end{bmatrix} \tag{38.1}$$

38.5.2.8 Gamma Correction

This module is used to adjust the gamma curve of an image. The gamma curve should be configured before gamma correction is enabled. Gamma curves can be configured using registers, with each R, G, B channel having an independent curve consisting of 16 sampling points. For the X component (input value), the values are indirectly obtained through ISP_GAMMA_R/G/B_Xn (where n ranges from 00 to 0F). The Y component (output value) can be directly set using ISP_GAMMA_R/G/B_Yn (where n ranges from 00 to 0F). Once configuration is complete, writing 1 to ISP_GAMMA_UPDATE applies the gamma curve settings. The gamma curve is illustrated in Figure 38.5-1.

For the X component, taking the R channel as an example, the following conditions must be satisfied:

$$X(n) - X(n-1) = 2^{ISP_GAMMA_R_X(n)}$$

$$\sum(2^{ISP_GAMMA_R_X(n)}) = 256, n = 00\sim0F$$

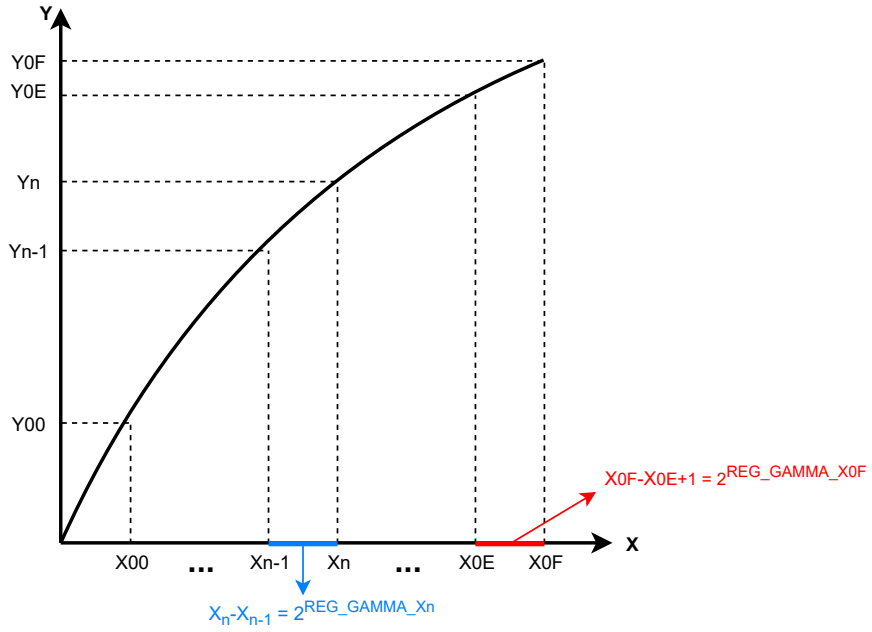

Figure 38.5-1. Gamma Curve

38.5.2.9 RGB2YUV

The RGB2YUV module converts RGB888 pixels into full-range YUV422 format. The conversion protocol can be configured with ISP_YUV_MODE.

38.5.2.10 Sharpen

The sharpen module is used to sharpen images. This module separates the low-frequency and high-frequency components of the image using a low-pass filter template (such as a mean template or Gaussian template) via ISP_SHARP_FILTER_COExx. For low-frequency components, no processing will be done. For high-frequency components, each pixel undergoes the following processing to achieve sharpening:

- Pixels with frequencies below ISP_SHARP_THRESHOLD_LOW are set to 0.
- Pixels with frequencies above ISP_SHARP_THRESHOLD_LOW but below ISP_SHARP_THRESHOLD_HIGH are multiplied by the coefficient ISP_SHARP_AMOUNT_LOW.
- Pixels with frequencies above ISP_SHARP_THRESHOLD_HIGH are multiplied by the coefficient ISP_SHARP_AMOUNT_HIGH.

At the end of each frame, the maximum value of high-frequency component pixels in that frame can be obtained by reading ISP_SHARP_GRADIENT_MAX. This value can serve as a reference for configuring settings for the next frame.

38.5.2.11 Contrast/Hue/Saturation/Luminance Adjustment (COLOR)

This module is designed to modify the contrast, saturation, hue, and luminance of an image. Contrast, saturation, and luminance are configured through ISP_COLOR_CONTRAST, ISP_COLOR_SATURATION, and ISP_COLOR_BRIGHTNESS, respectively. Hue adjustment is achieved by combining ISP_COLOR_HUE_H and ISP_COLOR_HUE to form a 9-bit control value.

38.5.2.12 YUV_Limit and YUV2RGB

The YUV_Limit module converts full-range YUV422 pixels to limited-range YUV422 pixels. This module is activated only when RGB2YUV is enabled, YUV2RGB is disabled, and ISP_YUV_RANGE is set to 1. With this configuration, the ISP output type is either YUV422 or YUV420.

YUV2RGB converts full-range YUV422 pixels to RGB888 format. The conversion protocol can be configured with ISP_YUV_MODE.

Note:
For full-range YUV, Y, U, and V channels range from 0 to 255.
For limited-range YUV, Y channel ranges from 16 to 235, and U and V channels range from 16 to 240.

38.5.2.13 Cropping (CROP)

The CROP module performs image cropping. The start and end coordinates in the X and Y directions are configured using ISP_CROP_X_START, ISP_CROP_X_END, ISP_CROP_Y_START, and ISP_CROP_Y_END, respectively. The start coordinates must be even, and the end coordinates must be odd.

38.5.2.14 Automatic Exposure Statistics (AE)

Auto Exposure (AE) uses 25 statistical sub-windows for image luminance statistics, forming a 5 x 5 grid of statistical window. The size of these windows is set using the register ISP_AE_BX/BY_REG. Each sub-window is numbered as shown in Figure 38.5-2. The average luminance of each sub-window, represented as an 8-bit value, can be read with ISP_AE_Bxx_MEAN. These statistics can be utilized to implement automatic exposure algorithms for cameras.

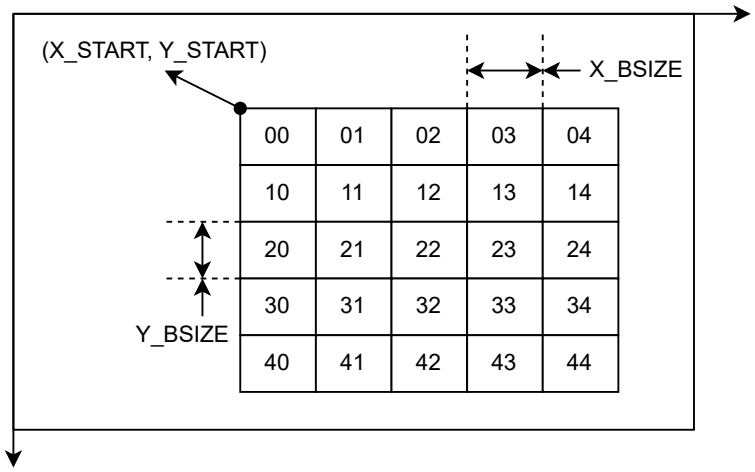

Figure 38.5-2. Sub-Window Numbering

AE utilizes two data sampling points: the output of the Demosaic module and the output of the Gamma module. These sampling points can be configured using ISP_AE_SELECT.

AE also includes a simple luminance monitoring module, implemented either by hardware or software. This module calculates the average luminance of all sub-windows every ISP_AE_MONITO_RPERIOD frames. If the average luminance falls outside the thresholds set by ISP_AE_MONITOR_TH/TL, interrupt for AE luminance

monitoring will be triggered. Note that the luminance monitoring module does not support setting different weights for individual sub-windows. Therefore, if you wish to implement monitoring with different weights (for instance, prioritize highlights), you need to perform software-triggered manual statistics and process the statistical data accordingly.

38.5.2.15 Automatic Focus Statistics (AF)

AF gathers luminance and sharpness information within specified statistical windows based on the output of the sharpen module. There are 3 independent statistical windows, and the size and position of each window can be configured using ISP_AF_H/VSCALE_A/B/C_REG. The module supports automatic and manual trigger modes for statistics collection. The results of luminance and sharpness statistics for each window can be accessed using ISP_AF_LUMA/B/C and ISP_AF_SUMA/B/C. These statistics can be used to implement automatic focus algorithms for cameras.

AF also includes a focus scene monitoring module, which users can choose to implement hardware-based monitoring with this module or implement via software. This module evaluates cumulative changes in luminance and sharpness across all statistical windows as criteria. It performs statistics every ISP_AF_ENV_PERIOD frames. If consecutive statistics show a difference from baseline values for luminance and sharpness that exceeds the specified threshold, an interrupt is triggered indicating a change in the focus scene that requires refocusing. The baseline values are automatically updated after each automatic or manually triggered statistics collection. There are three methods for setting the threshold:

- Directly set the luminance and sharpness thresholds using ISP_AF_ENV_USER_THRESHOLD_LUM and ISP_AF_ENV_USER_THRESHOLD_SUM
- If ISP_AF_ENV_USER_THRESHOLD_SUM is 0, use the corresponding baseline sharpness value multiplied by ISP_AF_ENV_THRESHOLD (4 fractional bits) as the sharpness threshold
- If ISP_AF_ENV_USER_THRESHOLD_LUM is 0, use the corresponding baseline luminance value multiplied by ISP_AF_ENV_THRESHOLD (4 fractional bits) as the luminance threshold

38.5.2.16 Automatic White Balance Statistics (AWB)

AWB gathers white balance information for specified windows containing white patches. The coordinates of the window can be set using ISP_AWB_H/VSCALE_REG. White patches are filtered based on luminance limits ISP_AWB_MAX/MIN_LUM, R/G limits ISP_AWB_MAX/MIN_RG, and B/G limits ISP_AWB_MAX/MIN_BG.

The statistics include the number of white patches and the accumulated values of the R, G, B components for all white patches. These statistics can be obtained using ISP_AWBO_WHITE_CNT and ISP_AWBO_ACC_R/G/B. They can be used to implement automatic white balance algorithms in cameras.

In addition, AWB supports dividing the window into 5 × 5 sub-windows, which are configured via ISP_AWB_X_START, ISP_AWB_X_BSIZE, ISP_AWB_Y_START, and ISP_AWB_Y_BSIZE. The sub-window range must not exceed the range of the main window, as shown in figure 38.5-3. The statistics results are written to the AWB LUT and can be accessed by setting ISP_LUT_NUM = 2. The detailed access procedure can be found in Section 38.5.2.4. The statistics are stored in the order of sub-windows from left to right and from top to bottom. Each sub-window occupies four consecutive addresses, which store, from low to high addresses, the number of white patches, and the accumulated values of the R, G, B components for white patches.

AWB relies on two data sampling points: the output of Demosaic and the output of CCM, which can be configured with ISP_AWB_SAMPLE.

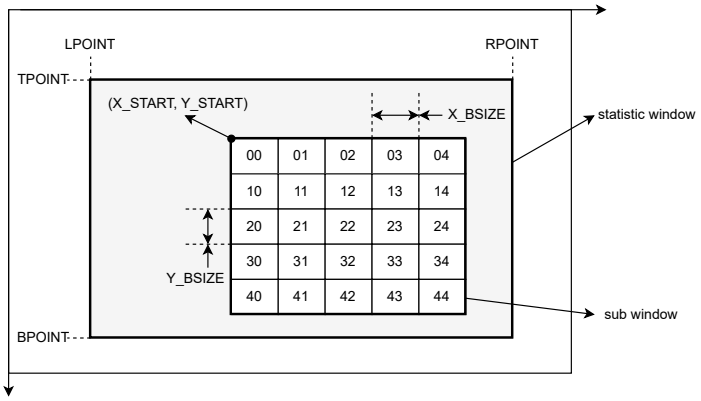

Figure 38.5-3. AWB window

38.5.2.17 Histogram Statistics (HIST)

HIST calculates brightness information for the image through statistical analysis. This module can define a statistical window, which can be divided into 5 x 5 sub-windows similar to AE. The configuration is done using registers ISP_HIST_OFFS_REG and ISP_HIST_SIZE_REG. The weight of each sub-window can be independently adjusted with ISP_HIST_WEIGHT_xx.

The statistics are presented as a histogram with 16 intervals. The x-axis of the histogram is defined using ISP_HIST_SEG_x_x, and the final statistics can be retrieved using ISP_HIST_BIN_x.

HIST involves three data sampling points: BF, demosaic, and RGB2YUV, corresponding to RAW, RGB, and YUV data sampling points respectively. These can be configured using ISP_HIST_MODE. When the sampling point is set to RGB, RGB weighting coefficients can be adjusted via ISP_HIST_COEFF_R/G/B.

38.5.3 ISP_Tail

ISP_Tail is the post-processing section that handles data from two input sources, ultimately outputting in Image Interface 64 format to CSI_Bridge.

When the ISP is turned off, ISP_Tail receives Image Interface 32 data from the MIPI CSI HOST, converts it to Image Interface 64 format, and outputs it to CSI_Bridge. The byte order of the input Image Interface 32 data can be adjusted using ISP_BYTE_ENDIAN_ORDER.

When the ISP is turned on, ISP_Tail receives data from ISP_Pipeline and processes them before outputting to CSI_Bridge. This processing includes:

- Converting RGB888 to RGB565 based on register configurations
- Converting YUV422 to YUV420 based on register configurations
- Converting data from ISP_Pipeline to Image Interface 64 format

38.5.4 Sequence Control

For modules involving matrix operations, it is necessary to buffer multiple lines of data before starting operations. In such cases, it is crucial for the module to generate an output sequence when the last few lines of image data are buffered. This output sequence can be controlled using ISP_BF/DEMOSAIC/SHARP_TAIL_PIXEN_PULSE_TH/TL, to prevent buffer overflow in the CSI_Bridge due to excessive speed. Please exercise caution when setting this register too large, as it may disrupt the normal data sequence. TH must be smaller than ISP_HADR_NUM-1, and it is recommended to set ISP_BF/DEMOSAIC/SHARP_TAIL_PIXEN_PULSE_TH/TL to a value less than or equal to 8.

38.5.5 Shadow Registers

Some ISP modules support shadow registers. The supported modules include:

- BLC
- DPC
- BF
- WBG
- CCM
- GAMMA
- SHARP
- COLOR

For the GAMMA module, the shadow register update method is fixed and must strictly follow the procedure described in Section 38.5.2.8. For all other modules, the update method can be configured via ISP_SHADOW_UPDATE_SEL.

38.5.6 CSI_CM

For MIPI CSI input, the CSI_CM module can perform simple data conversions by configuring CSI_BRIG_HOST_CM_CTRL_REG, including:

- Swapping high and low 8-bit data
- Swapping high and low 16-bit data
- Adjusting RGB888 color channel order (pixels per line must be a multiple of 4)
- Down-sampling from RGB888 to RGB565 (pixels per line must be a multiple of 4)
- Adjusting RGB565 color channel order (pixels per line must be a multiple of 2)
- Adjusting YUV422 color channel order (pixels per line must be a multiple of 2)
- Down-sampling from YUV422 to YUV420 (pixels per line must be a multiple of 16)

The module structure is shown in Figure 38.5-4.

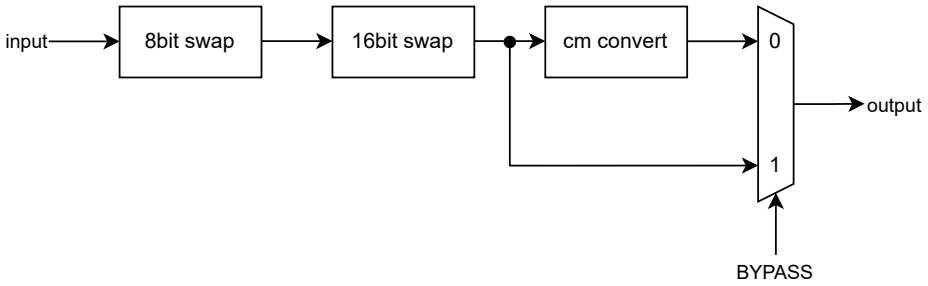

Figure 38.5-4. ESP32-P4 CSI CM Architecture

38.5.7 CSI_Bridge

CSI_Bridge serves as the interface between the ISP and the system memory. This module utilizes VDMA to transmit data from the ISP into the system memory. The image can be transferred either as a single block or divided into multiple blocks, which can be configured via CSI_BRIG_DMA_BURST_LEN and CSI_BRIG_DMABLK_SIZE.

- CSI_BRIG_DMA_BURST_LEN configures the amount of 64-bit data in a VDMA burst transfer.
- CSI_BRIG_DMABLK_SIZE configures the number of VDMA bursts in a VDMA block transfer. If an image frame is transferred with only one block, and this block contains n VDMA bursts, then configure this field to a value greater than n. It is recommended to set it to the maximum value, 0x1FFF.

38.5.8 Color Mode and Byte Order

38.5.8.1 Output Pixel Layout Format

When the ISP is disabled, ISP_Tail directly receives Image Interface 32 data from the MIPI CSI HOST. The pixel layout can be referenced from Chapter 42 *MIPI CSI*. In this case, the Image Interface 32 data output from CSI HOST can go through two levels of byte ordering in ISP_Tail and CSI_Bridge, refer to Byte Order for details.

After the ISP is enabled and the data has been processed by the ISP_Pipeline, the layout format of the output pixel is as shown in Table 38.5-2.

Table 38.5-2. ISP Output Pixel Layout Format

Color Mode	Addr + 7	Addr + 6	Addr + 5	Addr + 4	Addr + 3	Addr + 2	Addr + 1	Addr + 0
RAW8	RAW7[7:0]	RAW6[7:0]	RAW5[7:0]	RAW4[7:0]	RAW3[7:0]	RAW2[7:0]	RAW1[7:0]	RAW0[7:0]
RGB888	G2[7:0]	B2[7:0]	R1[7:0]	G1[7:0]	B1[7:0]	R0[7:0]	G0[7:0]	B0[7:0]
	B5[7:0]	R4[7:0]	G4[7:0]	B4[7:0]	R3[7:0]	G3[7:0]	B3[7:0]	R2[7:0]
	R7[7:0]	G7[7:0]	B7[7:0]	R6[7:0]	G6[7:0]	B6[7:0]	R5[7:0]	G5[7:0]
RGB565	R3[4:0]G3[5:3]	G3[2:0]B3[4:0]	R2[4:0]G2[5:3]	G2[2:0]B2[4:0]	R1[4:0]G1[5:3]	G1[2:0]B1[4:0]	R0[4:0]G0[5:3]	G0[2:0]B0[4:0]
YUV422	Y3[7:0]	V2[7:0]	Y2[7:0]	U2[7:0]	Y1[7:0]	V0[7:0]	Y0[7:0]	U0[7:0]
YUV420 (Odd-numbered rows)	Y4[7:0]	U4[7:0]	Y3[7:0]	Y2[7:0]	U2[7:0]	Y1[7:0]	Y0[7:0]	U0[7:0]
	U10[7:0]	Y9[7:0]	Y8[7:0]	U8[7:0]	Y7[7:0]	Y6[7:0]	U6[7:0]	Y5[7:0]
	Y15[7:0]	Y14[7:0]	U14[7:0]	Y13[7:0]	Y12[7:0]	U12[7:0]	Y11[7:0]	Y10[7:0]
YUV420 (Even-numbered rows)	Y4[7:0]	V4[7:0]	Y3[7:0]	Y2[7:0]	V2[7:0]	Y1[7:0]	Y0[7:0]	V0[7:0]
	V10[7:0]	Y9[7:0]	Y8[7:0]	V8[7:0]	Y7[7:0]	Y6[7:0]	V6[7:0]	Y5[7:0]
	Y15[7:0]	Y14[7:0]	V14[7:0]	Y13[7:0]	Y12[7:0]	V12[7:0]	Y11[7:0]	Y10[7:0]

38.5.8.2 Byte Order

CSI_Bridge can reorder the bytes of the input 64-bit data via CSI_BRIG_BYTE_ENDIAN_ORDER. ISP_Tail can also reorder the bytes via ISP_BYTE_ENDIAN_ORDER. The byte ordering functionality within ISP_Tail differs from that of CSI_Bridge, as illustrated in Figure 38.5-5.

- ISP_Tail byte ordering: This operation applies to its Image Interface 32 input. It reverses the high and low bytes of the 32-bit input data and then concatenates them to output 64-bit data. This step only functions when the ISP is disabled and is mainly used for processing Image Interface 32 YUV422 and YUV420 input types.
- CSI_Bridge byte ordering: This operation acts on the 64-bit input data (i.e., the output data from ISP_Tail) by reversing its high and low bytes.

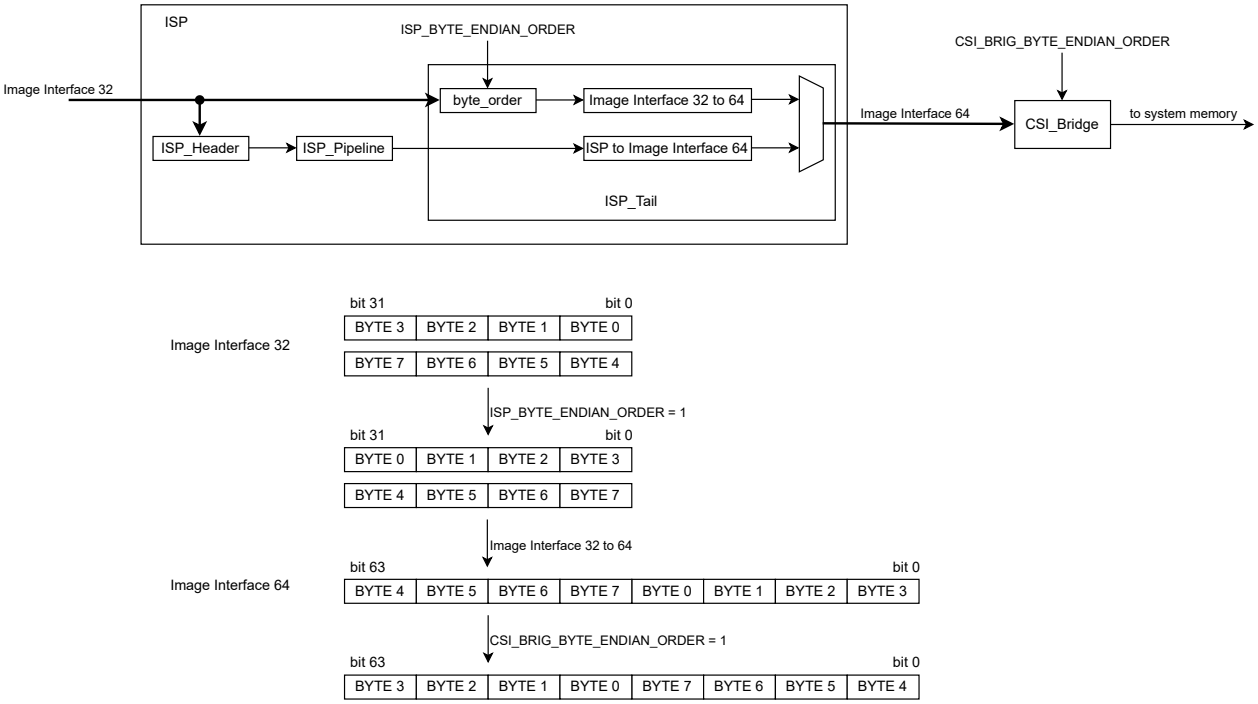

Figure 38.5-5. Byte Ordering

38.6 Interrupts

ESP32-P4's ISP can generate the following interrupt signals that will be sent to the Interrupt Matrix.

- isp_interrupt
- csi_bridge_interrupt

There are several internal interrupt sources from ISP that can generate the above interrupt signal. The interrupt sources from ISP are listed with their trigger conditions and the resulted interrupt signal in Table 38.6-1.

Table 38.6-1. ISP's Internal Interrupt Sources

Internal Interrupt Source	Trigger Condition	Interrupt Signal

ISP_CROP_ERR_INT	When the crop module window is configured incorrectly	isp_interrupt
ISP_WBG_FRAME_INT	After module WBG processes a frame	isp_interrupt
ISP_CROP_FRAME_INT	After module crop processes a frame	isp_interrupt
ISP_HEADER_IDI_FRAME_INT	After MIPI-CSI inputs a frame. This interrupt is not affected by whether ISP_MIPI_DATA_EN is enabled	isp_interrupt
ISP_TAIL_IDI_FRAME_INT	After ISP_Tail outputs a frame	isp_interrupt
ISP_YUV2RGB_FRAME_INT	After module YUV2RGB processes a frame	isp_interrupt
ISP_COLOR_FRAME_INT	After module contrast/hue/saturation/luminance adjustment processes a frame	isp_interrupt
ISP_SHARP_FRAME_INT	After module sharpen processes a frame	isp_interrupt
ISP_RGB2YUV_FRAME_INT	After module RGB2YUV processes a frame	isp_interrupt
ISP_GAMMA_FRAME_INT	After module gamma correction processes a frame	isp_interrupt
ISP_CCM_FRAME_INT	After module CCM processes a frame	isp_interrupt
ISP_DEMOSAIC_FRAME_INT	After module demosaic processes a frame	isp_interrupt
ISP_BF_FRAME_INT	After module BF processes a frame	isp_interrupt
ISP_DPC_FRAME_INT	After module DPC processes a frame	isp_interrupt
ISP_LSC_FRAME_INT	After module LSC processes a frame	isp_interrupt
ISP_BLC_FRAME_INT	After module BLC processes a frame	isp_interrupt
ISP_FRAME_INT	After ISP_Pipeline outputs a frame	isp_interrupt
ISP_HIST_FDONE_INT	After module HIST processes a frame	isp_interrupt
ISP_AWB_FDONE_INT	After module AWB processes a frame	isp_interrupt
ISP_AF_ENV_INT	When module AF detects a change in the focus scene	isp_interrupt
ISP_AF_FDONE_INT	After module AF processes a frame	isp_interrupt
ISP_AE_FRAME_DONE_INT	After module AE processes a frame	isp_interrupt
ISP_AE_MONITOR_INT	When module AE detects a change in the luminance	isp_interrupt
ISP_GAMMA_XCOORD_ERR_INT	When the GAMMA parameter is set incorrectly, the X length in ISP_GAMMA_R/G/B_X00-0F is not 256	isp_interrupt
ISP_DPC_CHECK_DONE_INT	After DPC static calibration processes a frame	isp_interrupt
ISP_MIPI_HNUM_UNMATCH_INT	When the width HNUM settings do not match the actual input from MIPI-CSI	isp_interrupt
ISP_DATA_TYPE_SETTING_ERR_INT	When DATA_TYPE settings do not match the actual input data	isp_interrupt

ISP_HVNUM_SETTING_ERR_INT	When the width HNUM and the height VNUM settings are incorrect: Image dimensions must be even; with the RAW10 input, HNUM must be a multiple of 4	isp_interrupt
ISP_BUF_FULL_INT	When ISP_Header buffer is full	isp_interrupt
ISP_ASYNC_FIFO_OVF_INT	When asynchronous FIFO of ISP_Header is overflowed	isp_interrupt
ISP_DATA_TYPE_ERR_INT	When illegal DATA_TYPE is used for input data (not RAW8/RAW10/RAW12)	isp_interrupt
CSI_BRIG_DMA_CFG_HAS_UPDATED_INT	When VDMA configuration of CSI_Bridge is updated	csi_bridge_interrupt
CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT	When asynchronous FIFO of CSI_Bridge is overflowed	csi_bridge_interrupt
CSI_BRIG_CSI_BUF_OVERRUN_INT	When CSI_Bridge buffer is overflowed	csi_bridge_interrupt
CSI_BRIG_DISCARD_INT	When any frame is discarded in CSI_Bridge	csi_bridge_interrupt
CSI_BRIG_VADR_NUM_LT_INT	When CSI_BRIG_VADR_NUM is less than the actual value	csi_bridge_interrupt
CSI_BRIG_VADR_NUM_GT_INT	When CSI_BRIG_VADR_NUM is greater than the actual value	csi_bridge_interrupt

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 38.8 *Register Summary*.

38.7 Programming Procedures

38.7.1 ISP Clock Reset Configuration

1. Enable the bus clock for the ISP and CSI_Bridge modules;
   - Set HP_SYS_CLKRST_CSI_BRG_SYS_CLK_EN to 1 to activate the clock for ISP and CSI_Bridge
2. Configure the working clock for ISP;
   - Choose the clock source via HP_SYS_CLKRST_ISP_CLK_SRC_SEL
   - Configure the clock divisor via HP_SYS_CLKRST_ISP_CLK_DIV_NUM
   - Set HP_SYS_CLKRST_ISP_CLK_EN to 1 to activate the ISP working clock
3. Reset ISP and CSI_Bridge modules.

- Set HP_SYS_CLKRST_RST_EN_CSI_BRG to 1 and then 0 to reset ISP and CSI_Bridge

38.7.2 CSI_Bridge Configuration

1. Set the width and height of the image via CSI_BRIG_HADR_NUM and CSI_BRIG_VADR_NUM. The width is measured in "64-bit" units, and the height is measured in rows;
2. Set the valid range for DATA_TYPE via CSI_BRIG_DATA_TYPE_MIN and CSI_BRIG_DATA_TYPE_MAX;
3. Specify the burst length via CSI_BRIG_DMA_BURST_LEN. Ensure that this value matches the SRC_MSIZE (length per burst) and SRC_TR_WIDTH (data width) of the corresponding VDMA channel. The data width for CSI_Bridge is measured in "64-bit" units;
4. If the image is transferred in multiple blocks, specify the maximum number of VDMA bursts per block via CSI_BRIG_DMABLK_SIZE;
5. Enable CSI_Bridge by writing 1 to CSI_BRIG_CSI_BRIG_EN.

38.7.3 VDMA Configuration

1. Configure the register corresponding to the channel;
   - Set SRC/DST_MULTBLK_TYPE to 3 (configure with linked list)
   - Configure TT_FC
     - For CSI_Bridge, set TT_FC to 4 (peripheral to memory with peripheral flow control)
     - For memory to ISP, set TT_FC to 6 (memory to peripheral with peripheral flow control)
   - Configure HS_SEL
     - For CSI_Bridge, set HS_SEL_SRC to 0 (peripheral uses hardware handshake), and set HS_SEL_DST to 1 (memory uses software handshake)
     - For memory to ISP, set HS_SEL_SRC to 1 (memory uses software handshake), and set HS_SEL_DST to 0 (peripheral uses hardware handshake)
   - Assign hardware handshake channels
     - For CSI_Bridge, set SRC_PER to 1
     - For memory to ISP, set DST_PER to 2
   - Set SRC/DST_TR_WIDTH to 3 (data width of 64 bits)
2. Establish the linked list based on the configured registers.

Note:
The VDMA configuration outlined in this section covers essential steps. For detailed procedures, refer to Chapter 7 *VDMA Controller (VDMA)*.
Ensure that image dimensions and start addresses are aligned to 8 bytes.

38.7.4 ISP General Configuration

1. Configure the input image size via ISP_HADR_NUM and ISP_VADR_NUM
2. Set image arrangement mode in the Bayer domain via ISP_BAYER_MODE;
3. Specify the ISP output data format via ISP_OUT_TYPE;
4. Configure each module in ISP_Pipeline. Refer to the corresponding section in 38.5.2 for details;
5. Enable the necessary Pipeline modules by setting the fields in register ISP_CNTL_REG. Ensure that the format conversion-related modules (Demosaic, RGB2YUV, YUV2RGB) are enabled before enabling the ISP, and that they match the final output format.

38.7.5 Enabling ISP for Image Capture from MIPI-CSI

1. Configure ISP and CSI_Bridge clocks and reset as described in Section 38.7.1;
2. Configure CSI_Bridge as described in Section 38.7.2;
3. Configure VDMA as described in Section 38.7.3;
4. Configure MIPI CSI HOST according to Chapter 42 *MIPI CSI*;
5. Configure ISP general settings as described in Section 38.7.4;
6. Select the input source as MIPI-CSI by setting ISP_IN_SRC to 0;
7. Configure the input data type via ISP_DATA_TYPE;
8. Enable the ISP by setting ISP_EN to 1;
9. Enable MIPI-CSI data input by setting ISP_MIPI_DATA_EN to 1.

38.7.6 Enabling ISP for Image Capture from DVP

1. Configure ISP and CSI_Bridge clocks and reset as described in Section 38.7.1;
2. Configure CSI_Bridge as described in Section 38.7.2;
3. Configure VDMA as described in Section 38.7.3;
4. Configure ISP general settings as described in Section 38.7.4;
5. Select the input source as DVP by setting ISP_IN_SRC to 1;
6. Configure the input data type via ISP_CAM_DATA_TYPE, and write 0 to ISP_DATA_TYPE;
7. Enable the ISP by setting ISP_EN to 1;
8. Configure the data mode for DVP interface via ISP_CAM_CONF_REG;
9. Reset the DVP interface by setting ISP_CAM_RESET to 1, waiting for a period, then setting it to 0;
10. Write 1 to ISP_CAM_UPDATE_REG;
11. Enable the DVP interface by setting ISP_CAM_EN to 1;
12. Wait for ISP_CAM_UPDATE_REG to automatically clear for initialization.

38.7.7 Enabling ISP for Image Capture from VDMA

1. Configure ISP and CSI_Bridge clocks and reset as described in Section 38.7.1;
2. Configure CSI_Bridge as described in Section 38.7.2;
3. Configure VDMA as described in Section 38.7.3;
4. Configure ISP general settings as described in Section 38.7.4;
5. Select the input source as VDMA by setting ISP_IN_SRC to 2;
6. Configure the input data type via ISP_DMA_DATA_TYPE and ISP_DATA_TYPE;
7. Configure the total amount of raw image data for one frame in "64-bit" units using ISP_DMA_RAW_NUM_TOTAL, which value should equal image width x image height x bits per pixel/64. Then, write 1 to ISP_DMA_RAW_NUM_TOTAL_SET to activate the configuration;
8. Configure the burst length via ISP_DMA_BURST_LEN, which needs to align with the VDMA configuration;
9. Write 1 to ISP_DMA_UPDATE_REG to update the VDMA configuration, and wait for the update to complete;
10. Send a frame of data by setting ISP_DMA_EN to 1.

38.7.8 LSC LUT Configuration

LSC can be configured after the ISP is enabled. Before enabling LSC, initialize the LSC LUT as follows:

1. Write to LUT;
   - Write the data to be stored in the LUT by writing to ISP_LUT_WDATA_REG
   - Store the data at the specified address by writing to ISP_LUT_CMD_REG
2. Read from LUT.
   - Retrieve the data stored at the specified address by writing to ISP_LUT_CMD_REG
   - Obtain the data read from the LUT by reading from ISP_LUT_RDATA_REG

38.7.9 AE Configuration

AE can be configured after the ISP is enabled as follows:

1. Select sampling points via ISP_AE_SELECT;
2. Set up statistical windows;
   - Set the horizontal starting point with ISP_AE_X_START
   - Configure the horizontal dimension of each sub-window with ISP_AE_X_BSIZE
   - Set the vertical starting point with ISP_AE_Y_START
   - Configure the vertical dimension of each sub-window with ISP_AE_Y_BSIZE
   - Specify the number of pixels in each sub-window with ISP_AE_SUBWIN_PIXNUM
   - Set the reciprocal of the number of pixels in each sub-window with ISP_AE_SUBWIN_RECIP (20 fractional bits)

3. Enable luminance monitoring;
    - If monitoring is required, set ISP_AE_MONITOR_TH and ISP_AE_MONITOR_TL to non-zero values
    - Specify the monitoring statistical period in frames via ISP_AE_MONITOR_PERIOD
4. Enable AE by writing 1 to ISP_AE_EN;
5. Obtain statistics;
    - Clear the completion status by writing 1 to ISP_AE_FRAME_DONE_INT_CLR
    - Initiate statistics by writing 1 to ISP_AE_UPDATE. Each write to this register resets the frame count for monitoring. It is recommended to disable monitoring before manual statistics and re-enable it after completion to prevent automatic results from overwriting manual results prematurely
    - Wait for the statistics to complete
        - Wait for the ISP interrupt triggered by AE_FDONE_INT
        - Or query the status using ISP_AE_FRAME_DONE_INT_RAW
    - Obtain statistics for each sub-window by reading ISP_AE_Bxx_MEAN
6. Perform luminance monitoring.
    - Wait for the ISP interrupt triggered by AE_MONITOR_INT
    - Or query the status using ISP_AE_MONITOR_INT_RAW
    - After detecting a change in luminance, disable luminance monitoring, re-initiate camera exposure, and then re-enable monitoring

38.7.10 AF Configuration

AF can be configured after the ISP is enabled as follows:

1. Set up three statistical windows A, B, and C, ensuring each window does not exceed 1024 x 1024;
    - Set the left boundary using ISP_AF_LPOINT_A/B/C
    - Set the right boundary using ISP_AF_RPOINT_A/B/C
    - Set the top boundary using ISP_AF_TPOINT_A/B/C
    - Set the bottom boundary using ISP_AF_BPOINT_A/B/C
2. Set the sharpness threshold via ISP_AF_THRESHOLD;
3. Configure focus scene monitoring;
    - If focus scene monitoring is required, set the monitoring period ISP_AF_ENV_PERIOD to a non-zero value
    - There are two ways to set the threshold
        - If ISP_AF_ENV_USER_THRESHOLD_SUM or ISP_AF_ENV_USER_THRESHOLD_LUM is non-zero, use the specified values as thresholds for sharpness and brightness changes

  - If ISP_AF_ENV_USER_THRESHOLD_SUM or ISP_AF_ENV_USER_THRESHOLD_LUM is zero, use the sharpness and brightness of the most recent statistics multiplied by ISP_AF_ENV_THRESHOLD (4 fractional bits) as the change threshold

4. Configure the statistical trigger mode. After each trigger completes, update the monitoring baseline;
   - If ISP_AF_AUTO_UPDATE is 1, it is in automatic triggering mode, which performs statistics for every frame with AF enabled. Since each statistical calculation clears the frame count for monitoring, the monitoring will be disabled
   - If ISP_AF_AUTO_UPDATE is 0, it is in manual triggering mode. The monitoring is working only under this condition
5. Enable AF by writing 1 to ISP_AF_EN;
6. Obtain statistics;
   - Clear the completion status by writing 1 to ISP_AF_FDONE_INT_CLR
   - Trigger statistics
     - With automatic triggering, statistics are performed for every frame
     - With manual triggering, write 1 to ISP_AF_MANUAL_UPDATE to trigger statistics manually
   - Wait for the statistics to complete
     - Wait for the ISP interrupt triggered by AF_FDONE_INT.
     - Or query the status using ISP_AF_FDONE_INT_RAW
   - Obtain sharpness statistics by reading ISP_AF_SUMA/B/C and obtain brightness statistics by reading ISP_AF_LUMA/B/C
7. Performs focus scene monitoring.
   - Wait for the ISP interrupt triggered by AF_ENV_INT
   - Or query the status using ISP_AF_ENV_INT_RAW
   - After detecting a change in the focus scene, disable monitoring, refocus the camera, and then re-enable monitoring

38.7.11 AWB Configuration

AWB can be configured after the ISP is enabled.

1. Select sampling points via ISP_AWB_SAMPLE and write 1 to ISP_AWB_MODE;
2. Set up statistical windows;
   - Set the left boundary using ISP_AWB_LPOINT
   - Set the right boundary using ISP_AWB_RPOINT
   - Set the top boundary using ISP_AWB_TPOINT
   - Set the bottom boundary using ISP_AWB_BPOINT
3. Configure white patch constraints;

- Set maximum luminance with ISP_AWB_MAX_LUM
- Set minimum luminance with ISP_AWB_MIN_LUM
- Set maximum R/G ratio with ISP_AWB_MAX_RG (2 integer bits, 8 fractional bits)
- Set minimum R/G ratio with ISP_AWB_MIN_RG (2 integer bits, 8 fractional bits)
- Set maximum B/G ratio with ISP_AWB_MAX_BG (2 integer bits, 8 fractional bits)
- Set minimum B/G ratio with ISP_AWB_MIN_BG (2 integer bits, 8 fractional bits)

4. Obtain statistics;
   - Clear the completion status by writing 1 to ISP_AWB_FDONE_INT_CLR
   - Trigger statistics by writing 0 and then 1 to ISP_AWB_EN
   - Wait for the statistics to complete
     - Wait for the ISP interrupt triggered by AWB_FDONE_INT
     - Or query the status using ISP_AWB_FDONE_INT_RAW
   - Get the number of white patches within the statistical window by reading ISP_AWBO_WHITE_CNT
   - Get the accumulated values of the R, G, B components for the white patches within the statistical window by reading ISP_AWBO_ACC_R/G/B

38.7.12 HIST Configuration

HIST can be configured after the ISP is enabled.

1. Select sampling points via ISP_HIST_MODE;
   - If sampling points are set to RGB, use ISP_HIST_COEFF_R/G/B to set RGB weights with 8 fractional bits
2. Set up statistical windows;
   - Set the horizontal start point with ISP_HIST_X_OFFS
   - Configure the horizontal dimension of each sub-window with ISP_HIST_X_SIZE
   - Set the vertical start point with ISP_HIST_Y_OFFS
   - Configure the vertical dimension of each sub-window with ISP_HIST_Y_SIZE
3. Configure histograms;
   - Set histogram interval divisions using ISP_HIST_SEG_x_x
   - Set window weights using ISP_HIST_WEIGHT_xx with 8 fractional bits
4. Enable HIST by writing 1 to ISP_HIST_EN;
5. Obtain statistics.
   - Clear the completion status by writing 1 to ISP_HIST_FDONE_INT_CLR
   - With HIST enabled, statistics are performed at the end of every frame. Wait for the statistics to complete

  - Wait for the ISP interrupt triggered by HIST_FDONE_INT
  - Or query the status using ISP_HIST_FDONE_INT_RAW.
- Obtain the statistics for each interval by reading ISP_HIST_BIN_x.

38.7.13 ISP_Pipeline Module Update Configuration

1. Disable the module via ISP_CNTL_REG;
2. Wait for the interrupt from the corresponding module;
3. Update module configurations;
4. Re-enable the module.

38.8 Register Summary

38.8.1 ISP Register Summary

The addresses in this section are relative to **ISP** base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Configuration Registers			
ISP_CLK_EN_REG	ISP clock control register	0x0004	R/W
ISP_CNTL_REG	ISP enable register	0x0008	R/W
ISP_HSYNC_CNT_REG	Hsync interval control register	0x000C	R/W
ISP_FRAME_CFG_REG	Image control register	0x0010	R/W
ISP_CCM_COEF0_REG	CCM parameter register 0	0x0014	R/W
ISP_CCM_COEF1_REG	CCM parameter register 1	0x0018	R/W
ISP_CCM_COEF3_REG	CCM parameter register 3	0x001C	R/W
ISP_CCM_COEF4_REG	CCM parameter register 4	0x0020	R/W
ISP_CCM_COEF5_REG	CCM parameter register 5	0x0024	R/W
ISP_BF_MATRIX_CTRL_REG	BF pixel-to-matrix control register	0x0028	R/W
ISP_BF_SIGMA_REG	BF noise reduction strength control register	0x002C	R/W
ISP_BF_GAU0_REG	BF noise reduction template register 0	0x0030	R/W
ISP_BF_GAU1_REG	BF noise reduction template register 1	0x0034	R/W
ISP_DPC_CTRL_REG	DPC control register	0x0038	R/W
ISP_DPC_CONF_REG	DPC parameter register	0x003C	R/W
ISP_DPC_MATRIX_CTRL_REG	DPC pixel-to-matrix control register	0x0040	R/W
ISP_LUT_CMD_REG	LUT command register	0x0048	WT
ISP_LUT_WDATA_REG	LUT write register	0x004C	R/W
ISP_LSC_TABLESIZE_REG	LSC parameter control register	0x0054	R/W
ISP_DEMOSAIC_MATRIX_CTRL_REG	Demosaic pixel-to-matrix control register	0x0058	R/W
ISP_DEMOSAIC_GRAD_RATIO_REG	Demosaic parameter control register	0x005C	R/W
ISP_GAMMA_CTRL_REG	Gamma correction control register	0x0074	R/W
ISP_GAMMA_RY1_REG	Gamma curve R channel Y axis configuration register 1	0x0078	R/W
ISP_GAMMA_RY2_REG	Gamma curve R channel Y axis configuration register 2	0x007C	R/W
ISP_GAMMA_RY3_REG	Gamma curve R channel Y axis configuration register 3	0x0080	R/W
ISP_GAMMA_RY4_REG	Gamma curve R channel Y axis configuration register 4	0x0084	R/W
ISP_GAMMA_GY1_REG	Gamma curve G channel Y axis configuration register 1	0x0088	R/W
ISP_GAMMA_GY2_REG	Gamma curve G channel Y axis configuration register 2	0x008C	R/W

Name	Description	Address	Access
ISP_GAMMA_GY3_REG	Gamma curve G channel Y axis configuration register 3	0x0090	R/W
ISP_GAMMA_GY4_REG	Gamma curve G channel Y axis configuration register 4	0x0094	R/W
ISP_GAMMA_BY1_REG	Gamma curve B channel Y axis configuration register 1	0x0098	R/W
ISP_GAMMA_BY2_REG	Gamma curve B channel Y axis configuration register 2	0x009C	R/W
ISP_GAMMA_BY3_REG	Gamma curve B channel Y axis configuration register 3	0x00A0	R/W
ISP_GAMMA_BY4_REG	Gamma curve B channel Y axis configuration register 4	0x00A4	R/W
ISP_GAMMA_RX1_REG	Gamma curve R channel X axis configuration register 1	0x00A8	R/W
ISP_GAMMA_RX2_REG	Gamma curve R channel X axis configuration register 2	0x00AC	R/W
ISP_GAMMA_GX1_REG	Gamma curve G channel X axis configuration register 1	0x00B0	R/W
ISP_GAMMA_GX2_REG	Gamma curve G channel X axis configuration register 2	0x00B4	R/W
ISP_GAMMA_BX1_REG	Gamma curve B channel X axis configuration register 1	0x00B8	R/W
ISP_GAMMA_BX2_REG	Gamma curve B channel X axis configuration register 2	0x00BC	R/W
ISP_AE_CTRL_REG	AE control register	0x00C0	varies
ISP_AE_MONITOR_REG	AE monitoring control register	0x00C4	R/W
ISP_AE_BX_REG	AE statistical window X direction configuration register	0x00C8	R/W
ISP_AE_BY_REG	AE statistical window Y direction configuration register	0x00CC	R/W
ISP_AE_WINPIXNUM_REG	AE sub-window pixel number configuration register	0x00D0	R/W
ISP_AE_WIN_RECIPROCAL_REG	AE sub-window pixel number reciprocal configuration register	0x00D4	R/W
ISP_SHARP_CTRL0_REG	Sharpen control register 0	0x00F4	R/W
ISP_SHARP_FILTER0_REG	Sharpen low-frequency template configuration register 0	0x00F8	R/W
ISP_SHARP_FILTER1_REG	Sharpen low-frequency template configuration register 1	0x00FC	R/W
ISP_SHARP_FILTER2_REG	Sharpen low-frequency template configuration register 2	0x0100	R/W
ISP_SHARP_MATRIX_CTRL_REG	Sharpen pixel-to-matrix control register	0x0104	R/W
ISP_SHARP_CTRL1_REG	Sharpen control register 1	0x0108	RO
ISP_DMA_CNTL_REG	ISP VDMA input control register	0x010C	varies

Name	Description	Address	Access
ISP_DMA_RAW_DATA_REG	ISP VDMA input data amount configuration register	0x0110	varies
ISP_CAM_CNTL_REG	ISP DVP input control register	0x0114	R/W
ISP_CAM_CONF_REG	ISP DVP input configuration register	0x0118	R/W
ISP_AF_CTRL0_REG	AF control register 0	0x011C	varies
ISP_AF_ENV_USER_TH_SUM_REG	AF scene monitoring sharpness threshold configuration register	0x0128	R/W
ISP_AF_ENV_USER_TH_LUM_REG	AF scene monitoring luminance threshold configuration register	0x012C	R/W
ISP_AF_THRESHOLD_REG	AF statistics threshold configuration register	0x0130	varies
ISP_AF_HSCALE_A_REG	AF statistical window A horizontal direction configuration register	0x0134	R/W
ISP_AF_VSCALE_A_REG	AF statistical window A vertical direction configuration register	0x0138	R/W
ISP_AF_HSCALE_B_REG	AF statistical window B horizontal direction configuration register	0x013C	R/W
ISP_AF_VSCALE_B_REG	AF statistical window B vertical direction configuration register	0x0140	R/W
ISP_AF_HSCALE_C_REG	AF statistical window C horizontal direction configuration register	0x0144	R/W
ISP_AF_VSCALE_C_REG	AF statistical window C vertical direction configuration register	0x0148	R/W
ISP_AWB_MODE_REG	AWB control register	0x0164	R/W
ISP_AWB_HSCALE_REG	AWB statistical window horizontal direction configuration register	0x0168	R/W
ISP_AWB_VSCALE_REG	AWB statistical window vertical direction configuration register	0x016C	R/W
ISP_AWB_TH_LUM_REG	AWB white patch luminance threshold configuration register	0x0170	R/W
ISP_AWB_TH_RG_REG	AWB white patch R/G threshold configuration register	0x0174	R/W
ISP_AWB_TH_BG_REG	AWB white patch B/G threshold configuration register	0x0178	R/W
ISP_COLOR_CTRL_REG	Contrast/saturation/luminance control register	0x018C	R/W
ISP_BLC_VALUE_REG	BLC control register	0x0190	R/W
ISP_BLC_CTRL0_REG	BLC pixel stretch register	0x0194	R/W
ISP_HIST_MODE_REG	HIST control register	0x01A4	R/W
ISP_HIST_COEFF_REG	HIST RGB parameter configuration register	0x01A8	R/W
ISP_HIST_OFFS_REG	HIST statistical window starting point configuration register	0x01AC	R/W
ISP_HIST_SIZE_REG	HIST statistical sub-window size configuration register	0x01B0	R/W
ISP_HIST_SEG0_REG	HIST X coordinate interval configuration register 0	0x01B4	R/W

Name	Description	Address	Access
ISP_HIST_SEG1_REG	HIST X coordinate interval configuration register 1	0x01B8	R/W
ISP_HIST_SEG2_REG	HIST X coordinate interval configuration register 2	0x01BC	R/W
ISP_HIST_SEG3_REG	HIST X coordinate interval configuration register 3	0x01C0	R/W
ISP_HIST_WEIGHT0_REG	HIST sub-window weight configuration register 0	0x01C4	R/W
ISP_HIST_WEIGHT1_REG	HIST sub-window weight configuration register 1	0x01C8	R/W
ISP_HIST_WEIGHT2_REG	HIST sub-window weight configuration register 2	0x01CC	R/W
ISP_HIST_WEIGHT3_REG	HIST sub-window weight configuration register 3	0x01D0	R/W
ISP_HIST_WEIGHT4_REG	HIST sub-window weight configuration register 4	0x01D4	R/W
ISP_HIST_WEIGHT5_REG	HIST sub-window weight configuration register 5	0x01D8	R/W
ISP_HIST_WEIGHT6_REG	HIST sub-window weight configuration register 6	0x01DC	R/W
ISP_YUV_FORMAT_REG	YUV format control register	0x0234	R/W
ISP_CROP_CTRL_REG	CROP control register	0x0244	WT
ISP_CROP_Y_CAPTURE_REG	CROP Y direction control register	0x0248	R/W
ISP_CROP_X_CAPTURE_REG	CROP X direction control register	0x024C	R/W
ISP_CROP_ERR_ST_REG	CROP error status register	0x0250	RO
ISP_WBG_COEF_R_REG	WBG R channel gain register	0x0254	R/W
ISP_WBG_COEF_G_REG	WBG G channel gain register	0x0258	R/W
ISP_WBG_COEF_B_REG	WBG B channel gain register	0x025C	R/W
ISP_COLOR_HUE_CTRL_REG	Hue control register	0x0260	R/W
ISP_AWB_BX_REG	AWB sub-window X direction control register	0x0264	R/W
ISP_AWB_BY_REG	AWB sub-window Y direction control register	0x0268	R/W
ISP_STATE_REG	ISP state register	0x026C	RO
ISP_SHADOW_REG_CTRL_REG	Shadow register control register	0x0270	R/W
Status Registers			
ISP_DPC_DEADPIX_CNT_REG	DPC static calibration defective pixel number register	0x0044	RO
ISP_LUT_RDATA_REG	LUT read register	0x0050	RO
ISP_AE_BLOCK_MEAN_0_REG	AE statistics register 0	0x00D8	RO
ISP_AE_BLOCK_MEAN_1_REG	AE statistics register 1	0x00DC	RO
ISP_AE_BLOCK_MEAN_2_REG	AE statistics register 2	0x00E0	RO

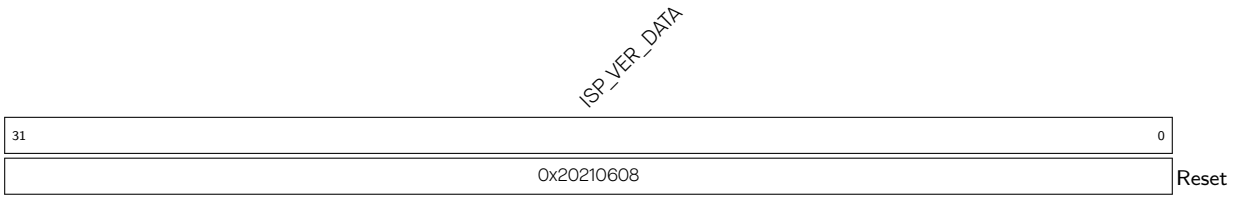
38.8.2 MIPI CSI_Bridge Register Summary

The addresses in this section are relative to **MIPI CSI_Bridge** base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Clock Gating Control Register			

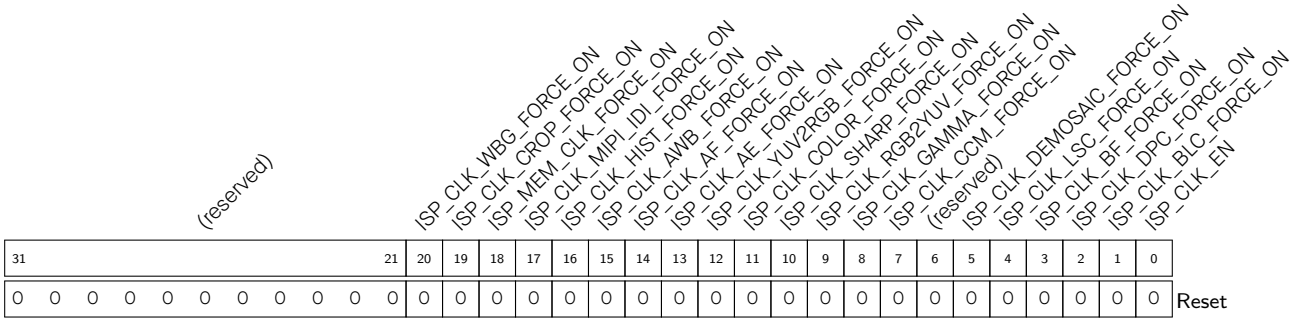
Name	Description	Address	Access
CSI_BRIG_CLK_EN_REG	CSI_Bridge clock gate register	0x0000	R/W
CSI_Bridge Control Registers			
CSI_BRIG_CSI_EN_REG	CSI_Bridge enable register	0x0004	R/W
CSI_BRIG_BUF_FLOW_CTL_REG	CSI_Bridge buffer control register	0x000C	varies
DMA Control Registers			
CSI_BRIG_DMA_REQ_CFG_REG	DMA request control register	0x0008	R/W
CSI_BRIG_DMA_REQ_INTERVAL_REG	DMA request interval register	0x002C	R/W
CSI_BRIG_DMABLK_SIZE_REG	DMA data block size control register	0x0030	R/W
Frame Format Configuration Registers			
CSI_BRIG_DATA_TYPE_CFG_REG	DATA_TYPE control register	0x0010	R/W
CSI_BRIG_FRAME_CFG_REG	Image control register	0x0014	R/W
CSI_BRIG_ENDIAN_MODE_REG	Byte order control register	0x0018	R/W
Interrupt Registers			
CSI_BRIG_INT_RAW_REG	CSI_Bridge raw interrupt status register	0x001C	R/ WTC/ SS
CSI_BRIG_INT_CLR_REG	CSI_Bridge interrupt clear register	0x0020	WT
CSI_BRIG_INT_ST_REG	CSI_Bridge masked interrupt status register	0x0024	RO
CSI_BRIG_INT_ENA_REG	CSI_Bridge interrupt enable register	0x0028	R/W
CSI HOST Control Register			
CSI_BRIG_HOST_CTRL_REG	CSI HOST control register	0x0040	R/W



38.9 Registers

38.9.1 ISP Registers

The addresses in this section are relative to **ISP** base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 38.1. ISP_VER_DATE_REG (0x0000)

ISP_VER_DATA ISP version control register. (R/W)

Register 38.2. ISP_CLK_EN_REG (0x0004)

ISP_CLK_EN Configures whether the ISP clock is always on.

0: The clock is enabled only during register access

1: The clock is always on

(R/W)

ISP_CLK_BLC_FORCE_ON Configures whether to force enable the BLC clock.

0: Not force enable

1: Force enable

(R/W)

ISP_CLK_DPC_FORCE_ON Configures whether to force enable the DPC clock.

0: Not force enable

1: Force enable

(R/W)

ISP_CLK_BF_FORCE_ON Configures whether to force enable the BF clock.

0: Not force enable

1: Force enable

(R/W)

ISP_CLK_LSC_FORCE_ON Configures whether to force enable the LSC clock.

0: Not force enable

1: Force enable

(R/W)

ISP_CLK_DEMOSAIC_FORCE_ON Configures whether to force enable the demosaic clock.

0: Not force enable

1: Force enable

(R/W)

ISP_CLK_CCM_FORCE_ON Configures whether to force enable the CCM clock.

0: Not force enable

1: Force enable

(R/W)

Continued on the next page...

Register 38.2. ISP_CLK_EN_REG (0x0004)

Continued from the previous page...

ISP_CLK_GAMMA_FORCE_ON Configures whether to force enable the gamma correction clock.
0: Not force enable
1: Force enable
(R/W)

ISP_CLK_RGB2YUV_FORCE_ON Configures whether to force enable the RGB2YUV clock.
0: Not force enable
1: Force enable
(R/W)

ISP_CLK_SHARP_FORCE_ON Configures whether to force enable the sharpen clock.
0: Not force enable
1: Force enable
(R/W)

ISP_CLK_COLOR_FORCE_ON Configures whether to force enable the contrast/hue/saturation/luminance clock.
0: Not force enable
1: Force enable
(R/W)

ISP_CLK_YUV2RGB_FORCE_ON Configures whether to force enable the YUV2RGB clock.
0: Not force enable
1: Force enable
(R/W)

ISP_CLK_AE_FORCE_ON Configures whether to force enable the AE clock.
0: Not force enable
1: Force enable
(R/W)

ISP_CLK_AF_FORCE_ON Configures whether to force enable the AF clock.
0: Not force enable
1: Force enable
(R/W)

ISP_CLK_AWB_FORCE_ON Configures whether to force enable the AWB clock.
0: Not force enable
1: Force enable
(R/W)

ISP_CLK_HIST_FORCE_ON Configures whether to force enable the HIST clock.
0: Not force enable
1: Force enable
(R/W)

Continued on the next page...

Register 38.2. ISP_CLK_EN_REG (0x0004)

Continued from the previous page...

ISP_CLK_MIPI_IDI_FORCE_ON Configures whether to force enable the MIPI Image Interface 32 input clock.

0: Not force enable

1: Force enable

(R/W)

ISP_MEM_CLK_FORCE_ON Configures whether to force enable all the ISP memory clocks.

0: Not force enable

1: Force enable

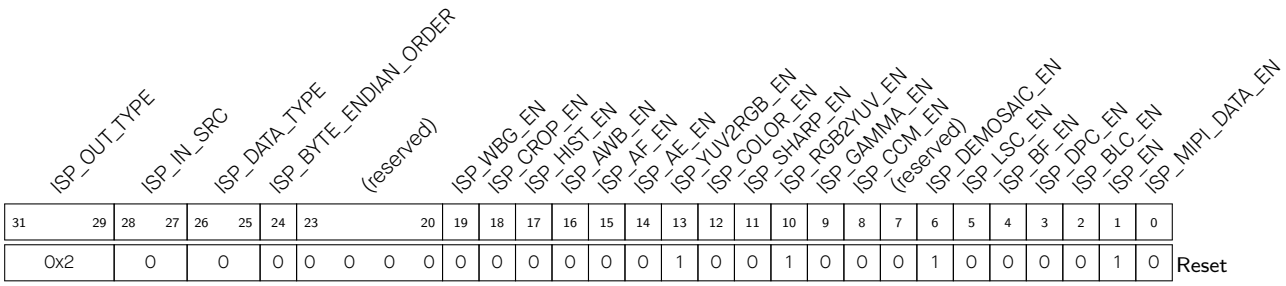
(R/W)

ISP_CLK_CROP_FORCE_ON Configures whether to force enable the CROP clock.

0: Not force enable

1: Force enable

(R/W)



ISP_CLK_WBG_FORCE_ON Configures whether to force enable the WBG clock.

0: Not force enable

1: Force enable

(R/W)

Register 38.3. ISP_CNTL_REG (0x0008)

ISP_MIPI_DATA_EN Configures whether to enable the MIPI Image Interface 32 input.

0: Disable

1: Enable

(R/W)

ISP_EN Configures whether to enable the ISP.

0: Disable

1: Enable

(R/W)

ISP_BLC_EN Configures whether to enable the BLC module.

0: Disable

1: Enable

(R/W)

ISP_DPC_EN Configures whether to enable the DPC module.

0: Disable

1: Enable

(R/W)

ISP_BF_EN Configures whether to enable the BF module.

0: Disable

1: Enable

(R/W)

ISP_LSC_EN Configures whether to enable the LSC module.

0: Disable

1: Enable

(R/W)

ISP_DEMOSAIC_EN Configures whether to enable the demosaic module.

0: Disable

1: Enable

(R/W)

ISP_CCM_EN Configures whether to enable the CCM module.

0: Disable

1: Enable

(R/W)

Continued on the next page...

Register 38.3. ISP_CNTL_REG (0x0008)

Continued from the previous page...

ISP_GAMMA_EN Configures whether to enable the gamma correction module.

0: Disable

1: Enable

(R/W)

ISP_RGB2YUV_EN Configures whether to enable the RGB2YUV module.

0: Disable

1: Enable

(R/W)

ISP_SHARP_EN Configures whether to enable the sharpen module.

0: Disable

1: Enable

(R/W)

ISP_COLOR_EN Configures whether to enable the contrast/hue/saturation/luminance module.

0: Disable

1: Enable

(R/W)

ISP_YUV2RGB_EN Configures whether to enable the YUV2RGB module.

0: Disable

1: Enable

(R/W)

ISP_AE_EN Configures whether to enable the AE module.

0: Disable

1: Enable

(R/W)

ISP_AF_EN Configures whether to enable the AF module.

0: Disable

1: Enable

(R/W)

ISP_AWB_EN Configures whether to enable the AWB module.

0: Disable

1: Enable

(R/W)

ISP_HIST_EN Configures whether to enable the HIST module.

0: Disable

1: Enable

(R/W)

Continued on the next page...

Register 38.3. ISP_CNTL_REG (0x0008)

Continued from the previous page...

ISP_CROP_EN Configures whether to enable the CROP module.

0: Disable

1: Enable

(R/W)

ISP_WBG_EN Configures whether to enable the WBG module.

0: Disable

1: Enable

(R/W)

ISP_BYTE_ENDIAN_ORDER Configures the byte order for MIPI Image Interface 32 input when ISP is disabled.

0: csi_data[31:0]

1: [7:0], [15:8], [23:16], [31:24]

(R/W)

ISP_DATA_TYPE Configures the input data type.

0: RAW8

1: RAW10

2: RAW12

3: invalid

(R/W)

ISP_IN_SRC Configures the input data source.

0: MIPI Image Interface 32 data from CSI HOST

1: Data from DVP

2: Data from VDMA

3: invalid

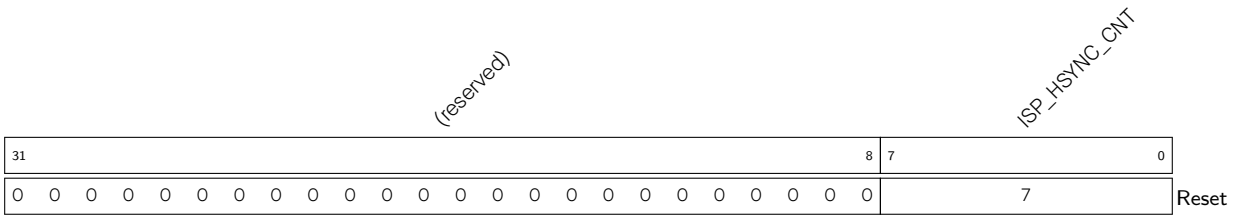
(R/W)

ISP_OUT_TYPE Configures the output data type.

0: RAW8

1: YUV422

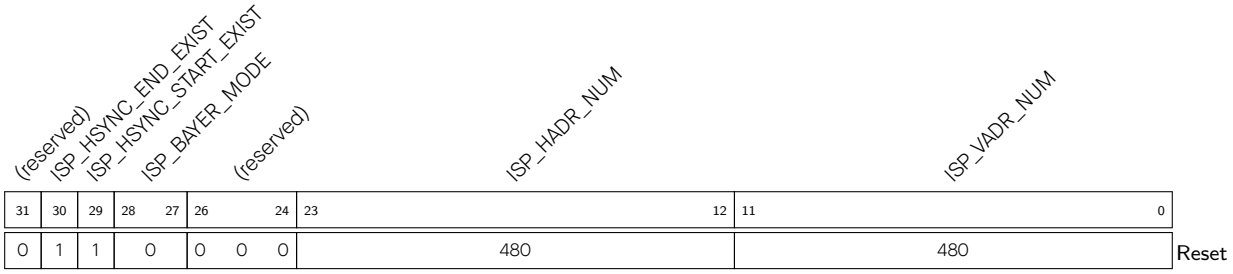
2: RGB888



3: YUV420

4: RGB565

Others: Invalid



(R/W)

Register 38.4. ISP_HSYNC_CNT_REG (0x000C)

ISP_HSYNC_CNT Configures the interval between hsync and the previous vsync or line_end when converting Image Interface 32 data to ISP data. Generally, the default value is used. Measurement unit: Number of ISP_CLK clock cycles. (R/W)

Register 38.5. ISP_FRAME_CFG_REG (0x0010)

ISP_VADR_NUM Configures the height of the input image, which should be set as the actual number of lines - 1. (R/W)

ISP_HADR_NUM Configures the width of the input image, which should be set as the actual width of lines - 1. (R/W)

ISP_BAYER_MODE Configures the Bayer mode of the input image.

0: BG/GR

1: GB/RG

2: GR/BG

3: RG/GB

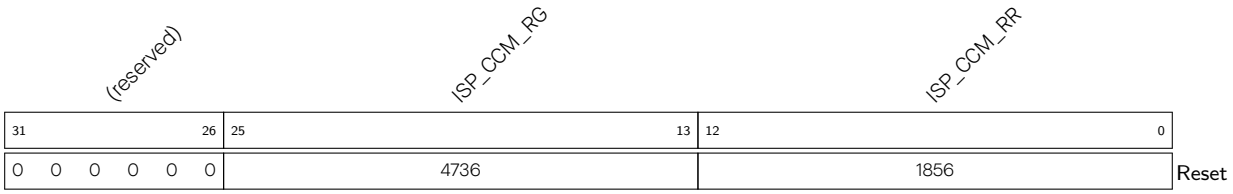
(R/W)

ISP_HSYNC_START_EXIST Configures whether the hsync_start packet exists.

0: Not exist

1: Exist

(R/W)

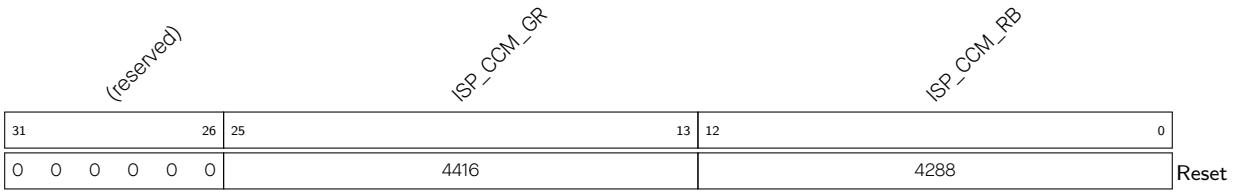


ISP_HSYNC_END_EXIST Configures whether the hsync_end packet exists. This must have the same value as the ISP_HSYNC_START_EXIST field.

0: Not exist

1: Exist

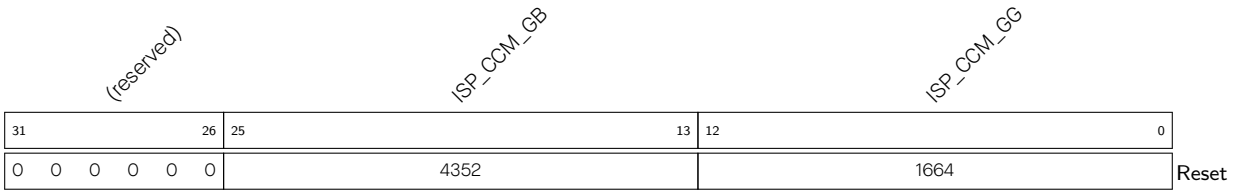
(R/W)



Register 38.6. ISP_CCM_COEF0_REG (0x0014)

ISP_CCM_RR Configures the CCM RR parameter. The 12th bit is the sign bit, and bits [11:0] represent the absolute value. Bits [11:10] are the integer part, and bits [9:0] are the fractional part. (R/W)

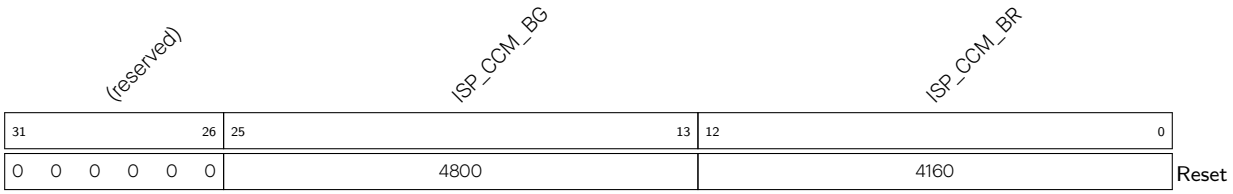
ISP_CCM_RG Configures the CCM RG parameter, following the same bit structure and interpretation as ISP_CCM_RR. (R/W)



Register 38.7. ISP_CCM_COEF1_REG (0x0018)

ISP_CCM_RB Configures the CCM RB parameter, following the same bit structure and interpretation as ISP_CCM_RR. (R/W)

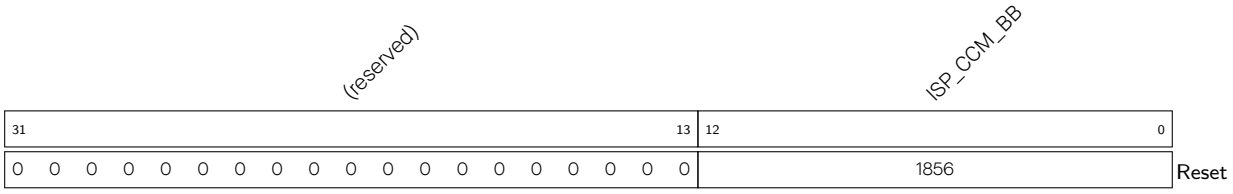
ISP_CCM_GR Configures the CCM GR parameter, following the same bit structure and interpretation as ISP_CCM_RR. (R/W)



Register 38.8. ISP_CCM_COEF3_REG (0x001C)

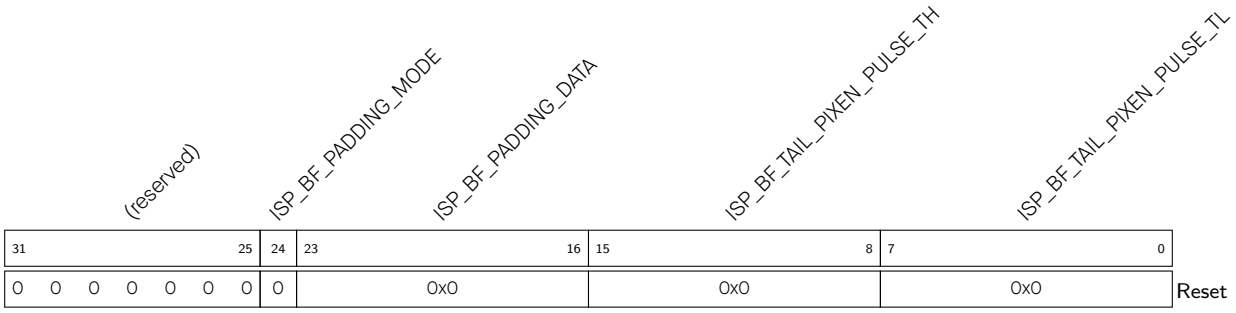
ISP_CCM_GG Configures the CCM GG parameter, following the same bit structure and interpretation as ISP_CCM_RR. (R/W)

ISP_CCM_GB Configures the CCM GB parameter, following the same bit structure and interpretation as ISP_CCM_RR. (R/W)



Register 38.9. ISP_CCM_COEF4_REG (0x0020)

ISP_CCM_BR Configures the CCM BR parameter, following the same bit structure and interpretation as ISP_CCM_RR. (R/W)



ISP_CCM_BG Configures the CCM BG parameter, following the same bit structure and interpretation as ISP_CCM_RR. (R/W)

Register 38.10. ISP_CCM_COEF5_REG (0x0024)

ISP_CCM_BB Configures the CCM BB parameter, following the same bit structure and interpretation as ISP_CCM_RR. (R/W)

Register 38.11. ISP_BF_MATRIX_CTRL_REG (0x0028)

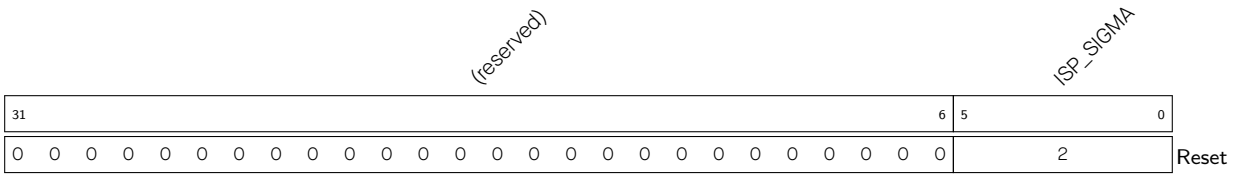
ISP_BF_TAIL_PIXEN_PULSE_TL Configures the data control cycle for the tail-row data rate during pixel-to-matrix conversion in the BF module.

Within ISP_BF_TAIL_PIXEN_PULSE_TL clock cycles, only the first ISP_BF_TAIL_PIXEN_PULSE_TH cycles are valid. Be cautious to configure this field, to prevent data processing from being deferred to the next frame.

This feature is enabled only when both ISP_BF_TAIL_PIXEN_PULSE_TL and ISP_BF_TAIL_PIXEN_PULSE_TH are non-zero, and ISP_BF_TAIL_PIXEN_PULSE_TH < ISP_BF_TAIL_PIXEN_PULSE_TL. (R/W)

ISP_BF_TAIL_PIXEN_PULSE_TH Configures the valid data cycle of the tail-row data rate during pixel-to-matrix conversion in the BF module, which must be less than ISP_HADR_NUM - 1. (R/W)

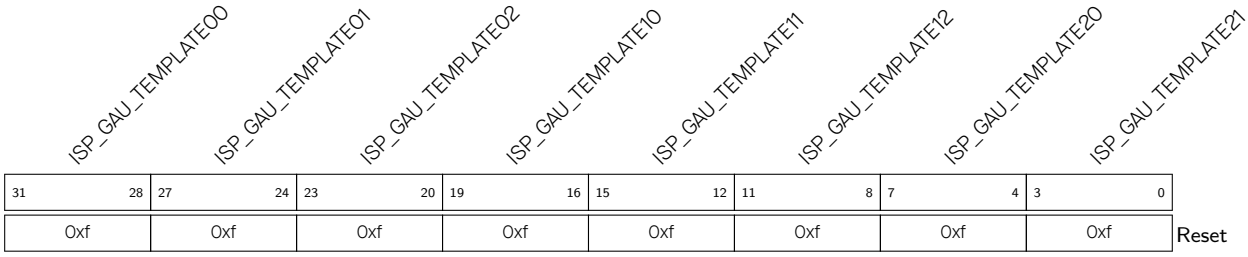
ISP_BF_PADDING_DATA Configures the padding data used during image edge expansion in pixel-to-matrix conversion of the BF module. (R/W)



ISP_BF_PADDING_MODE Configures the method of image edge expansion during pixel-to-matrix conversion in the BF module.

0: Automatically padded with pixel values from the image edge

1: Padded with the data in ISP_BF_PADDING_DATA



(R/W)

Register 38.12. ISP_BF_SIGMA_REG (0x002C)

ISP_SIGMA Configures the strength of noise reduction in the BF module. Values from 2 to 20 represent increasing strength, while other values indicate maximum strength. (R/W)

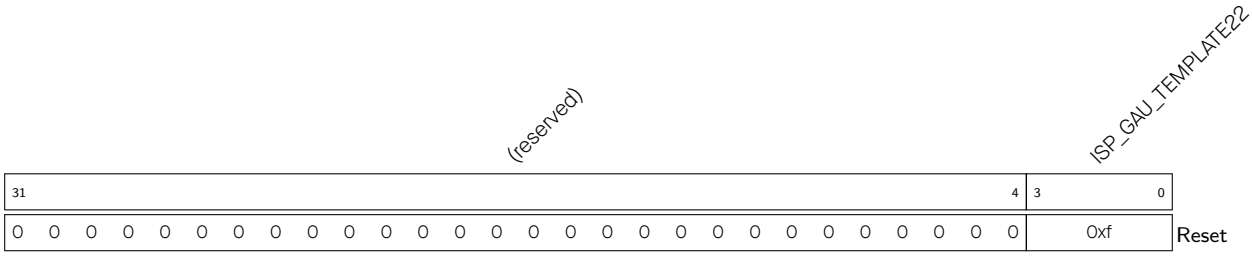
Register 38.13. ISP_BF_GAU0_REG (0x0030)

ISP_GAU_TEMPLATE21 Configures the value of coordinate 21 in the noise reduction template of the BF module. (R/W)

ISP_GAU_TEMPLATE20 Configures the value of coordinate 20 in the noise reduction template of the BF module. (R/W)

ISP_GAU_TEMPLATE12 Configures the value of coordinate 12 in the noise reduction template of the BF module. (R/W)

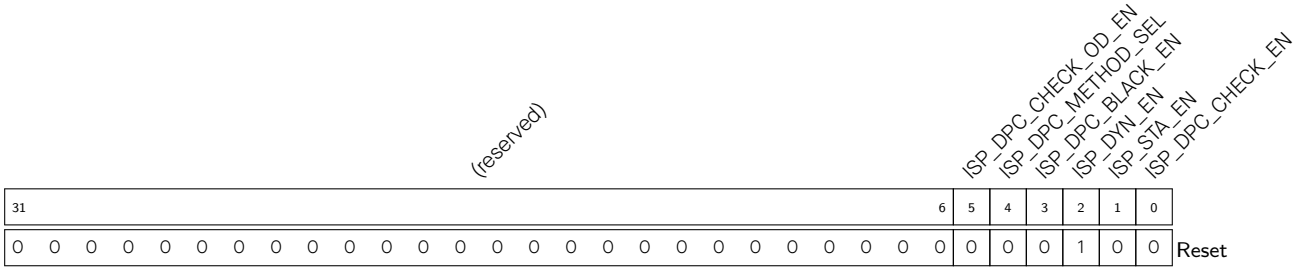
ISP_GAU_TEMPLATE11 Configures the value of coordinate 11 in the noise reduction template of the BF module. (R/W)



ISP_GAU_TEMPLATE10 Configures the value of coordinate 10 in the noise reduction template of the BF module. (R/W)

ISP_GAU_TEMPLATE02 Configures the value of coordinate 02 in the noise reduction template of the BF module. (R/W)

ISP_GAU_TEMPLATE01 Configures the value of coordinate 01 in the noise reduction template of the BF module. (R/W)



ISP_GAU_TEMPLATE00 Configures the value of coordinate 00 in the noise reduction template of the BF module. (R/W)

Register 38.14. ISP_BF_GAU1_REG (0x0034)

ISP_GAU_TEMPLATE22 Configures the value of coordinate 22 in the noise reduction template of the BF module. (R/W)

Register 38.15. ISP_DPC_CTRL_REG (0x0038)

ISP_DPC_CHECK_EN Configures whether to enable the static calibration function. Calibration and correction cannot be enabled at the same time.

0: Disable

1: Enable

(R/W)

ISP_STA_EN Configures whether to enable the static correction function.

0: Disable

1: Enable

(R/W)

ISP_DYN_EN Configures whether to enable the dynamic correction function.

0: Disable

1: Enable

(R/W)

ISP_DPC_BLACK_EN Configures the image type used for static calibration.

0: White image

1: Black image

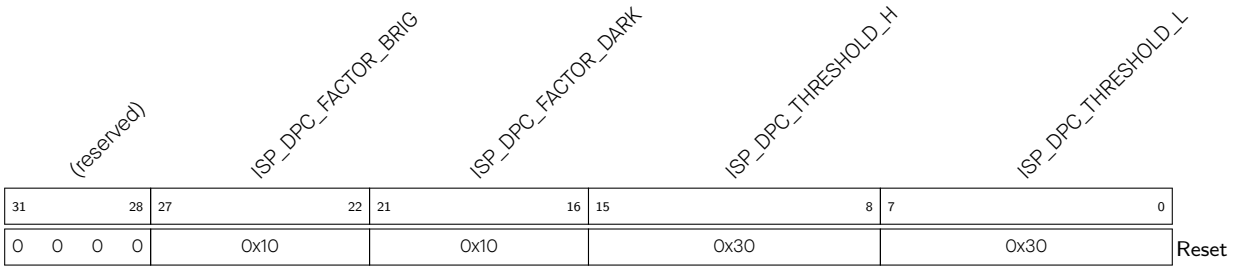
(R/W)

ISP_DPC_METHOD_SEL Configures the algorithm selection for dynamic correction.

0: Select Algorithm 0

1: Select Algorithm 1

(R/W)



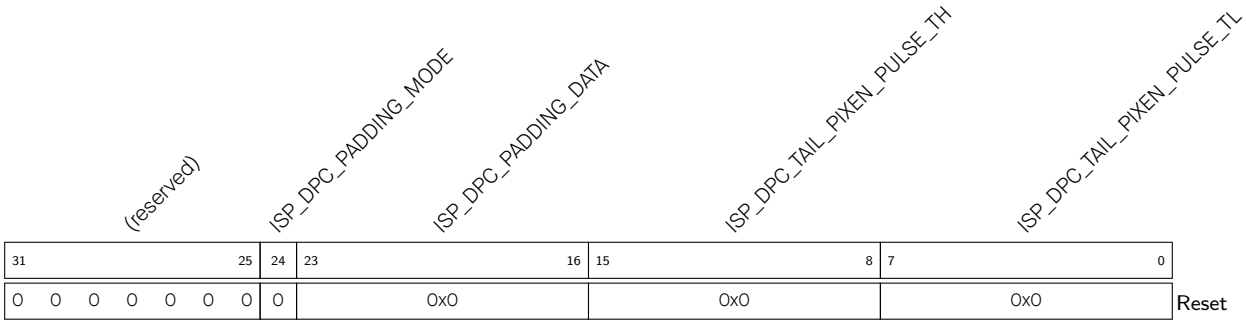
ISP_DPC_CHECK_OD_EN Configures whether to output image data during the static calibration process.

0: Do not output image

1: Output image

(R/W)

Register 38.16. ISP_DPC_CONF_REG (0x003C)



ISP_DPC_THRESHOLD_L Configures the defective pixel threshold for black image static calibration, or the low threshold in dynamic correction Algorithm 0 (8-bit valid), or the low threshold in dynamic correction Algorithm 1 (5-bit valid, maximum value is 16). For details, refer to Section 38.5.2.2. (R/W)

ISP_DPC_THRESHOLD_H Configures the defective pixel threshold for white image static calibration, or the high threshold in dynamic correction Algorithm 0 (8-bit valid), or the high threshold in dynamic correction Algorithm 1 (5-bit valid, maximum value is 16). For details, refer to Section 38.5.2.2. (R/W)

ISP_DPC_FACTOR_DARK Configures the dark pixel factor used in dynamic correction Algorithm 1. (R/W)

ISP_DPC_FACTOR_BRIG Configures the bright pixel factor used in dynamic correction Algorithm 1. (R/W)

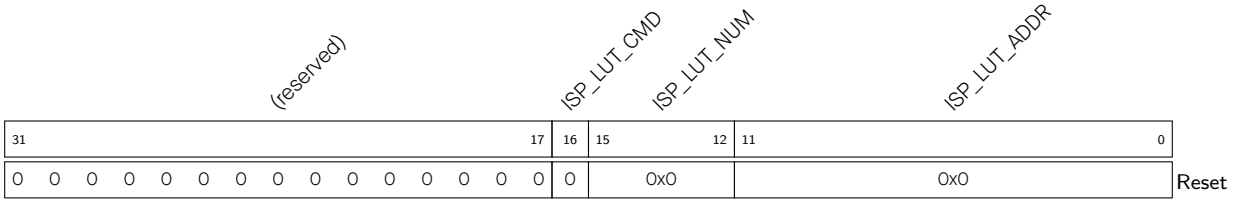
Register 38.17. ISP_DPC_MATRIX_CTRL_REG (0x0040)

ISP_DPC_TAIL_PIXEN_PULSE_TL Configures the data control cycle for the tail-row data rate during pixel-to-matrix conversion in the DPC module. Within the ISP_DPC_TAIL_PIXEN_PULSE_TL clock cycles, only the first ISP_DPC_TAIL_PIXEN_PULSE_TH cycles are valid. Be cautious to configure this field, to prevent data processing from being deferred to the next frame.

This function is enabled only when both ISP_DPC_TAIL_PIXEN_PULSE_TL and ISP_DPC_TAIL_PIXEN_PULSE_TH are non-zero, and ISP_DPC_TAIL_PIXEN_PULSE_TH < ISP_DPC_TAIL_PIXEN_PULSE_TL. (R/W)

ISP_DPC_TAIL_PIXEN_PULSE_TH Configures the valid data cycle of the tail-row data rate during pixel-to-matrix conversion in the DPC module, which must be less than ISP_HADR_NUM − 1. (R/W)

ISP_DPC_PADDING_DATA Configures the padding data used for image edge expansion during pixel-to-matrix conversion in the DPC module. (R/W)



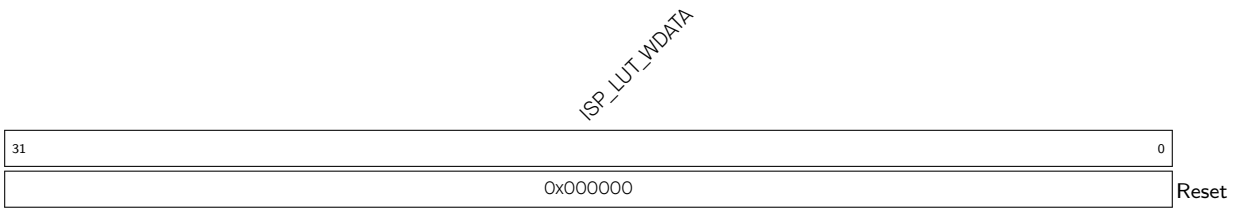
ISP_DPC_PADDING_MODE Configures the method of image edge expansion during pixel-to-matrix conversion in the DPC module.

0: Automatically padded with pixel values from the image edge

1: Padded with the data in ISP_DPC_PADDING_DATA

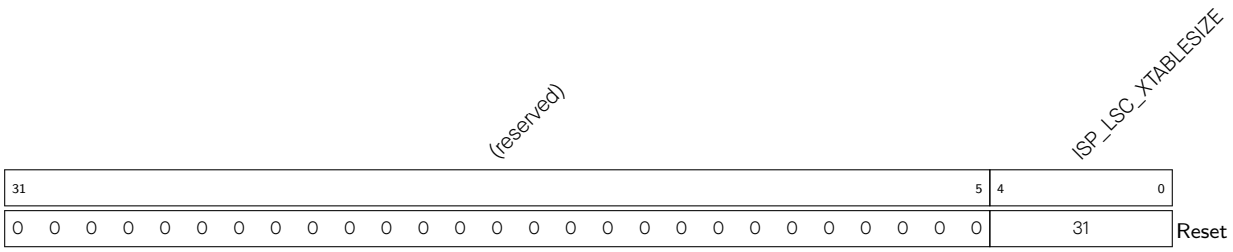
(R/W)

Register 38.18. ISP_LUT_CMD_REG (0x0048)



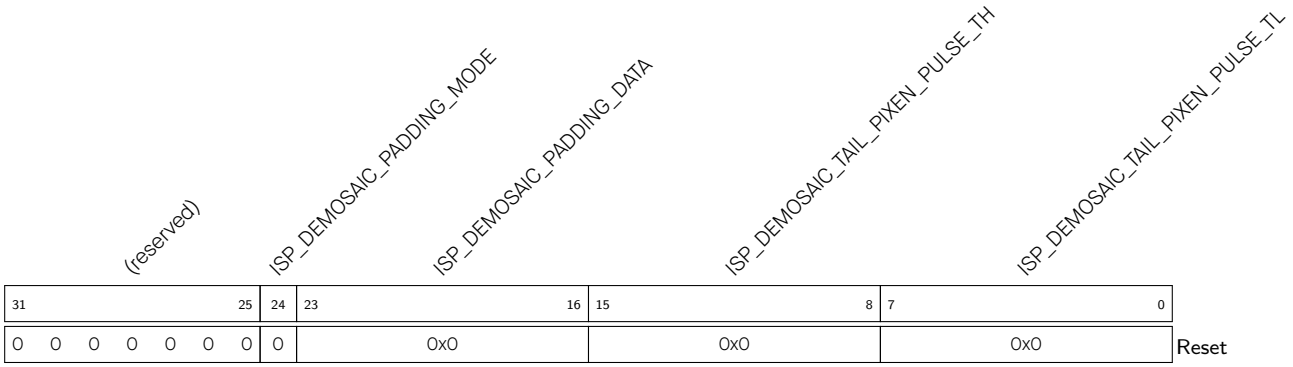
ISP_LUT_ADDR Configures the LUT address. When ISP_LUT_NUM selects LSC LUT, [11:10] being 0 indicates selecting Gb_B LUT, and being 1 indicates selecting R_Gr LUT. Bits [9:0] represent the actual LUT address.
(WT)

ISP_LUT_NUM Configures the LUT selection.
0: Select LSC LUT
Others: Invalid
(WT)



ISP_LUT_CMD Configures whether to read from or write to the LUT.
0: Read from the LUT
1: Write to the LUT
(WT)

Register 38.19. ISP_LUT_WDATA_REG (0x004C)



ISP_LUT_WDATA Data to be written to the LUT, which must be configured before writing to ISP_LUT_CMD_REG. (R/W)

Register 38.20. ISP_LSC_TABLESIZE_REG (0x0054)

ISP_LSC_XTABLESIZE Configures the number of horizontal grids in the LSC module. This value is obtained by $fix((line_number - 1)/2/32) + 2$, where $fix()$ denotes the rounding. (R/W)

Register 38.21. ISP_DEMOSAIC_MATRIX_CTRL_REG (0x0058)

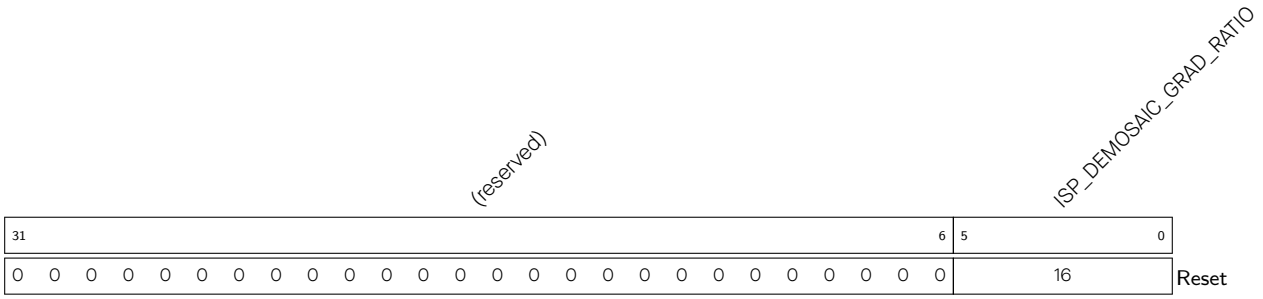
ISP_DEMOSAIC_TAIL_PIXEN_PULSE_TL Configures the data control cycle for the tail-row data rate during pixel-to-matrix conversion in the demosaic module.

Within ISP_DEMOSAIC_TAIL_PIXEN_PULSE_TL clock cycles, only the first ISP_DEMOSAIC_TAIL_PIXEN_PULSE_TH cycles are valid. Be cautious to configure this field, to prevent data processing from being deferred to the next frame.

This feature is enabled only when both ISP_DEMOSAIC_TAIL_PIXEN_PULSE_TL and ISP_DEMOSAIC_TAIL_PIXEN_PULSE_TH are non-zero, and ISP_DEMOSAIC_TAIL_PIXEN_PULSE_TH < ISP_DEMOSAIC_TAIL_PIXEN_PULSE_TL. (R/W)

ISP_DEMOSAIC_TAIL_PIXEN_PULSE_TH Configures the valid data cycle of the tail-row data rate during pixel-to-matrix conversion in the demosaic module, which must be less than ISP_HADR_NUM - 1. (R/W)

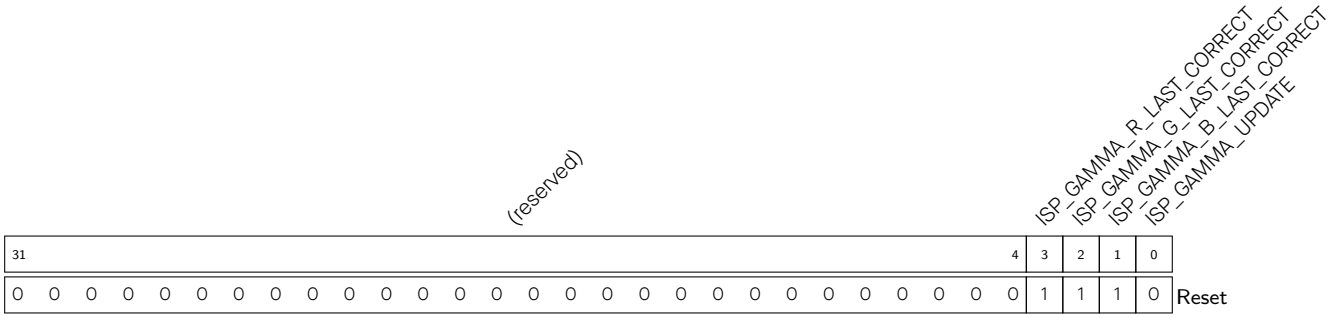
ISP_DEMOSAIC_PADDING_DATA Configures the padding data used during image edge expansion in pixel-to-matrix conversion of the demosaic module. (R/W)



ISP_DEMOSAIC_PADDING_MODE Configures the method of image edge expansion during pixel-to-matrix conversion in the demosaic module.

0: Automatically padded with pixel values from the image edge

1: Padded with the data in ISP_DEMOSAIC_PADDING_DATA

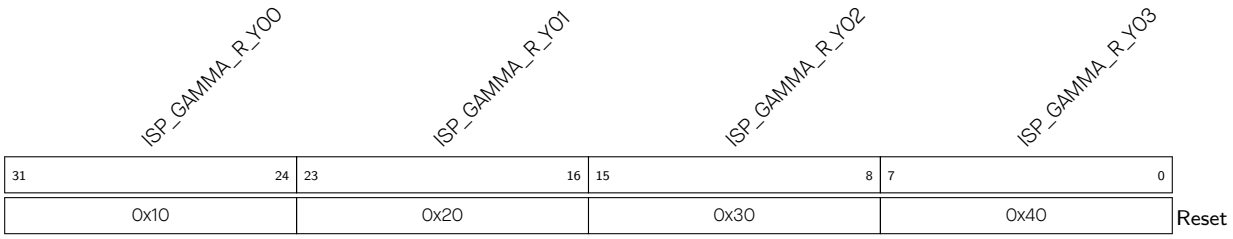


(R/W)

Register 38.22. ISP_DEMOSAIC_GRAD_RATIO_REG (0x005C)

ISP_DEMOSAIC_GRAD_RATIO Configures the demosaic effect, with bits [5:4] as the integer part and bits [3:0] as the fractional part. (R/W)

Register 38.23. ISP_GAMMA_CTRL_REG (0x0074)



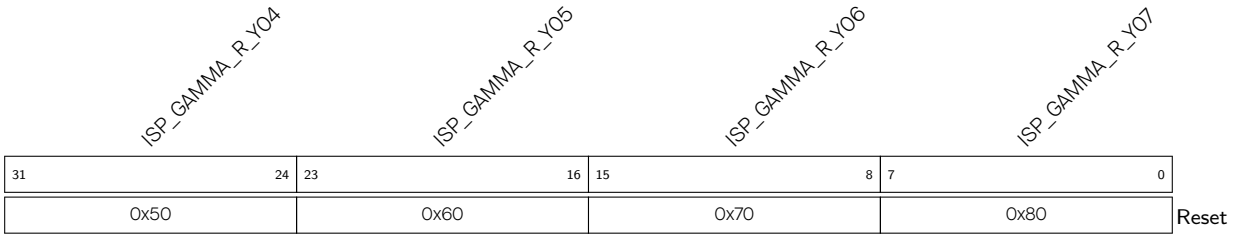
ISP_GAMMA_UPDATE Configures whether to update the gamma curve parameters. Writing 1 to this field updates the gamma curve parameters. It will be automatically cleared to 0 after the update is complete. (R/W)

ISP_GAMMA_B_LAST_CORRECT Configures whether to enable correction for the parameters of the last interval on the X axis of B channel gamma curve.
0: Not enable
1: Enable
(R/W)

ISP_GAMMA_G_LAST_CORRECT Configures whether to enable correction for the parameters of the last interval on the X axis of G channel gamma curve.
0: Not enable
1: Enable
(R/W)

ISP_GAMMA_R_LAST_CORRECT Configures whether to enable correction for the parameters of the last interval on the X axis of X channel gamma curve.
0: Not enable
1: Enable
(R/W)

Register 38.24. ISP_GAMMA_RY1_REG (0x0078)



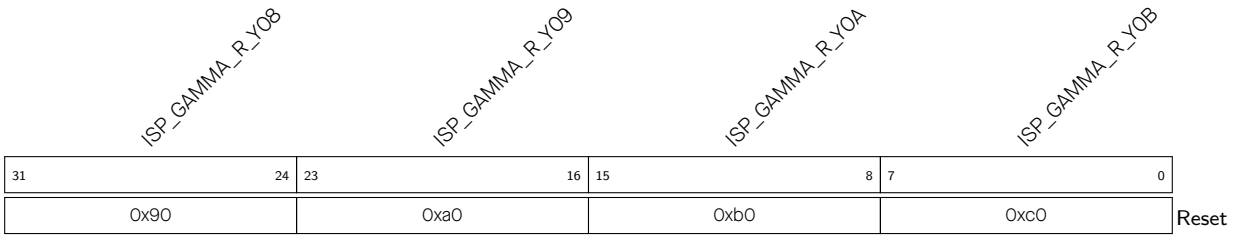
ISP_GAMMA_R_Y03 Configures the value of the 3rd point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y02 Configures the value of the 2nd point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y01 Configures the value of the 1st point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y00 Configures the value of the 0th point on the Y axis of R channel gamma curve. (R/W)

Register 38.25. ISP_GAMMA_RY2_REG (0x007C)



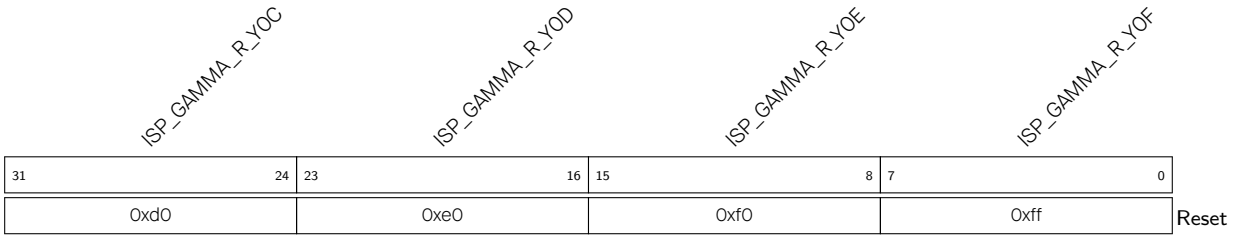
ISP_GAMMA_R_Y07 Configures the value of the 7th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y06 Configures the value of the 6th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y05 Configures the value of the 5th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y04 Configures the value of the 4th point on the Y axis of R channel gamma curve. (R/W)

Register 38.26. ISP_GAMMA_RY3_REG (0x0080)



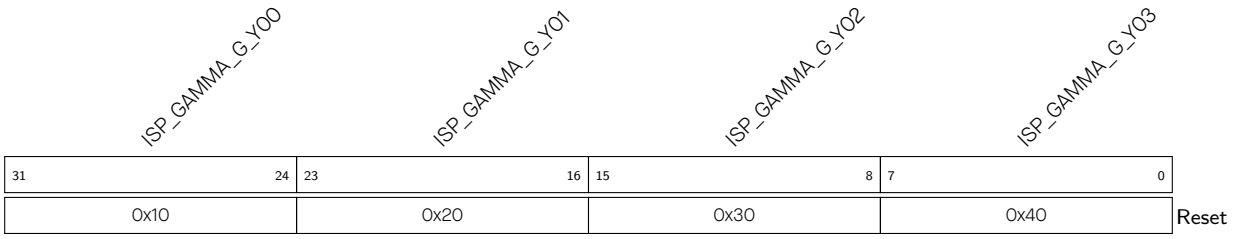
ISP_GAMMA_R_Y0B Configures the value of the 11th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y0A Configures the value of the 10th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y09 Configures the value of the 9th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y08 Configures the value of the 8th point on the Y axis of R channel gamma curve. (R/W)

Register 38.27. ISP_GAMMA_RY4_REG (0x0084)



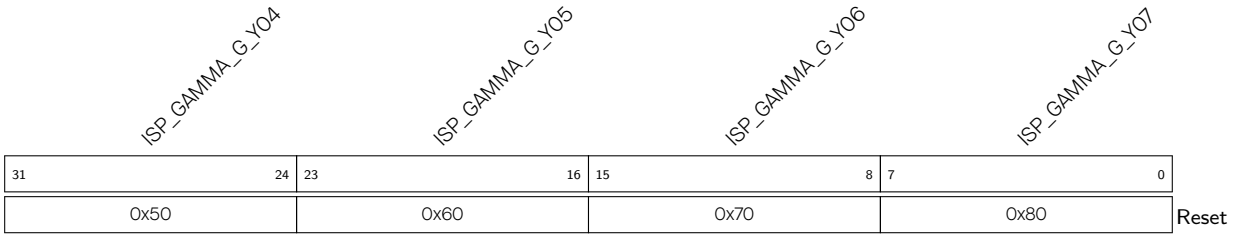
ISP_GAMMA_R_Y0F Configures the value of the 15th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y0E Configures the value of the 14th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y0D Configures the value of the 13th point on the Y axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_Y0C Configures the value of the 12th point on the Y axis of R channel gamma curve. (R/W)

Register 38.28. ISP_GAMMA_GY1_REG (0x0088)



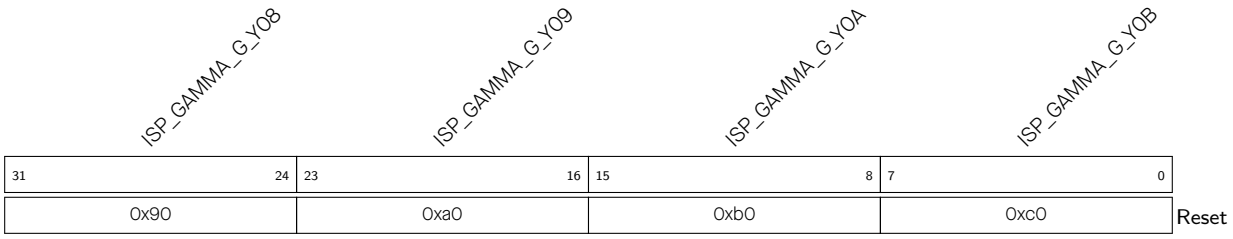
ISP_GAMMA_G_Y03 Configures the value of the 3rd point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y02 Configures the value of the 2nd point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y01 Configures the value of the 1st point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y00 Configures the value of the 0th point on the Y axis of G channel gamma curve. (R/W)

Register 38.29. ISP_GAMMA_GY2_REG (0x008C)



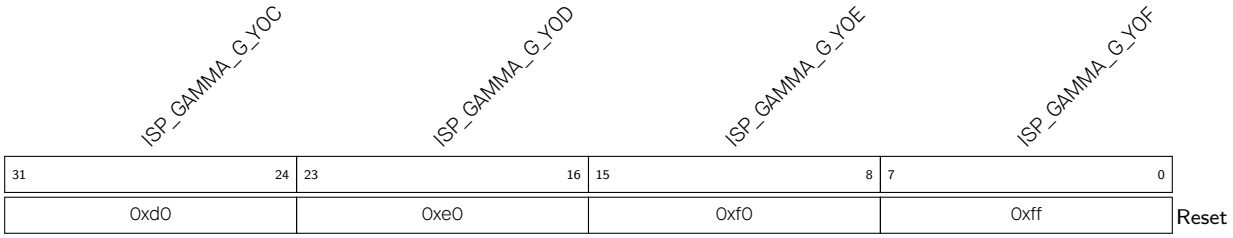
ISP_GAMMA_G_Y07 Configures the value of the 7th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y06 Configures the value of the 6th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y05 Configures the value of the 5th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y04 Configures the value of the 4th point on the Y axis of G channel gamma curve. (R/W)

Register 38.30. ISP_GAMMA_GY3_REG (0x0090)



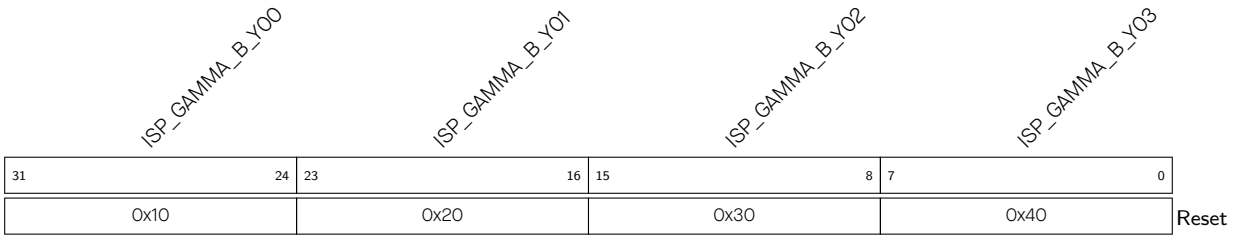
ISP_GAMMA_G_Y0B Configures the value of the 11th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y0A Configures the value of the 10th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y09 Configures the value of the 9th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y08 Configures the value of the 8th point on the Y axis of G channel gamma curve. (R/W)

Register 38.31. ISP_GAMMA_GY4_REG (0x0094)



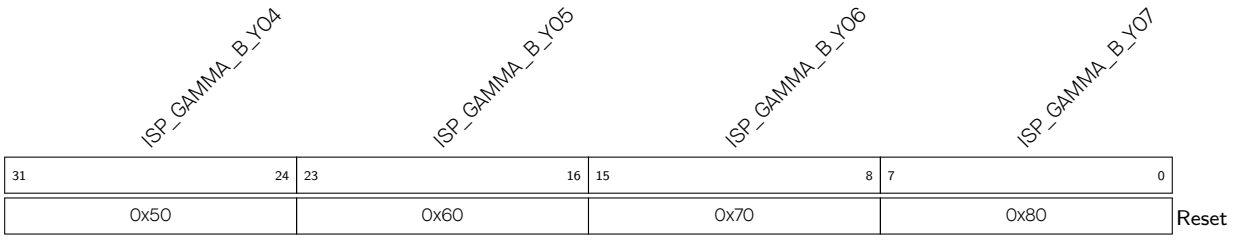
ISP_GAMMA_G_Y0F Configures the value of the 15th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y0E Configures the value of the 14th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y0D Configures the value of the 13th point on the Y axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_Y0C Configures the value of the 12th point on the Y axis of G channel gamma curve. (R/W)

Register 38.32. ISP_GAMMA_BY1_REG (0x0098)



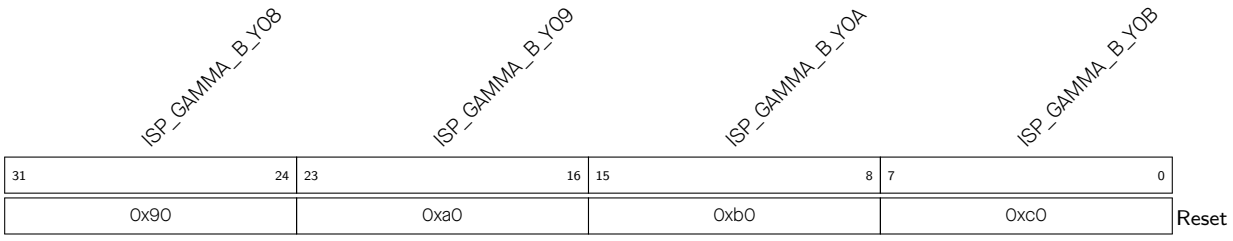
ISP_GAMMA_B_Y03 Configures the value of the 3rd point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y02 Configures the value of the 2nd point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y01 Configures the value of the 1st point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y00 Configures the value of the 0th point on the Y axis of B channel gamma curve. (R/W)

Register 38.33. ISP_GAMMA_BY2_REG (0x009C)



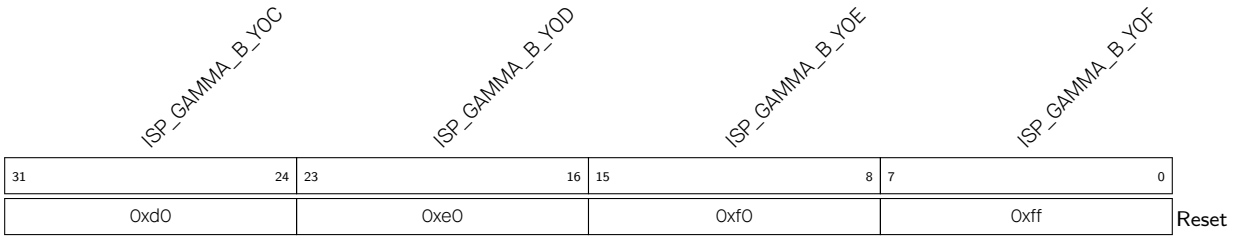
ISP_GAMMA_B_Y07 Configures the value of the 7th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y06 Configures the value of the 6th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y05 Configures the value of the 5th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y04 Configures the value of the 4th point on the Y axis of B channel gamma curve. (R/W)

Register 38.34. ISP_GAMMA_BY3_REG (0x00A0)



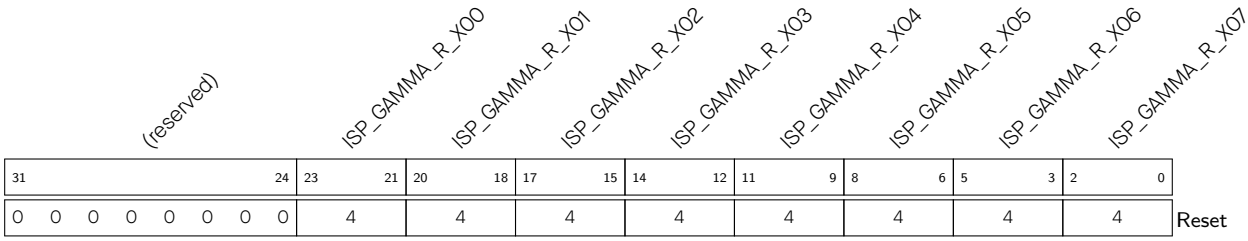
ISP_GAMMA_B_Y0B Configures the value of the 11th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y0A Configures the value of the 10th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y09 Configures the value of the 9th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y08 Configures the value of the 8th point on the Y axis of B channel gamma curve. (R/W)

Register 38.35. ISP_GAMMA_BY4_REG (0x00A4)



ISP_GAMMA_B_Y0F Configures the value of the 15th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y0E Configures the value of the 14th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y0D Configures the value of the 13th point on the Y axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_Y0C Configures the value of the 12th point on the Y axis of B channel gamma curve. (R/W)

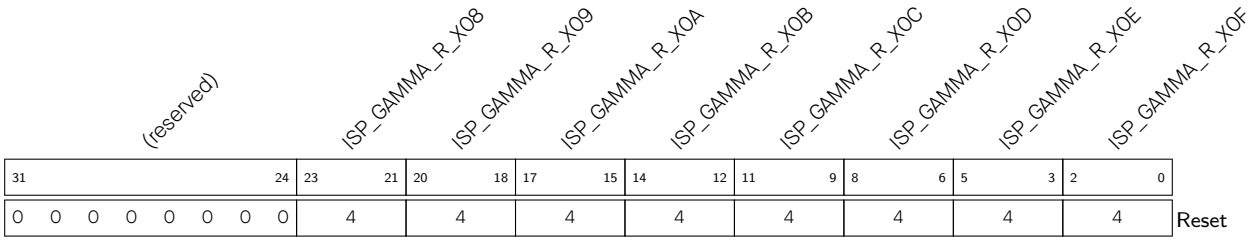
Register 38.36. ISP_GAMMA_RX1_REG (0x00A8)

ISP_GAMMA_R_X07 Configures the width of the 7th interval on the X axis of R channel gamma curve. Refer to section 38.5.2.8 for configuration. (R/W)

ISP_GAMMA_R_X06 Configures the width of the 6th interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X05 Configures the width of the 5th interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X04 Configures the width of the 4th interval on the X axis of R channel gamma curve. (R/W)



ISP_GAMMA_R_X03 Configures the width of the 3rd interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X02 Configures the width of the 2nd interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X01 Configures the width of the 1st interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X00 Configures the width of the 0th interval on the X axis of R channel gamma curve. (R/W)

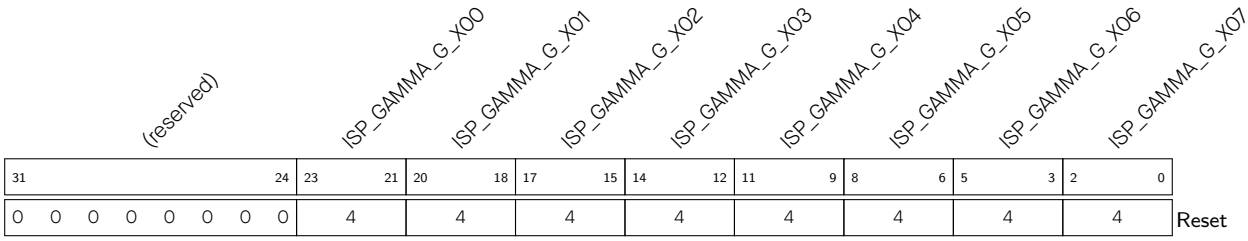
Register 38.37. ISP_GAMMA_RX2_REG (0x00AC)

ISP_GAMMA_R_X0F Configures the width of the 15th interval on the X axis of R channel gamma curve. Refer to section 38.5.2.8 for configuration. (R/W)

ISP_GAMMA_R_X0E Configures the width of the 14th interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X0D Configures the width of the 13th interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X0C Configures the width of the 12th interval on the X axis of R channel gamma curve. (R/W)



ISP_GAMMA_R_X0B Configures the width of the 11th interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X0A Configures the width of the 10th interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X09 Configures the width of the 9th interval on the X axis of R channel gamma curve. (R/W)

ISP_GAMMA_R_X08 Configures the width of the 8th interval on the X axis of R channel gamma curve. (R/W)

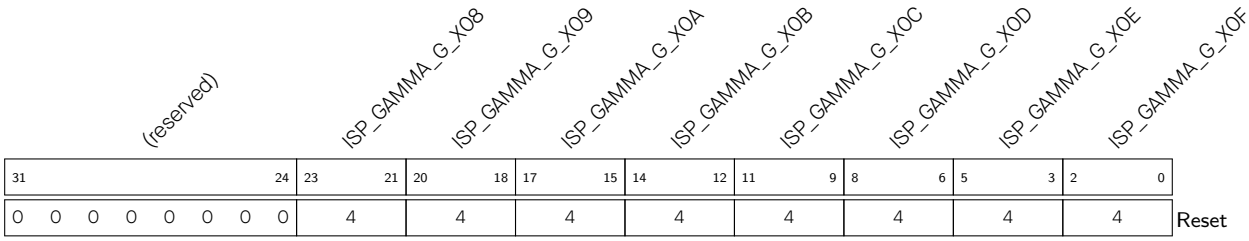
Register 38.38. ISP_GAMMA_GX1_REG (0x00B0)

ISP_GAMMA_G_X07 Configures the width of the 7th interval on the X axis of G channel gamma curve. Refer to section 38.5.2.8 for configuration. (R/W)

ISP_GAMMA_G_X06 Configures the width of the 6th interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X05 Configures the width of the 5th interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X04 Configures the width of the 4th interval on the X axis of G channel gamma curve. (R/W)



ISP_GAMMA_G_X03 Configures the width of the 3rd interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X02 Configures the width of the 2nd interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X01 Configures the width of the 1st interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X00 Configures the width of the 0th interval on the X axis of G channel gamma curve. (R/W)

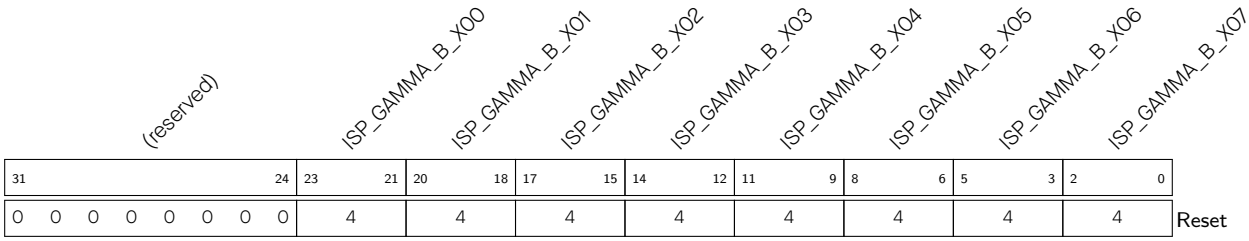
Register 38.39. ISP_GAMMA_GX2_REG (0x00B4)

ISP_GAMMA_G_X0F Configures the width of the 15th interval on the X axis of G channel gamma curve. Refer to section 38.5.2.8 for configuration. (R/W)

ISP_GAMMA_G_X0E Configures the width of the 14th interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X0D Configures the width of the 13th interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X0C Configures the width of the 12th interval on the X axis of G channel gamma curve. (R/W)



ISP_GAMMA_G_X0B Configures the width of the 11th interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X0A Configures the width of the 10th interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X09 Configures the width of the 9th interval on the X axis of G channel gamma curve. (R/W)

ISP_GAMMA_G_X08 Configures the width of the 8th interval on the X axis of G channel gamma curve. (R/W)

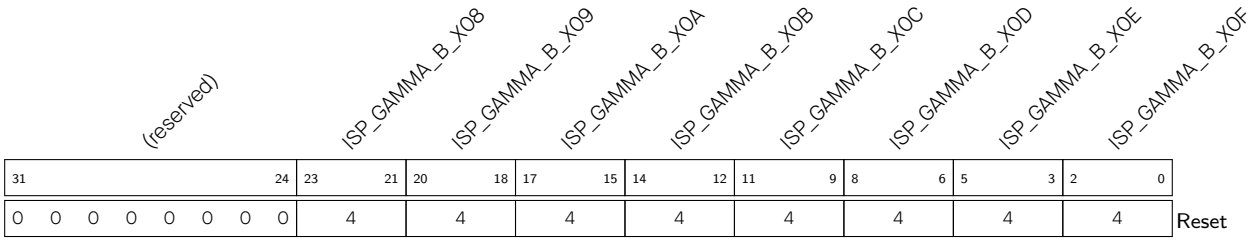
Register 38.40. ISP_GAMMA_BX1_REG (0x00B8)

ISP_GAMMA_B_X07 Configures the width of the 7th interval on the X axis of B channel gamma curve. Refer to section 38.5.2.8 for configuration. (R/W)

ISP_GAMMA_B_X06 Configures the width of the 6th interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X05 Configures the width of the 5th interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X04 Configures the width of the 4th interval on the X axis of B channel gamma curve. (R/W)



ISP_GAMMA_B_X03 Configures the width of the 3rd interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X02 Configures the width of the 2nd interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X01 Configures the width of the 1st interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X00 Configures the width of the 0th interval on the X axis of B channel gamma curve. (R/W)

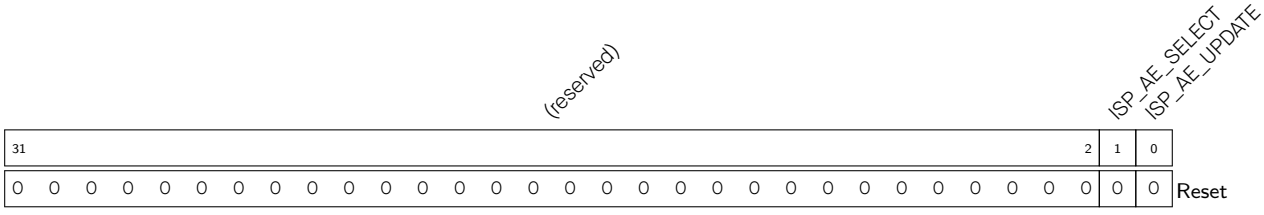
Register 38.41. ISP_GAMMA_BX2_REG (0x00BC)

ISP_GAMMA_B_X0F Configures the width of the 15th interval on the X axis of B channel gamma curve. Refer to section 38.5.2.8 for configuration. (R/W)

ISP_GAMMA_B_X0E Configures the width of the 14th interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X0D Configures the width of the 13th interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X0C Configures the width of the 12th interval on the X axis of B channel gamma curve. (R/W)



ISP_GAMMA_B_X0B Configures the width of the 11th interval on the X axis of B channel gamma curve. (R/W)

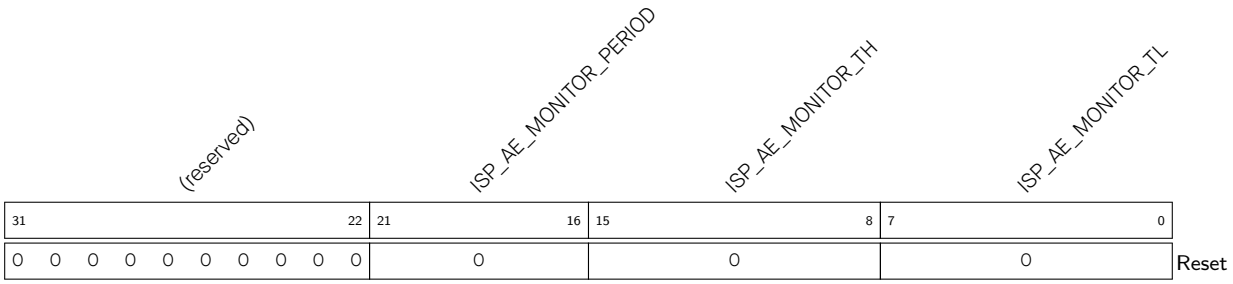
ISP_GAMMA_B_X0A Configures the width of the 10th interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X09 Configures the width of the 9th interval on the X axis of B channel gamma curve. (R/W)

ISP_GAMMA_B_X08 Configures the width of the 8th interval on the X axis of B channel gamma curve. (R/W)

Register 38.42. ISP_AE_CTRL_REG (0x00C0)

ISP_AE_UPDATE Configures AE statistics sampling. With AE enabled, writing 1 triggers a statistics collection. (WT)



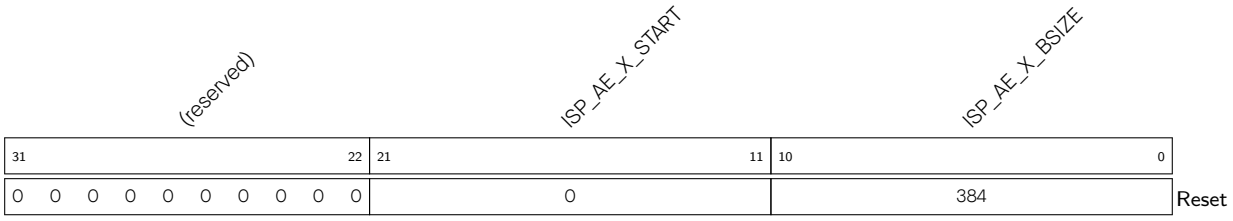
ISP_AE_SELECT Configures the AE sampling point.

0: Use data output from the demosaic module

1: Use data output from the gamma correction module

(R/W)

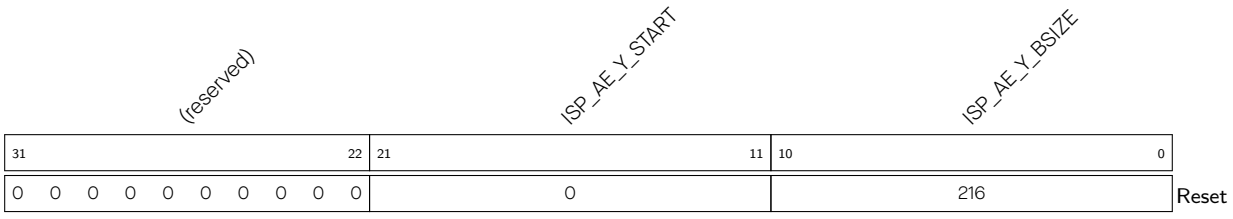
Register 38.43. ISP_AE_MONITOR_REG (0x00C4)



ISP_AE_MONITOR_TL Configures the lower threshold for AE luminance monitoring. (R/W)

ISP_AE_MONITOR_TH Configures the upper threshold for AE luminance monitoring. (R/W)

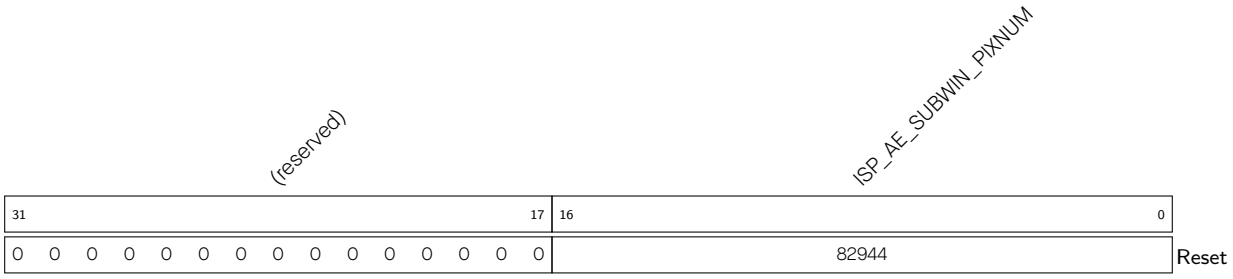
ISP_AE_MONITOR_PERIOD Configures the frame interval for AE monitoring. (R/W)



Register 38.44. ISP_AE_BX_REG (0x00C8)

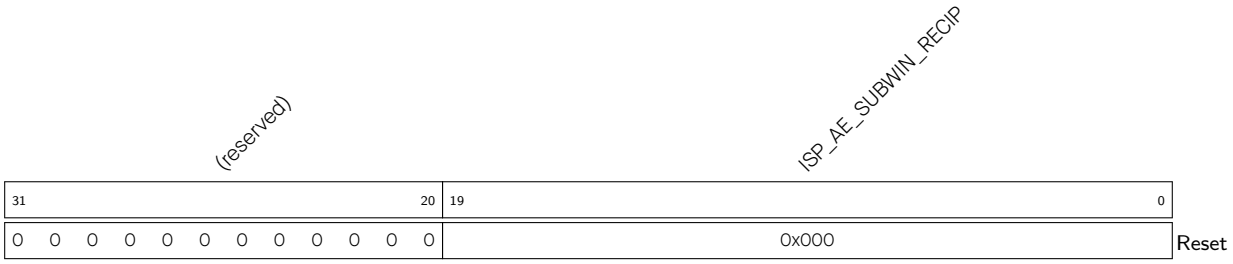
ISP_AE_X_BSIZE Configures the horizontal size of each sub-window. (R/W)

ISP_AE_X_START Configures the start coordinate of the AE statistical window in the horizontal direction. (R/W)



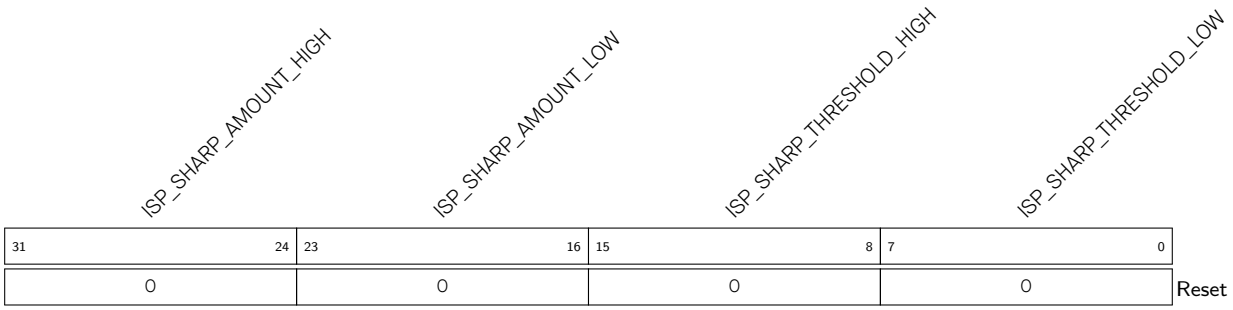
Register 38.45. ISP_AE_BY_REG (0x00CC)

ISP_AE_Y_BSIZE Configures the vertical dimension of each sub-window. (R/W)



ISP_AE_Y_START Configures the start coordinate of the AE statistical window in the vertical direction. (R/W)

Register 38.46. ISP_AE_WINPIXNUM_REG (0x00D0)

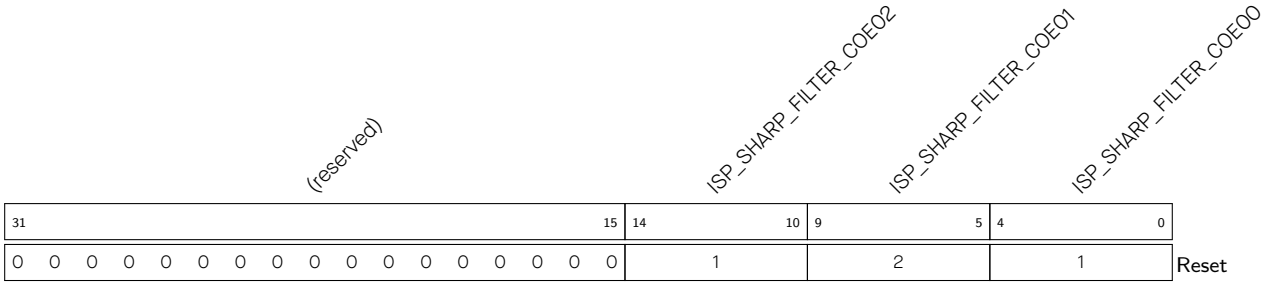


ISP_AE_SUBWIN_PIXNUM Configures the number of pixels in each sub-window. (R/W)

Register 38.47. ISP_AE_WIN_RECIPROCAL_REG (0x00D4)

ISP_AE_SUBWIN_RECIP Configures the reciprocal of the number of pixels in each sub-window. It is a 20-bit fractional number, with [19:0] representing the fractional part. (R/W)

Register 38.48. ISP_SHARP_CTRL0_REG (0x00F4)



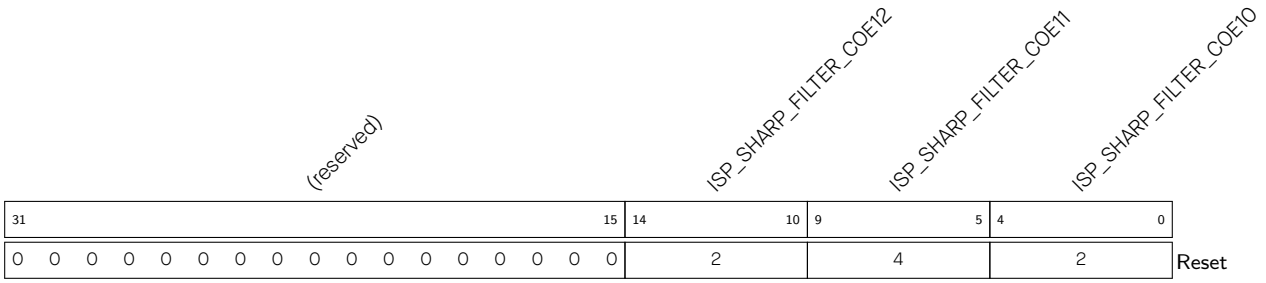
ISP_SHARP_THRESHOLD_LOW Configures the threshold for sharpening high-frequency details. Refer to section 38.5.2.10 for configuration. (R/W)

ISP_SHARP_THRESHOLD_HIGH Configures the threshold for sharpening high-frequency edges. Refer to section 38.5.2.10 for configuration. (R/W)

ISP_SHARP_AMOUNT_LOW Configures the gain for sharpening high-frequency details. Refer to section 38.5.2.10 for configuration. (R/W)

ISP_SHARP_AMOUNT_HIGH Configures the gain for sharpening high-frequency edges. Refer to section 38.5.2.10 for configuration. (R/W)

Register 38.49. ISP_SHARP_FILTER0_REG (0x00F8)

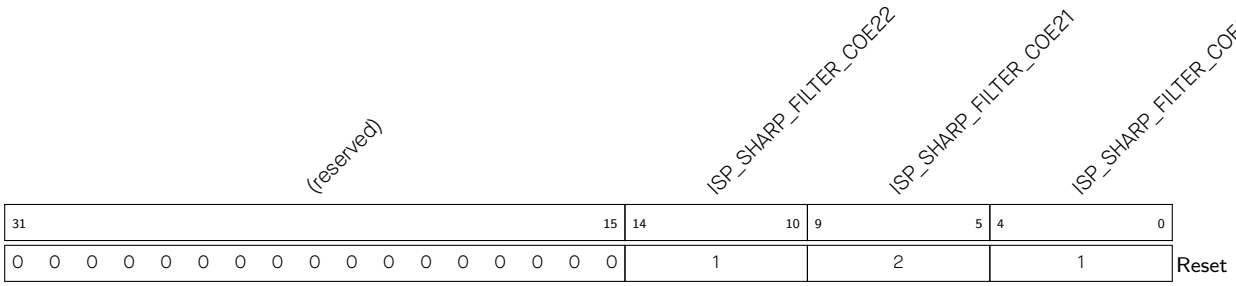


ISP_SHARP_FILTER_COE00 Configures the value of coordinate 00 in the low-pass filter template of the sharpen module. (R/W)

ISP_SHARP_FILTER_COE01 Configures the value of coordinate 01 in the low-pass filter template of the sharpen module. (R/W)

ISP_SHARP_FILTER_COE02 Configures the value of coordinate 02 in the low-pass filter template of the sharpen module. (R/W)

Register 38.50. ISP_SHARP_FILTER1_REG (0x00FC)

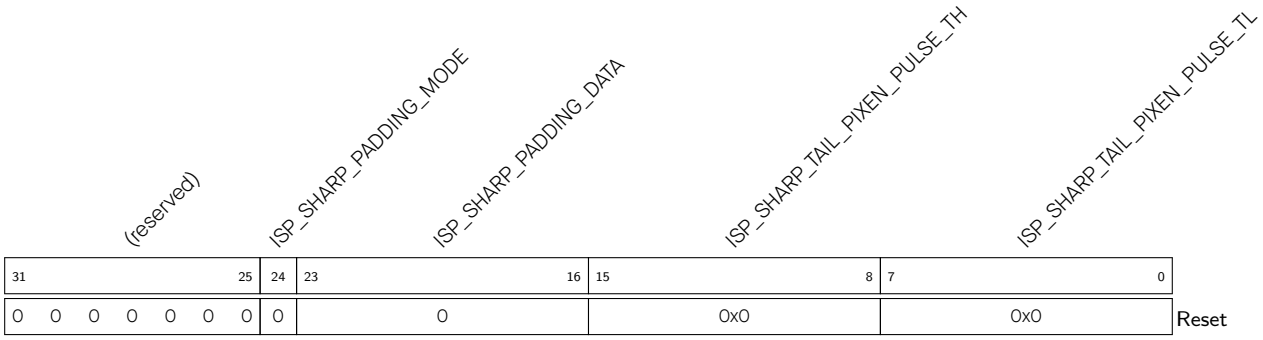


ISP_SHARP_FILTER_COE10 Configures the value of coordinate 10 in the low-pass filter template of the sharpen module. (R/W)

ISP_SHARP_FILTER_COE11 Configures the value of coordinate 11 in the low-pass filter template of the sharpen module. (R/W)

ISP_SHARP_FILTER_COE12 Configures the value of coordinate 12 in the low-pass filter template of the sharpen module. (R/W)

Register 38.51. ISP_SHARP_FILTER2_REG (0x0100)



ISP_SHARP_FILTER_COE20 Configures the value of coordinate 20 in the low-pass filter template of the sharpen module. (R/W)

ISP_SHARP_FILTER_COE21 Configures the value of coordinate 21 in the low-pass filter template of the sharpen module. (R/W)

ISP_SHARP_FILTER_COE22 Configures the value of coordinate 22 in the low-pass filter template of the sharpen module. (R/W)

Register 38.52. ISP_SHARP_MATRIX_CTRL_REG (0x0104)

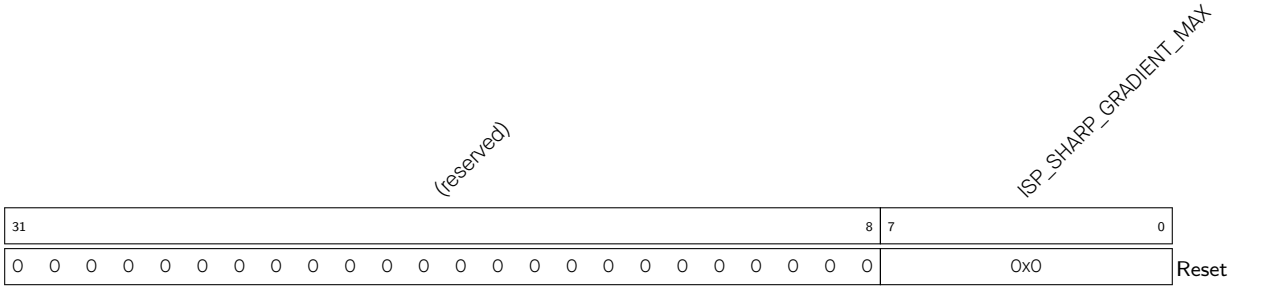
ISP_SHARP_TAIL_PIXEN_PULSE_TL Configures the data control cycle for the tail-row data rate during pixel-to-matrix conversion in the sharpen module.

Within ISP_SHARP_TAIL_PIXEN_PULSE_TL clock cycles, only the first ISP_SHARP_TAIL_PIXEN_PULSE_TH cycles are valid. Be cautious to configure this field, to prevent data processing from being deferred to the next frame.

This feature is enabled only when both ISP_SHARP_TAIL_PIXEN_PULSE_TL and ISP_SHARP_TAIL_PIXEN_PULSE_TH are non-zero, and ISP_SHARP_TAIL_PIXEN_PULSE_TH < ISP_SHARP_TAIL_PIXEN_PULSE_TL. (R/W)

ISP_SHARP_TAIL_PIXEN_PULSE_TH Configures the valid data cycle of the tail-row data rate during pixel-to-matrix conversion in the sharpen module, which must be less than ISP_HADR_NUM - 1. (R/W)

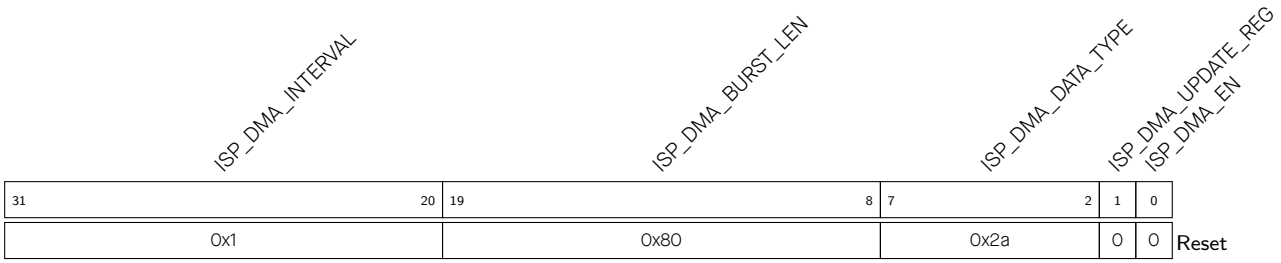
ISP_SHARP_PADDING_DATA Configures the padding data used during image edge expansion in pixel-to-matrix conversion of the sharpen module. (R/W)



ISP_SHARP_PADDING_MODE Configures the method of image edge expansion during pixel-to-matrix conversion in the sharpen module.

0: Automatically padded with pixel values from the image edge

1: Padded with the data in ISP_SHARP_PADDING_DATA



(R/W)

Register 38.53. ISP_SHARP_CTRL1_REG (0x0108)

ISP_SHARP_GRADIENT_MAX Represents the maximum pixel value of high-frequency components in the sharpen module, automatically refreshed every frame. (RO)

Register 38.54. ISP_DMA_CNTL_REG (0x010C)

ISP_DMA_EN Configures whether to trigger VDMA transfer of one frame of data.

0: Not trigger

1: Trigger

(WT)

ISP_DMA_UPDATE_REG Configures whether to update the configuration for ISP_DMA_DATA_TYPE, ISP_DMA_BURST_LEN, and ISP_DMA_INTERVAL.

0: Not update

1: Update, will be automatically cleared to 0 after the update is complete

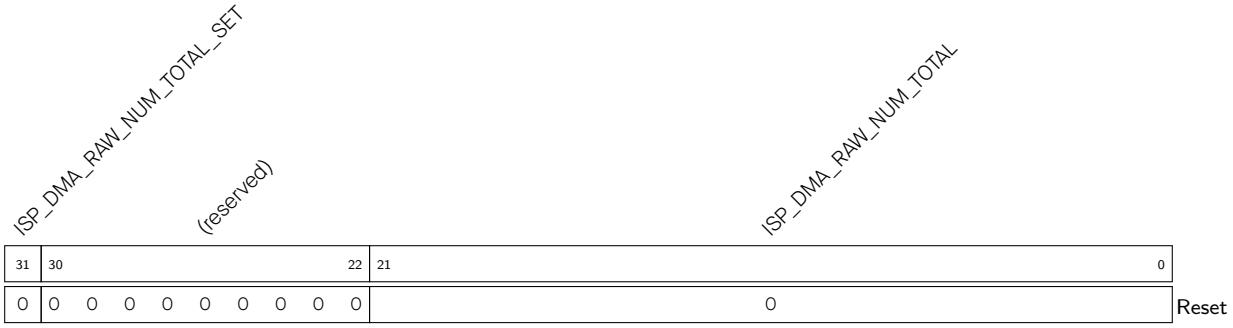
(R/W)

ISP_DMA_DATA_TYPE Configures the Image Interface data_type for the transferred data.

0x2A: RAW8

0x2B: RAW10

0x2C: RAW12



Others: Invalid

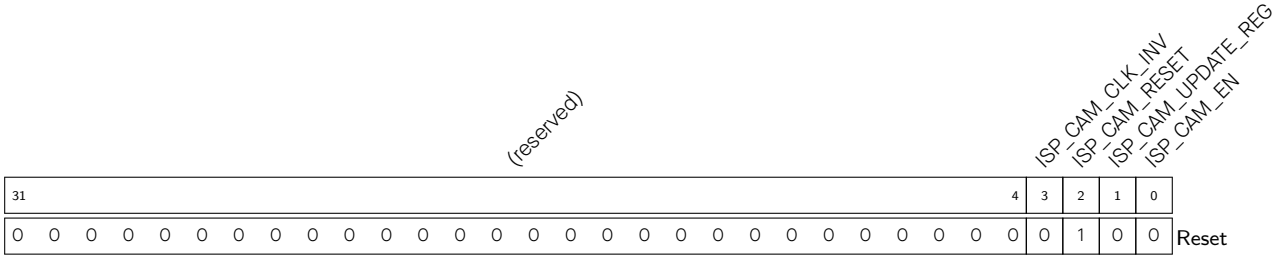
(R/W)

ISP_DMA_BURST_LEN Configures the burst length for one VDMA transfer, which needs to align with the VDMA configuration. (R/W)

ISP_DMA_INTERVAL Configures the interval of VDMA requests. 12'b1: 1 clock cycle, 12'b11: 2 clock cycles, etc. (R/W)

Register 38.55. ISP_DMA_RAW_DATA_REG (0x0110)

ISP_DMA_RAW_NUM_TOTAL Configures the amount of 64-bit data in a frame of image. (R/W)



ISP_DMA_RAW_NUM_TOTAL_SET Configures whether to update the configuration for ISP_DMA_RAW_NUM_TOTAL.

0: Not update

1: Update

(WT)

Register 38.56. ISP_CAM_CNTL_REG (0x0114)

ISP_CAM_EN Configures whether to enable the input via the DVP interface.

0: Disable

1: Enable

(R/W)

ISP_CAM_UPDATE_REG Configures whether to update the configuration for ISP_CAM_CONF_REG.

0: Not update

1: Update

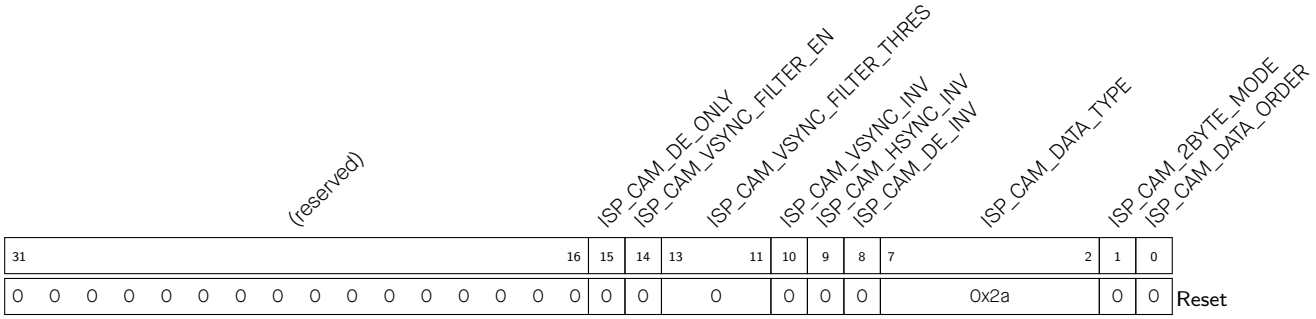
(R/W)

ISP_CAM_RESET Configures whether to reset the DVP input configuration.

0: Not reset

1: Reset

(R/W)



ISP_CAM_CLK_INV Configures whether to invert the DVP clock.

0: Not invert

1: Invert

(R/W)

Register 38.57. ISP_CAM_CONF_REG (0x0118)

ISP_CAM_DATA_ORDER Configures the order of DVP input data.

0: cam_data_in

1: cam_data_in[7:0], cam_data_in[15:8]

(R/W)

ISP_CAM_2BYTE_MODE Configures whether to enable the 2-byte mode.

0: Disable

1: Enable

(R/W)

ISP_CAM_DATA_TYPE Configures the format of DVP input data.

0x2a: RAW8

0x2b: RAW10

0x2c: RAW12

(R/W)

ISP_CAM_DE_INV Configures whether to invert the DVP de signal.

0: Not invert

1: Invert

(R/W)

ISP_CAM_HSYNC_INV Configures whether to invert the DVP hsync signal.

0: Not invert

1: Invert

(R/W)

ISP_CAM_VSYNC_INV Configures whether to invert the DVP vsync signal.

0: Not invert

1: Invert

(R/W)

ISP_CAM_VSYNC_FILTER_THRES Configures vsync filtering. Vsyncs shorter than this length will be filtered out. (R/W)

Continued on the next page...

Register 38.57. ISP_CAM_CONF_REG (0x0118)

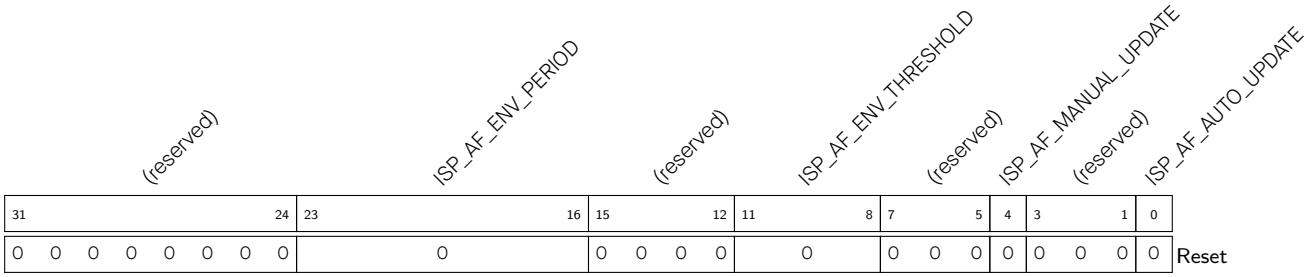
Continued from the previous page...

ISP_CAM_VSYNC_FILTER_EN Configures whether to enable the vsync filtering.

0: Disable

1: Enable

(R/W)



ISP_CAM_DE_ONLY Configures whether the DVP interface uses only DE data without HSYNC data.

0: HSYNC is present

1: HSYNC is not present

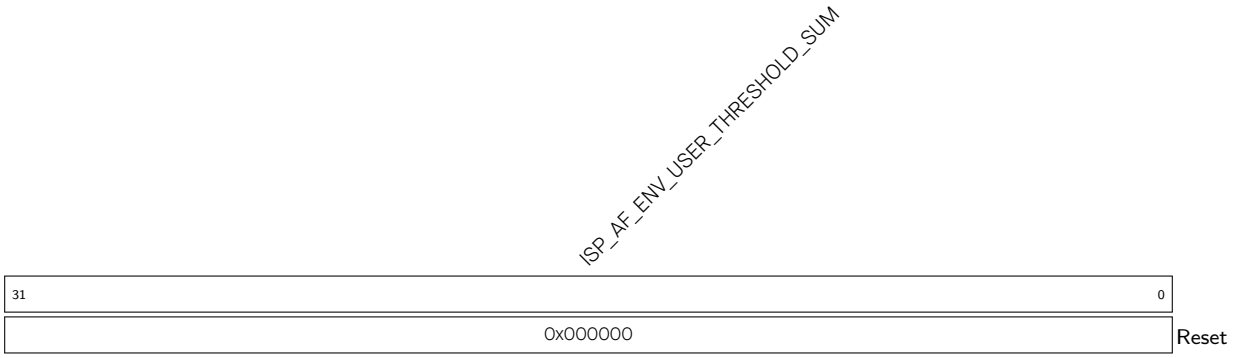
(R/W)

Register 38.58. ISP_AF_CTRL0_REG (0x011C)

ISP_AF_AUTO_UPDATE Configures whether to enable AF automatic statistics.

0: Disable automatic statistics, and manual trigger is required

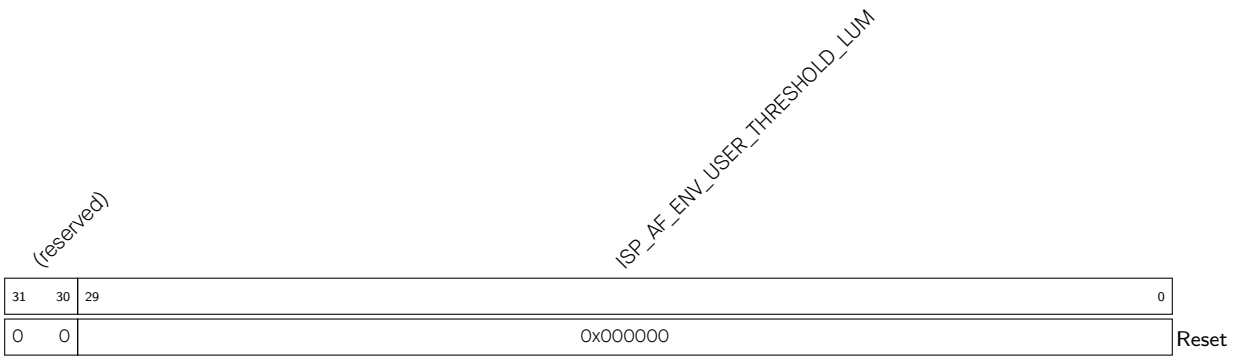
1: Enable automatic statistics, and AF will perform statistics for every frame with the AF module enabled



(R/W)

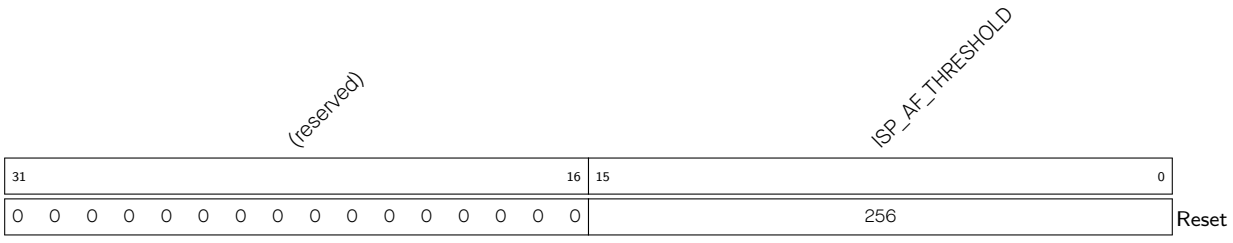
ISP_AF_MANUAL_UPDATE Configures AF manual statistics. With AF automatic statistics disabled, writing 1 triggers a statistics collection. (WT)

ISP_AF_ENV_THRESHOLD Configures the threshold for AF scene monitoring. If ISP_AF_ENV_USER_THRESHOLD_SUM or ISP_AF_ENV_USER_THRESHOLD_LUM is 0, an interrupt for scene monitoring will be triggered when the changes in sharpness or luminance exceed the product of the baseline value and this field for two consecutive times. 4 fractional bits. (R/W)



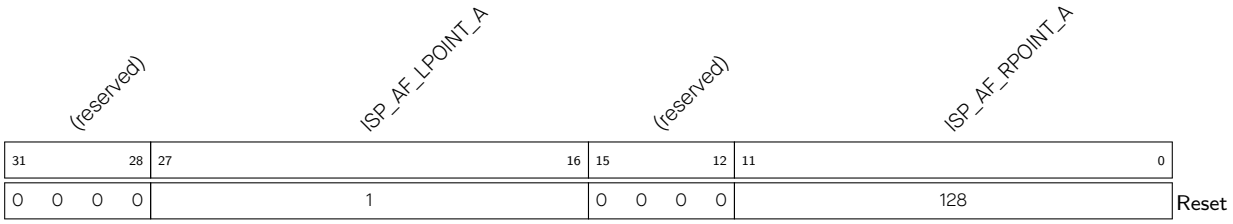
ISP_AF_ENV_PERIOD Configures the statistical interval frames for AF scene monitoring. Setting this filed to 0 disables the scene monitoring. (R/W)

Register 38.59. ISP_AF_ENV_USER_TH_SUM_REG (0x0128)



ISP_AF_ENV_USER_THRESHOLD_SUM Configures the threshold for sharpness change in AF scene monitoring. (R/W)

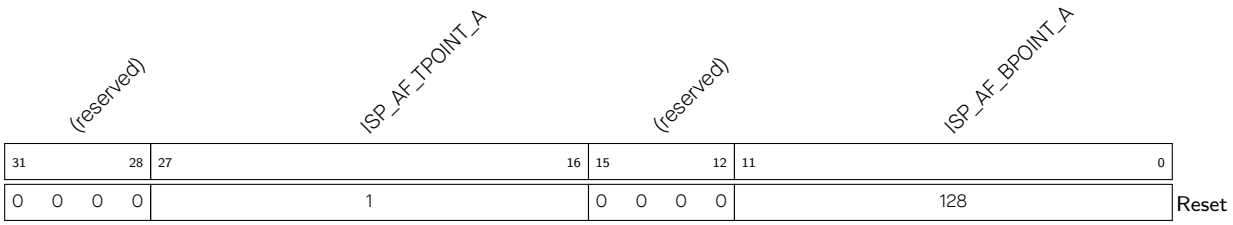
Register 38.60. ISP_AF_ENV_USER_TH_LUM_REG (0x012C)



ISP_AF_ENV_USER_THRESHOLD_LUM Configures the threshold for luminance change in AF scene monitoring. (R/W)

Register 38.61. ISP_AF_THRESHOLD_REG (0x0130)

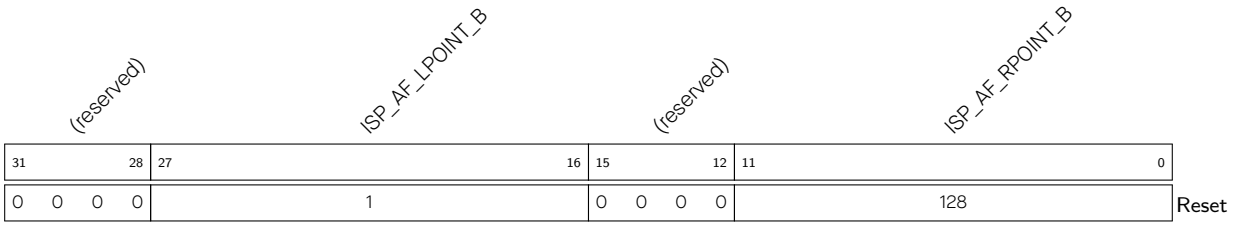
ISP_AF_THRESHOLD Configures the sharpness threshold for AF statistics. (R/W)



Register 38.62. ISP_AF_HSCALE_A_REG (0x0134)

ISP_AF_RPOINT_A Configures the right boundary coordinate of AF statistical window A, recommended to be less than HNUM-1. (R/W)

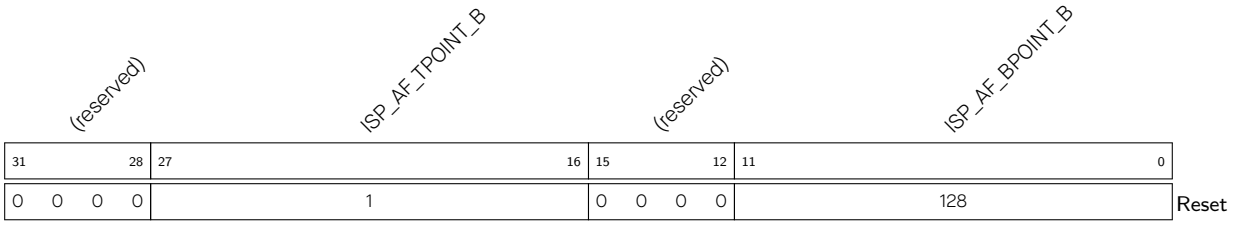
ISP_AF_LPOINT_A Configures the left boundary coordinate of AF statistical window A, recommended to be greater than or equal to 2. (R/W)



Register 38.63. ISP_AF_VSCALE_A_REG (0x0138)

ISP_AF_BPOINT_A Configures the bottom boundary coordinate of AF statistical window A, recommended to be less than HNUM-1. (R/W)

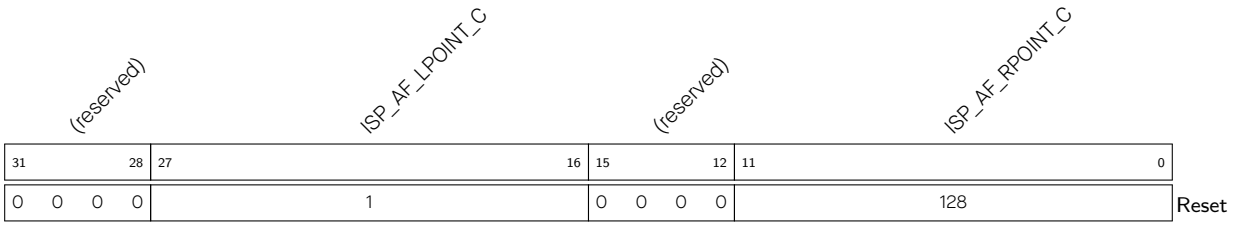
ISP_AF_TPOINT_A Configures the top boundary coordinate of AF statistical window A, recommended to be greater than or equal to 2. (R/W)



Register 38.64. ISP_AF_HSCALE_B_REG (0x013C)

ISP_AF_RPOINT_B Configures the right boundary coordinate of AF statistical window B, recommended to be less than HNUM-1. (R/W)

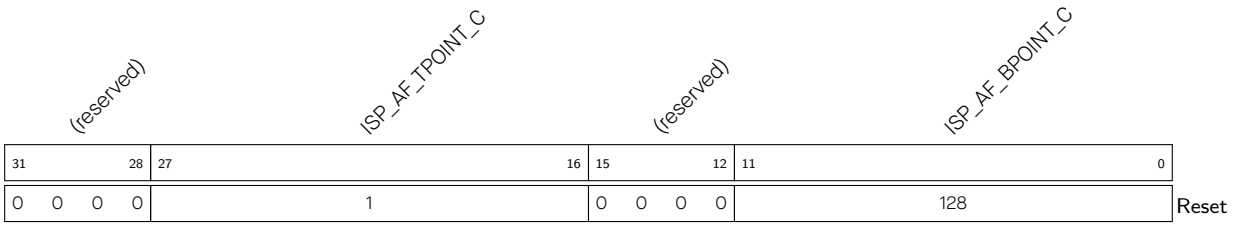
ISP_AF_LPOINT_B Configures the left boundary coordinate of AF statistical window B, recommended to be greater than or equal to 2. (R/W)



Register 38.65. ISP_AF_VSCALE_B_REG (0x0140)

ISP_AF_BPOINT_B Configures the bottom boundary coordinate of AF statistical window B, recommended to be less than HNUM-1. (R/W)

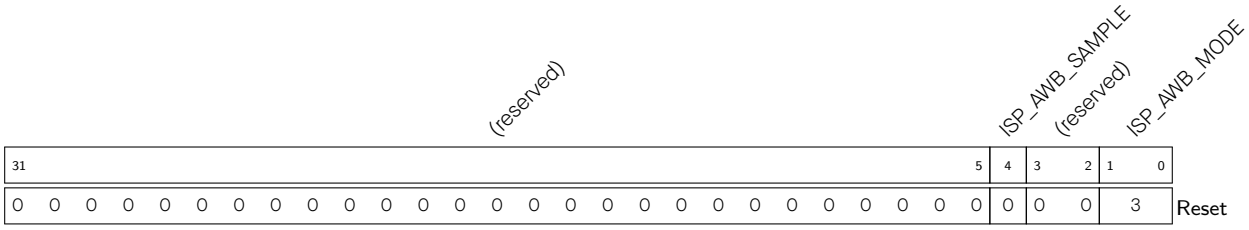
ISP_AF_TPOINT_B Configures the top boundary coordinate of AF statistical window B, recommended to be greater than or equal to 2. (R/W)



Register 38.66. ISP_AF_HSCALE_C_REG (0x0144)

ISP_AF_RPOINT_C Configures the right boundary coordinate of AF statistical window C, recommended to be less than HNUM-1. (R/W)

ISP_AF_LPOINT_C Configures the left boundary coordinate of AF statistical window C, recommended to be greater than or equal to 2. (R/W)



Register 38.67. ISP_AF_VSCALE_C_REG (0x0148)

ISP_AF_BPOINT_C Configures the bottom boundary coordinate of AF statistical window C, recommended to be less than HNUM-1. (R/W)

ISP_AF_TPOINT_C Configures the top boundary coordinate of AF statistical window C, recommended to be greater than or equal to 2. (R/W)

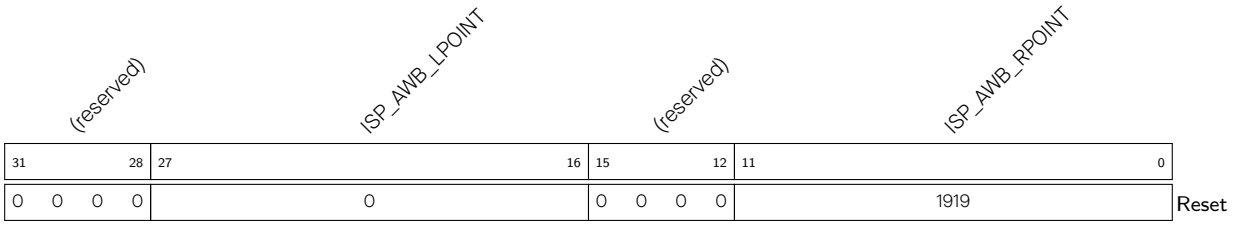
Register 38.68. ISP_AWB_MODE_REG (0x0164)

ISP_AWB_MODE Configures whether to enable the AWB algorithm.

1: Enable

Others: Invalid

(R/W)

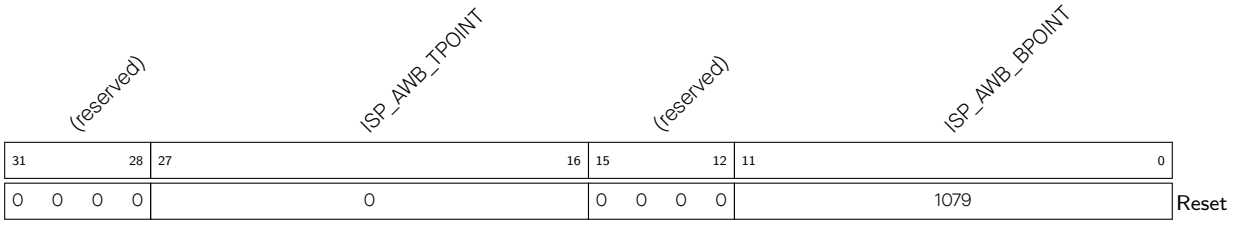


ISP_AWB_SAMPLE Configures the AWB sampling point.

0: Use data output before processed by CCM

1: Use data output after processed by CCM

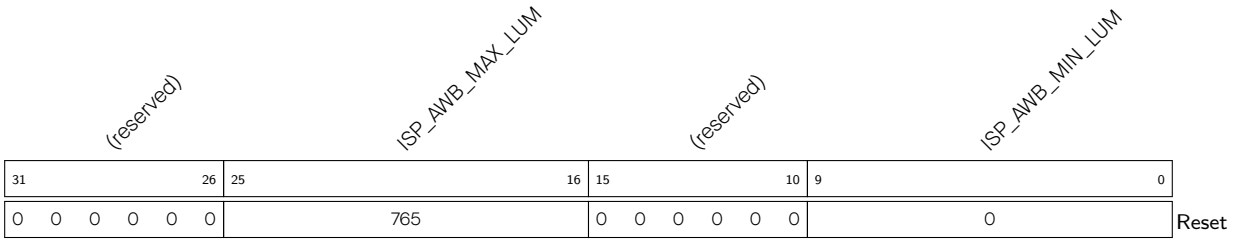
(R/W)



Register 38.69. ISP_AWB_HSCALE_REG (0x0168)

ISP_AWB_RPOINT Configures the right boundary coordinate of the AWB statistical window. (R/W)

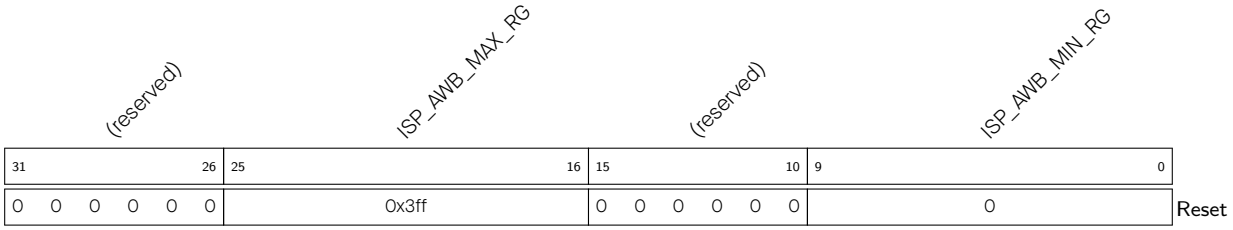
ISP_AWB_LPOINT Configures the left boundary coordinate of the AWB statistical window. (R/W)



Register 38.70. ISP_AWB_VSCALE_REG (0x016C)

ISP_AWB_BPOINT Configures the bottom boundary coordinate of the AWB statistical window. (R/W)

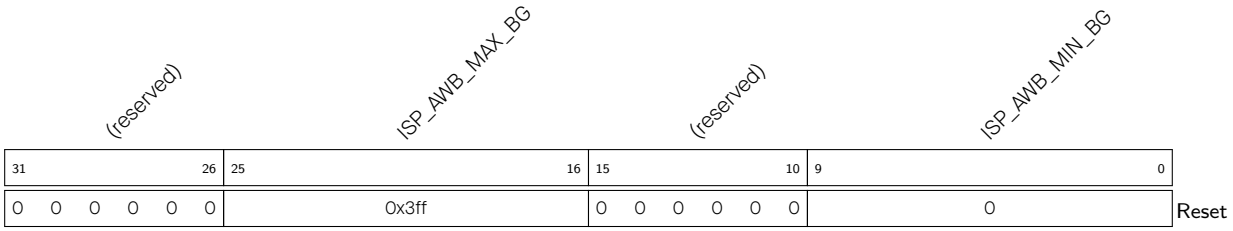
ISP_AWB_TPOINT Configures the top boundary coordinate of the AWB statistical window. (R/W)



Register 38.71. ISP_AWB_TH_LUM_REG (0x0170)

ISP_AWB_MIN_LUM Configures the lower limit of R+G+B luminance for AWB white patch filtering. (R/W)

ISP_AWB_MAX_LUM Configures the upper limit of R+G+B luminance for AWB white patch filtering. (R/W)



Register 38.72. ISP_AWB_TH_RG_REG (0x0174)

ISP_AWB_MIN_RG Configures the lower limit of R/G ratio for AWB white point filtering. Bits [9:8] are the integer part, and bits [7:0] are the fractional part. (R/W)

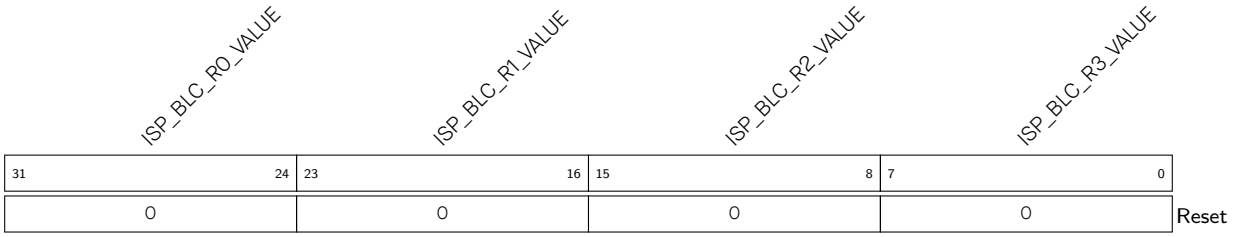
ISP_AWB_MAX_RG Configures the upper limit of R/G ratio for AWB white point filtering. Bits [9:8] are the integer part, and bits [7:0] are the fractional part. (R/W)

Register 38.73. ISP_AWB_TH_BG_REG (0x0178)

ISP_AWB_MIN_BG Configures the lower limit of B/G ratio for AWB white point filtering. Bits [9:8] are the integer part, and bits [7:0] are the fractional part. (R/W)

ISP_AWB_MAX_BG Configures the upper limit of B/G ratio for AWB white point filtering. Bits [9:8] are the integer part, and bits [7:0] are the fractional part. (R/W)

Register 38.74. ISP_COLOR_CTRL_REG (0x018C)



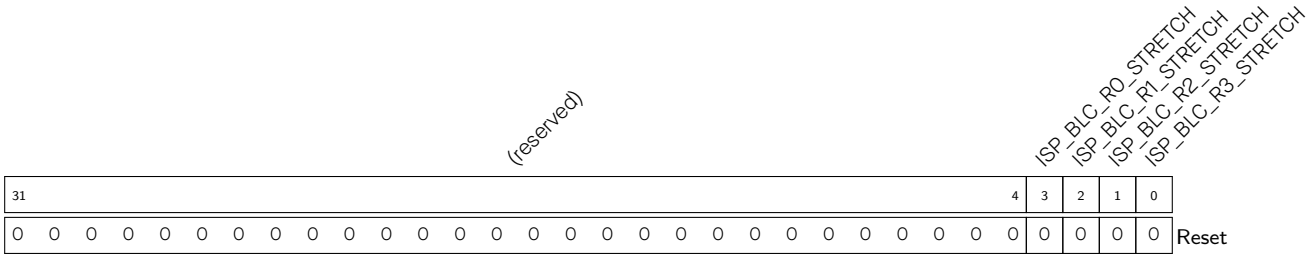
ISP_COLOR_SATURATION Configures the saturation. Bit [7] is the integer part, and bits [6:0] are the fractional part. (R/W)

ISP_COLOR_HUE Configures the lower 8 bits of the hue value. The hue value is 9 bits in total, with the MSB provided by ISP_COLOR_HUE_H. Valid range: 0–359. (R/W)

ISP_COLOR_CONTRAST Configures the saturation. Bit [7] is the integer part, and bits [6:0] are the fractional part. (R/W)

ISP_COLOR_BRIGHTNESS Configures the brightness in two's complement. (R/W)

Register 38.75. ISP_BLC_VALUE_REG (0x0190)



ISP_BLC_R3_VALUE Configures the black level offset of channel 3 in the Bayer image. (R/W)

ISP_BLC_R2_VALUE Configures the black level offset of channel 2 in the Bayer image. (R/W)

ISP_BLC_R1_VALUE Configures the black level offset of channel 1 in the Bayer image. (R/W)

ISP_BLC_R0_VALUE Configures the black level offset of channel 0 in the Bayer image. (R/W)

Register 38.76. ISP_BLC_CTRL0_REG (0x0194)

ISP_BLC_R3_STRETCH Configures whether to stretch the pixel range of channel 3.

0: Stretch

1: Not stretch

(R/W)

ISP_BLC_R2_STRETCH Configures whether to stretch the pixel range of channel 2.

0: Stretch

1: Not stretch

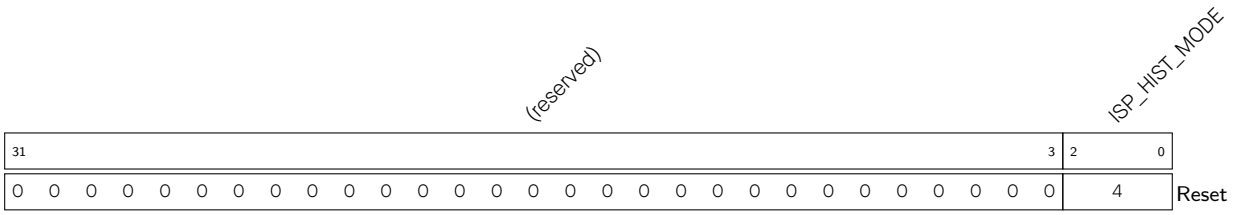
(R/W)

ISP_BLC_R1_STRETCH Configures whether to stretch the pixel range of channel 1.

0: Stretch

1: Not stretch

(R/W)



ISP_BLC_R0_STRETCH Configures whether to stretch the pixel range of channel 0.

0: Stretch

1: Not stretch

(R/W)

Register 38.77. ISP_HIST_MODE_REG (0x01A4)

ISP_HIST_MODE Configures the HIST sampling mode.

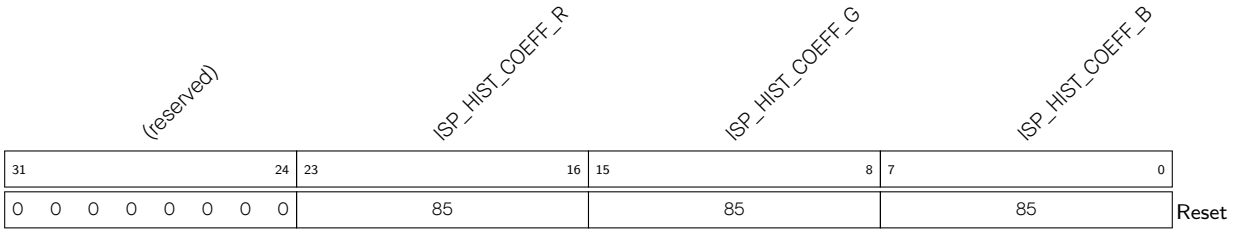
0: RAW_B

1: RAW_GB

2: RAW_GR

3: RAW_R

4: RGB



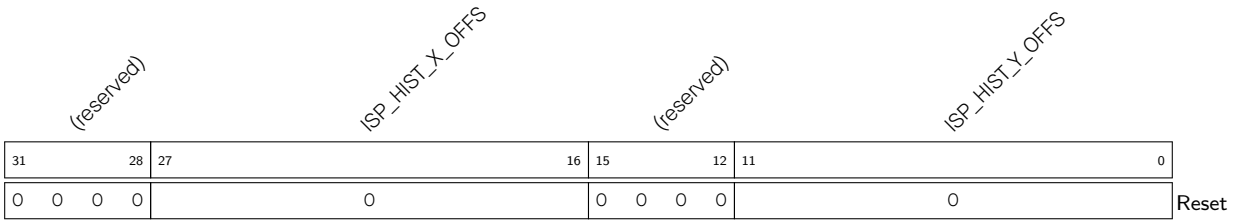
5: YUV_Y

6: YUV_U

7: YUV_V

(R/W)

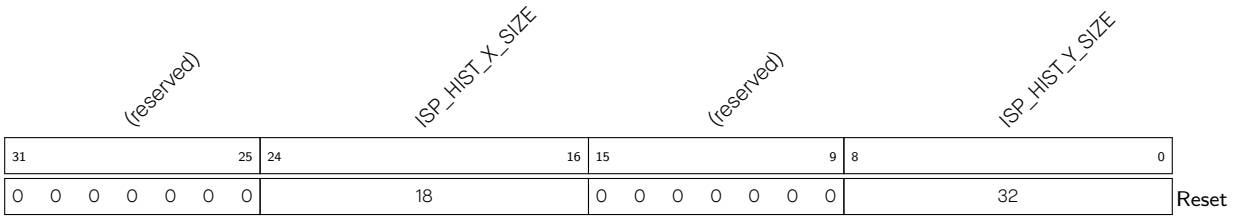
Register 38.78. ISP_HIST_COEFF_REG (0x01A8)



ISP_HIST_COEFF_B Configures the B weight for RGB to brightness conversion when HIST statistics mode set to RGB. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_COEFF_G Configures the G weight for RGB to brightness conversion when HIST statistics mode set to RGB. Bits [7:0] are the fractional part. (R/W)

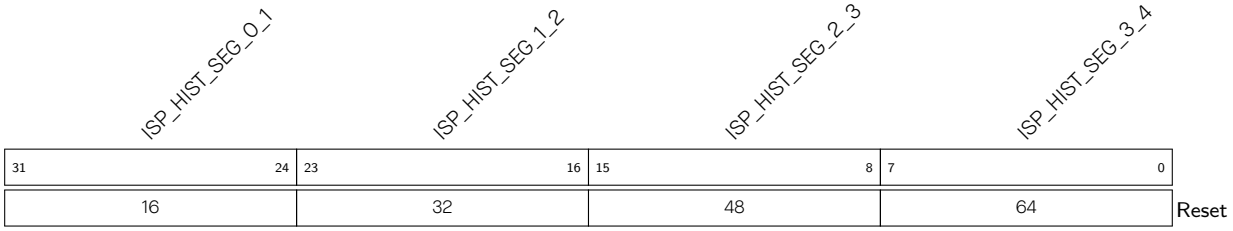
ISP_HIST_COEFF_R Configures the R weight for RGB to brightness conversion when HIST statistics mode set to RGB. Bits [7:0] are the fractional part. (R/W)



Register 38.79. ISP_HIST_OFFS_REG (0x01AC)

ISP_HIST_Y_OFFS Configures the start coordinate of the HIST statistics window in the vertical direction. (R/W)

ISP_HIST_X_OFFS Configures the start coordinate of the HIST statistics window in the horizontal direction. (R/W)

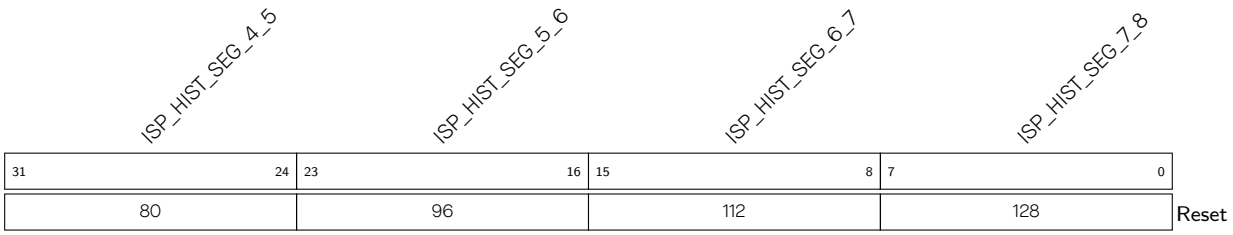


Register 38.80. ISP_HIST_SIZE_REG (0x01B0)

ISP_HIST_Y_SIZE Configures the vertical dimension of the HIST sub-window. (R/W)

ISP_HIST_X_SIZE Configures the horizontal dimension of the HIST sub-window. (R/W)

Register 38.81. ISP_HIST_SEG0_REG (0x01B4)



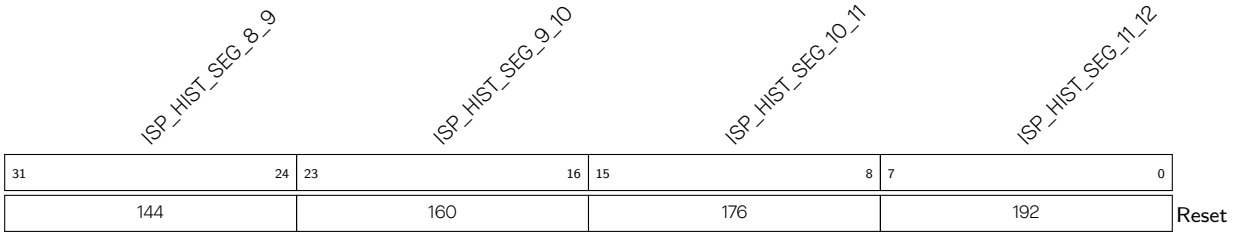
ISP_HIST_SEG_3_4 Configures the threshold between the HIST interval 3 and 4. (R/W)

ISP_HIST_SEG_2_3 Configures the threshold between the HIST interval 2 and 3. (R/W)

ISP_HIST_SEG_1_2 Configures the threshold between the HIST interval 1 and 2. (R/W)

ISP_HIST_SEG_0_1 Configures the threshold between the HIST interval 0 and 1. (R/W)

Register 38.82. ISP_HIST_SEG1_REG (0x01B8)



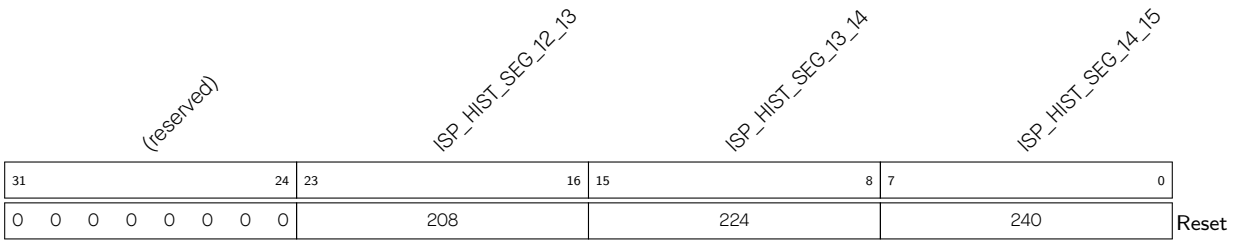
ISP_HIST_SEG_7_8 Configures the threshold between the HIST interval 7 and 8. (R/W)

ISP_HIST_SEG_6_7 Configures the threshold between the HIST interval 6 and 7. (R/W)

ISP_HIST_SEG_5_6 Configures the threshold between the HIST interval 5 and 6. (R/W)

ISP_HIST_SEG_4_5 Configures the threshold between the HIST interval 4 and 5. (R/W)

Register 38.83. ISP_HIST_SEG2_REG (0x01BC)



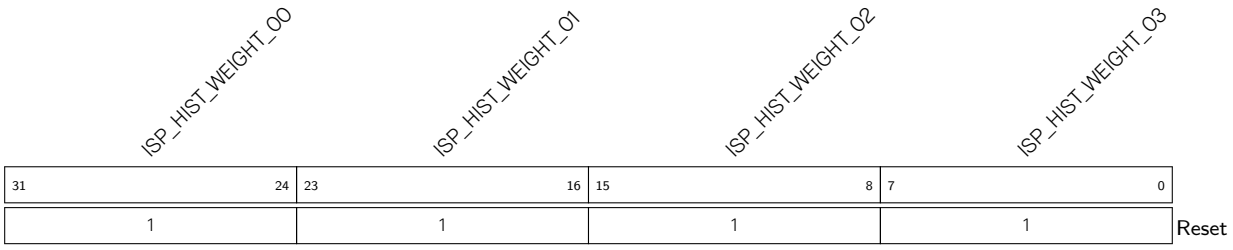
ISP_HIST_SEG_11_12 Configures the threshold between the HIST interval 11 and 12. (R/W)

ISP_HIST_SEG_10_11 Configures the threshold between the HIST interval 10 and 11. (R/W)

ISP_HIST_SEG_9_10 Configures the threshold between the HIST interval 9 and 10. (R/W)

ISP_HIST_SEG_8_9 Configures the threshold between the HIST interval 8 and 9. (R/W)

Register 38.84. ISP_HIST_SEG3_REG (0x01C0)

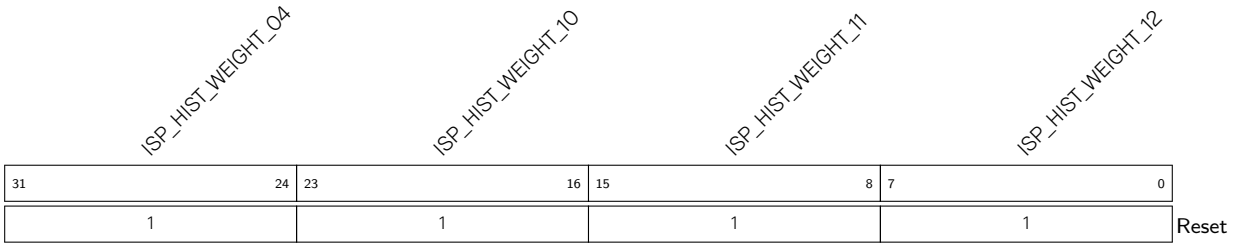


ISP_HIST_SEG_14_15 Configures the threshold between the HIST interval 14 and 15. (R/W)

ISP_HIST_SEG_13_14 Configures the threshold between the HIST interval 13 and 14. (R/W)

ISP_HIST_SEG_12_13 Configures the threshold between the HIST interval 12 and 13. (R/W)

Register 38.85. ISP_HIST_WEIGHT0_REG (0x01C4)



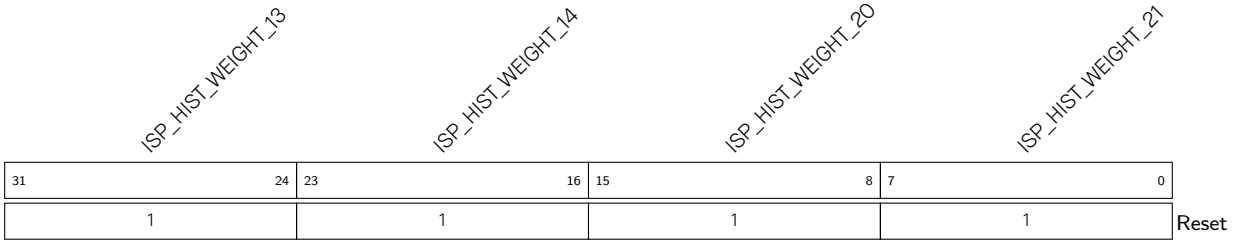
ISP_HIST_WEIGHT_03 Configures the weight of HIST sub-window 03. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_02 Configures the weight of HIST sub-window 02. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_01 Configures the weight of HIST sub-window 01. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_00 Configures the weight of HIST sub-window 00. Bits [7:0] are the fractional part. (R/W)

Register 38.86. ISP_HIST_WEIGHT1_REG (0x01C8)



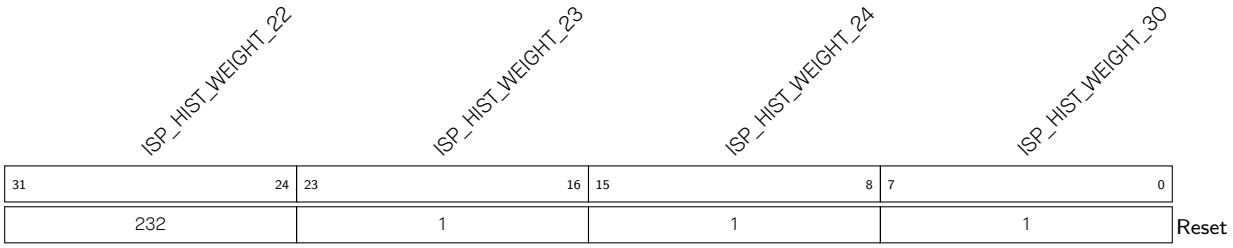
ISP_HIST_WEIGHT_12 Configures the weight of HIST sub-window 12. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_11 Configures the weight of HIST sub-window 11. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_10 Configures the weight of HIST sub-window 10. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_04 Configures the weight of HIST sub-window 04. Bits [7:0] are the fractional part. (R/W)

Register 38.87. ISP_HIST_WEIGHT2_REG (0x01CC)



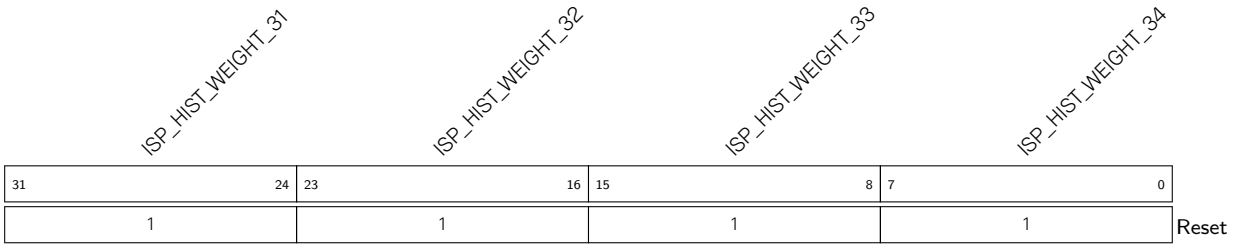
ISP_HIST_WEIGHT_21 Configures the weight of HIST sub-window 21. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_20 Configures the weight of HIST sub-window 20. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_14 Configures the weight of HIST sub-window 14. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_13 Configures the weight of HIST sub-window 13. Bits [7:0] are the fractional part. (R/W)

Register 38.88. ISP_HIST_WEIGHT3_REG (0x01D0)



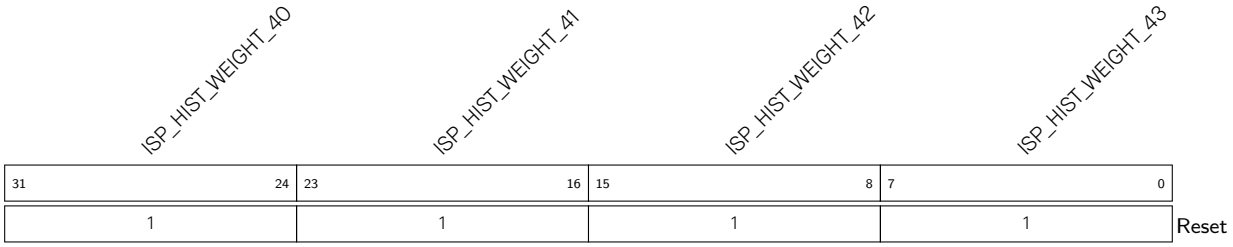
ISP_HIST_WEIGHT_30 Configures the weight of HIST sub-window 30. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_24 Configures the weight of HIST sub-window 24. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_23 Configures the weight of HIST sub-window 23. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_22 Configures the weight of HIST sub-window 22. Bits [7:0] are the fractional part. (R/W)

Register 38.89. ISP_HIST_WEIGHT4_REG (0x01D4)



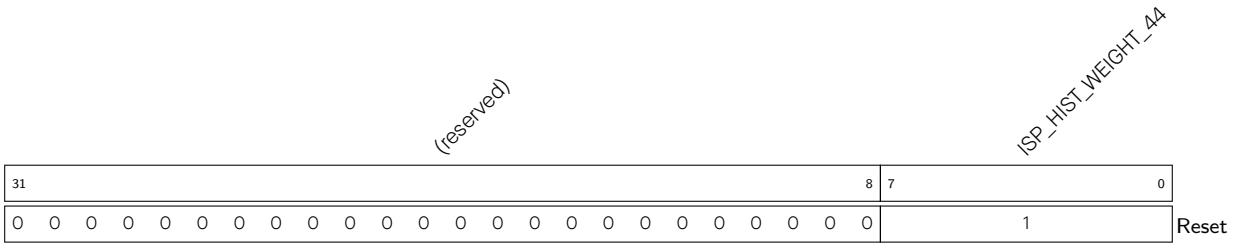
ISP_HIST_WEIGHT_34 Configures the weight of HIST sub-window 34. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_33 Configures the weight of HIST sub-window 33. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_32 Configures the weight of HIST sub-window 32. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_31 Configures the weight of HIST sub-window 31. Bits [7:0] are the fractional part. (R/W)

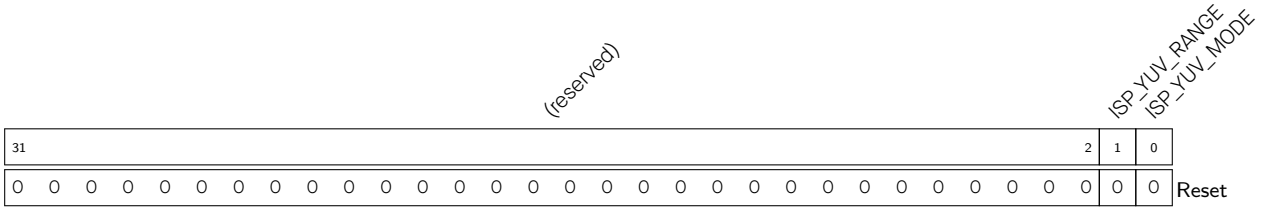
Register 38.90. ISP_HIST_WEIGHT5_REG (0x01D8)



ISP_HIST_WEIGHT_43 Configures the weight of HIST sub-window 43. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_42 Configures the weight of HIST sub-window 42. Bits [7:0] are the fractional part. (R/W)

ISP_HIST_WEIGHT_41 Configures the weight of HIST sub-window 41. Bits [7:0] are the fractional part. (R/W)



ISP_HIST_WEIGHT_40 Configures the weight of HIST sub-window 40. Bits [7:0] are the fractional part. (R/W)

Register 38.91. ISP_HIST_WEIGHT6_REG (0x01DC)

ISP_HIST_WEIGHT_44 Configures the weight of HIST sub-window 44. Bits [7:0] are the fractional part. (R/W)

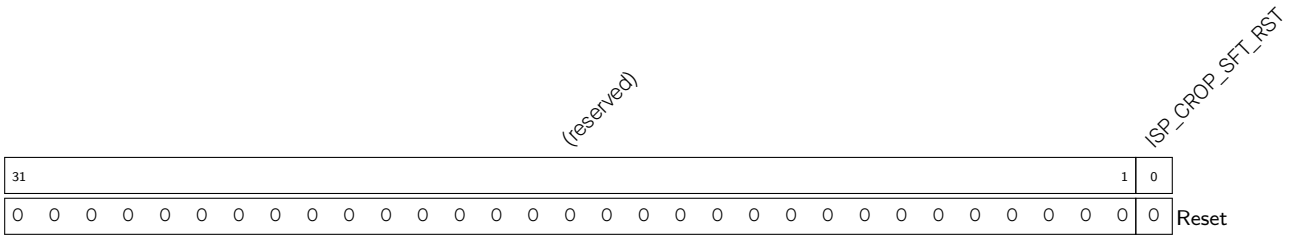
Register 38.92. ISP_YUV_FORMAT_REG (0x0234)

ISP_YUV_MODE Configures the YUV output mode.

0: ITU-R BT.601

1: ITU-R BT.709

(R/W)



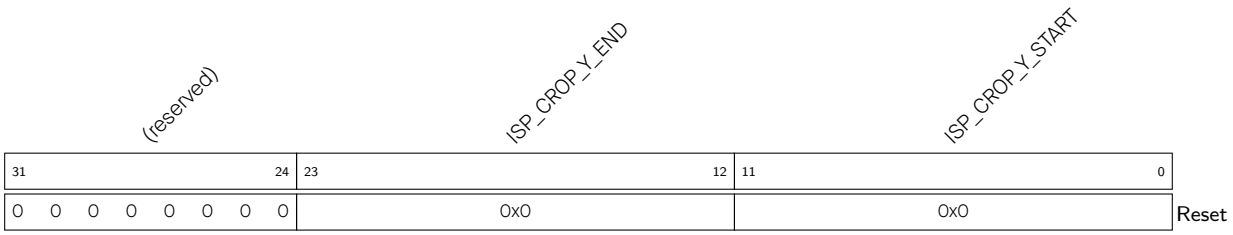
ISP_YUV_RANGE Configures the YUV output range.

0: Full range (YUV2RGB)

1: Limit range (YUV_Limit)

(R/W)

Register 38.93. ISP_CROP_CTRL_REG (0x0244)

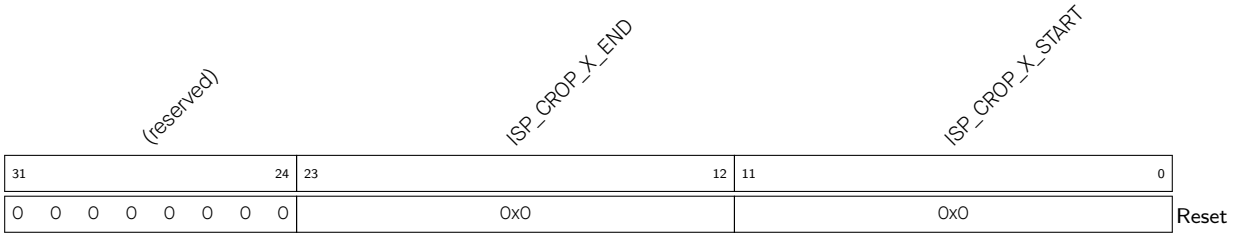


ISP_CROP_SFT_RST Configures whether to reset the CROP error status.

0: Not reset

1: Reset

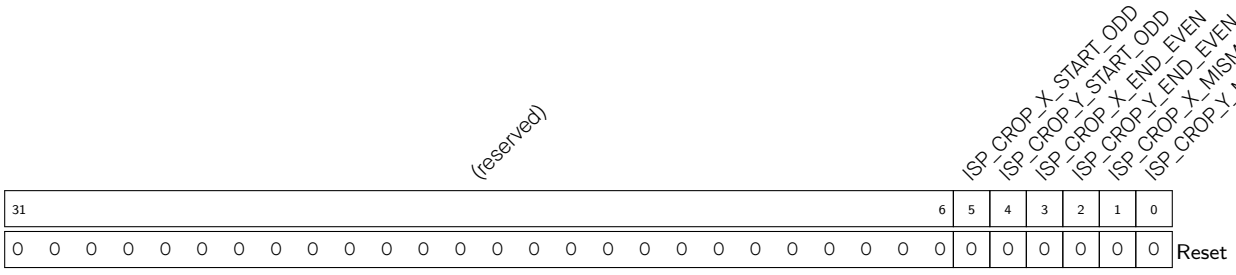
(WT)



Register 38.94. ISP_CROP_Y_CAPTURE_REG (0x0248)

ISP_CROP_Y_START Configures the start coordinate in the Y direction. (R/W)

ISP_CROP_Y_END Configures the end coordinate in the Y direction. (R/W)



Register 38.95. ISP_CROP_X_CAPTURE_REG (0x024C)

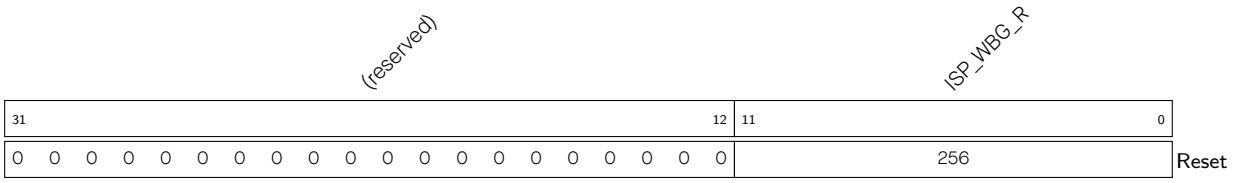
ISP_CROP_X_START Configures the start coordinate in the X direction. (R/W)

ISP_CROP_X_END Configures the end coordinate in the X direction. (R/W)

Register 38.96. ISP_CROP_ERR_ST_REG (0x0250)

ISP_CROP_Y_MISMATCH Represents an error where the configured CROP Y coordinate exceeds the image boundary. (RO)

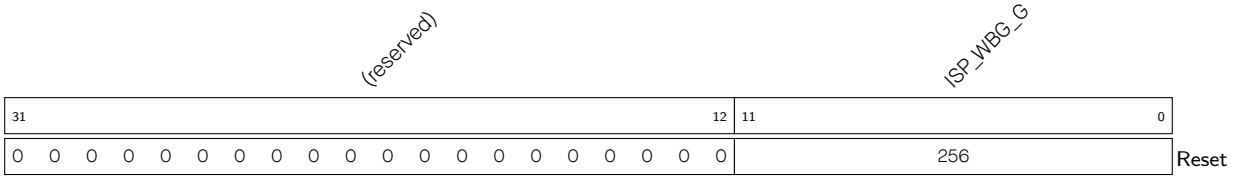
ISP_CROP_X_MISMATCH Represents an error where the configured CROP X coordinate exceeds the image boundary. (RO)



ISP_CROP_Y_END_EVEN Represents an error where the Y-direction end coordinate is even. (RO)

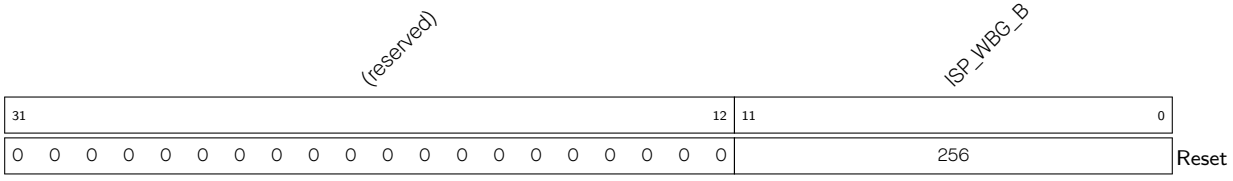
ISP_CROP_X_END_EVEN Represents an error where the X-direction end coordinate is even. (RO)

ISP_CROP_Y_START_ODD Represents an error where the Y-direction start coordinate is odd. (RO)



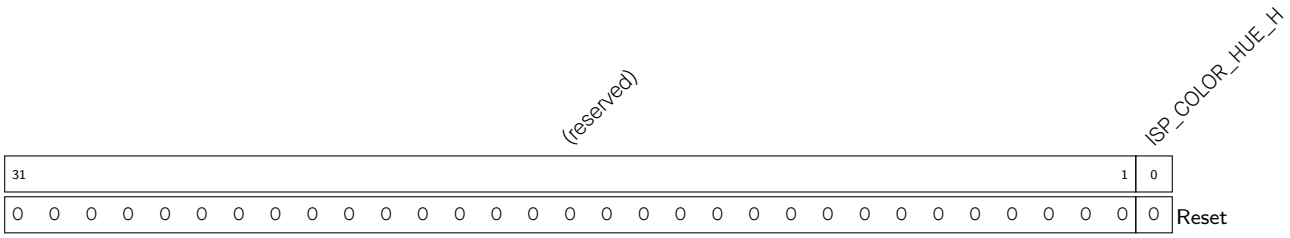
ISP_CROP_X_START_ODD Represents an error where the X-direction start coordinate is odd. (RO)

Register 38.97. ISP_WBG_COEF_R_REG (0x0254)



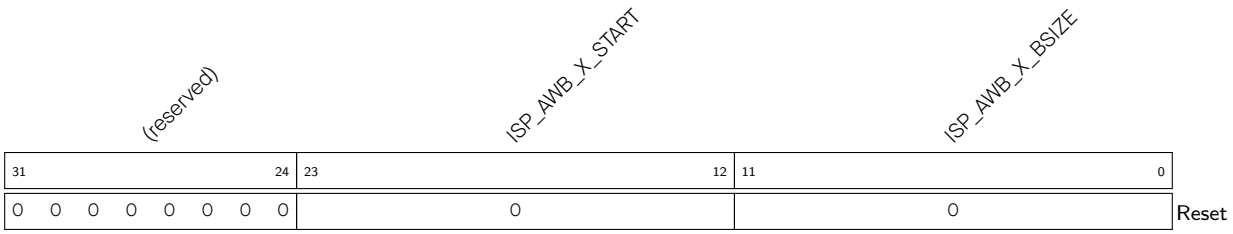
ISP_WBG_R Configures the WBG R-channel gain: 4-bit integer and 8-bit fractional. (R/W)

Register 38.98. ISP_WBG_COEF_G_REG (0x0258)



ISP_WBG_G Configures the WBG G-channel gain: 4-bit integer and 8-bit fractional. (R/W)

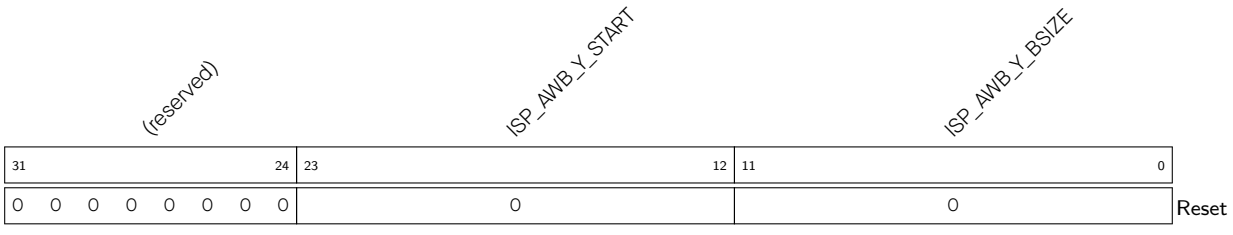
Register 38.99. ISP_WBG_COEF_B_REG (0x025C)



ISP_WBG_B Configures the WBG B-channel gain: 4-bit integer and 8-bit fractional. (R/W)

Register 38.100. ISP_COLOR_HUE_CTRL_REG (0x0260)

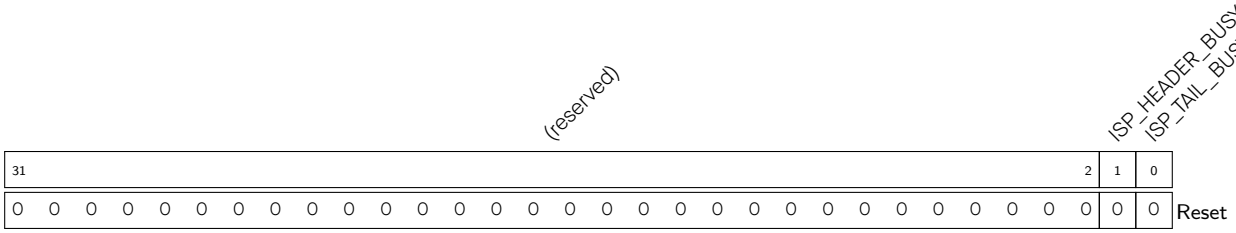
ISP_COLOR_HUE_H Configures the most significant bit of HUE. (R/W)



Register 38.101. ISP_AWB_BX_REG (0x0264)

ISP_AWB_X_BSIZE Configures the AWB sub-window size in the X direction; minimum is 4. (R/W)

ISP_AWB_X_START Configures the AWB sub-window start coordinate in the X direction. (R/W)



Register 38.102. ISP_AWB_BY_REG (0x0268)

ISP_AWB_Y_BSIZE Configures the AWB sub-window size in the Y direction. (R/W)

ISP_AWB_Y_START Configures the AWB sub-window start coordinate in the Y direction. (R/W)

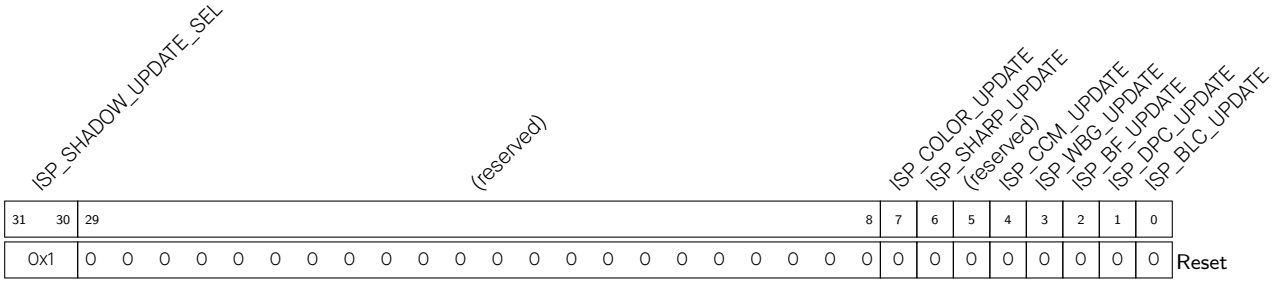
Register 38.103. ISP_STATE_REG (0x026C)

ISP_TAIL_BUSY Represents whether isp_tail is busy.

0: Idle

1: Busy

(RO)



ISP_HEADER_BUSY Represents whether isp_header is busy.

0: Idle

1: Busy

(RO)

Register 38.104. ISP_SHADOW_REG_CTRL_REG (0x0270)

ISP_BLC_UPDATE Write 1 to update the BLC registers. (R/W)

ISP_DPC_UPDATE Write 1 to update the DPC registers. (R/W)

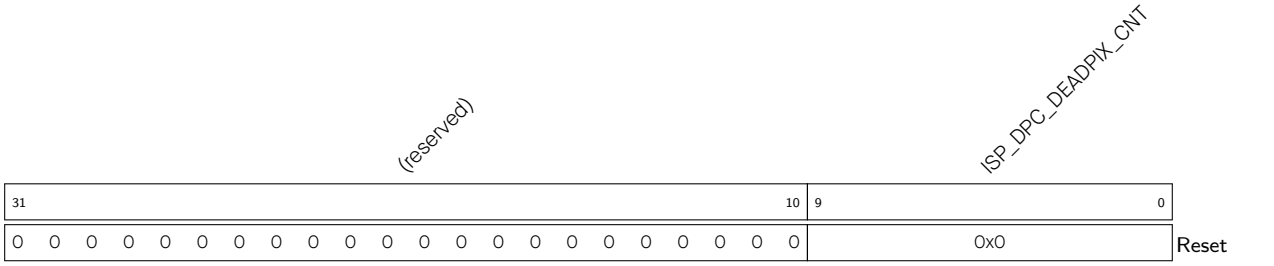
ISP_BF_UPDATE Write 1 to update the BF registers. (R/W)

ISP_WBG_UPDATE Write 1 to update the WBG registers. (R/W)

ISP_CCM_UPDATE Write 1 to update the CCM registers. (R/W)

ISP_SHARP_UPDATE Write 1 to update the SHARP registers. (R/W)

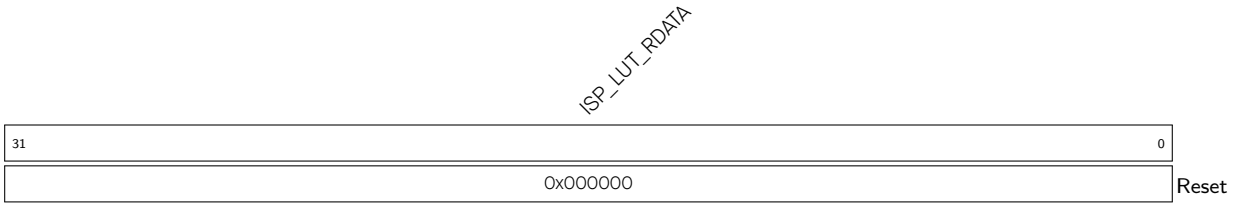
ISP_COLOR_UPDATE Write 1 to update the COLOR registers. (R/W)



ISP_SHADOW_UPDATE_SEL Configures the shadow register update mode.

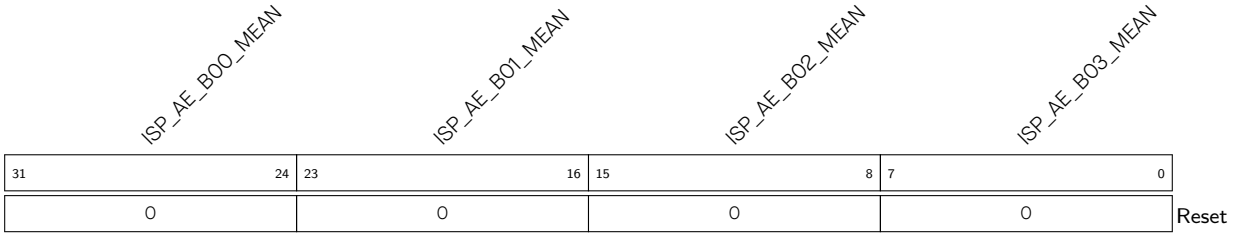
0: Disable shadow registers

1: Automatically update at every vsync



2: After writing 1 to the corresponding update register, automatically update at the next vsync (R/W)

Register 38.105. ISP_DPC_DEADPIX_CNT_REG (0x0044)

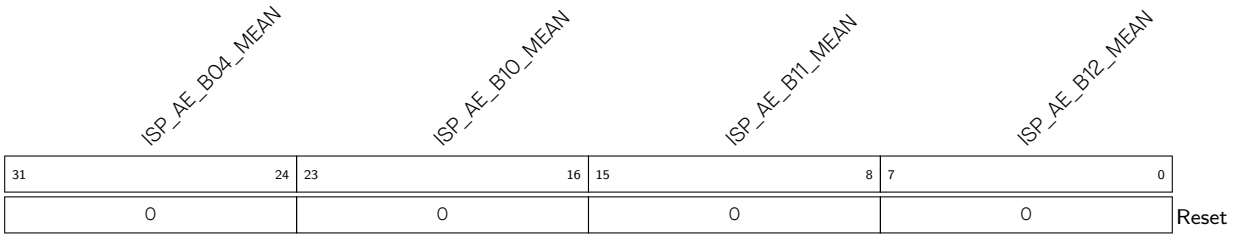


ISP_DPC_DEADPIX_CNT Represents the number of dead pixels counted during static calibration. (RO)

Register 38.106. ISP_LUT_RDATA_REG (0x0050)

ISP_LUT_RDATA Data read from the LUT. Read from this field after configuring ISP_LUT_CMD. (RO)

Register 38.107. ISP_AE_BLOCK_MEAN_0_REG (0x00D8)



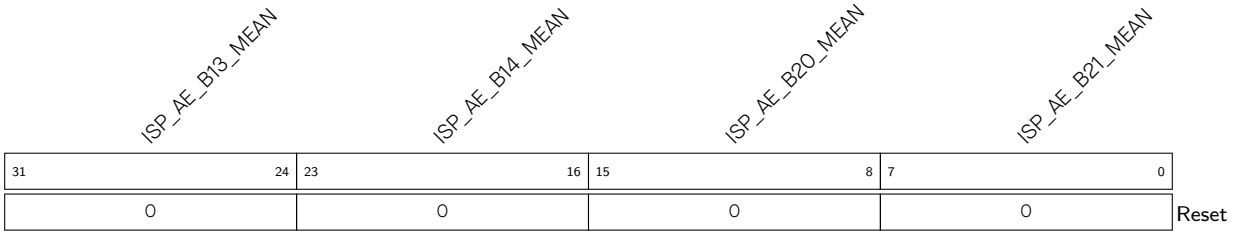
ISP_AE_B03_MEAN Represents the statistics from AE sub-window 03. (RO)

ISP_AE_B02_MEAN Represents the statistics from AE sub-window 02. (RO)

ISP_AE_B01_MEAN Represents the statistics from AE sub-window 01. (RO)

ISP_AE_B00_MEAN Represents the statistics from AE sub-window 00. (RO)

Register 38.108. ISP_AE_BLOCK_MEAN_1_REG (0x00DC)



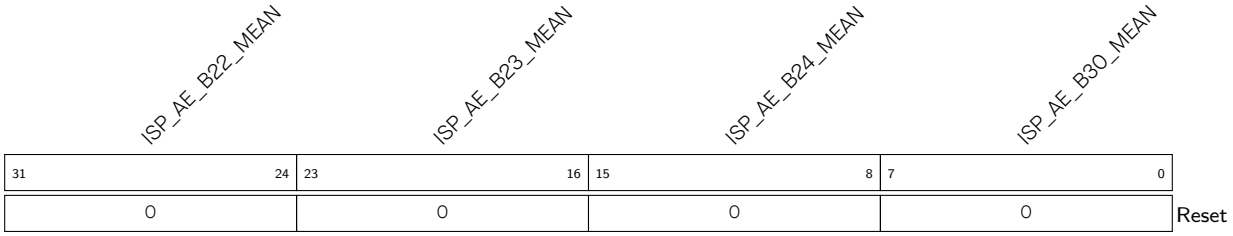
ISP_AE_B12_MEAN Represents the statistics from AE sub-window 12. (RO)

ISP_AE_B11_MEAN Represents the statistics from AE sub-window 11. (RO)

ISP_AE_B10_MEAN Represents the statistics from AE sub-window 10. (RO)

ISP_AE_B04_MEAN Represents the statistics from AE sub-window 04. (RO)

Register 38.109. ISP_AE_BLOCK_MEAN_2_REG (0x00E0)



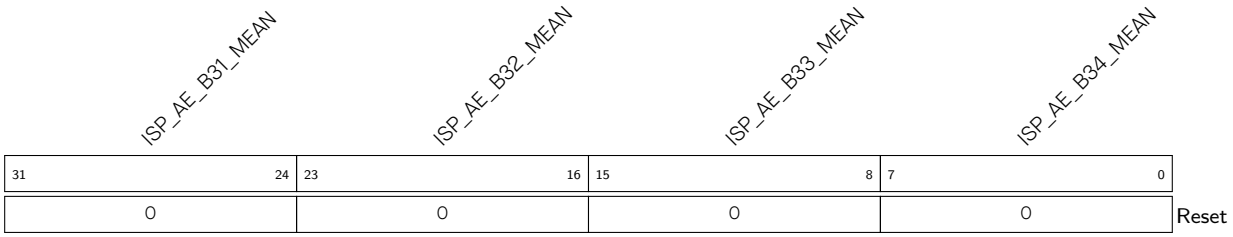
ISP_AE_B21_MEAN Represents the statistics from AE sub-window 21. (RO)

ISP_AE_B20_MEAN Represents the statistics from AE sub-window 20. (RO)

ISP_AE_B14_MEAN Represents the statistics from AE sub-window 14. (RO)

ISP_AE_B13_MEAN Represents the statistics from AE sub-window 13. (RO)

Register 38.110. ISP_AE_BLOCK_MEAN_3_REG (0x00E4)



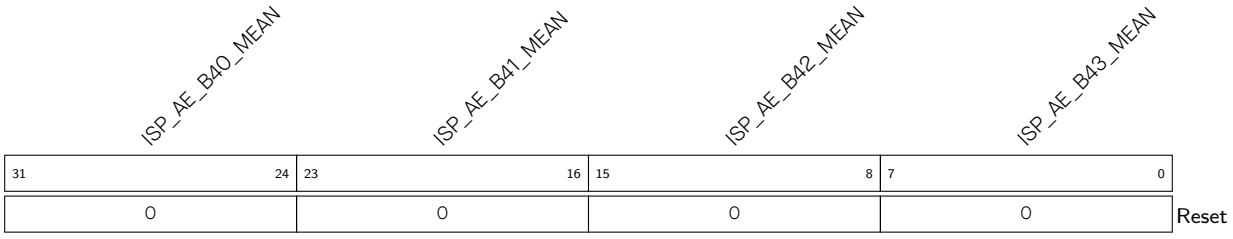
ISP_AE_B30_MEAN Represents the statistics from AE sub-window 30. (RO)

ISP_AE_B24_MEAN Represents the statistics from AE sub-window 24. (RO)

ISP_AE_B23_MEAN Represents the statistics from AE sub-window 23. (RO)

ISP_AE_B22_MEAN Represents the statistics from AE sub-window 22. (RO)

Register 38.111. ISP_AE_BLOCK_MEAN_4_REG (0x00E8)



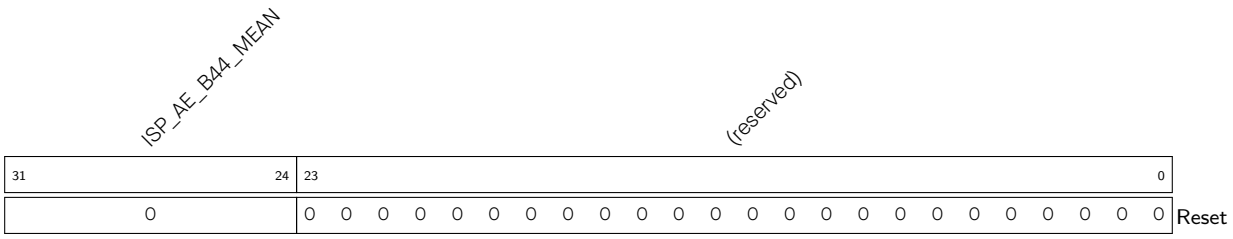
ISP_AE_B34_MEAN Represents the statistics from AE sub-window 34. (RO)

ISP_AE_B33_MEAN Represents the statistics from AE sub-window 33. (RO)

ISP_AE_B32_MEAN Represents the statistics from AE sub-window 32. (RO)

ISP_AE_B31_MEAN Represents the statistics from AE sub-window 31. (RO)

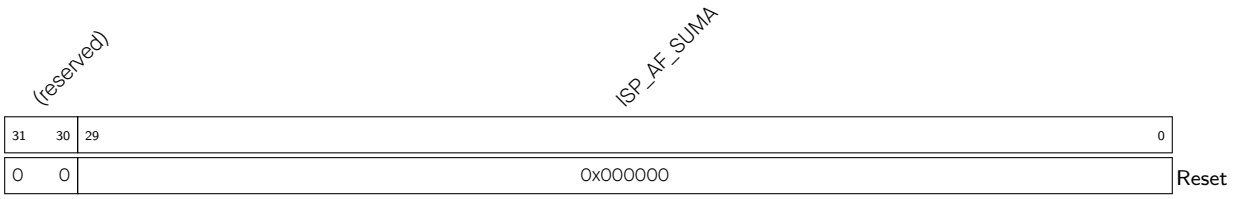
Register 38.112. ISP_AE_BLOCK_MEAN_5_REG (0x00EC)



ISP_AE_B43_MEAN Represents the statistics from AE sub-window 43. (RO)

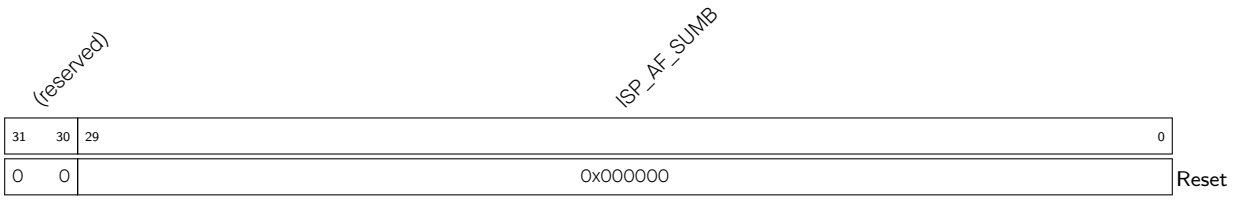
ISP_AE_B42_MEAN Represents the statistics from AE sub-window 42. (RO)

ISP_AE_B41_MEAN Represents the statistics from AE sub-window 41. (RO)



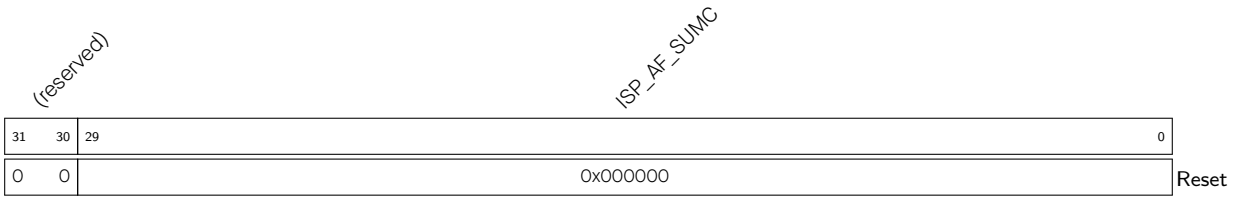
ISP_AE_B40_MEAN Represents the statistics from AE sub-window 40. (RO)

Register 38.113. ISP_AE_BLOCK_MEAN_6_REG (0x00F0)



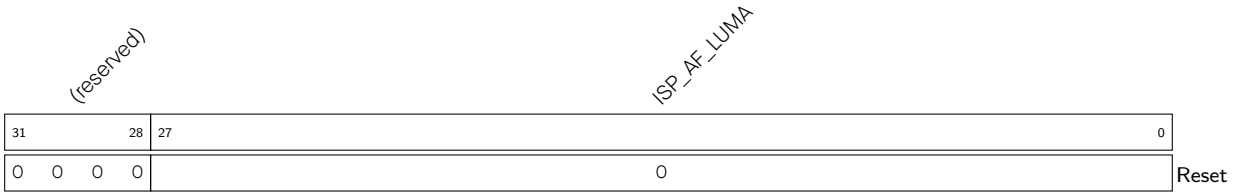
ISP_AE_B44_MEAN Represents the statistics from AE sub-window 44. (RO)

Register 38.114. ISP_AF_SUM_A_REG (0x014C)



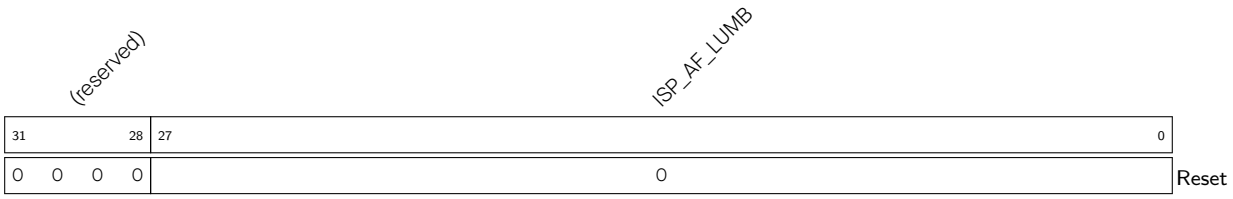
ISP_AF_SUMA Represents the sharpness statistics from AF window A. (RO)

Register 38.115. ISP_AF_SUM_B_REG (0x0150)



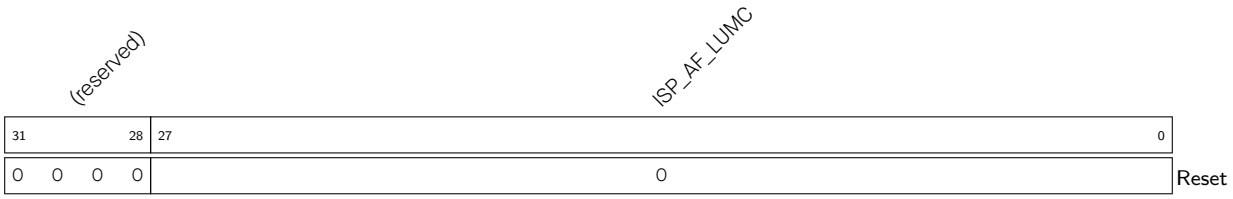
ISP_AF_SUMB Represents the sharpness statistics from AF window B. (RO)

Register 38.116. ISP_AF_SUM_C_REG (0x0154)



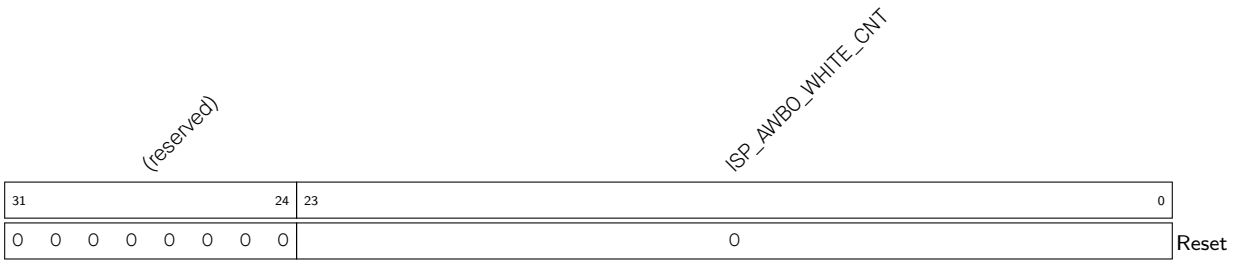
ISP_AF_SUMC Represents the sharpness statistics from AF window C. (RO)

Register 38.117. ISP_AF_LUM_A_REG (0x0158)



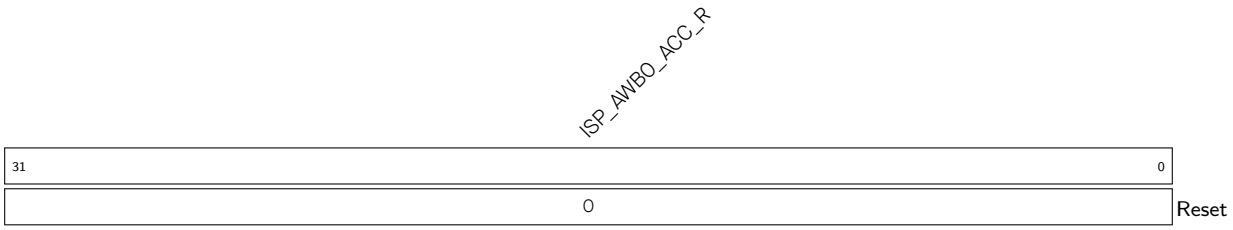
ISP_AF_LUMA Represents the luminance statistics from AF window A. (RO)

Register 38.118. ISP_AF_LUM_B_REG (0x015C)



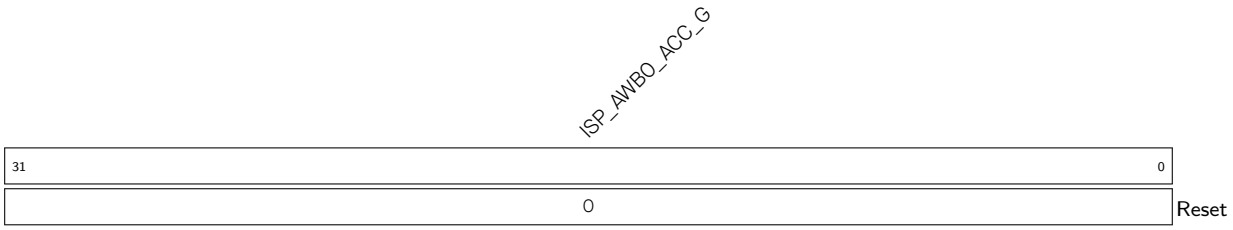
ISP_AF_LUMB Represents the luminance statistics from AF window B. (RO)

Register 38.119. ISP_AF_LUM_C_REG (0x0160)



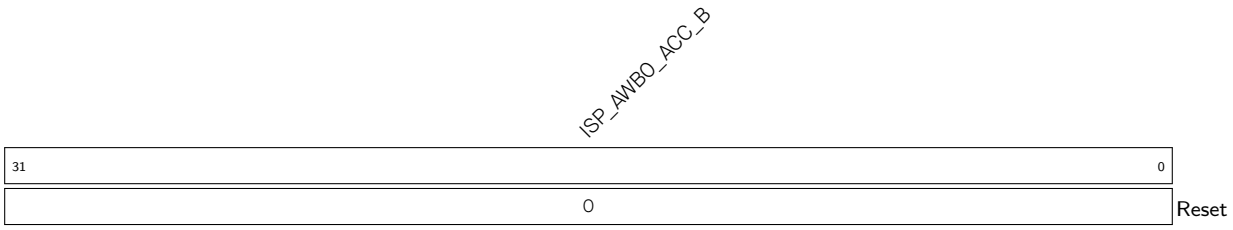
ISP_AF_LUMC Represents the luminance statistics from AF window C. (RO)

Register 38.120. ISP_AWB0_WHITE_CNT_REG (0x017C)



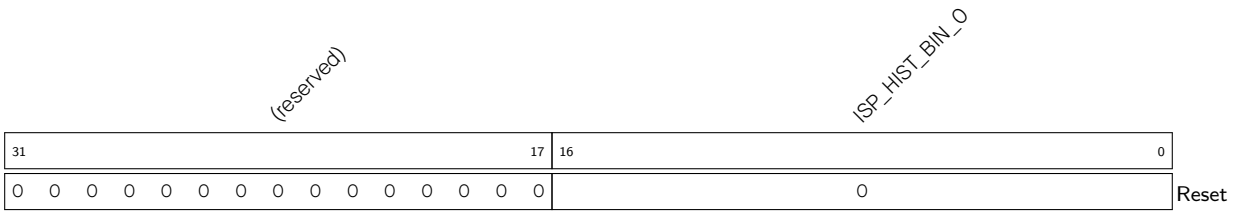
ISP_AWB0_WHITE_CNT Represents the number of white patches within the AWB statistical window. (RO)

Register 38.121. ISP_AWB0_ACC_R_REG (0x0180)



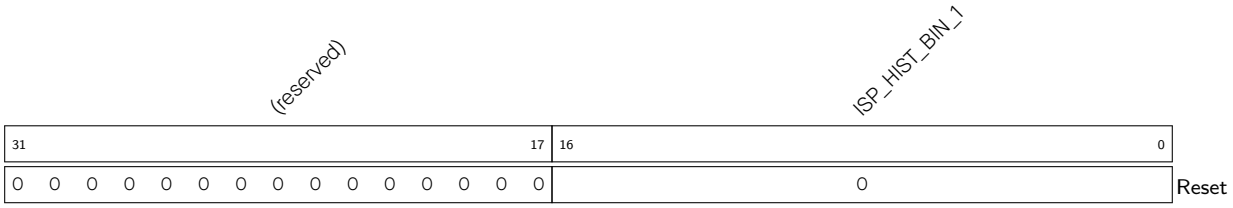
ISP_AWB0_ACC_R Represents the accumulated value of the R component for white patches within the AWB statistical window. (RO)

Register 38.122. ISP_AWB0_ACC_G_REG (0x0184)



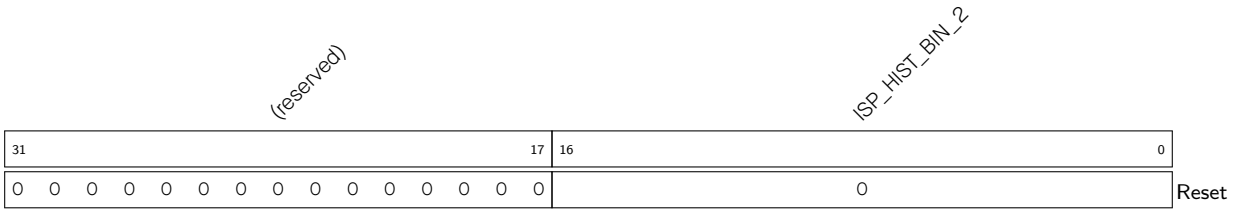
ISP_AWB0_ACC_G Represents the accumulated value of the G component for white patches within the AWB statistical window. (RO)

Register 38.123. ISP_AWB0_ACC_B_REG (0x0188)



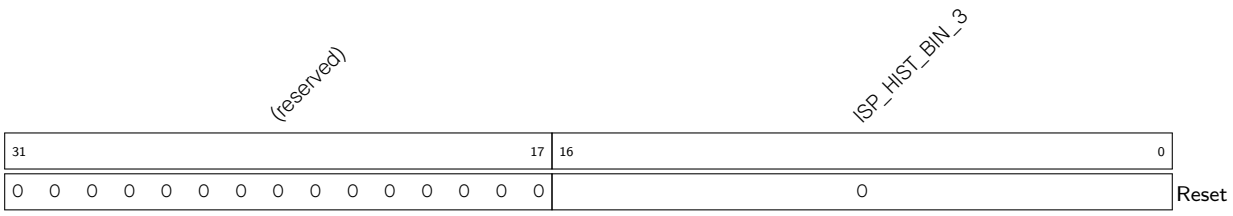
ISP_AWB0_ACC_B Represents the accumulated value of the B component for white patches within the AWB statistical window. (RO)

Register 38.124. ISP_HIST_BIN0_REG (0x01E0)



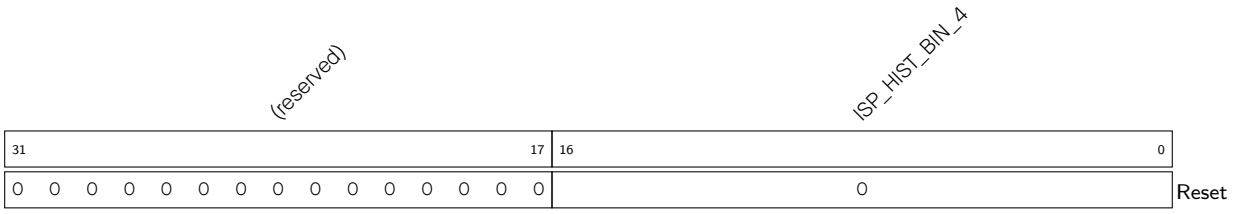
ISP_HIST_BIN_0 Represents the number of pixels where the luminance falls in the range of interval 0 in the HIST statistical window. (RO)

Register 38.125. ISP_HIST_BIN1_REG (0x01E4)



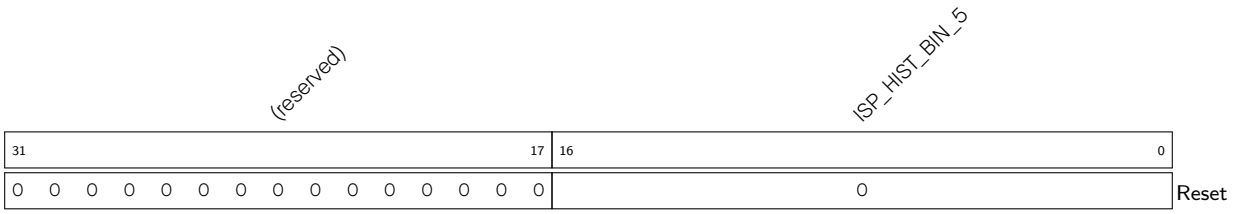
ISP_HIST_BIN_1 Represents the number of pixels where the luminance falls in the range of interval 1 in the HIST statistical window. (RO)

Register 38.126. ISP_HIST_BIN2_REG (0x01E8)



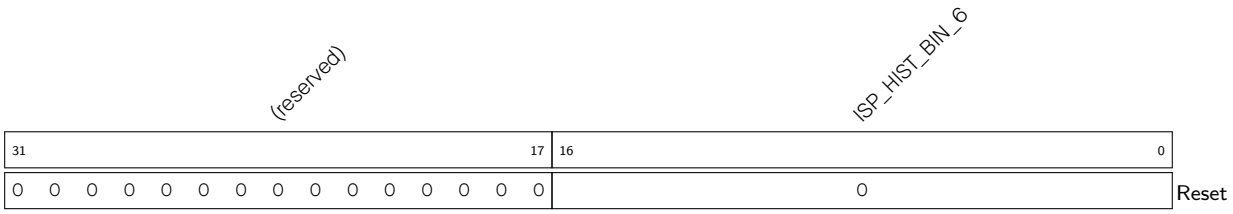
ISP_HIST_BIN_2 Represents the number of pixels where the luminance falls in the range of interval 2 in the HIST statistical window. (RO)

Register 38.127. ISP_HIST_BIN3_REG (0x01EC)



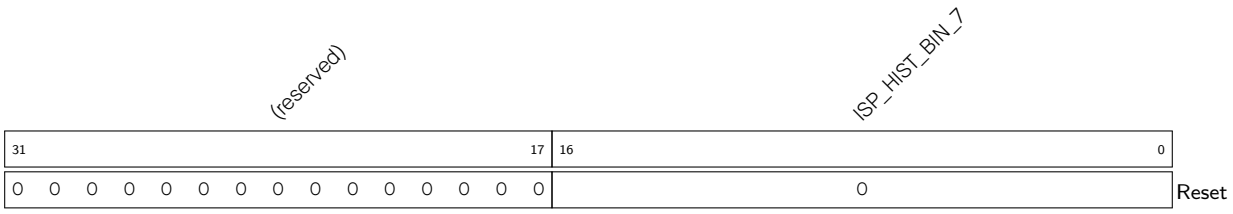
ISP_HIST_BIN_3 Represents the number of pixels where the luminance falls in the range of interval 3 in the HIST statistical window. (RO)

Register 38.128. ISP_HIST_BIN4_REG (0x01F0)



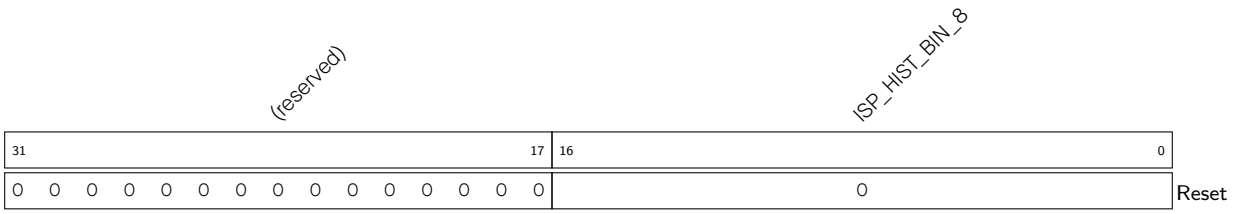
ISP_HIST_BIN_4 Represents the number of pixels where the luminance falls in the range of interval 4 in the HIST statistical window. (RO)

Register 38.129. ISP_HIST_BIN5_REG (0x01F4)



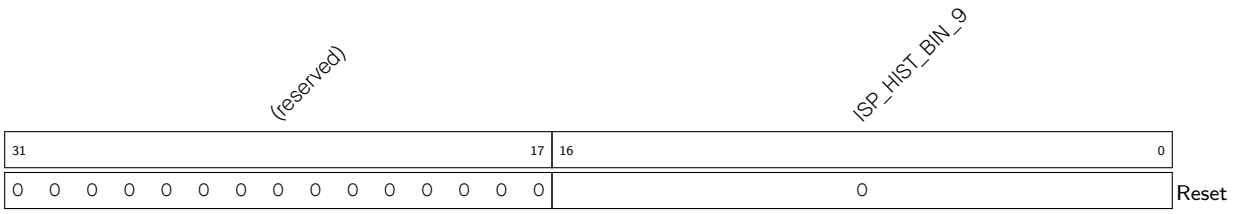
ISP_HIST_BIN_5 Represents the number of pixels where the luminance falls in the range of interval 5 in the HIST statistical window. (RO)

Register 38.130. ISP_HIST_BIN6_REG (0x01F8)



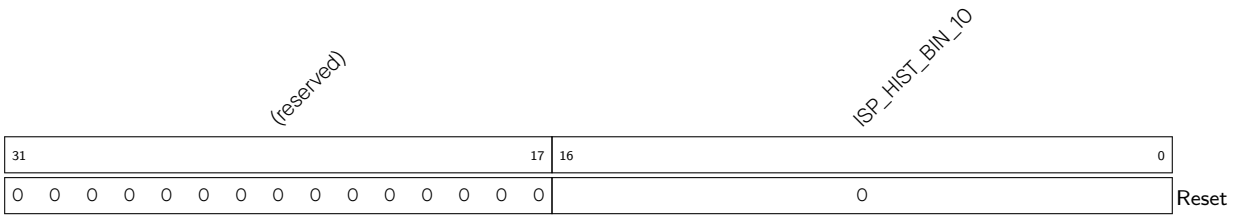
ISP_HIST_BIN_6 Represents the number of pixels where the luminance falls in the range of interval 6 in the HIST statistical window. (RO)

Register 38.131. ISP_HIST_BIN7_REG (0x01FC)



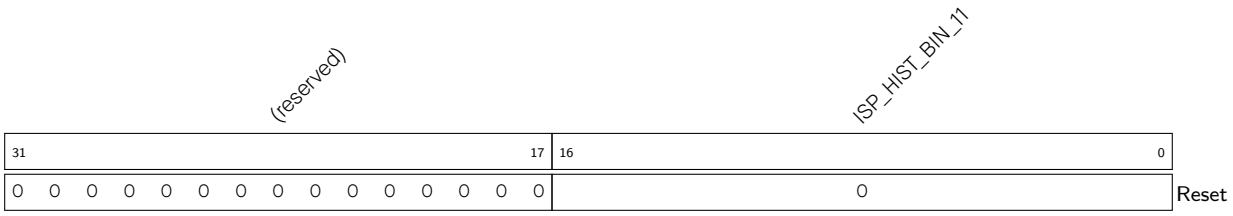
ISP_HIST_BIN_7 Represents the number of pixels where the luminance falls in the range of interval 7 in the HIST statistical window. (RO)

Register 38.132. ISP_HIST_BIN8_REG (0x0200)



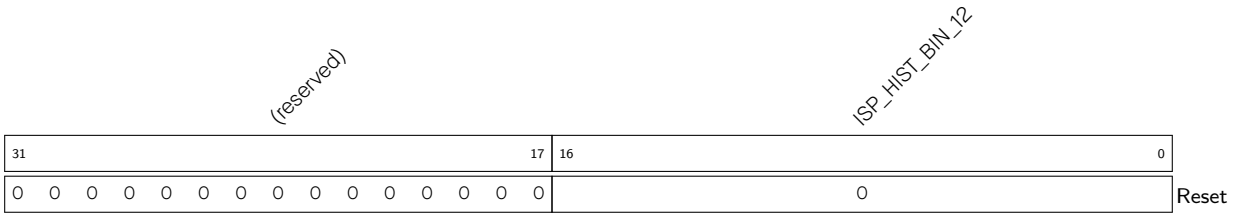
ISP_HIST_BIN_8 Represents the number of pixels where the luminance falls in the range of interval 8 in the HIST statistical window. (RO)

Register 38.133. ISP_HIST_BIN9_REG (0x0204)



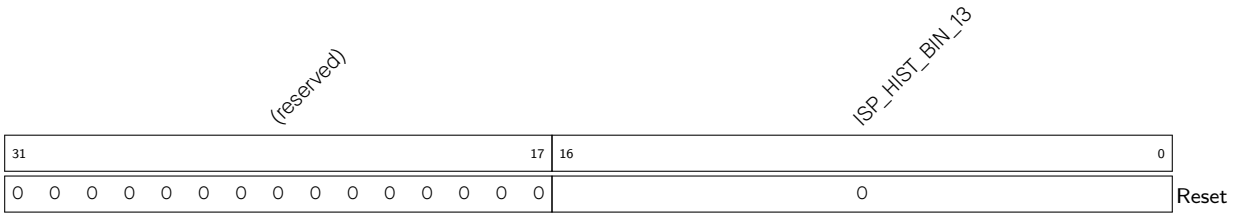
ISP_HIST_BIN_9 Represents the number of pixels where the luminance falls in the range of interval 9 in the HIST statistical window. (RO)

Register 38.134. ISP_HIST_BIN10_REG (0x0208)



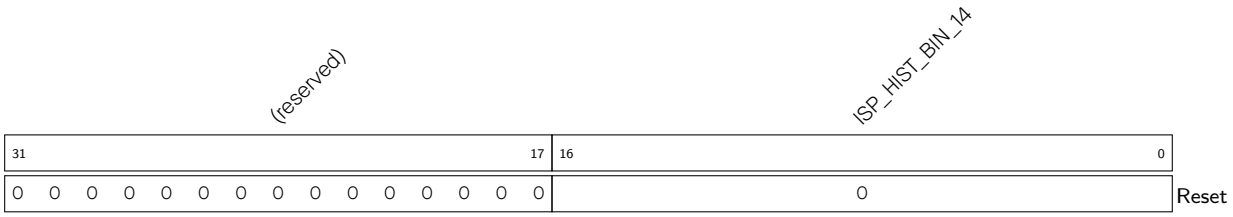
ISP_HIST_BIN_10 Represents the number of pixels where the luminance falls in the range of interval 10 in the HIST statistical window. (RO)

Register 38.135. ISP_HIST_BIN11_REG (0x020C)



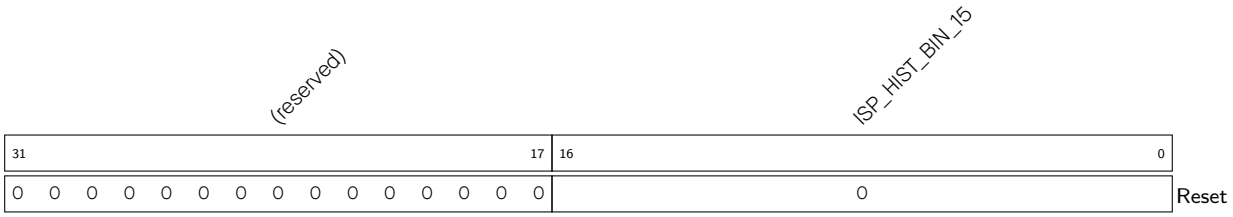
ISP_HIST_BIN_11 Represents the number of pixels where the luminance falls in the range of interval 11 in the HIST statistical window. (RO)

Register 38.136. ISP_HIST_BIN12_REG (0x0210)



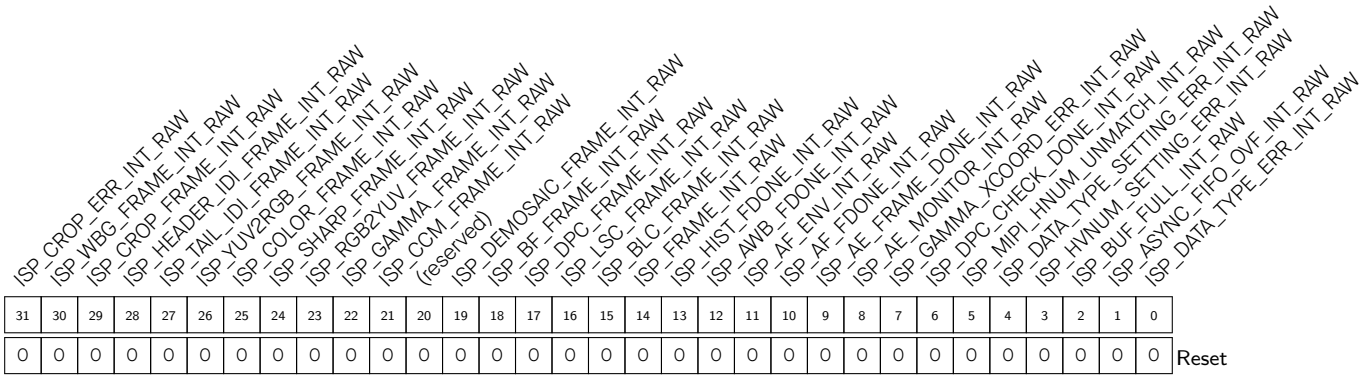
ISP_HIST_BIN_12 Represents the number of pixels where the luminance falls in the range of interval 12 in the HIST statistical window. (RO)

Register 38.137. ISP_HIST_BIN13_REG (0x0214)



ISP_HIST_BIN_13 Represents the number of pixels where the luminance falls in the range of interval 13 in the HIST statistical window. (RO)

Register 38.138. ISP_HIST_BIN14_REG (0x0218)



ISP_HIST_BIN_14 Represents the number of pixels where the luminance falls in the range of interval 14 in the HIST statistical window. (RO)

Register 38.139. ISP_HIST_BIN15_REG (0x021C)

ISP_HIST_BIN_15 Represents the number of pixels where the luminance falls in the range of interval 15 in the HIST statistical window. (RO)

Register 38.140. ISP_INT_RAW_REG (0x0064)

ISP_DATA_TYPE_ERR_INT_RAW The raw interrupt status of ISP_DATA_TYPE_ERR_INT. (R/SS/WTC)

ISP_ASYNC_FIFO_OVF_INT_RAW The raw interrupt status of ISP_ASYNC_FIFO_OVF_INT. (R/SS/WTC)

ISP_BUF_FULL_INT_RAW The raw interrupt status of ISP_BUF_FULL_INT. (R/SS/WTC)

ISP_HVNUM_SETTING_ERR_INT_RAW The raw interrupt status of ISP_HVNUM_SETTING_ERR_INT. (R/SS/WTC)

ISP_DATA_TYPE_SETTING_ERR_INT_RAW The raw interrupt status of ISP_DATA_TYPE_SETTING_ERR_INT. (R/SS/WTC)

ISP_MIPI_HNUM_UNMATCH_INT_RAW The raw interrupt status of ISP_MIPI_HNUM_UNMATCH_INT. (R/SS/WTC)

ISP_DPC_CHECK_DONE_INT_RAW The raw interrupt status of ISP_DPC_CHECK_DONE_INT. (R/SS/WTC)

ISP_GAMMA_XCOORD_ERR_INT_RAW The raw interrupt status of ISP_GAMMA_XCOORD_ERR_INT. (R/SS/WTC)

ISP_AE_MONITOR_INT_RAW The raw interrupt status of ISP_AE_MONITOR_INT. (R/SS/WTC)

ISP_AE_FRAME_DONE_INT_RAW The raw interrupt status of ISP_AE_FRAME_DONE_INT. (R/SS/WTC)

ISP_AF_FDONE_INT_RAW The raw interrupt status of ISP_AF_FDONE_INT. (R/SS/WTC)

ISP_AF_ENV_INT_RAW The raw interrupt status of ISP_AF_ENV_INT. (R/SS/WTC)

ISP_AWB_FDONE_INT_RAW The raw interrupt status of ISP_AWB_FDONE_INT. (R/SS/WTC)

ISP_HIST_FDONE_INT_RAW The raw interrupt status of ISP_HIST_FDONE_INT. (R/SS/WTC)

ISP_FRAME_INT_RAW The raw interrupt status of ISP_FRAME_INT. (R/SS/WTC)

ISP_BLC_FRAME_INT_RAW The raw interrupt status of ISP_BLC_FRAME_INT. (R/SS/WTC)

ISP_LSC_FRAME_INT_RAW The raw interrupt status of ISP_LSC_FRAME_INT. (R/SS/WTC)

ISP_BUF_FULL_INT_ENA Write 1 to enable ISP_BUF_FULL_INT. (R/W)

ISP_HVNUM_SETTING_ERR_INT_ENA Write 1 to enable ISP_HVNUM_SETTING_ERR_INT. (R/W)

ISP_DATA_TYPE_SETTING_ERR_INT_ENA Write 1 to enable ISP_DATA_TYPE_SETTING_ERR_INT. (R/W)

ISP_MIPI_HNUM_UNMATCH_INT_ENA Write 1 to enable ISP_MIPI_HNUM_UNMATCH_INT. (R/W)

ISP_DPC_CHECK_DONE_INT_ENA Write 1 to enable ISP_DPC_CHECK_DONE_INT. (R/W)

ISP_GAMMA_XCOORD_ERR_INT_ENA Write 1 to enable ISP_GAMMA_XCOORD_ERR_INT. (R/W)

ISP_AE_MONITOR_INT_ENA Write 1 to enable ISP_AE_MONITOR_INT. (R/W)

ISP_AE_FRAME_DONE_INT_ENA Write 1 to enable ISP_AE_FRAME_DONE_INT. (R/W)

ISP_AF_FDONE_INT_ENA Write 1 to enable ISP_AF_FDONE_INT. (R/W)

ISP_AF_ENV_INT_ENA Write 1 to enable ISP_AF_ENV_INT. (R/W)

ISP_AWB_FDONE_INT_ENA Write 1 to enable ISP_AWB_FDONE_INT. (R/W)

ISP_HIST_FDONE_INT_ENA Write 1 to enable ISP_HIST_FDONE_INT. (R/W)

ISP_FRAME_INT_ENA Write 1 to enable ISP_FRAME_INT. (R/W)

ISP_BLC_FRAME_INT_ENA Write 1 to enable ISP_BLC_FRAME_INT. (R/W)

ISP_LSC_FRAME_INT_ENA Write 1 to enable ISP_LSC_FRAME_INT. (R/W)

ISP_DPC_FRAME_INT_ENA Write 1 to enable ISP_DPC_FRAME_INT. (R/W)

ISP_BF_FRAME_INT_ENA Write 1 to enable ISP_BF_FRAME_INT. (R/W)

ISP_DEMOSAIC_FRAME_INT_ENA Write 1 to enable ISP_DEMOSAIC_FRAME_INT. (R/W)

Continued on the next page...

Register 38.142. ISP_INT_ENA_REG (0x006C)

Continued from the previous page...

ISP_CCM_FRAME_INT_ENA Write 1 to enable ISP_CCM_FRAME_INT. (R/W)

ISP_GAMMA_FRAME_INT_ENA Write 1 to enable ISP_GAMMA_FRAME_INT. (R/W)

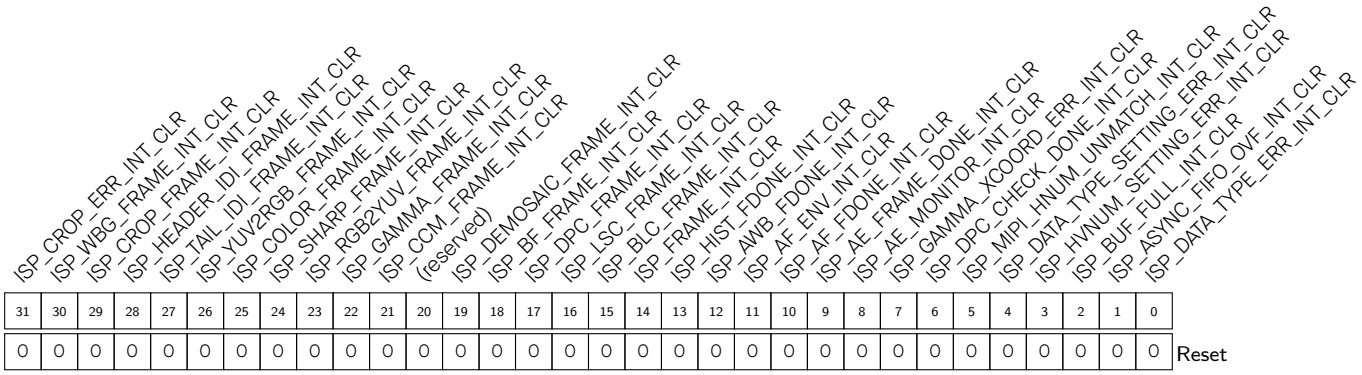
ISP_RGB2YUV_FRAME_INT_ENA Write 1 to enable ISP_RGB2YUV_FRAME_INT. (R/W)

ISP_SHARP_FRAME_INT_ENA Write 1 to enable ISP_SHARP_FRAME_INT. (R/W)

ISP_COLOR_FRAME_INT_ENA Write 1 to enable ISP_COLOR_FRAME_INT. (R/W)

ISP_YUV2RGB_FRAME_INT_ENA Write 1 to enable ISP_YUV2RGB_FRAME_INT. (R/W)

ISP_TAIL_IDI_FRAME_INT_ENA Write 1 to enable ISP_TAIL_IDI_FRAME_INT. (R/W)



ISP_HEADER_IDI_FRAME_INT_ENA Write 1 to enable ISP_HEADER_IDI_FRAME_INT. (R/W)

ISP_CROP_FRAME_INT_ENA Write 1 to enable ISP_CROP_FRAME_INT. (R/W)

ISP_WBG_FRAME_INT_ENA Write 1 to enable ISP_WBG_FRAME_INT. (R/W)

ISP_CROP_ERR_INT_ENA Write 1 to enable ISP_CROP_ERR_INT. (R/W)

Register 38.143. ISP_INT_CLR_REG (0x0070)

ISP_DATA_TYPE_ERR_INT_CLR Write 1 to clear ISP_DATA_TYPE_ERR_INT. (WT)

ISP_ASYNC_FIFO_OVF_INT_CLR Write 1 to clear ISP_ASYNC_FIFO_OVF_INT. (WT)

ISP_BUF_FULL_INT_CLR Write 1 to clear ISP_BUF_FULL_INT. (WT)

ISP_HVNUM_SETTING_ERR_INT_CLR Write 1 to clear ISP_HVNUM_SETTING_ERR_INT. (WT)

ISP_DATA_TYPE_SETTING_ERR_INT_CLR Write 1 to clear ISP_DATA_TYPE_SETTING_ERR_INT. (WT)

ISP_MIPI_HNUM_UNMATCH_INT_CLR Write 1 to clear ISP_MIPI_HNUM_UNMATCH_INT. (WT)

ISP_DPC_CHECK_DONE_INT_CLR Write 1 to clear ISP_DPC_CHECK_DONE_INT. (WT)

ISP_GAMMA_XCOORD_ERR_INT_CLR Write 1 to clear ISP_GAMMA_XCOORD_ERR_INT. (WT)

ISP_AE_MONITOR_INT_CLR Write 1 to clear ISP_AE_MONITOR_INT. (WT)

ISP_AE_FRAME_DONE_INT_CLR Write 1 to clear ISP_AE_FRAME_DONE_INT. (WT)

ISP_AF_FDONE_INT_CLR Write 1 to clear ISP_AF_FDONE_INT. (WT)

ISP_AF_ENV_INT_CLR Write 1 to clear ISP_AF_ENV_INT. (WT)

ISP_AWB_FDONE_INT_CLR Write 1 to clear ISP_AWB_FDONE_INT. (WT)

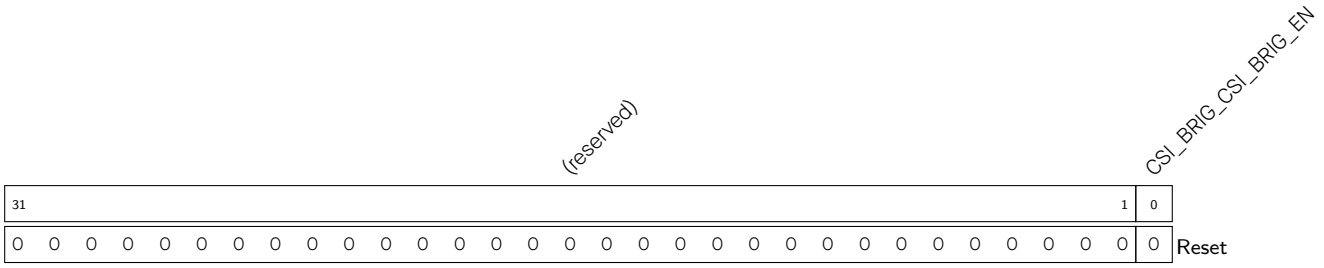
38.9.2 MIPI CSI_Bridge Registers

The addresses in this section are relative to **MIPI CSI_Bridge** base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 38.144. CSI_BRIG_CLK_EN_REG (0x0000)



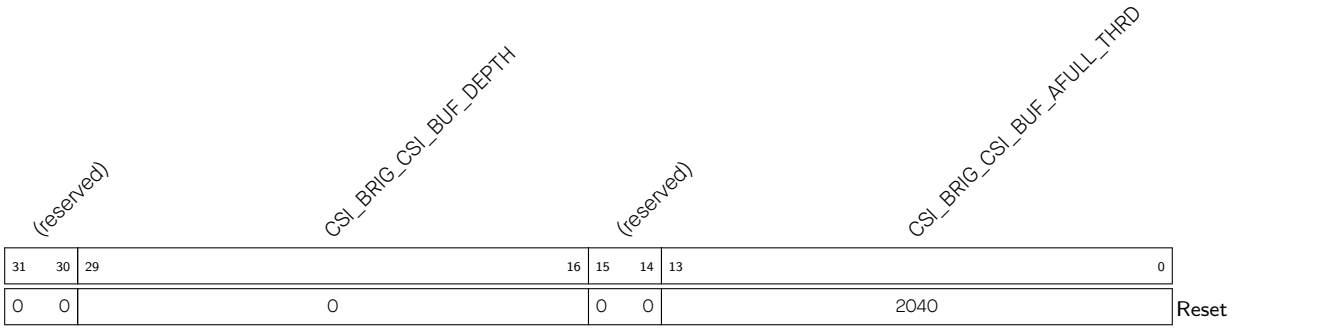
CSI_BRIG_CLK_EN Configures whether the CSI_Bridge clock is always on.

0: The clock is on only during register access

1: The clock is always on

(R/W)

Register 38.145. CSI_BRIG_CSI_EN_REG (0x0004)

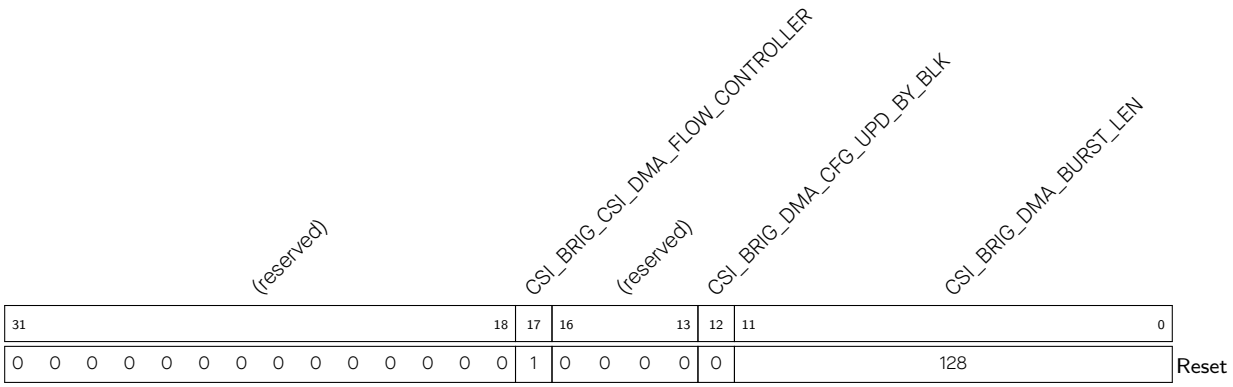


CSI_BRIG_CSI_BRIG_EN Configures whether to enable CSI_Bridge.

0: Disable

1: Enable

(R/W)



Register 38.146. CSI_BRIG_BUF_FLOW_CTL_REG (0x000C)

CSI_BRIG_CSI_BUF_AFULL_THRD Configures the size threshold at which the CSI_Bridge buffer is about to be full. (R/W)

CSI_BRIG_CSI_BUF_DEPTH Represents the size of the CSI_Bridge buffer in use. (RO)

Register 38.147. CSI_BRIG_DMA_REQ_CFG_REG (0x0008)

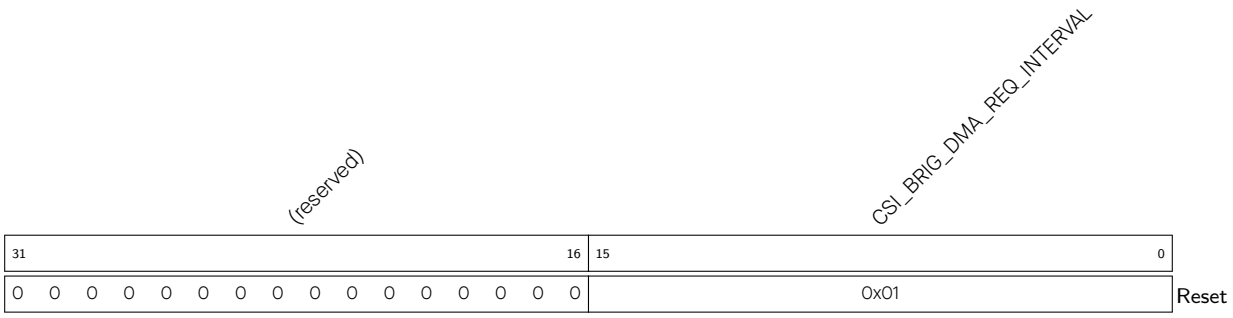
CSI_BRIG_DMA_BURST_LEN Configures the amount of 64-bit data in a VDMA burst transfer. (R/W)

CSI_BRIG_DMA_CFG_UPD_BY_BLK Configures when CSI_BRIG_DMA_BURST_LEN and CSI_BRIG_DMABLK_SIZE are updated.

0: Update upon completion of each VDMA block transfer

1: Update at the end of each frame transfer

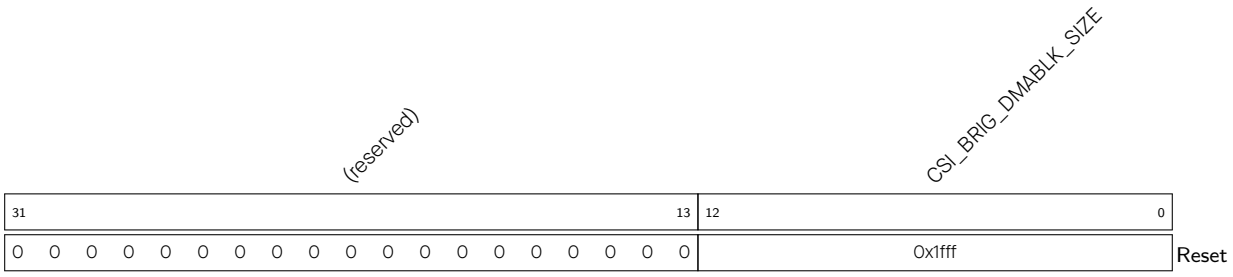
(R/W)



CSI_BRIG_CSI_DMA_FLOW_CONTROLLER Configures the DMA flow controller.

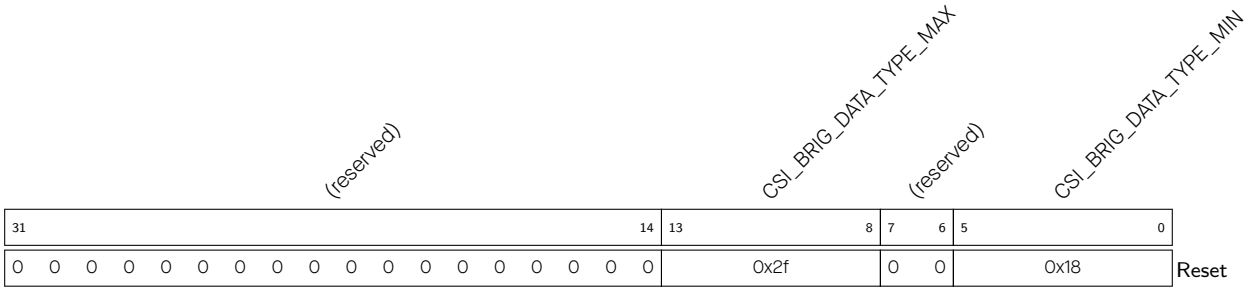
0: DMA acts as the flow controller

1: CSI_bridge acts as the flow controller



(R/W)

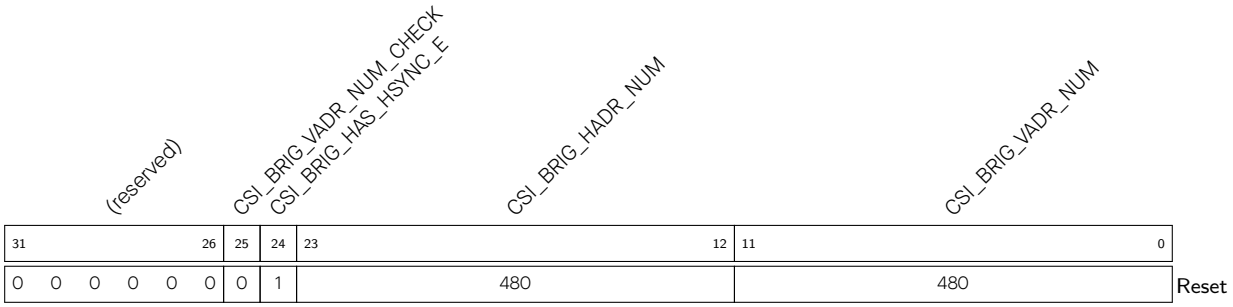
Register 38.148. CSI_BRIG_DMA_REQ_INTERVAL_REG (0x002C)



CSI_BRIG_DMA_REQ_INTERVAL Configures the interval of VDMA requests. 16'b1: 1 clock cycle, 16'b11: 2 clock cycles, 16'hFFFF: 16 clock cycles, etc. (R/W)

Register 38.149. CSI_BRIG_DMABLK_SIZE_REG (0x0030)

CSI_BRIG_DMABLK_SIZE Configures the number of VDMA bursts in a VDMA block transfer. (R/W)



Register 38.150. CSI_BRIG_DATA_TYPE_CFG_REG (0x0010)

CSI_BRIG_DATA_TYPE_MIN Configures the minimum value of DATA_TYPE for valid pixels. (R/W)

CSI_BRIG_DATA_TYPE_MAX Configures the maximum value of DATA_TYPE for valid pixels. (R/W)

Register 38.151. CSI_BRIG_FRAME_CFG_REG (0x0014)

CSI_BRIG_VADR_NUM Configures the height of an image frame. Measurement unit: line. (R/W)

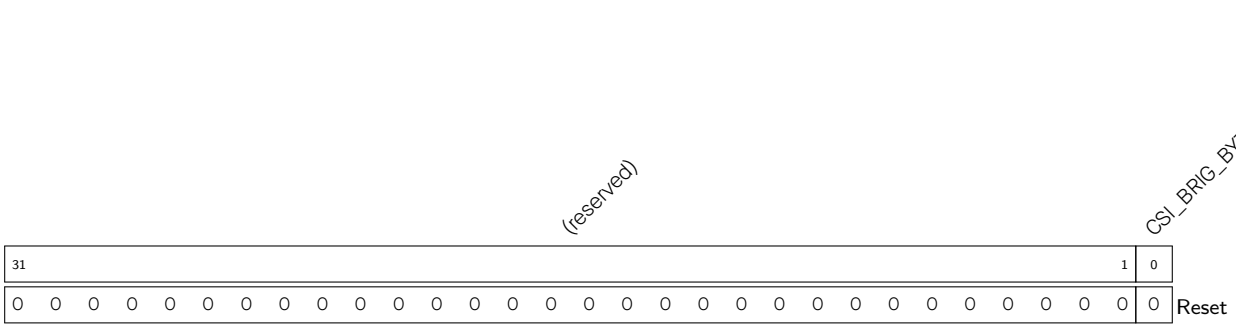
CSI_BRIG_HADR_NUM Configures the amount of 64-bit data in the width of an image frame. (R/W)

CSI_BRIG_HAS_HSYNC_E Configures whether the Image Interface 64 input includes HSYNC_START and HSYNC_END packets.

0: Not included

1: Included

(R/W)



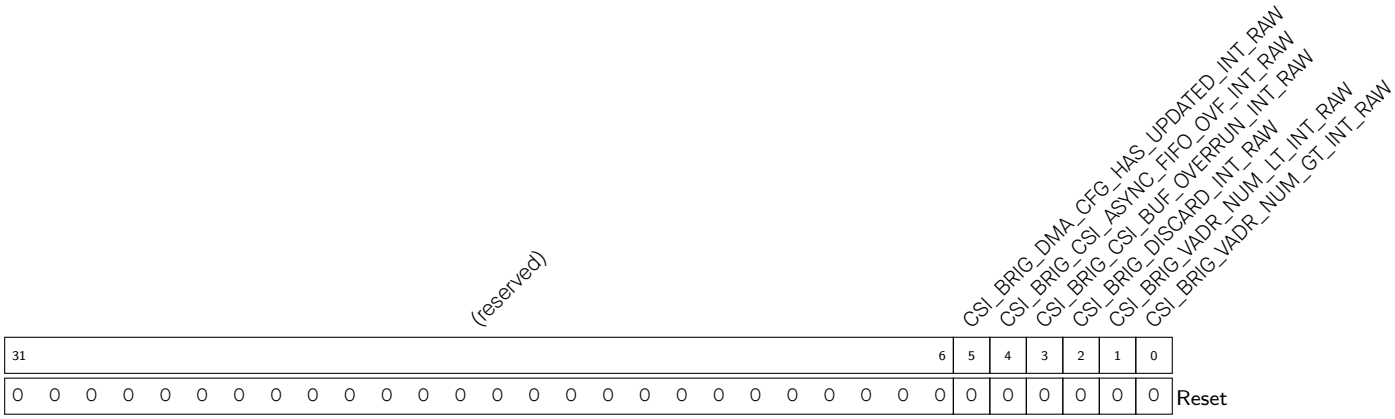
CSI_BRIG_VADR_NUM_CHECK Configures whether to enable line number checking.

0: Disable

1: Enable

(R/W)

Register 38.152. CSI_BRIG_ENDIAN_MODE_REG (0x0018)



CSI_BRIG_BYTE_ENDIAN_ORDER Configures the byte order of 64-bit data.

0: Byte order remains unchanged

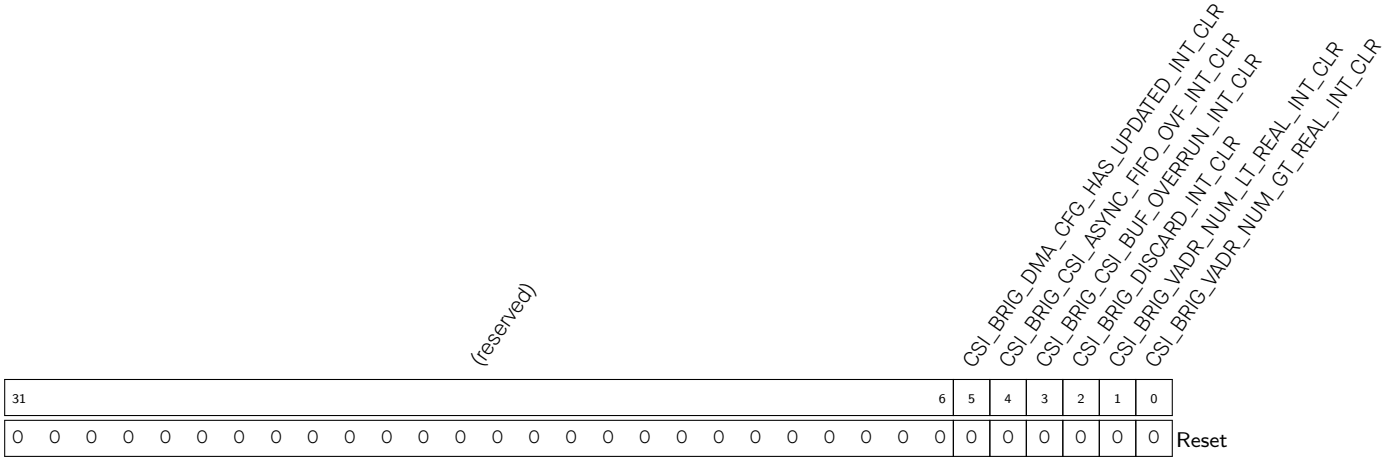
1: Reverse the high and low bytes

(R/W)

Register 38.153. CSI_BRIG_INT_RAW_REG (0x001C)

CSI_BRIG_VADR_NUM_GT_INT_RAW The raw interrupt status of CSI_BRIG_VADR_NUM_GT_INT. (R/WTC/SS)

CSI_BRIG_VADR_NUM_LT_INT_RAW The raw interrupt status of CSI_BRIG_VADR_NUM_LT_INT. (R/WTC/SS)



CSI_BRIG_DISCARD_INT_RAW The raw interrupt status of CSI_BRIG_DISCARD_INT. (R/WTC/SS)

CSI_BRIG_CSI_BUF_OVERRUN_INT_RAW The raw interrupt status of CSI_BRIG_CSI_BUF_OVERRUN_INT. (R/WTC/SS)

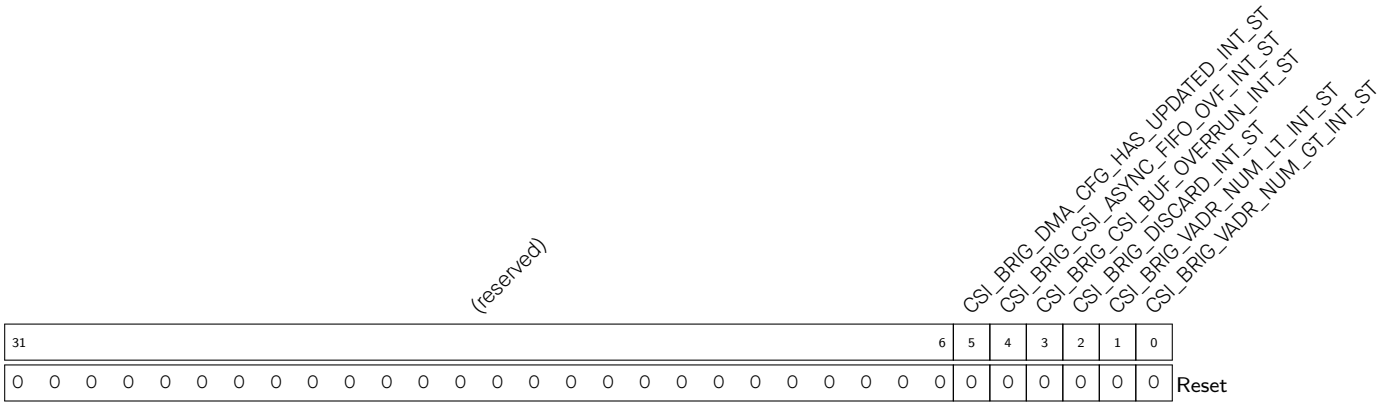
CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT_RAW The raw interrupt status of CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT. (R/WTC/SS)

CSI_BRIG_DMA_CFG_HAS_UPDATED_INT_RAW The raw interrupt status of CSI_BRIG_DMA_CFG_HAS_UPDATED_INT. (R/WTC/SS)

Register 38.154. CSI_BRIG_INT_CLR_REG (0x0020)

CSI_BRIG_VADR_NUM_GT_REAL_INT_CLR Write 1 to clear CSI_BRIG_VADR_NUM_GT_REAL_INT. (WT)

CSI_BRIG_VADR_NUM_LT_REAL_INT_CLR Write 1 to clear CSI_BRIG_VADR_NUM_LT_REAL_INT. (WT)



CSI_BRIG_DISCARD_INT_CLR Write 1 to clear CSI_BRIG_DISCARD_INT. (WT)

CSI_BRIG_CSI_BUF_OVERRUN_INT_CLR Write 1 to clear CSI_BRIG_CSI_BUF_OVERRUN_INT. (WT)

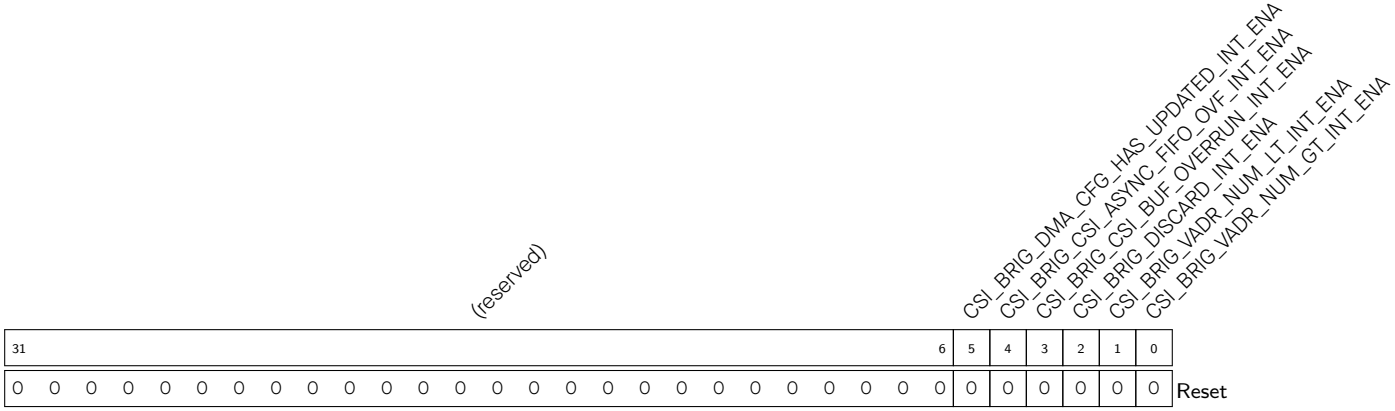
CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT_CLR Write 1 to clear CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT. (WT)

CSI_BRIG_DMA_CFG_HAS_UPDATED_INT_CLR Write 1 to clear CSI_BRIG_DMA_CFG_HAS_UPDATED_INT. (WT)

Register 38.155. CSI_BRIG_INT_ST_REG (0x0024)

CSI_BRIG_VADR_NUM_GT_INT_ST The masked interrupt status of CSI_BRIG_VADR_NUM_GT_INT. (RO)

CSI_BRIG_VADR_NUM_LT_INT_ST The masked interrupt status of CSI_BRIG_VADR_NUM_LT_INT. (RO)



CSI_BRIG_DISCARD_INT_ST The masked interrupt status of CSI_BRIG_DISCARD_INT. (RO)

CSI_BRIG_CSI_BUF_OVERRUN_INT_ST The masked interrupt status of CSI_BRIG_CSI_BUF_OVERRUN_INT. (RO)

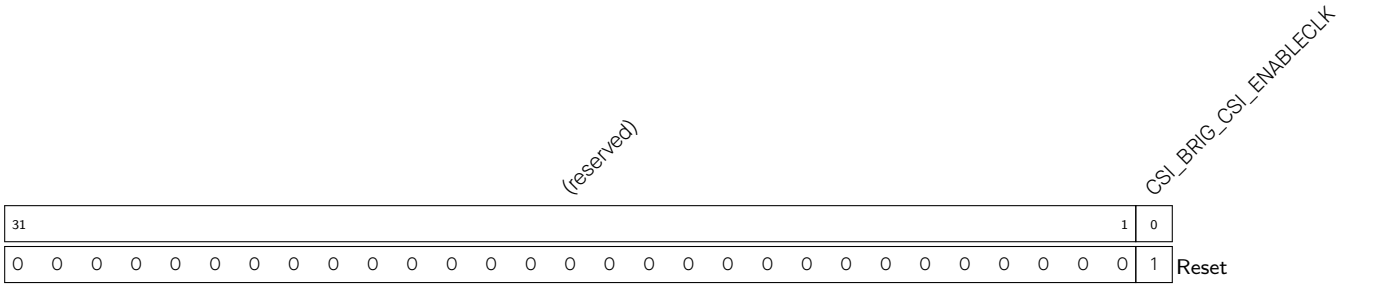
CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT_ST The masked interrupt status of CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT. (RO)

CSI_BRIG_DMA_CFG_HAS_UPDATED_INT_ST The masked interrupt status of CSI_BRIG_DMA_CFG_HAS_UPDATED_INT. (RO)

Register 38.156. CSI_BRIG_INT_ENA_REG (0x0028)

CSI_BRIG_VADR_NUM_GT_INT_ENA Write 1 to enable CSI_BRIG_VADR_NUM_GT_INT. (R/W)

CSI_BRIG_VADR_NUM_LT_INT_ENA Write 1 to enable CSI_BRIG_VADR_NUM_LT_INT. (R/W)



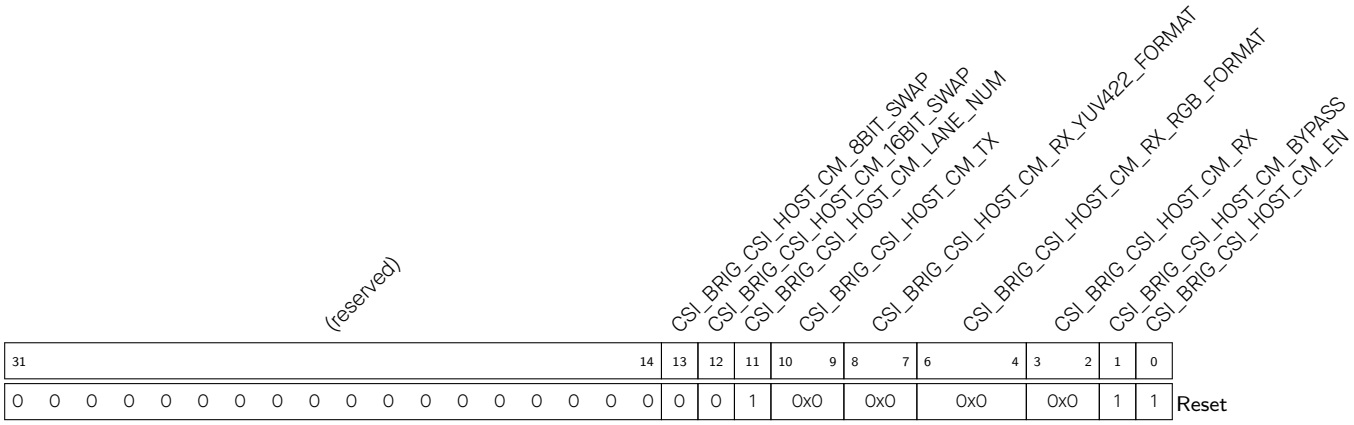
CSI_BRIG_DISCARD_INT_ENA Write 1 to enable CSI_BRIG_DISCARD_INT. (R/W)

CSI_BRIG_CSI_BUF_OVERRUN_INT_ENA Write 1 to enable CSI_BRIG_CSI_BUF_OVERRUN_INT. (R/W)

CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT_ENA Write 1 to enable CSI_BRIG_CSI_ASYNC_FIFO_OVF_INT. (R/W)

CSI_BRIG_DMA_CFG_HAS_UPDATED_INT_ENA Write 1 to enable CSI_BRIG_DMA_CFG_HAS_UPDATED_INT. (R/W)

Register 38.157. CSI_BRIG_HOST_CTRL_REG (0x0040)



CSI_BRIG_CSI_ENABLECLK Configures whether to enable the clock lane of CSI PHY.

0: Disable

1: Enable

(R/W)

Register 38.158. CSI_BRIG_HOST_CM_CTRL_REG (0x0048)

CSI_BRIG_CSI_HOST_CM_EN Configures whether to enable CSI CM.

0: Disable. In this case, no data is output from CSI CM, and the downstream ISP cannot receive data.

1: Enable

(R/W)

CSI_BRIG_CSI_HOST_CM_BYPASS Configures whether to bypass CSI CM.

0: Do not bypass

1: Bypass

(R/W)

CSI_BRIG_CSI_HOST_CM_RX Configures the input image format of CSI CM.

0: RGB888

1: RGB565

2: YUV422

3: YUV420

(R/W)

CSI_BRIG_CSI_HOST_CM_RX_RGB_FORMAT Configures the channel order of input RGB data.

0: RGB

1: BGR

2: RGB

3: BRG

4: GRB

5: GBR

Others: Invalid

(R/W)

Continued on the next page...

Register 38.158. CSI_BRIG_HOST_CM_CTRL_REG (0x0048)

Continued from the previous page...

CSI_BRIG_CSI_HOST_CM_RX_YUV422_FORMAT Configures the channel order of input YUV422 data.

0: YVYU

1: YUYV

2: VYUY

3: UYVY

(R/W)

CSI_BRIG_CSI_HOST_CM_TX Configures the output image format of CSI CM.

0: RGB888

1: RGB565

2: YUV422

3: YUV420

(R/W)

CSI_BRIG_CSI_HOST_CM_LANE_NUM Configures the number of CSI channels; valid only when both input and output formats are RGB888.

0: 1 channel

1: 2 channels

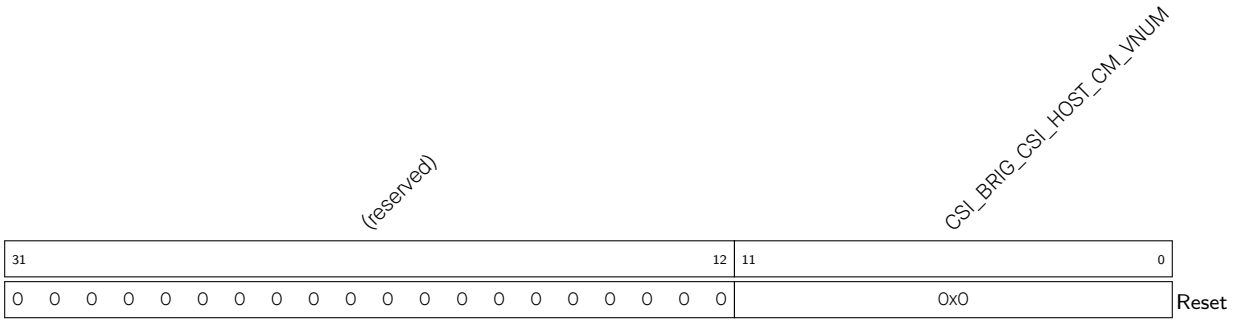
(R/W)

CSI_BRIG_CSI_HOST_CM_16BIT_SWAP Configures whether to enable 16-bit high/low swapping.

0: Disable

1: Enable

(R/W)



CSI_BRIG_CSI_HOST_CM_8BIT_SWAP Configures whether to enable 8-bit high/low swapping.

0: Disable

1: Enable

(R/W)

Register 38.159. CSI_BRIG_HOST_SIZE_CTRL_REG (0x004C)

CSI_BRIG_CSI_HOST_CM_HNUM Configures the horizontal size of the MIPI CSI input image interface (in units of 32-bit data). The value is line_pix_num * bits_per_pix / 32 - 1, and is valid only when converting from YUV422 to YUV420. (R/W)

Chapter 39

Pixel-Processing Accelerator (PPA)

39.1 Overview

ESP32-P4 includes a pixel-processing accelerator (PPA) designed for 2D image display. This module realizes hardware-level acceleration of image algorithms and implements functions such as image rotation, scaling, mirroring, and blending.

PPA consists of two functional modules: scaling-rotation-mirroring (SRM) and image blending (BLEND). The SRM module implements image rotation, scaling, and XY-axis mirroring functions, while the BLEND module achieves the blending of two layers of the same size based on the Alpha channel, i.e., transparency.

PPA processes images in units of pixel block. These pixel blocks are acquired from memory through 2D-DMA. The connection between PPA and 2D-DMA is shown in Figure 39.1-1.

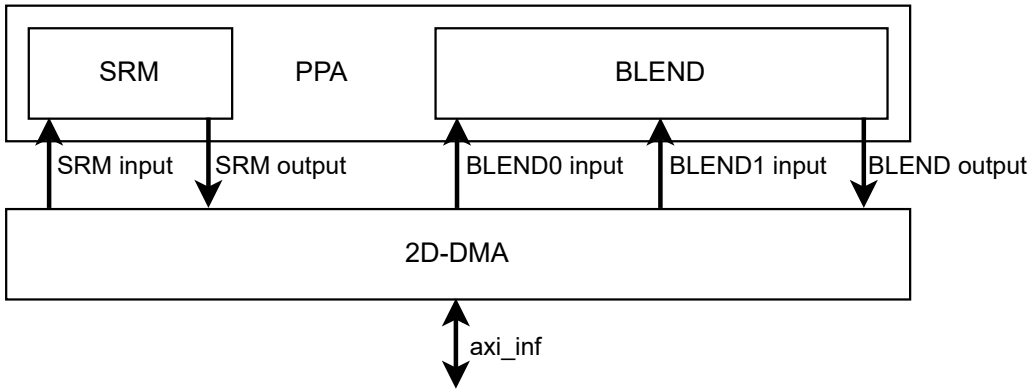


Figure 39.1-1. PPA 2D-DMA Connection

39.2 Terminology

To better illustrate the functions of the PPA module, the following terms are used in this chapter:

image	A complete image stored in the system memory
image block	A portion cropped from an image at a certain size, with the maximum size equivalent to the entire image. i.e., hb, vb size under 2D-DMA 2D-MODO.
pixel block	A portion cropped from an image block. SRM reads and writes data in pixel blocks.

39.3 Features

- Image rotation, scaling, and mirroring by SRM:

  - Input formats: ARGB8888, RGB888, RGB565, YUV422, YUV420, GRAY
  - Output formats: ARGB8888, RGB888, RGB565, YUV422, YUV420, GRAY
  - Counterclockwise rotation angles: 0°, 90°, 180°, 270°
  - Horizontal and vertical scaling with scaling factors of 8-bit integer part and 4-bit fractional part
  - Horizontal and vertical mirroring
- Blending two layers of the same size and filling images with specific pixels by BLEND:
  - Foreground input formats: ARGB8888, RGB888, RGB565, L4, L8, A4, A8
  - Background input formats: ARGB8888, RGB888, RGB565, YUV422, YUV420, GRAY, L4, L8
  - Output formats: ARGB8888, RGB888, RGB565, YUV422, YUV420, GRAY
  - Layer blending based on the Alpha channel. If layers lack an Alpha channel, it can be provided through register configuration.
  - Special color filtering by setting color-key ranges of foreground and background layers

39.4 Architectural Overview

As shown in figure 39.4-1, there are two independent functional modules in PPA: SRM and BLEND.

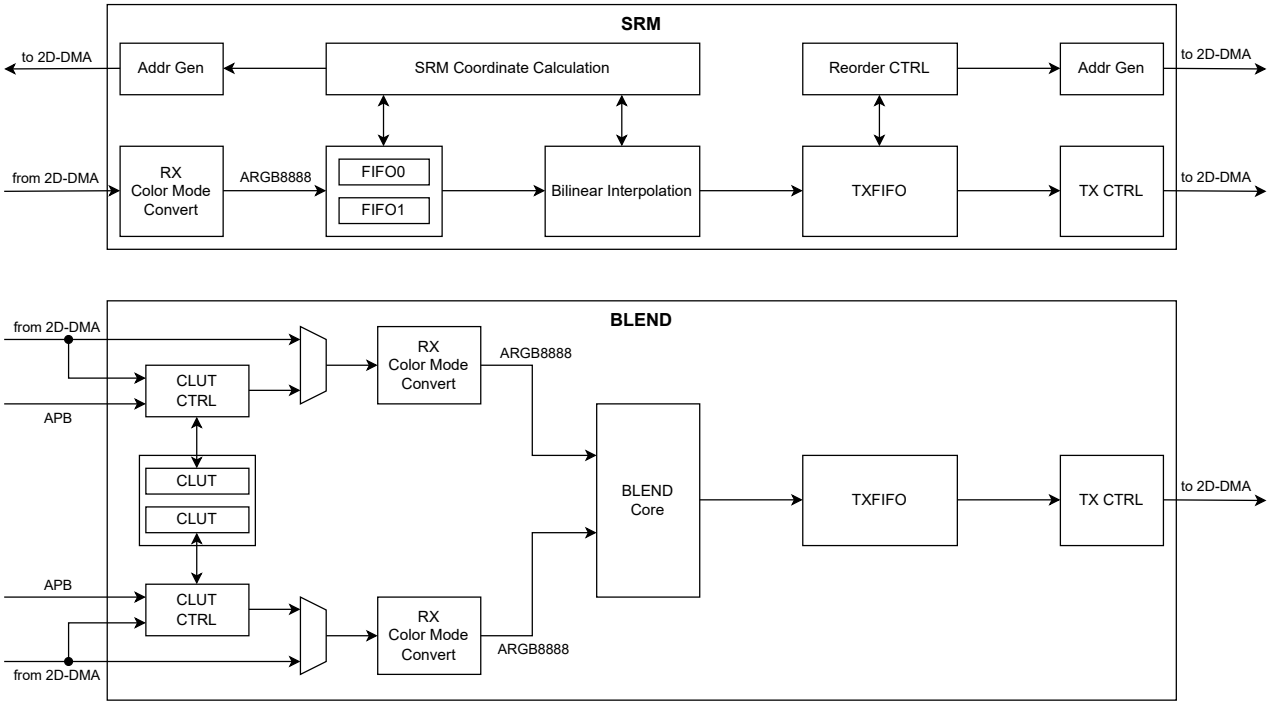

Figure 39.4-1. PPA Architecture

For SRM, SRM Coordinate Calculation scans coordinates of the output pixel blocks and calculates coordinates of the corresponding input pixel blocks. Addr Gen calculates the address according to the input pixel block coordinates and sends them to 2D-DMA. After that, the PPA receives the pixel block data from 2D-DMA, converts it into ARGB8888 format according to the register configuration, and stores it into the RX FIFO (a ping-pong FIFO composed of two SRAMs, each of which can store the whole pixel block). When a complete

pixel block is cached, Bilinear Interpolation reads the input pixels from RX FIFO, interpolates them to get the output pixels, and outputs them to TX FIFO. Reorder CTRL then calculates the output pixel block coordinates and address according to the register configuration and sends them to 2D-DMA. At the same time, Reorder CTRL takes out the corresponding pixels from TX FIFO according to the output pixel block coordinates and sends them to 2D-DMA, which saves them to the corresponding address.

For BLEND, PPA also receives data from 2D-DMA and converts it to ARGB8888 format based on the input data type. Yet the converted pixels will be processed directly by the BLEND Core algorithm module, enter the TX FIFO, and ultimately output to the system memory through 2D-DMA. Unlike SRM, BLEND does not need to calculate the address itself as it is completely controlled by 2D-DMA through a linked list.

39.5 Functional Description

39.5.1 PPA Color Space

PPA supports both true color and pseudo color. True color refers to a color representation in which each pixel in a color image consists of three primary color components: R (red), G (green), and B (blue). Each of these components directly determines the intensity of the corresponding primary color on the display device. The true color formats supported by PPA include ARGB8888, RGB888, and RGB565.

Pseudo color refers to a color representation in which the color of each pixel in a color image is not directly determined by the numerical values of the primary color components. Instead, the pixel value serves as an entry into a Color Look-Up Table (CLUT) to retrieve the corresponding A, R, G, and B values. PPA supports CLUT entry addresses with 8-bit or 4-bit width.

In addition, SRM supports the YUV422, YUV420, and GRAY data formats. The storage order of supported color formats in memory is shown in Table 39.5-1. The input YUV422 storage order can be set using the SRM or BLEND YUV422_BYTE_ORDER register; the output, however, is always stored with YUV422_BYTE_ORDER = 1.

Table 39.5-1. Pixel Storage Order

Color Format	Start Addr + 3	Start Addr + 2	Start Addr + 1	Start Addr + 0
ARGB8888	A0[7:0]	R0[7:0]	G0[7:0]	B0[7:0]
RGB888	B1[7:0]	R0[7:0]	G0[7:0]	B0[7:0]
	G2[7:0]	B2[7:0]	R1[7:0]	G1[7:0]
	R3[7:0]	G3[7:0]	B3[7:0]	R2[7:0]
RGB565	R1[4:0]G1[5:3]	G1[2:0]B1[4:0]	R0[4:0]G0[5:3]	G0[2:0]B0[4:0]
L8	L3[7:0]	L2[7:0]	L1[7:0]	L0[7:0]

A8	A3[7:0]	A2[7:0]	A1[7:0]	A0[7:0]
A4	A7[3:0]A6[3:0]	A5[3:0]A4[3:0]	A3[3:0]A2[3:0]	A1[3:0]A0[3:0]
YUV422 YUV422_BYTE_ORDER=0	Y1[7:0]	V1[7:0]	Y0[7:0]	U0[7:0]

Continued on the next page...

Table 39.5-1 – ...Continued from the previous page

Color Format	Start Addr + 3	Start Addr + 2	Start Addr + 1	Start Addr + 0
YUV422 YUV422_BYTE_ORDER=1	Y1[7:0]	U1[7:0]	Y0[7:0]	V0[7:0]
YUV422 YUV422_BYTE_ORDER=2	v1[7:0]	y1[7:0]	U0[7:0]	Y0[7:0]
YUV422 YUV422_BYTE_ORDER=3	U1[7:0]	Y1[7:0]	V0[7:0]	Y0[7:0]
YUV420 Odd rows such as 1, 3, 5...	U2[7:0]	Y1[7:0]	Y0[7:0]	U0[7:0]
	Y4[7:0]	U4[7:0]	Y3[7:0]	Y2[7:0]
	Y7[7:0]	Y6[7:0]	U6[7:0]	Y5[7:0]
YUV420 Even rows such as 2, 4, 6...	V2[7:0]	Y1[7:0]	Y0[7:0]	V0[7:0]
	Y4[7:0]	V4[7:0]	Y3[7:0]	Y2[7:0]
	Y7[7:0]	Y6[7:0]	V6[7:0]	Y5[7:0]
GRAY	P3[7:0]	P2[7:0]	P1[7:0]	P0[7:0]

39.5.1.1 SRM Color Space

SRM supports ARGB8888, RGB888, RGB565, and YUV422, YUV420, and GRAY formats for both input and output. The input format is configured by PPA_SRM_RX_CM, while the output format is configured by PPA_SRM_TX_CM. The SRM input pixel processing steps are shown in Figure 39.5-1.

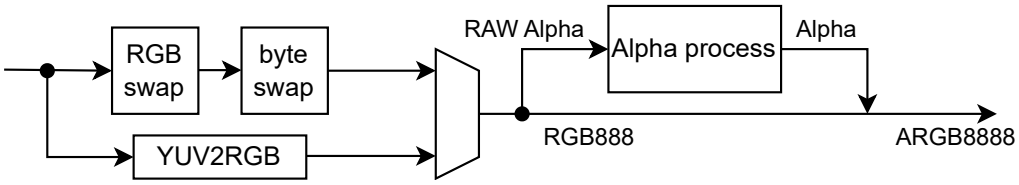

Figure 39.5-1. PPA SRM Input Pixel Processing

SRM supports RGB and byte swapping for ARGB8888, RGB888, and RGB565 input formats. The specific configurations are as follows:

- Set PPA_SRM_RX_RGB_SWAP_EN to 1 to reverse RGB to BGR and ARGB to BGRA.
- Set PPA_SRM_RX_BYTE_SWAP_EN to 1 to reverse bytes 0, 1 and 2, 3 respectively, i.e., {0, 1, 2, 3} will be reverted to {1, 0, 3, 2}. RGB888 would not be affected by this configuration as it only has three bytes per pixel.

SRM uses ARGB8888 when processing images internally. When the input lacks an Alpha channel, the default Alpha channel value for the image is set to 255. The Alpha channel can be further configured using the PPA_SRM_FIX_ALPHA_REG register, as shown in Figure 39.5-2. For specific configuration effects, please refer to Table 39.5-2.

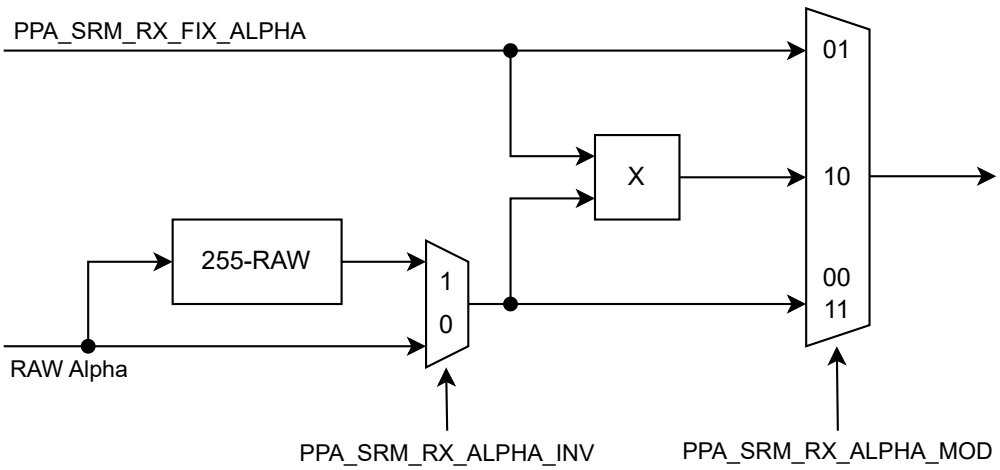

Figure 39.5-2. PPA SRM Alpha Configuration Logic

Table 39.5-2. PPA SRM Alpha Configuration

PPA_SRM_RX_ALPHA_INV	PPA_SRM_RX_ALPHA_MOD	Output
0	00/11	Original Alpha value
	01	The configuration value of PPA_SRM_RX_FIX_ALPHA
	10	The high 8 bits of the value obtained by multiplying the original Alpha value with PPA_SRM_RX_FIX_ALPHA
1	00/11	The value obtained by subtracting the original Alpha value from 255
	01	The configuration value of PPA_SRM_RX_FIX_ALPHA
	10	The high 8 bits of the value obtained by multiplying the result of subtracting the original Alpha value from 255 by PPA_SRM_RX_FIX_ALPHA

Note that when the input or output format is YUV, further configuration of YUV to RGB color conversion is required.

When the input format is YUV420, the input YUV data range needs to be configured as full-range or limit-range via the PPA_YUV_RX_RANGE field, and the protocol used for YUV to RGB conversion needs to be configured as BT601 or BT709 via the PPA_YUV2RGB_PROTOCAL field. The conversion formulas are as follows:

- YUV_{full} to YUV_{limit}
  - $Y_{limit} = \frac{220}{256} Y_{full} + 16$
  - $U_{limit} = \frac{225}{256} U_{full} + 16$
  - $V_{limit} = \frac{225}{256} V_{full} + 16$
- YUV_{limit} to RGB in BT601
  - $R = \frac{298}{256} Y_{limit} + \frac{409}{256} V_{limit} - \frac{56906}{256}$
  - $G = \frac{298}{256} Y_{limit} - \frac{100}{256} U_{limit} - \frac{208}{256} V_{limit} + \frac{34707}{256}$
  - $B = \frac{298}{256} Y_{limit} + \frac{516}{256} U_{limit} - \frac{70836}{256}$

- YUV_{limit} to RGB in BT709
  - $R = \frac{298}{256}Y_{limit} + \frac{459}{256}V_{limit} - \frac{63367}{256}$
  - $G = \frac{298}{256}Y_{limit} - \frac{55}{256}U_{limit} - \frac{136}{256}V_{limit} + \frac{19681}{256}$
  - $B = \frac{298}{256}Y_{limit} + \frac{541}{256}U_{limit} - \frac{73918}{256}$

When the output format is YUV420, the output YUV data range needs to be configured as full-range or limit-range via the PPA_YUV_TX_RANGE field, and the protocol used for YUV to RGB conversion needs to be configured as BT601 or BT709 via the PPA_RGB2YUV_PROTOCAL field. The conversion formulas are as follows:

- YUV_{limit} to YUV_{full}
  - $Y_{full} = \frac{298}{256}Y_{limit} + \frac{4768}{256}$
  - $U_{full} = \frac{291}{256}U_{limit} + \frac{4550}{256}$
  - $V_{full} = \frac{291}{256}V_{limit} + \frac{4550}{256}$
- RGB to YUV_{limit} in BT601
  - $Y_{limit} = \frac{4096}{256} + \frac{66}{256}R + \frac{129}{256}G + \frac{25}{256}B$
  - $U_{limit} = \frac{32768}{256} - \frac{38}{256}R - \frac{74}{256}G + \frac{112}{256}B$
  - $V_{limit} = \frac{32768}{256} + \frac{112}{256}R - \frac{94}{256}G - \frac{18}{256}B$
- RGB to YUV_{limit} in BT709
  - $Y_{limit} = \frac{4096}{256} + \frac{47}{256}R + \frac{157}{256}G + \frac{16}{256}B$
  - $U_{limit} = \frac{32768}{256} - \frac{26}{256}R - \frac{86}{256}G + \frac{112}{256}B$
  - $V_{limit} = \frac{32768}{256} + \frac{112}{256}R - \frac{102}{256}G - \frac{10}{256}B$

39.5.1.2 BLEND Color Space

BLEND supports ARGB8888, RGB888, RGB565, L4, L8, A4, and A8 foreground input formats, and ARGB8888, RGB888, RGB565, YUV422, YUV420, GRAY, L4, L8 background input formats. The input color format of the foreground and background layers can be configured respectively via the PPA_BLEND0/1_RX_CM field. Among the above input formats, A4 and A8 only support the foreground layer, and when the input format is L4 or A4, the size of the image block, hb, and the offset in the image, x, must be an even number. For the output format, BLEND supports ARGB8888, RGB888, and RGB565, which can be configured via the PPA_BLEND_TX_CM field.

BLEND's RGB conversion, byte conversion, and alpha channel configuration are consistent with SRM input. Additionally, when the foreground layer data format is A4 or A8, the input data will be Alpha channel values. In this case, if PPA_BLEND_BYPASS is set as 1, the foreground layer's input Alpha value replaces the background layer's Alpha channel and output. If set as 0, it will be a normal BLEND operation, and the foreground layer's RGB values will be specified by PPA_BLEND_RGB_REG.

When the input data format is L4 or L8, it requires to first initialize the CLUT for BLEND. BLEND has two CLUTs with a depth of 256 and a width of 32. There are two initialization modes: FIFO and MEM.

- Write 0 to PPA_APB_FIFO_MASK to enter the FIFO mode.

In the FIFO mode, access to CLUT is achieved by reading/writing PPA_RDWR_WORD_BLENDx_CLUT, where 0 corresponds to the background channel CLUT and 1 corresponds to the foreground channel CLUT.
Each time this register is read/written, the corresponding read/write address is automatically incremented by 1. The read/write address can be reset by writing 1 and then 0 to PPA_BLENDx_CLUT_MEM_RST. The read address can be reset by writing 1 then 0 to PPA_BLENDx_CLUT_MEM_RDADDR_RST.

- Write 1 to PPA_APB_FIFO_MASK to enter the MEM mode.
  In the MEM mode, CLUT can be directly accessed through addresses. The CLUT addresses in the PPA's bus address range are as shown in Table 39.5-3.

Table 39.5-3. BLEND CLUT Address

addr[11:10]	addr[9:2]	addr[1:0]
01: Select BLEND0 CLUT 10: Select BLEND1 CLUT	CLUT actual address, 0 ~ 255	00

39.5.2 PPA 2D-DMA Linked List Configuration

PPA exchanges data with the system memory via 2D-DMA. For both SRM and BLEND, it is necessary to configure the 2D-DMA linked list information for the required image block operations in one go. The 2D-DMA linked list is shown in Figure 39.5-3. For detailed information, please refer to 8 *2D-DMA Controller (2D-DMA)*.

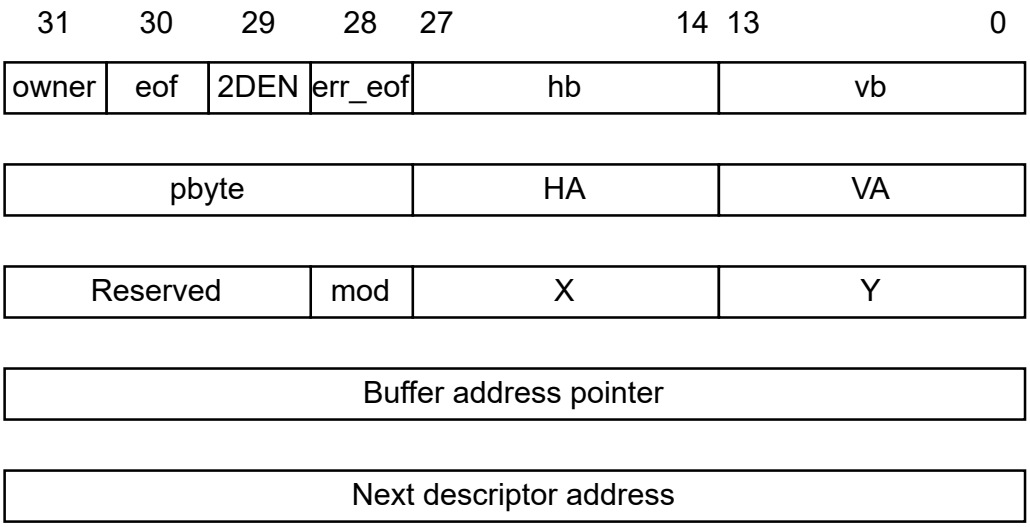

Figure 39.5-3. 2D-DMA Linked List

The corresponding linked list parameters of PPA are shown in Table 39.5-4.

Table 39.5-4. PPA Linked List Configuration

Field	Configuration
owner	1
eof	1
2DEN	1
err_eof	0
hb	Horizontal size of the image block. Must be even if the input or output data format is YUV420
vb	Vertical size of the image block. Must be even if the input or output data format is YUV420
pbyte	ARGB8888: 5 (4 byte/pixel) RGB888: 4 (3 byte/pixel) RGB565: 3 (2 byte/pixel) YUV420: 2 (1.5 byte/pixel) A8/L8: 1 (1 byte/pixel) A4/L4: 0 (0.5 byte/pixel)
HA	Horizontal size of the entire image. Must be even if the input or output data format is YUV420
VA	Vertical size of the entire image. Must be even if the input or output data format is YUV420
mod	0
X	Horizontal offset of the image block within the image (offset starts from 0). Must be even if the input or output data is YUV420
Y	Vertical offset of the image block within the image (offset starts from 0). Must be even if the input or output data is YUV420
Buffer address pointer	Starting address of the image
Next descriptor address	N/A

39.5.2.1 SRM Special Configuration

Once the 2D-DMA linked lists for input and output image blocks are configured, SRM needs to select the required pixel blocks from the input image block memory space and process them in units of pixel blocks. The processed pixel blocks are then stored in the corresponding memory space of the output image block. Throughout this process, the starting address of each pixel block needs to be controlled by SRM. To realize this functionality, write 1 to the DMA2D_IN/OUT_DSCR_PORT_EN_CHx field of the corresponding channel of the 2D-DMA to enable the descriptor interface (also called DSCR-PORT in 2D-DMA), allowing PPA to control

the starting address of the next pixel block in real-time.

For the data input, SRM must receive a complete pixel block each time. When the pixel block selection reaches the boundary of the image block, 2D-DMA needs to automatically pad the pixel block beyond the boundary. This can be achieved by configuring the DMA2D_OUT_DSCR_PORT_BLK_V/H_CHx field of the corresponding channel of 2D-DMA to the pixel block size. The required values depend on the image format, as shown in Table 39.5-5 below.

Table 39.5-5. Automatic Padding Block Size Configuration

PPA_SRM_BK_SIZE_SEL	Pixel Format	DMA2D_OUT_DSCR_PORT_BLK_H_CHx	DMA2D_OUT_DSCR_PORT_BLK_V_CHx
0	ARGB8888 RGB888 RGB565 GRAY	34	34
0	YUV422	36	34
0	YUV420	36	36
1	ARGB8888 RGB888 RGB565 GRAY	18	18
1	YUV422	20	18
1	YUV420	20	20

Note:
For optimal memory-access performance, use the default setting PPA_SRM_BK_SIZE_SEL = 0.

39.5.3 Scaling - Rotation - Mirroring (SRM)

39.5.3.1 Basic Functionality

SRM supports scaling, rotation, and mirroring. It first scales the image based on the origin point, then rotates it around the center point (X_{middle}, Y_{middle}), and finally mirrors it horizontally and vertically based on the center point (X_{target}, Y_{target}), as shown in Figure 39.5-4. Scaling, rotation, and mirroring parameters are all configured through registers:

- PPA_SRM_SCAL_X_INT: Integer part of the horizontal scaling factor
- PPA_SRM_SCAL_X_FRAG: Fractional part of the horizontal scaling factor
- PPA_SRM_SCAL_Y_INT: Integer part of the vertical scaling factor
- PPA_SRM_SCAL_Y_FRAG: Fractional part of the vertical scaling factor
- PPA_SRM_ROTATE_ANGLE: Counterclockwise rotation angle
- PPA_SRM_MIRROR_X: Enable horizontal mirroring
- PPA_SRM_MIRROR_Y: Enable vertical mirroring

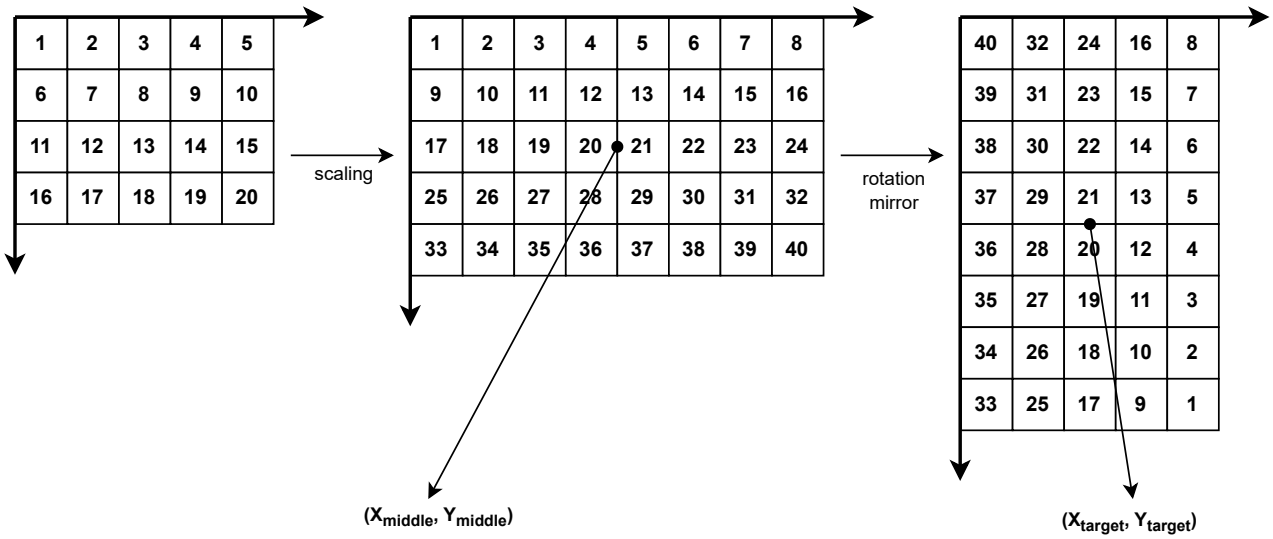

Figure 39.5-4. SRM Procedure

39.5.3.2 Pixel Block Rearrangement

When the output pixel block is small, initiating a 2D-DMA transfer for each pixel block would result in low bus bandwidth utilization. To improve bus bandwidth utilization, SRM can cache and concatenate output pixel blocks into a larger pixel block before outputting them all at once. This feature is enabled by default and can be disabled by setting PPA_SRM_MACRO_BK_RO_BYPASS to 1.

Once pixel block rearrangement is enabled, under certain conditions, the output pixel blocks will be automatically rearranged and concatenated, as specified in Table 39.5-6.

- For the output pixel block in ARGB8888/RGB888 format, if its vertical height is less than or equal to 32, and the horizontal width is less than or equal to 16, pixel block rearrangement will be automatically enabled.
- For the output pixel block in RGB565 format, if its vertical height is less than or equal to 32, and the horizontal width is less than or equal to 32, pixel block rearrangement will be automatically enabled.
- For the output pixel block in YUV420 format, if its vertical height is less than or equal to 32, and horizontal width is less than or equal to 32, pixel block rearrangement will be automatically enabled.

Table 39.5-6. Number of Pixel Block Rearrangements in SRM Output

ARGB8888/RGB888		RGB565		YUV420	
Horizontal Size	Rearrangemer Number	Horizontal Size	Rearrangemer Number	Horizontal Size (Even)	Rearrangement Number
1	32	1	64	2	32
2	16	2	32	4	16
3	10	3	20	6	10
4	8	4	16	8	8
5	6	5	12	10	6
6	5	6	10	12	5
7	4	7	9	14	4

Continued on the next page...

Table 39.5-6 – ...Continued from the previous page

ARGB8888/RGB888		RGB565		YUV420	
Horizontal Size	Rearrangemer Number	Horizontal Size	Rearrangemer Number	Horizontal Size (Even)	Rearrangement Number
8	4	8	8	16	4
9	3	9	7	18	3
10	3	10	6	20-32	2
11	2	11	5		
12	2	12	5		
13	2	13	4		
14	2	14	4		
15	2	15	4		
16	2	16	4		
		17	3		
		18	3		
		19-32	2		

39.5.4 Layer Blending (BLEND)

39.5.4.1 Basic Functionality

BLEND combines two image blocks of the same size using the Alpha channel and then outputs the result. The blending formula is as follows, where Ab is the Alpha channel of the background layer, Af is the Alpha channel of the foreground layer, Cb corresponds to the R, G, and B components of the background layer, and Cf corresponds to the R, G, B components of the foreground layer:

- $Aout = Ab + Af - Ab * Af$
- $Cout = (Cb * Ab * (1 - Af) + Cf * Af)/(Ab + Af - Ab * Af)$

Additionally, BLEND supports color-keying based on pixel color. By configuring color ranges via PPA_CK_FG/BG_HIGH/LOW_REG, BLEND allows for image segmentation into four distinct regions, each subjected to different operations:

- When the foreground pixel falls within the color-key range and the background pixel falls outside the color-key range, output the background pixel.
- When the background pixel falls within the color-key range and the foreground pixel falls outside the color-key range, the output depends on the value of PPA_COLORKEY_FG_BG_REVERSE. If 0, output the background pixel; if 1, output the foreground pixel.
- When both the background and foreground pixels fall within the color-key range, the output is set to the color defined by PPA_COLORKEY_DEFAULT_R/G/B.
- When neither the background nor foreground pixels fall within the color-key range, output follows the normal Alpha Blending process.

When PPA_BLEND_BYPASS is set to 1, BLEND directly outputs the background layer data. If the foreground input data type is A4/A8 at this time, the foreground input data will replace the background input data's Alpha channel and then be output.

39.5.4.2 Filled Image Output

BLEND also supports filled image output. When this feature is enabled, only the output side of BLEND works, continuously outputting the filled image. The size and data of the filled image can be configured via PPA_BLEND_TX_SIZE_REG and PPA_BLEND_TX_FIX_PIXEL.

39.6 Interrupts

ESP32-P4's PPA can generate the following interrupt signal that will be sent to the Interrupt Matrix.

- PPA_INTR

The following interrupt sources can generate PPA_INTR interrupt signal:

- PPA_SRM_PARAM_CFG_ERR_INT: Triggered when invalid parameters are configured in the SRM mode. You can acquire the specific error type through PPA_SRM_PARAM_ERR_ST_REG, as shown in Table 39.6-1.
- PPA_BLEND_PARAM_CFG_ERR_INT: Triggered when invalid parameters are configured in the BLEND mode. You can acquire the specific error type through PPA_BLEND_ST_REG, as shown in Table 39.6-2.
- PPA_SRM_EOF_INT: Triggered when SRM workflow reaches EOF.
- PPA_BLEND_EOF_INT: Triggered when BLEND workflow reaches EOF.

Table 39.6-1. SRM Parameter Error Types

Error Type	Details
PPA_TX_DSCR_VB_ERR_ST	The sum of the vertical size of the output image block from SRM and the vertical offset Y specified in the output descriptor exceeds the total vertical size of the image configured in the output descriptor (VA)
PPA_TX_DSCR_HB_ERR_ST	The sum of the horizontal size of the output image block from SRM and the vertical offset X specified in the output descriptor exceeds the total horizontal size of the image configured in the output descriptor (HA)
PPA_Y_RX_SCAL_EQUAL_0_ERR_ST	The vertical scaling factor for the input image block in SRM is set to 0
PPA_RX_DSCR_VB_ERR_ST	The sum of the vertical size VB and the vertical offset Y in the SRM input descriptor exceeds the overall vertical size VA in the output descriptor
PPA_YDST_LEN_TOO_SAMLL_ERR_ST	The vertical size of the image block after SRM scaling is 0. For example, if the vertical size of the image block is 14 and the vertical scaling factor is 1/16 without rotation, the scaled vertical size of the image block becomes 0
PPA_YDST_LEN_TOO_LARGE_ERR_ST	The vertical size of the image block after SRM scaling exceeds 8191
PPA_X_RX_SCAL_EQUAL_0_ERR_ST	The horizontal scaling factor for the input image block in SRM is 0

Continued on the next page...

Table 39.6-1 – ...Continued from the previous page

Error Type	Details
PPA_RX_DSCR_HB_ERR_ST	The sum of the horizontal size HB of the input image block configured in the SRM input descriptor and the horizontal offset X exceeds the entire image's horizontal size HA configured in the output descriptor
PPA_XDST_LEN_TOO_SAMLL_ERR_ST	The horizontal size of the image block after SRM scaling is 0
PPA_XDST_LEN_TOO_LARGE_ERR_ST	The horizontal size of the image block after SRM scaling exceeds 8191
PPA_X_YUV420_RX_SCALE_ERR_ST	The input descriptor parameters HA/hb/X happen to be odd numbers when the SRM input format is YUV420
PPA_Y_YUV420_RX_SCALE_ERR_ST	The input descriptor parameters VA/vb/Y happen to be odd numbers when the SRM input format is YUV420
PPA_X_YUV420_TX_SCALE_ERR_ST	The output descriptor parameters HA/hb/X happen to be odd numbers when the SRM output format is YUV420
PPA_Y_YUV420_TX_SCALE_ERR_ST	The output descriptor parameters VA/vb/Y happen to be odd numbers when the SRM output format is YUV420

Table 39.6-2. BLEND Parameter Error Types

Error Type	Details
PPA_BLEND_SIZE_DIFF_ST	The BLEND foreground and background sizes do not match
PPA_BLEND_YUV_X_SCALE_ERR_ST	The BLEND background image format is YUV422 or YUV420, the horizontal size is an odd number
PPA_BLEND_YUV_Y_SCALE_ERR_ST	The BLEND background image format is YUV420, the vertical size is an odd number

39.7 Programming Procedures

39.7.1 PPA Clock Reset Configuration

1. Enable the clock of the PPA and 2D-DMA modules:
   - Write 1 to HP_SYS_CLKRST_PPA_SYS_CLK_EN to enable the PPA clock
   - Write 1 to HP_SYS_CLKRST_DMA2D_SYS_CLK_EN to enable the 2D-DMA clock
2. Reset the PPA and 2D-DMA modules:
   - Write 1 and then 0 to HP_SYS_CLKRST_RST_EN_PPA reset PPA
   - Write 1 and then 0 to HP_SYS_CLKRST_RST_EN_DMA2D reset 2D-DMA

39.7.2 SRM Configuration

1. Refer to Section 39.7.1 to enable and reset PPA and 2D-DMA.
2. Configure the inlink and outlink of 2D-DMA. For detailed parameters, please refer to Table 39.5-4.

3. Select the input and output channels of 2D-DMA:
   - Write 0x1 to DMA2D_OUT_PERI_SEL_CHx to allocate one 2D-DMA output channel to the PPA SRM input
   - Write 0x1 to DMA2D_IN_PERI_SEL_CHx to allocate one 2D-DMA input channel to the PPA SRM output
4. Enable descriptor interface for 2D-DMA channels used by PPA:
   - Write 1 to DMA2D_OUT_DSCR_PORT_EN_CHx to enable descriptor interface
   - Write 1 to DMA2D_IN_DSCR_PORT_EN_CHx to enable descriptor interface
5. Configure the descriptor interface completion parameters of 2D-DMA:
   - Configure the horizontal completion parameters via DMA2D_OUT_DSCR_PORT_BLK_H_CHx. See Table 39.5-5 for details
   - Configure the vertical completion parameters via DMA2D_OUT_DSCR_PORT_BLK_V_CHx. See Table 39.5-5 for details
6. Enable the input and output channels of 2D-DMA:
   - Write 1 to DMA2D_OUTLINK_START_CHx to enable the output channel of 2D-DMA
   - Write 1 to DMA2D_INLINK_START_CHx to enable the input channel of 2D-DMA
7. Configure SRM parameters:
   - Configure the size of image blocks to be processed via PPA_SRM_BK_SIZE_SEL
   - Configure SRM input data format via PPA_SRM_RX_CM
   - Configure SRM output data format via PPA_SRM_TX_CM
   - Configure the integer part of the horizontal scaling factor via PPA_SRM_SCAL_X_INT
   - Configure the fractional part of the horizontal scaling factor via PPA_SRM_SCAL_X_FRAG
   - Configure the integer part of the vertical scaling factor via PPA_SRM_SCAL_Y_INT
   - Configure the fractional part of the vertical scaling factor via PPA_SRM_SCAL_Y_FRAG
   - Configure the counterclockwise rotation angle via PPA_SRM_ROTATE_ANGLE
   - Enable horizontal mirroring via PPA_SRM_MIRROR_X
   - Enable vertical mirroring via PPA_SRM_MIRROR_Y
8. Write 1 to PPA_SCAL_ROTATE_START to start the SRM workflow.

39.7.3 BLEND CLUT Configuration

1. In the FIFO mode:
   - Write 0 to PPA_APB_FIFO_MASK to enter the FIFO mode
   - Write data to PPA_RDWR_WORD_BLEND0_CLUT to initialize the background layer's CLUT
   - Write data to PPA_RDWR_WORD_BLEND1_CLUT to initialize the foreground layer's CLUT
2. In the MEM mode:
   - Write 1 to PPA_APB_FIFO_MASK to enter the MEM mode

- Initialize the CLUT by writing data directly to the corresponding address, referring to Table 39.5-3

39.7.4 BLEND Configuration

1. Refer to Section 39.7.1 to enable and reset PPA and 2D-DMA.

2. Configure the input and output link lists of 2D-DMA. For detailed parameters, please refer to Table 39.5-4.

3. Select the input and output channels of 2D-DMA:

   - Write 0x2 to DMA2D_OUT_PERI_SEL_CHx to allocate one 2D-DMA output channel to PPA BLEND for background layer input
   - Write 0x3 to DMA2D_OUT_PERI_SEL_CHx to allocate one 2D-DMA output channel to PPA BLEND for foreground layer input
   - Write 0x2 to DMA2D_IN_PERI_SEL_CHx to allocate one 2D-DMA input channel to PPA BLEND for output

4. Enable the input and output channels for 2D-DMA. The x in the registers refers to the two channels allocated to BLEND foreground and background respectively:

   - Write 1 to DMA2D_OUTLINK_START_CHx to enable the output channel of 2D-DMA
   - Write 1 to DMA2D_INLINK_START_CHx to enable the input channel of 2D-DMA

5. Configure BLEND parameter:

   - Configure the data type for the background layer input of BLEND via PPA_BLEND0_RX_CM. If the format is L4/L8, initialize the CLUT first as described in 39.7.3
   - Configure the data type for the background layer input of BLEND via PPA_BLEND1_RX_CM. If the format is L4/L8, initialize the CLUT first as described in 39.7.3
   - Configure the output data format of BLEND via PPA_BLEND_TX_CM
   - Configure the upper and lower limits of the color-key for the background layer via PPA_CK_BG_HIGH_REG and PPA_CK_BG_LOW_REG
   - Configure the upper and lower limits of the color-key for the foreground layer via PPA_CK_FG_HIGH_REG and PPA_CK_FG_LOW_REG
   - Configure the default value and behavior for the color-key via PPA_CK_DEFAULT_REG
   - Write 1 to PPA_BLEND_EN to enable BLEND

6. Write 1 to PPA_BLEND_TRANS_MODE_UPDATE to start BLEND workflow

39.7.5 BLEND Image Filling Configuration

1. Refer to Section 39.7.1 to enable and reset PPA and 2D-DMA.

2. Configure the input link lists of 2D-DMA (output link lists of PPA BLEND). For detailed parameters, please refer to Table 39.5-4.

3. Write 0x2 to DMA2D_IN_PERI_SEL_CHx to allocate one 2D-DMA input channel to PPA BLEND output.

4. Write 1 to DMA2D_INLINK_START_CHx to enable the output channel of 2D-DMA.

5. Configure BLEND parameters:
   - Configure the output data format of BLEND via PPA_BLEND_TX_CM
   - Write 1 to PPA_BLEND_FIX_PIXEL_FILL_EN to enable image filling
   - Configure the pixel value for image filling via PPA_BLEND_TX_FIX_PIXEL
   - Configure the filled image size via PPA_BLEND_HB and PPA_BLEND_VB
6. Write 1 to PPA_BLEND_TRANS_MODE_UPDATE to start BLEND workflow.

39.7.6 Error Handling

- Refer to Section 39.7.1 to reset the whole PPA, and configure again.
- Or write 1 and then 0 to reset SRM and BLEND via PPA_SCAL_ROTATE_RST, PPA_BLEND_RST, and configure again.

Note:

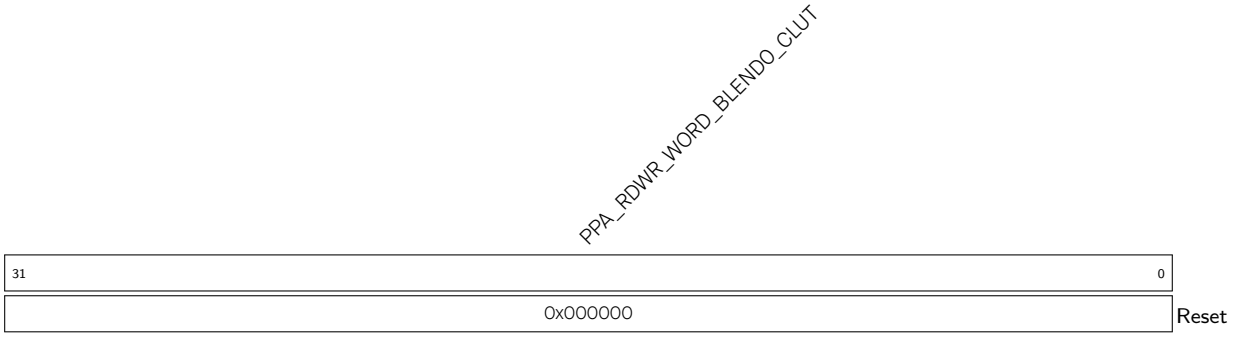
- The 2D-DMA configurations mentioned in this chapter involve only key steps. For detailed procedures, please refer to 8 *2D-DMA Controller (2D-DMA)*.
- In this chapter, DMA2D_OUT corresponds to the PPA input direction, and DMA2D_IN corresponds to the PPA output direction.

39.8 Register Summary

The addresses in this section are relative to the Pixel-Processing Accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Configuration Registers			
PPA_BLEND0_CLUT_DATA_REG	CLUT SRAM data read/write register of BLEND background layer	0x0000	R/W
PPA_BLEND1_CLUT_DATA_REG	CLUT SRAM data read/write register of BLEND foreground layer	0x0004	R/W
PPA_CLUT_CONF_REG	Configures BLEND CLUT	0x000C	R/W
PPA_SRM_COLOR_MODE_REG	Configures SRM color space	0x0020	R/W
PPA_BLEND_COLOR_MODE_REG	Configures BLEND color space	0x0024	R/W
PPA_SRM_BYTE_ORDER_REG	Configures SRM byte order	0x0028	R/W
PPA_BLEND_BYTE_ORDER_REG	Configures BLEND byte order	0x002C	R/W
PPA_BLEND_TRANS_MODE_REG	Configures the BLEND mode	0x0034	varies
PPA_SRM_FIX_ALPHA_REG	Configures SRM Alpha channel	0x0038	R/W
PPA_BLEND_TX_SIZE_REG	Configures BLEND image filling size	0x003C	R/W
PPA_BLEND_FIX_ALPHA_REG	Configures BLEND Alpha override	0x0040	R/W
PPA_BLEND_RGB_REG	Configures RGB color	0x0048	R/W
PPA_BLEND_FIX_PIXEL_REG	Configures BLEND image filling pixel	0x004C	R/W
PPA_CK_FG_LOW_REG	Configures the foreground color-key lower threshold of BLEND	0x0050	R/W
PPA_CK_FG_HIGH_REG	Configures the foreground color-key higher threshold of BLEND	0x0054	R/W
PPA_CK_BG_LOW_REG	Configures the background color-key lower threshold of BLEND	0x0058	R/W
PPA_CK_BG_HIGH_REG	Configures the background color-key higher threshold of BLEND	0x005C	R/W
PPA_CK_DEFAULT_REG	Configures the default color-key value of BLEND	0x0060	R/W
PPA_SRM_SCAL_ROTATE_REG	Configures the SRM mode	0x0064	varies
PPA_SRM_MEM_PD_REG	Configures SRM memory	0x0068	R/W
PPA_REG_CONF_REG	Enables register clock	0x006C	R/W
PPA_RGB2GRAY_REG	Configures the coefficient in RGB to GRAY conversion	0x0098	R/W
Interrupt Registers			
PPA_INT_RAW_REG	Raw status interrupt	0x0010	R/WTC/SS
PPA_INT_ST_REG	Masked interrupt	0x0014	RO
PPA_INT_ENA_REG	Interrupt enable bits	0x0018	R/W



Name	Description	Address	Access
PPA_INT_CLR_REG	Interrupt clear bits	0x001C	WT
Status Registers			
PPA_CLUT_CNT_REG	BLEND CLUT write counter register	0x0070	RO
PPA_BLEND_ST_REG	BLEND status register	0x0074	RO
PPA_SRM_PARAM_ERR_ST_REG	SRM configuration error status register	0x0078	RO
PPA_SRM_STATUS_REG	SRM FSM register	0x007C	RO
Debug Register			
PPA_DEBUG_CTRLO_REG	Debug register	0x0090	R/W
PPA_DEBUG_CTRL1_REG	Debug register	0x0094	R/W
Version Register

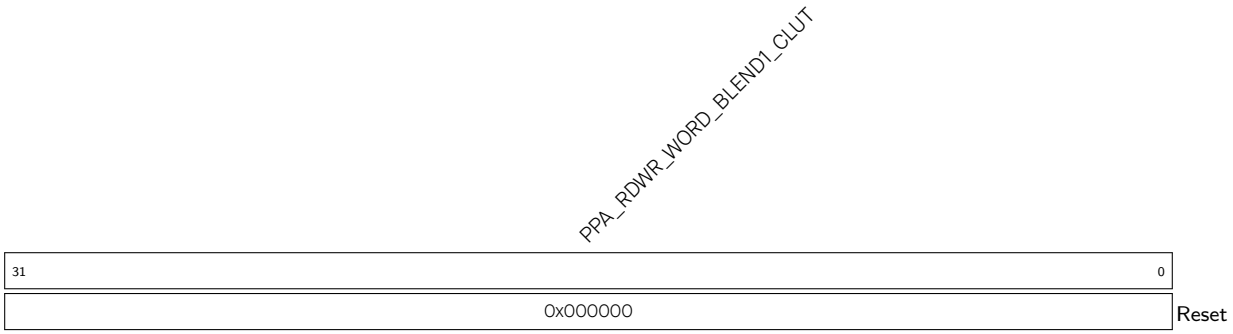
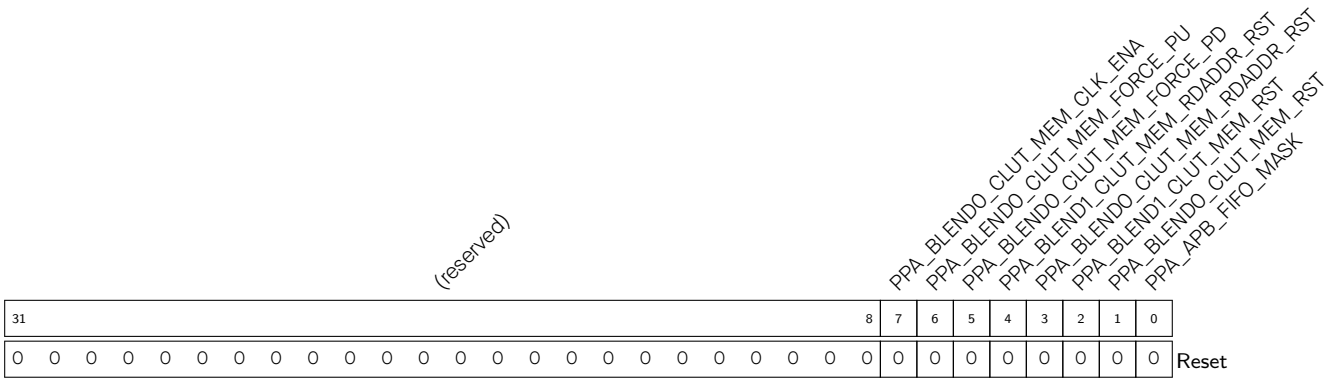
39.9 Registers

The addresses in this section are relative to the Pixel-Processing Accelerator base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 39.1. PPA_BLEND0_CLUT_DATA_REG (0x0000)



PPA_RDWR_WORD_BLEND0_CLUT Configures BLEND background layer CLUT access in FIFO mode. (R/W)

Register 39.2. PPA_BLEND1_CLUT_DATA_REG (0x0004)

PPA_RDWR_WORD_BLEND1_CLUT Configures BLEND foreground layer CLUT access in FIFO mode. (R/W)

Register 39.3. PPA_CLUT_CONF_REG (0x000C)

PPA_APB_FIFO_MASK Configures the access mode of BLEND CLUT

1'b0: Access CLUT in FIFO mode. For details, please refer to 39.5.1.2.

1'b1: Access CLUT in MEM mode. For details, please refer to 39.5.1.2.

(R/W)

PPA_BLEND0_CLUT_MEM_RST Configures whether to reset BLEND0 CLUT.

0: Release reset

1: Reset

(R/W)

PPA_BLEND1_CLUT_MEM_RST Configures whether to reset BLEND1 CLUT.

0: Release reset

1: Reset

(R/W)

PPA_BLEND0_CLUT_MEM_RDADDR_RST Configures whether to reset BLEND0 CLUT read address in FIFO mode.

0: Release reset

1: Reset

(R/W)

PPA_BLEND1_CLUT_MEM_RDADDR_RST Configures whether to reset BLEND1 CLUT read address in FIFO mode.

0: Release reset

1: Reset

(R/W)

PPA_BLEND0_CLUT_MEM_FORCE_PD Configures whether to enable the force power down of BLEND CLUT.

0: Disable

1: Enable

(R/W)

Continued on the next page...

Register 39.3. PPA_CLUT_CONF_REG (0x000C)

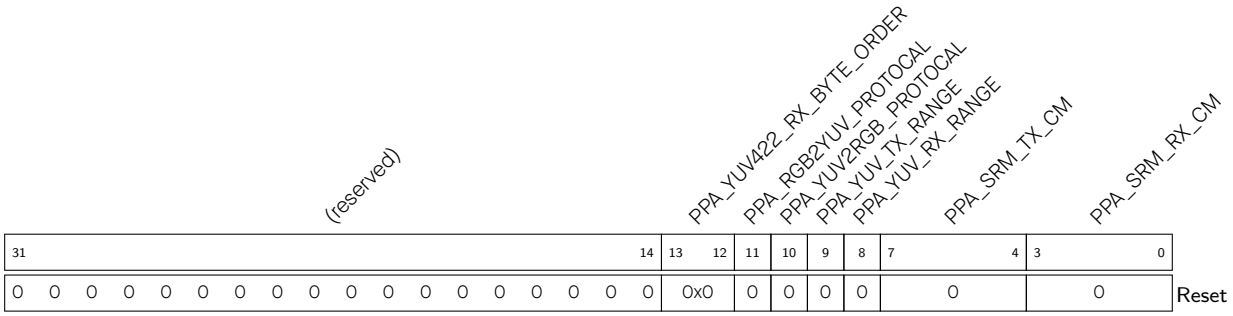
Continued from the previous page...

PPA_BLEND0_CLUT_MEM_FORCE_PU Configures whether to enable the force power up of BLEND CLUT.

0: Disable

1: Enable

(R/W)



PPA_BLEND0_CLUT_MEM_CLK_ENA Configures whether to enable the force clock on of BLEND CLUT.

0: Disable

1: Enable

(R/W)

Register 39.4. PPA_SRM_COLOR_MODE_REG (0x0020)

PPA_SRM_RX_CM Configures the input image color format for SRM.

0: ARGB8888

1: RGB888

2: RGB565

8: YUV420

Others: Reserved

(R/W)

PPA_SRM_TX_CM Configures the output image color format for SRM.

0: ARGB8888

1: RGB888

2: RGB565

8: YUV420

Others: Reserved

(R/W)

PPA_YUV_RX_RANGE Configures the YUV range when the SRM input format is YUV.

0: limit range

1: full range

(R/W)

PPA_YUV_TX_RANGE Configures the YUV range when the SRM output format is YUV.

0: limit range

1: full range

(R/W)

PPA_YUV2RGB_PROTOCAL Configures the protocol used for the SRM input direction YUV to RGB.

0: BT601

1: BT709

(R/W)

PPA_RGB2YUV_PROTOCAL Configures the protocol used for the SRM output direction RGB to YUV.

0: BT601

1: BT709

(R/W)

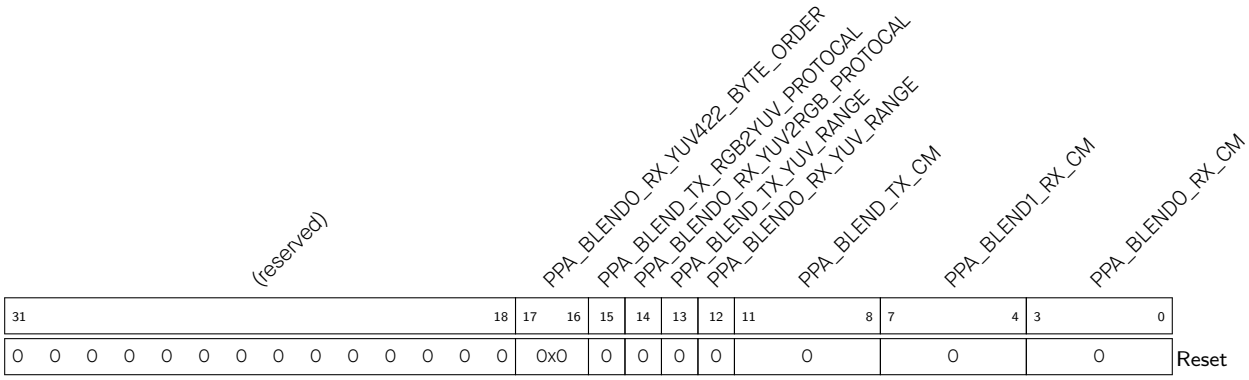
Continued on the next page...

Register 39.4. PPA_SRM_COLOR_MODE_REG (0x0020)

Continued from the previous page...

PPA_YUV422_RX_BYTE_ORDER Configures the byte order when the SRM input format is YUV422.

0: YVYU



1: YUYV

2: VYUY

3: UYVY

(R/W)

Register 39.5. PPA_BLEND_COLOR_MODE_REG (0x0024)

PPA_BLEND0_RX_CM Configures the input image color format for BLEND background layer.

0: ARGB8888
1: RGB888
2: RGB565
4: L8
5: L4
8: YUV420
9: YUV422
12: GRAY
Others: Reserved
(R/W)

PPA_BLEND1_RX_CM Configures the input image color format for BLEND foreground layer.

0: ARGB8888
1: RGB888
2: RGB565
4: L8
5: L4
6: A8
7: A4
Others: Reserved
(R/W)

PPA_BLEND_TX_CM Configures the output image color format of BLEND.

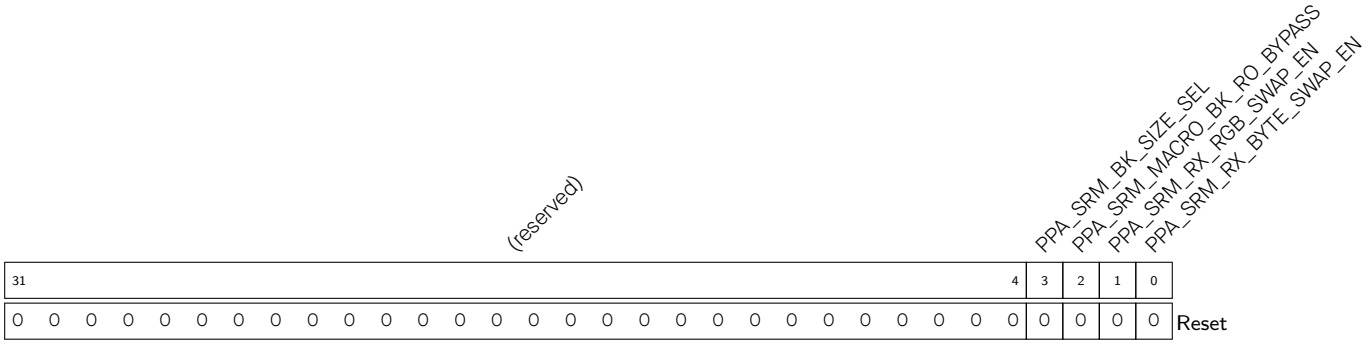
0: ARGB8888
1: RGB888
2: RGB565
8: YUV420
9: YUV422
12: GRAY
Others: Reserved
(R/W)

Continued on the next page...

Register 39.5. PPA_BLEND_COLOR_MODE_REG (0x0024)

Continued from the previous page...

PPA_BLEND0_RX_YUV_RANGE Configures the YUV range when the BLEND background input is YUV.
0: Limited range
1: Full range
(R/W)



PPA_BLEND_TX_YUV_RANGE Configures the YUV range when the BLEND output is YUV.
0: Limited range
1: Full range
(R/W)

PPA_BLEND0_RX_YUV2RGB_PROTOCAL Configures the YUV to RGB conversion protocol for the BLEND background input.
0: BT601
1: BT709
(R/W)

PPA_BLEND_TX_RGB2YUV_PROTOCAL Configures the YUV to RGB conversion protocol for the BLEND output.
0: BT601
1: BT709
(R/W)

PPA_BLEND0_RX_YUV422_BYTE_ORDER Configures the byte order when the BLEND background input is YUV422.
0: YVYU
1: YUYV
2: VYUY
3: UYVY
(R/W)

Register 39.6. PPA_SRM_BYTE_ORDER_REG (0x0028)

PPA_SRM_RX_BYTE_SWAP_EN Configures whether to swap the SRM valid data input in byte.

0: Not swap

1: Swap

(R/W)

PPA_SRM_RX_RGB_SWAP_EN Configures whether to swap the order of each channel when the SRM input is RGB or ARGB.

0: Not swap

1: Swap RGB to BGR, and ARGB to BGRA

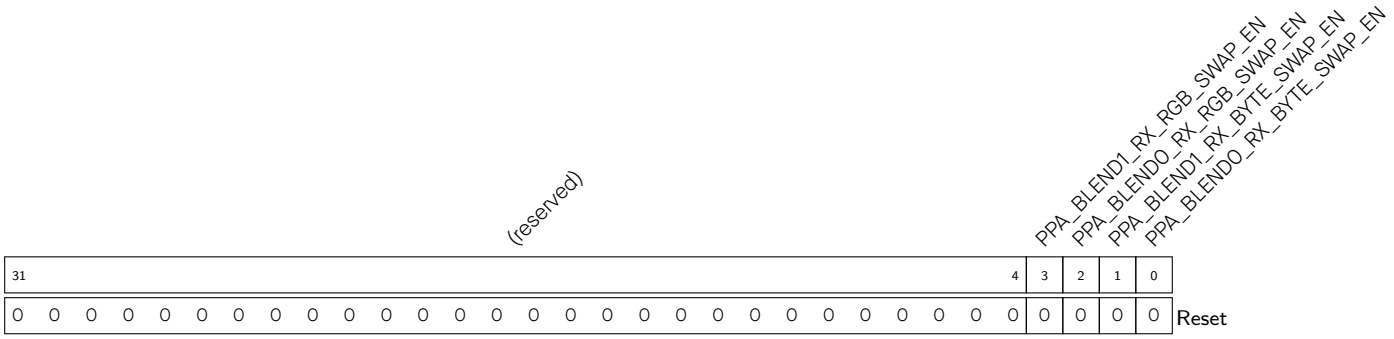
(R/W)

PPA_SRM_MACRO_BK_RO_BYPASS Configures whether to enable the pixel block order function

0: Enable and automatically calculate if the current block needs to be reordered

1: Disable

(R/W)



PPA_SRM_BK_SIZE_SEL Configures the size of SRM pixel blocks.

0: 32x32

1: 16x16

(R/W)

Register 39.7. PPA_BLEND_BYTE_ORDER_REG (0x002C)

PPA_BLEND0_RX_BYTE_SWAP_EN Configures whether to swap the BLEND background layer valid data input in byte.

0: Not swap

1: Swap

(R/W)

PPA_BLEND1_RX_BYTE_SWAP_EN Configures whether to swap the BLEND foreground layer valid data input in byte.

0: Not swap

1: Swap

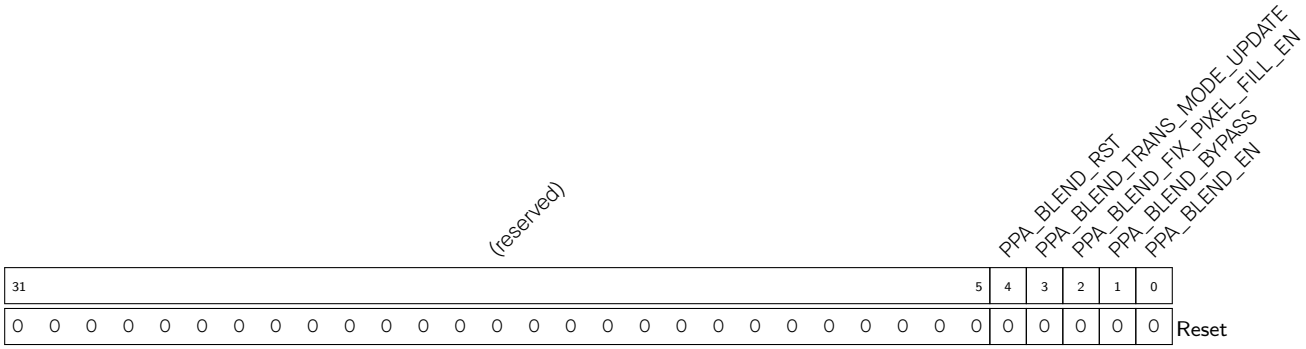
(R/W)

PPA_BLEND0_RX_RGB_SWAP_EN Configures whether to swap the order of each channel when the BLEND background layer input is RGB or ARGB.

0: Not swap

1: Swap RGB to BGR, and ARGB to BGRA

(R/W)



PPA_BLEND1_RX_RGB_SWAP_EN Configures whether to swap the order of each channel when the BLEND foreground layer input is RGB or ARGB.

0: Not swap

1: Swap RGB to BGR, and ARGB to BGRA

(R/W)

Register 39.8. PPA_BLEND_TRANS_MODE_REG (0x0034)

PPA_BLEND_EN Configures whether to enable BLEND.

0: Disable

1: Enable

(R/W)

PPA_BLEND_BYPASS Configures whether to bypass BLEND and directly output the background layer.

0: Bypass

1: Not bypass

(R/W)

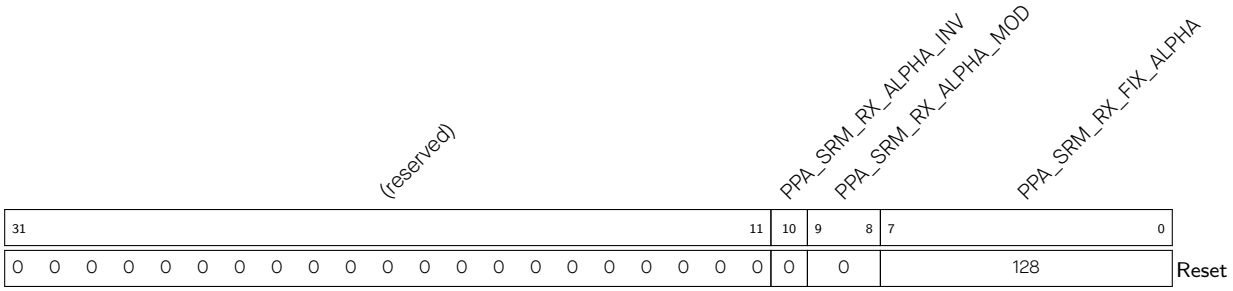
PPA_BLEND_FIX_PIXEL_FILL_EN Configures whether to enable filled image output.

0: Disable

1: Enable, where only BLEND TX works and the output pixel and size are configured by PPA_BLEND_TX_SIZE_REG and PPA_BLEND_TX_FIX_PIXEL.

(R/W)

PPA_BLEND_TRANS_MODE_UPDATE Write 1 to update the transfer mode, active PPA_BLEND_FIX_PIXEL_FILL_EN, and start BLEND workflow. (WT)



PPA_BLEND_RST Configures whether to reset BLEND.

0: Release reset

1: Reset

(R/W)

Register 39.9. PPA_SRM_FIX_ALPHA_REG (0x0038)

PPA_SRM_RX_FIX_ALPHA Configures the Alpha channal value of SRM. (R/W)

PPA_SRM_RX_ALPHA_MOD Configures the Alpha mode of SRM input data.

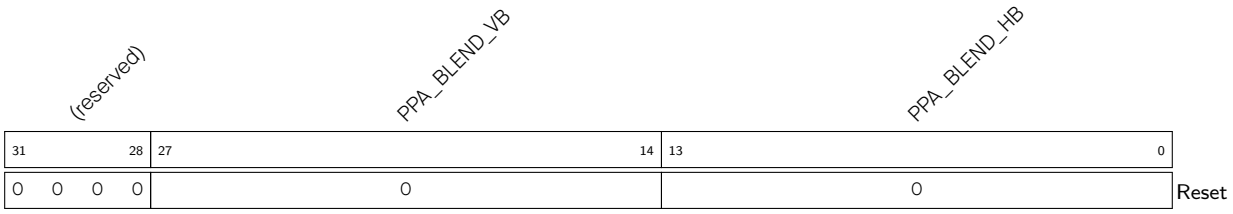
1: Use the value of PPA_SRM_RX_FIX_ALPHA

2: Use the value of the higher eight bits of the original Alpha value multiplied by PPA_SRM_RX_FIX_ALPHA

Others: Use the value of the original Alpha value

(R/W)

PPA_SRM_RX_ALPHA_INV Configures whether to invert the original Alpha value of SRM.

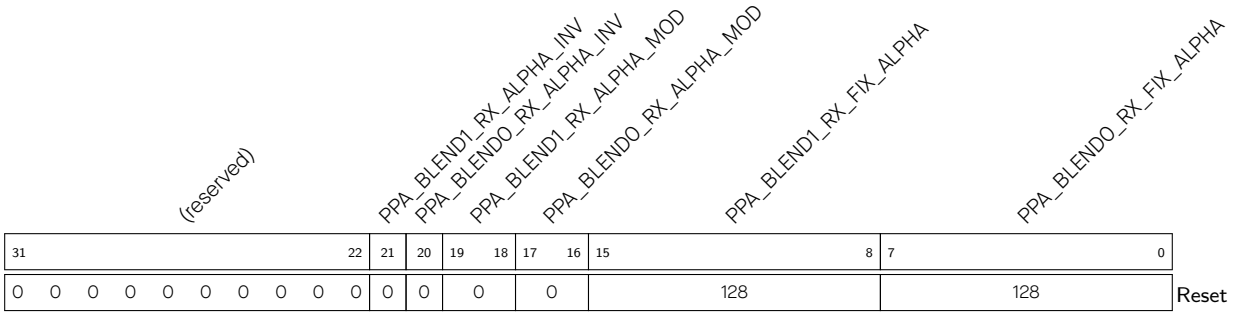


0: Not invert

1: Invert to 255 minus the original Alpha value

For data formats without Alpha channels, the original Alpha value is 255.

(R/W)



Register 39.10. PPA_BLEND_TX_SIZE_REG (0x003C)

PPA_BLEND_HB Configures the horizontal width of image block that would be filled in the image filling mode. Measurement unit: pixel. (R/W)

PPA_BLEND_VB Configures the vertical width of image block that would be filled in the image filling mode. Measurement unit: pixel. (R/W)

Register 39.11. PPA_BLEND_FIX_ALPHA_REG (0x0040)

PPA_BLEND0_RX_FIX_ALPHA Configures the Alpha channal value of the BLEND background layer. (R/W)

PPA_BLEND1_RX_FIX_ALPHA Configures the Alpha channal value of the BLEND foreground layer. (R/W)

PPA_BLEND0_RX_ALPHA_MOD Configures the Alpha mode of BLEND background layer data.

1: Use the value of PPA_BLEND0_RX_FIX_ALPHA

2: Use the value of the higher eight bits of the original Alpha value multiplied by PPA_BLEND0_RX_FIX_ALPHA

Others: Use the value of the original Alpha value

(R/W)

PPA_BLEND1_RX_ALPHA_MOD Configures the Alpha mode of BLEND foreground layer data.

1: Use the value of PPA_BLEND1_RX_FIX_ALPHA

2: Use the value of the higher eight bits of the original Alpha value multiplied by PPA_BLEND1_RX_FIX_ALPHA

Others: Use the value of the original Alpha value

(R/W)

PPA_BLEND0_RX_ALPHA_INV Configures whether to invert the original Alpha value of the BLEND background layer data.

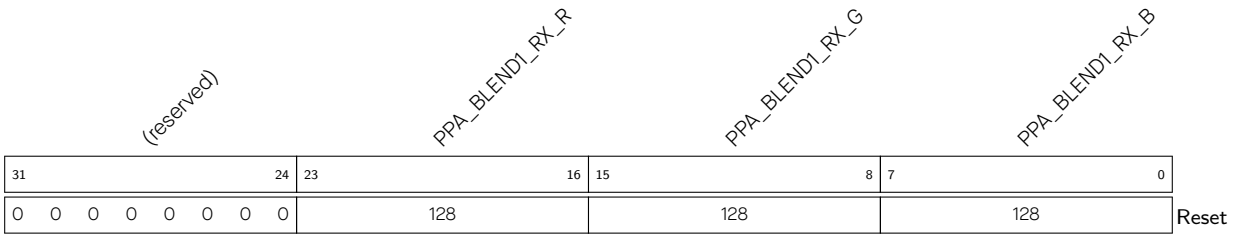
0: Not invert

1: Invert to 255 minus the original Alpha value

For data formats without Alpha channels, the original Alpha value is 255.

(R/W)

PPA_BLEND1_RX_ALPHA_INV Configures whether to invert the original Alpha value of the BLEND foreground layer data.



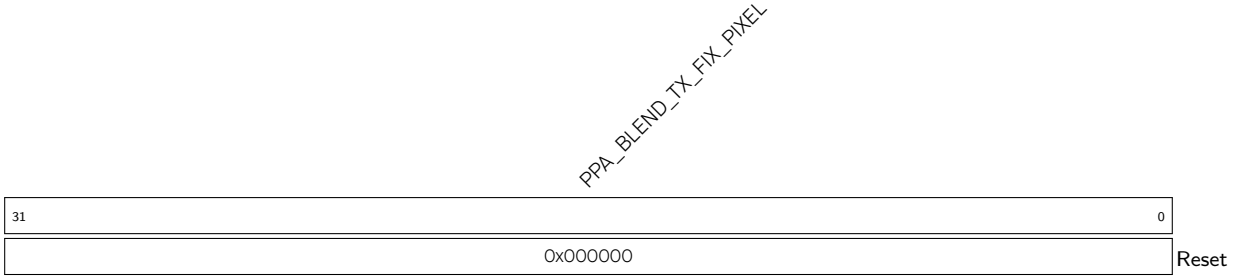
0: Not invert

1: Invert to 255 minus the original Alpha value

For data formats without Alpha channels, the original Alpha value is 255.

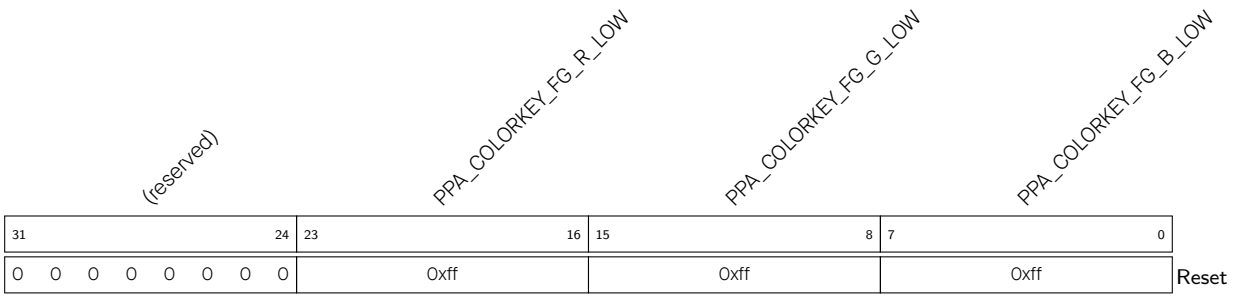
(R/W)

Register 39.12. PPA_BLEND_RGB_REG (0x0048)



PPA_BLEND1_RX_B Configures the B channel value when the BLEND foreground layer is in A4/A8. (R/W)

PPA_BLEND1_RX_G Configures the G channel value when the BLEND foreground layer is in A4/A8. (R/W)

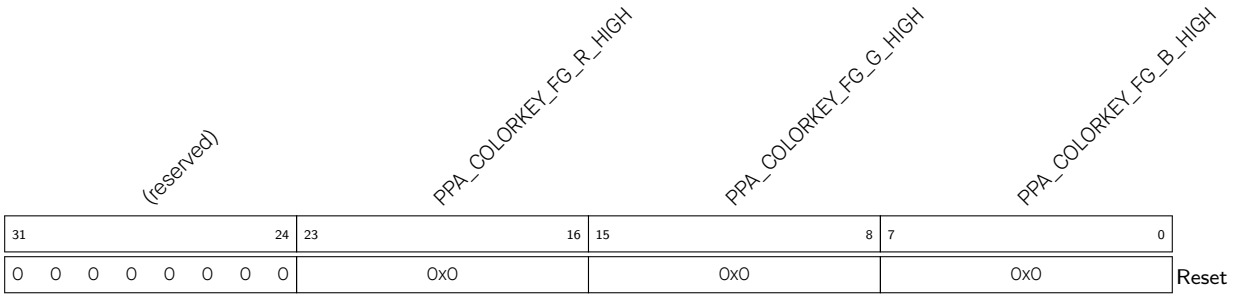


PPA_BLEND1_RX_R Configures the R channel value when the BLEND foreground layer is in A4/A8. (R/W)

Register 39.13. PPA_BLEND_FIX_PIXEL_REG (0x004C)

PPA_BLEND_TX_FIX_PIXEL Configures the pixel in the BLEND image filling mode.
[31:24]: A, [23:16]:R, [15:8]: G, [7:0]: B.
(R/W)

Register 39.14. PPA_CK_FG_LOW_REG (0x0050)

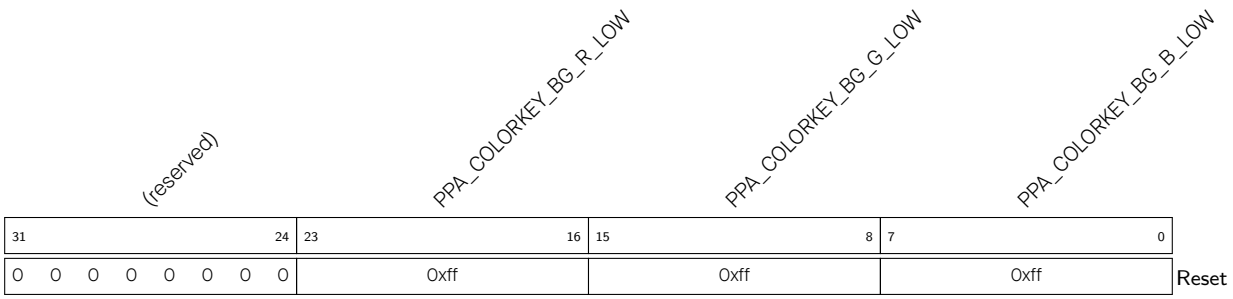


PPA_COLORKEY_FG_B_LOW Configures the color-key lower threshold of the B channel value of the BLEND foreground layer. (R/W)

PPA_COLORKEY_FG_G_LOW Configures the color-key lower threshold of the G channel value of the BLEND foreground layer. (R/W)

PPA_COLORKEY_FG_R_LOW Configures the color-key lower threshold of the R channel value of the BLEND foreground layer. (R/W)

Register 39.15. PPA_CK_FG_HIGH_REG (0x0054)

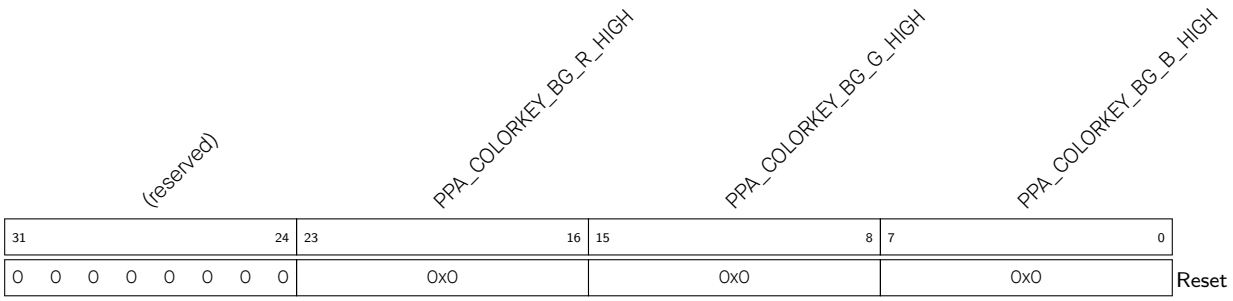


PPA_COLORKEY_FG_B_HIGH Configures the color-key higher threshold of the B channel value of the BLEND foreground layer. (R/W)

PPA_COLORKEY_FG_G_HIGH Configures the color-key higher threshold of the G channel value of the BLEND foreground layer. (R/W)

PPA_COLORKEY_FG_R_HIGH Configures the color-key higher threshold of the R channel value of the BLEND foreground layer. (R/W)

Register 39.16. PPA_CK_BG_LOW_REG (0x0058)



PPA_COLORKEY_BG_B_LOW Configures the color-key lower threshold of the B channel value of the BLEND background layer. (R/W)

PPA_COLORKEY_BG_G_LOW Configures the color-key lower threshold of the G channel value of the BLEND background layer. (R/W)

PPA_COLORKEY_BG_R_LOW Configures the color-key lower threshold of the R channel value of the BLEND background layer. (R/W)

Register 39.17. PPA_CK_BG_HIGH_REG (0x005C)

PPA_COLORKEY_BG_B_HIGH Configures the color-key higher threshold of the B channel value of the BLEND background layer. (R/W)

PPA_COLORKEY_BG_G_HIGH Configures the color-key higher threshold of the G channel value of the BLEND background layer. (R/W)

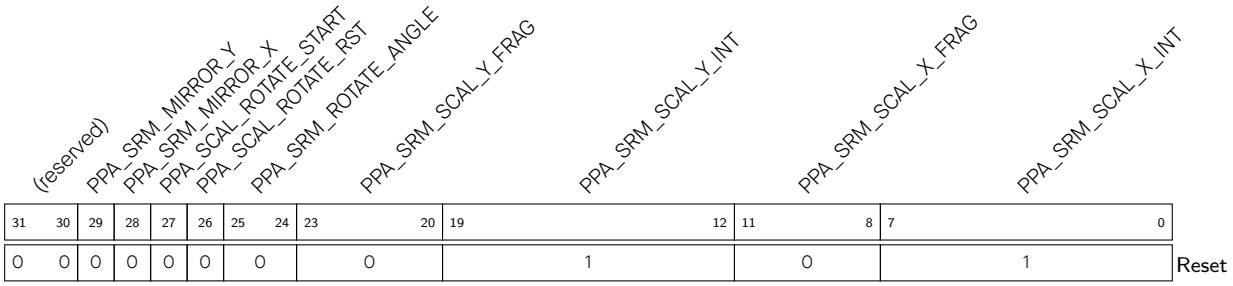
PPA_COLORKEY_BG_R_HIGH Configures the color-key higher threshold of the R channel value of the BLEND background layer. (R/W)

Register 39.18. PPA_CK_DEFAULT_REG (0x0060)

PPA_COLORKEY_DEFAULT_B Configures the default B channel value of BLEND color-key. (R/W)

PPA_COLORKEY_DEFAULT_G Configures the default G channel value of BLEND color-key. (R/W)

PPA_COLORKEY_DEFAULT_R Configures the default R channel value of BLEND color-key. (R/W)



PPA_COLORKEY_FG_BG_REVERSE Configures the workflow when when a pixel is within the background color-key range but not within the foreground color-key range.

0: Output background pixel

1: Output foreground pixel

(R/W)

Register 39.19. PPA_SRM_SCAL_ROTATE_REG (0x0064)

PPA_SRM_SCAL_X_INT Configures the integer part of the horizontal scaling factor for SRM. (R/W)

PPA_SRM_SCAL_X_FRAG Configures the fragment part of the horizontal scaling factor for SRM. (R/W)

PPA_SRM_SCAL_Y_INT Configures the integer part of the vertical scaling factor for SRM. (R/W)

PPA_SRM_SCAL_Y_FRAG Configures the fragment part of the vertical scaling factor for SRM. (R/W)

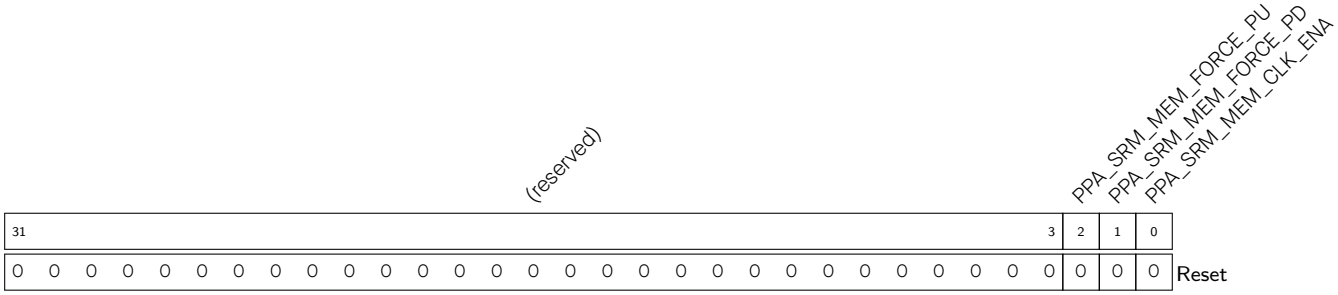
PPA_SRM_ROTATE_ANGLE Configures the counterclockwise rotation angle for the SRM.

0: 0 degree
1: 90 degree
2: 180 degree
3: 270 degree
(R/W)

PPA_SCAL_ROTATE_RST Configures whether to reset SRM.

0: Release reset
1: Reset
(R/W)

PPA_SCAL_ROTATE_START Write 1 to enable SRM. (WT)



PPA_SRM_MIRROR_X Configures whether to enable the horizontal mirroring for SRM.

0: Disable
1: Enable
(R/W)

PPA_SRM_MIRROR_Y Configures whether to enable the vertical mirroring for SRM.

0: Disable
1: Enable
(R/W)

Register 39.20. PPA_SRM_MEM_PD_REG (0x0068)

PPA_SRM_MEM_CLK_ENA Configures whether to enable the force enable of the SRM MEM clock.

0: Disable

1: Enable

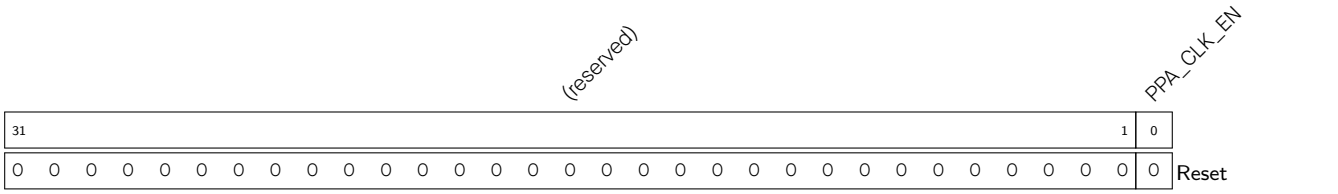
(R/W)

PPA_SRM_MEM_FORCE_PD Configures whether to enable the force power down of SRM MEM.

0: Disable

1: Enable

(R/W)



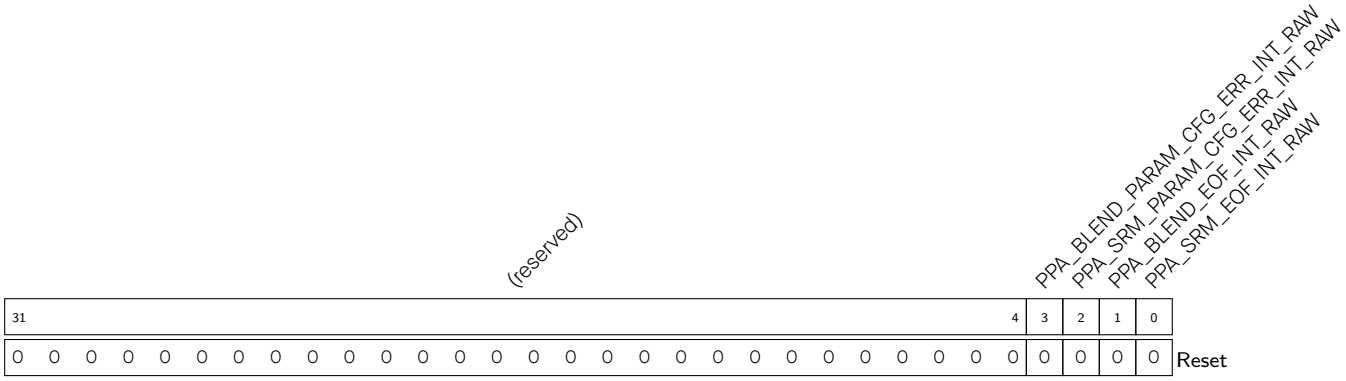
PPA_SRM_MEM_FORCE_PU Configures whether to enable the force power up of SRM MEM.

0: Disable

1: Enable

(R/W)

Register 39.21. PPA_REG_CONF_REG (0x006C)



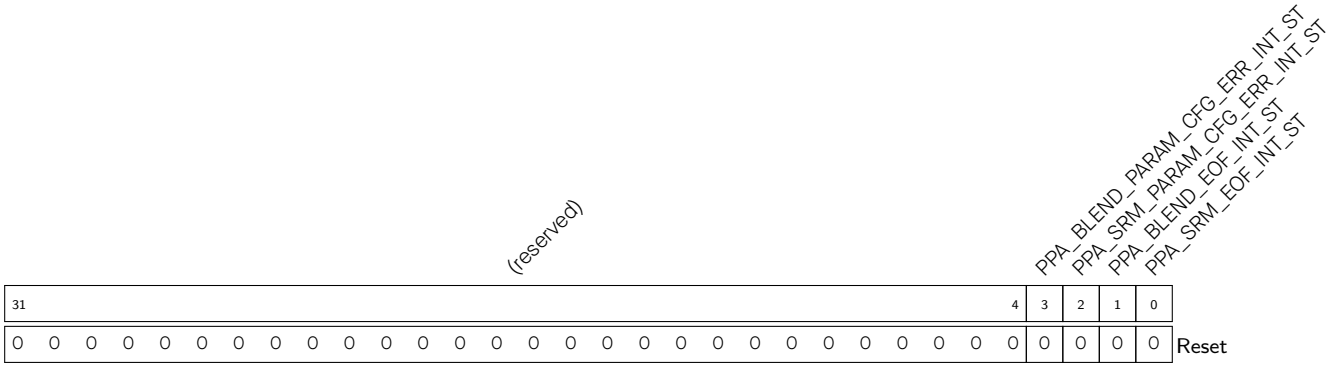
PPA_CLK_EN Configures whether to keep the PPA register clock always on.

0: Clock only turns on when there's a register access

1: Clock always on

(R/W)

Register 39.22. PPA_INT_RAW_REG (0x0010)



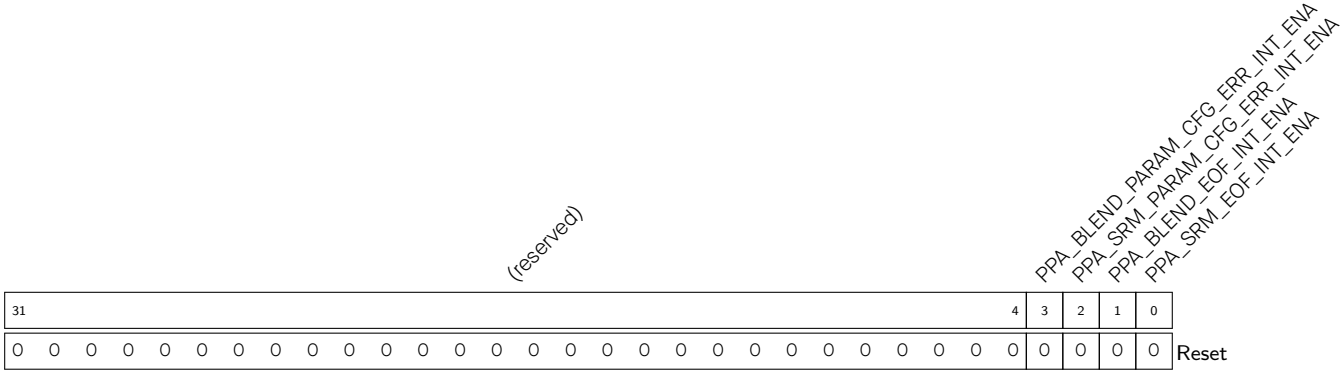
PPA_SRM_EOF_INT_RAW The raw interrupt status of PPA_SRM_EOF_INT.
(R/WTC/SS)

PPA_BLEND_EOF_INT_RAW The raw interrupt status of PPA_BLEND_EOF_INT.
(R/WTC/SS)

PPA_SRM_PARAM_CFG_ERR_INT_RAW The raw interrupt status of PPA_SRM_PARAM_CFG_ERR_INT. Check PPA_SRM_PARAM_ERR_ST_REG to get the specific error.
(R/WTC/SS)

PPA_BLEND_PARAM_CFG_ERR_INT_RAW The raw interrupt status of PPA_BLEND_PARAM_CFG_ERR_INT. Check PPA_BLEND_ST_REG to get the specific error.
(R/WTC/SS)

Register 39.23. PPA_INT_ST_REG (0x0014)



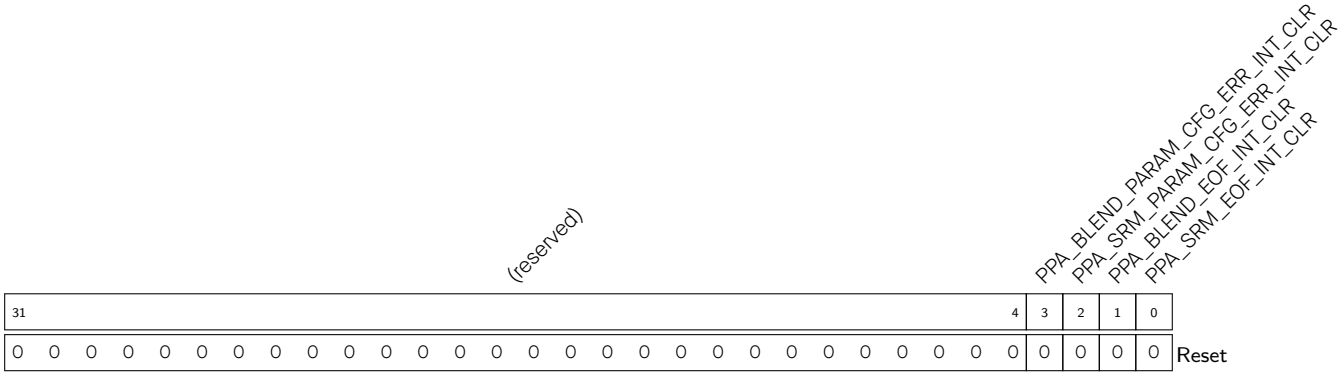
PPA_SRM_EOF_INT_ST The masked interrupt status of PPA_SRM_EOF_INT. (RO)

PPA_BLEND_EOF_INT_ST The masked interrupt status of PPA_BLEND_EOF_INT. (RO)

PPA_SRM_PARAM_CFG_ERR_INT_ST The masked interrupt status of PPA_SRM_PARAM_CFG_ERR_INT. (RO)

PPA_BLEND_PARAM_CFG_ERR_INT_ST The masked interrupt status of PPA_BLEND_PARAM_CFG_ERR_INT. (RO)

Register 39.24. PPA_INT_ENA_REG (0x0018)



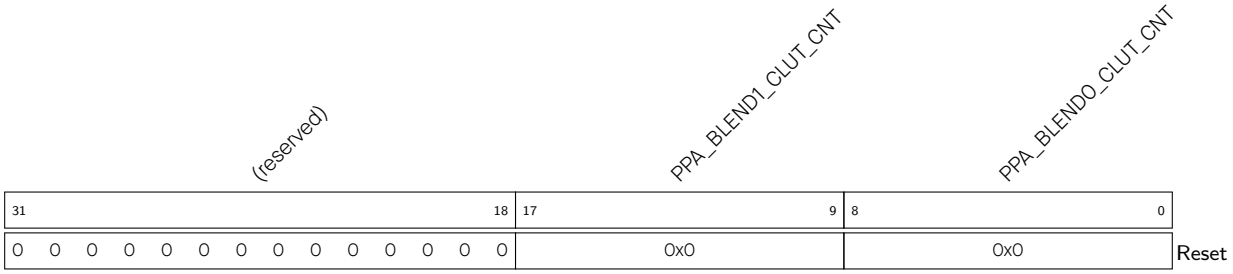
PPA_SRM_EOF_INT_ENA Write 1 to enable PPA_SRM_EOF_INT. (R/W)

PPA_BLEND_EOF_INT_ENA Write 1 to enable PPA_BLEND_EOF_INT. (R/W)

PPA_SRM_PARAM_CFG_ERR_INT_ENA Write 1 to enable PPA_SRM_PARAM_CFG_ERR_INT. (R/W)

PPA_BLEND_PARAM_CFG_ERR_INT_ENA Write 1 to enable PPA_BLEND_PARAM_CFG_ERR_INT. (R/W)

Register 39.25. PPA_INT_CLR_REG (0x001C)

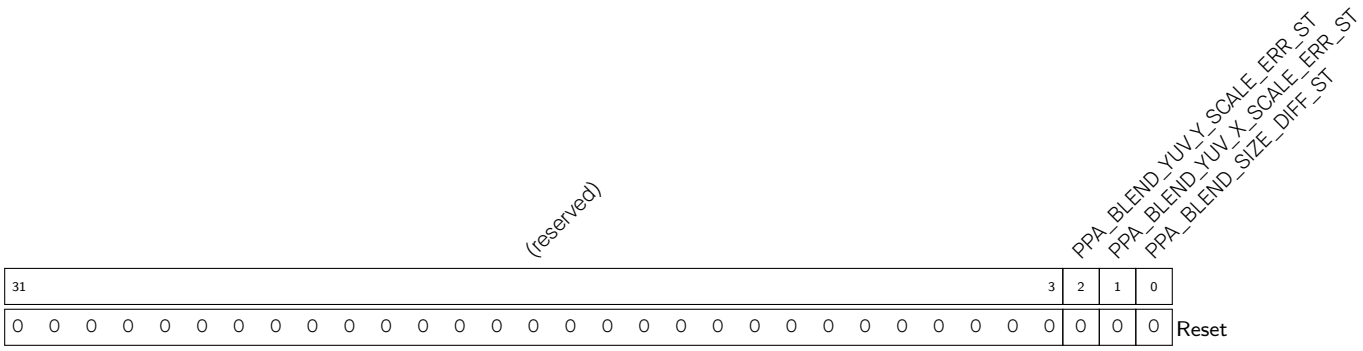


PPA_SRM_EOF_INT_CLR Write 1 to clear PPA_SRM_EOF_INT. (WT)

PPA_BLEND_EOF_INT_CLR Write 1 to clear PPA_BLEND_EOF_INT. (WT)

PPA_SRM_PARAM_CFG_ERR_INT_CLR Write 1 to clear PPA_SRM_PARAM_CFG_ERR_INT. (WT)

PPA_BLEND_PARAM_CFG_ERR_INT_CLR □ 1 □□ PPA_BLEND_PARAM_CFG_ERR_INT□ (WT)



Register 39.26. PPA_CLUT_CNT_REG (0x0070)

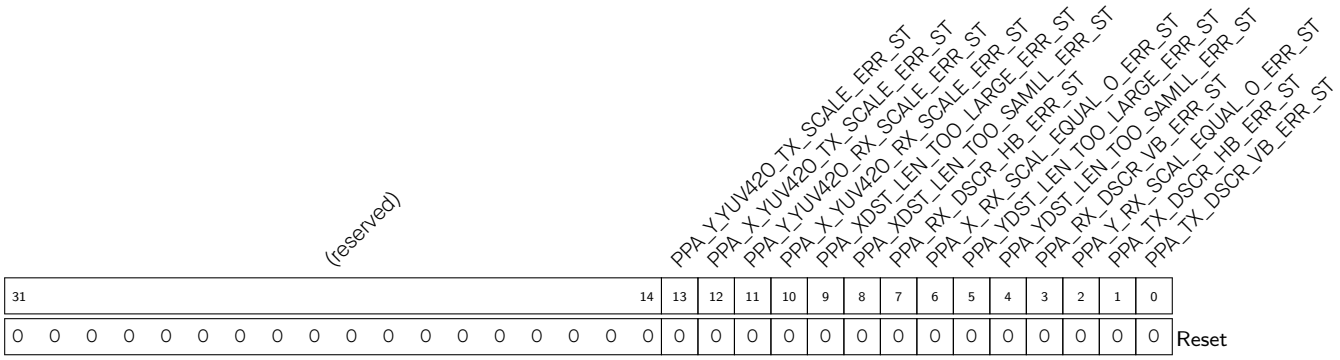
PPA_BLEND0_CLUT_CNT Represents the current write address of the BLEND background layer CLUT in FIFO mode. (RO)

PPA_BLEND1_CLUT_CNT Represents the current write address of the BLEND foreground layer CLUT in FIFO mode. (RO)

Register 39.27. PPA_BLEND_ST_REG (0x0074)

PPA_BLEND_SIZE_DIFF_ST Represents whether the size of the BLEND background and foreground images are consistent.

0: Consistent



1: Different

(RO)

PPA_BLEND_YUV_X_SCALE_ERR_ST Represents the image width (X) is odd for YUV422 or YUV420 formats. (RO)

PPA_BLEND_YUV_Y_SCALE_ERR_ST Represents the image height (Y) is odd for the YUV420 format. (RO)

Register 39.28. PPA_SRM_PARAM_ERR_ST_REG (0x0078)

PPA_TX_DSCR_VB_ERR_ST Represents whether the vertical size of the SRM output image block plus the vertical offset Y configured in the output list exceeds the vertical size of the entire image configured in the output list, VA.

0: Not exceeded

1: Exceeded

(RO)

PPA_TX_DSCR_HB_ERR_ST Represents whether the horizontal size of the SRM output image block plus the vertical offset X configured in the output list exceeds the horizontal size of the entire image configured in the output list, HA.

0: Not exceeded

1: Exceeded

(RO)

PPA_Y_RX_SCAL_EQUAL_0_ERR_ST Represents whether the vertical direction scaling factor of the SRM input image block is 0.

0: Not 0

1: 0

(RO)

PPA_RX_DSCR_VB_ERR_ST Represents whether the sum of the vertical direction image block size VB configured in the SRM input list and the vertical offset Y exceeds the entire image's vertical size VA.

0: Not exceeded

1: Exceeded

(RO)

PPA_YDST_LEN_TOO_SAMLL_ERR_ST Represents whether the vertical size of the image block after scaling in the SRM is 0.

0: Not 0

1: 0

(RO)

Continued on the next page...

Register 39.28. PPA_SRM_PARAM_ERR_ST_REG (0x0078)

Continued from the previous page...

PPA_YDST_LEN_TOO_LARGE_ERR_ST Represents whether the vertical size of the image block after scaling in the SRM is larger than 8191.
0: Within 8191
1: Larger than 8191
(RO)

PPA_X_RX_SCAL_EQUAL_0_ERR_ST Represents whether the horizontal direction scaling factor of the SRM input image block is 0.
0: Not 0
1: 0
(RO)

PPA_RX_DSCR_HB_ERR_ST Represents whether the sum of the horizontal direction image block size HB configured in the SRM input list and the horizontal offset X exceeds the entire image's horizontal size HA.
0: Not exceeded
1: Exceeded
(RO)

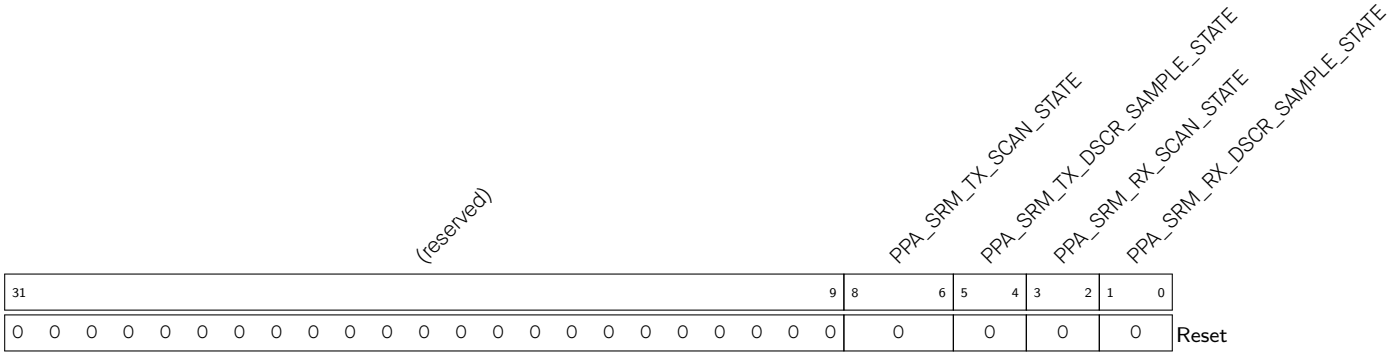
PPA_XDST_LEN_TOO_SAMLL_ERR_ST Represents whether the horizontal size of the image block after scaling in the SRM is 0.
0: Not 0
1: 0
(RO)

PPA_XDST_LEN_TOO_LARGE_ERR_ST Represents whether the horizontal size of the image block after scaling in the SRM is larger than 8191.
0: Within 8191
1: Larger than 8191
(RO)

PPA_X_YUV420_RX_SCALE_ERR_ST Represents whether the parameters HA/HB/X of the SRM input list are odd when the input format is YUV420.
0: Even
1: Odd
(RO)

PPA_Y_YUV420_RX_SCALE_ERR_ST Represents whether the parameters VA/VB/Y of the SRM input list are odd when the input format is YUV420.
0: Even
1: Odd
(RO)

Continued on the next page...



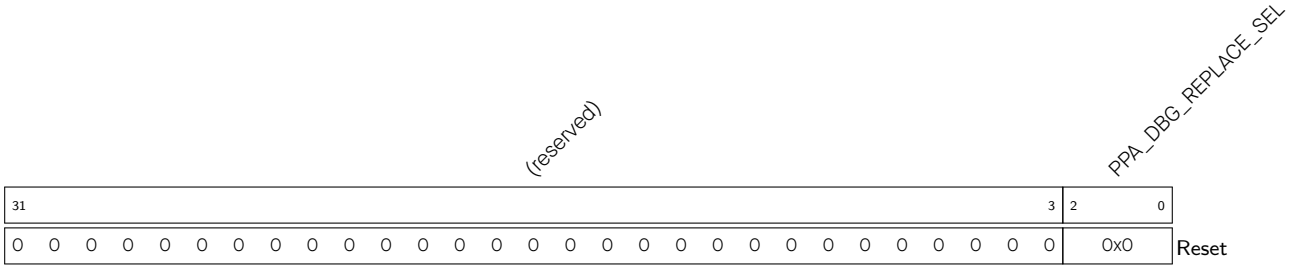
Register 39.28. PPA_SRM_PARAM_ERR_ST_REG (0x0078)

Continued from the previous page...

PPA_X_YUV420_TX_SCALE_ERR_ST Represents whether the parameters HA/HB/X of the SRM output list are odd when the output format is YUV420.
0: Even
1: Odd
(RO)

PPA_Y_YUV420_TX_SCALE_ERR_ST Represents whether the parameters VA/VB/Y of the SRM output list are odd when the output format is YUV420.
0: Even
1: Odd
(RO)

Register 39.29. PPA_SRM_STATUS_REG (0x007C)

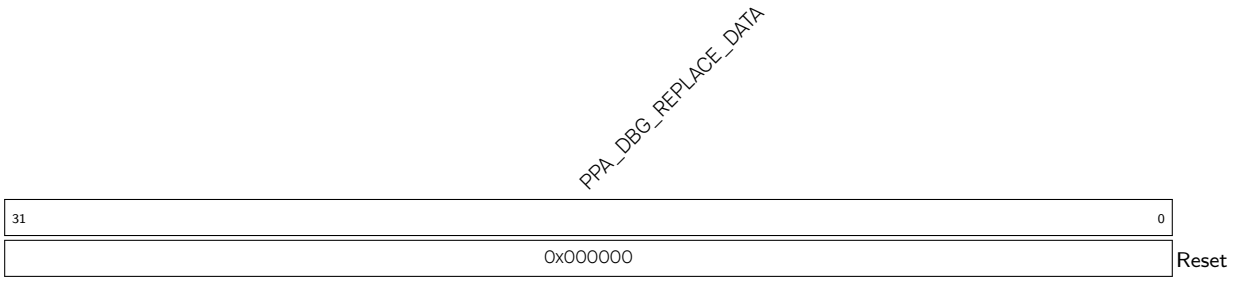


PPA_SRM_RX_DSCR_SAMPLE_STATE Represents the SRM RX descriptor state. (RO)

PPA_SRM_RX_SCAN_STATE Represents the SRM RX pixel scan state. (RO)

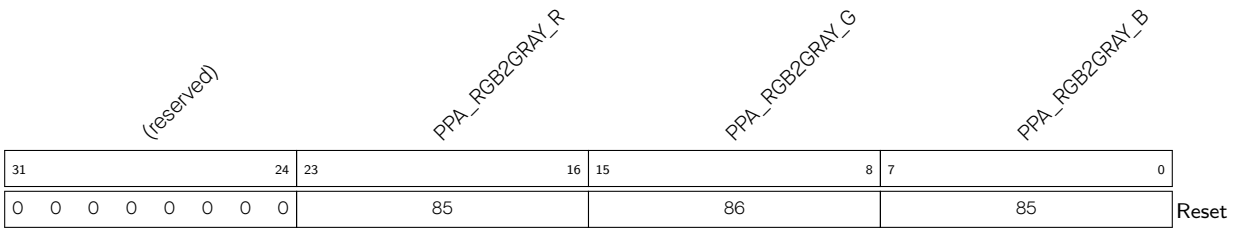
PPA_SRM_TX_DSCR_SAMPLE_STATE Represents the SRM TX descriptor state. (RO)

PPA_SRM_TX_SCAN_STATE Represents the SRM TX pixel scan state. (RO)



Register 39.30. PPA_DEBUG_CTRL0_REG (0x0090)

PPA_DBG_REPLACE_SEL Configures where the replacement pixel is inserted.

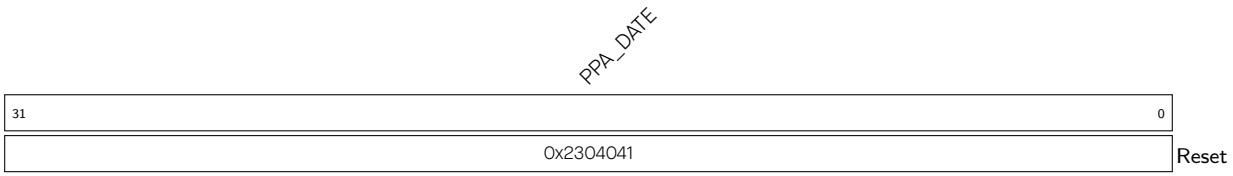


0: No replacement
1: SRM RX input
2: SRM interpolation output
3: SRM TX output
4: BLEND foreground input
5: BLEND background input
6: BLEND output
(R/W)

Register 39.31. PPA_DEBUG_CTRL1_REG (0x0094)

PPA_DBG_REPLACE_DATA Configures the replacement pixel value. (R/W)

Register 39.32. PPA_RGB2GRAY_REG (0x0098)



PPA_RGB2GRAY_B Configures the coefficient for B in RGB to GRAY conversion. (R/W)

PPA_RGB2GRAY_G Configures the coefficient for G in RGB to GRAY conversion. (R/W)

PPA_RGB2GRAY_R Configures the coefficient for R in RGB to GRAY conversion. (R/W)

Register 39.33. PPA_DATE_REG (0x0100)

PPA_DATE Version control register. (R/W)

Chapter 40

LCD and Camera Controller (LCD_CAM)

40.1 Overview

The LCD and Camera controller (LCD_CAM) on the ESP32-P4, consisting of an independent LCD control module and a camera control module, is a versatile component designed to facilitate interfacing with both LCDs and cameras.

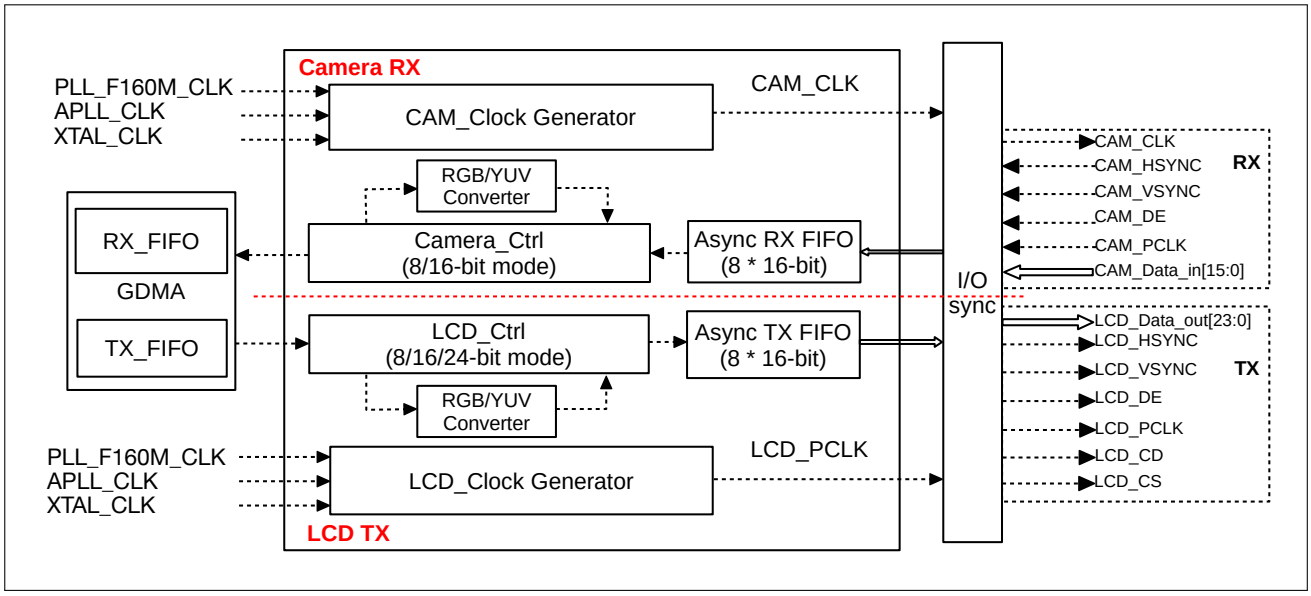
The LCD module provides an LCD interface that can connect to RGB, Motorola 6800 (MOTO6800), and Intel 8080 (I8080) compatible LCD devices. The LCD module is responsible for sending video data to the display.

The Camera module provides one parallel camera interface that can connect to external digital video port (DVP) cameras in 8/16-bit modes. It manages communication with the camera to capture images or video frames.

The LCD_CAM controller offers flexibility for projects that involve both displaying information on screens and working with cameras for image or video processing.

40.2 Features

LCD_CAM has the following features:



- Supports the following operation modes:
  - LCD master TX mode
  - Camera slave RX mode
  - Camera master RX mode
- Supports simultaneous connection to an external LCD and a camera
- When interfacing with an external LCD, the following is supported:
  - 8/16/24-bit parallel output modes
  - RGB, MOTO6800, and I8080 LCD formats
  - LCD data retrieved from internal memory or external memory via GDMA
- When interfacing with an external camera (i.e., DVP image sensor), the following is supported:
  - 8/16-bit parallel input modes
  - Camera data stored in internal or external memory via GDMA
- Supports interrupts

40.3 Functional Description

40.3.1 Block Diagram

Figure 40.3-1 shows the structure of LCD_CAM which includes:

- One TX control unit (LCD_Ctrl)
- One RX control unit (Camera_Ctrl)
- One asynchronous TX FIFO (Async TX FIFO) for communicating with external devices, e.g., LCDs
- One asynchronous RX FIFO (Async RX FIFO) for communicating with external devices, e.g., cameras
- Two clock generators (LCD_Clock Generator and CAM_Clock Generator) for generating clocks for each module
- Two format converters (RGB/YUV Converter) for converting video data into various formats

- →: control signal =>: data flow

Figure 40.3-1. LCD_CAM Block Diagram

40.3.2 Signal Description

Table 40.3-1 shows the input and output signals required for the operation of the LCD and Camera controller.

The definition of the three operation modes is as follows:

- **Camera Slave RX Mode:** In this mode, the Camera module is the receiver of control signals.
- **Camera Master RX Mode:** In this mode, the Camera module sends clock signals to the slave, which will transmit data to the master upon receiving the signals.
- **LCD Master TX Mode:** In this mode, the LCD module initiates communication with the slave and sends control signals to the slave.

Table 40.3-1. LCD_CAM Input and Output Signal Descriptions

Operation Mode	Signal[1]	Direction	Function
Camera Slave RX Mode	CAM_PCLK	Input	Camera pixel clock signal
	CAM_VSYNC	Input	Vertical synchronization signal (VSYNC)[3]
	CAM_HSYNC	Input	Horizontal synchronization signal (HSYNC)[3]
	CAM_DE	Input	Horizontal enable signal (DE)[3]
	CAM_Data_in[*N*:0][2]	Input	Camera parallel input data bus, 8/16-bit modes supported
Camera Master RX Mode	CAM_PCLK	Input	Camera pixel clock input signal
	CAM_CLK	Output	Camera master clock output signal
	CAM_VSYNC	Input	Vertical synchronization signal[3]
	CAM_HSYNC	Input	Horizontal synchronization signal[3]
	CAM_DE	Input	Horizontal enable signal[3]
	CAM_Data_in[*N*:0][2]	Input	Camera parallel input data bus, 8/16-bit modes supported
LCD Master TX Mode	LCD_PCLK	Output	LCD pixel clock signal
	LCD_HSYNC	Output	Horizontal synchronization signal in RGB format
	LCD_VSYNC	Output	Vertical synchronization signal in RGB format
	LCD_DE	Output	Horizontal enable signal in RGB format
	LCD_CD	Output	Command and data (CD) signal in I8080 format
	LCD_CS	Output	Chip select (CS) signal in I8080/MOTO6800 format
	LCD_Data_out[*M*:0][2]	Output	LCD parallel output data bus, 8/16/24-bit modes supported

[1] All the signals must be mapped to the chip's pins via GPIO matrix. For more information, see Chapter 10 *GPIO Matrix and IO MUX*.

[2] For the input signals with 8 or 16-bit width, *N* = 7 or 15 respectively. For the output signals with 8, 16, or 24-bit width, *M* = 7, 15, or 23 respectively.

[3] If LCD_CAM_CAM_VH_DE_MODE_EN is set, i.e., VSYNC + HSYNC mode is selected, then VSYNC, HSYNC, and DE signals control the data. In this case, users need to wire the three signal lines. If LCD_CAM_CAM_VH_DE_MODE_EN is cleared, i.e., DE mode is selected, then VSYNC and DE signals control the data. In this case, wiring HSYNC signal line is not a must. But in this case, the YUV-RGB conversion function of the Camera module is not available.

40.3.3 LCD_CAM Module Clocks

40.3.3.1 LCD Clock

The clocks used in the LCD module are generated from clock sources by the LCD_Clock Generator, see Figure 40.3-2. The clocks include:

- Master clock: LCD_CLK, divided from the clock sources
- Pixel clock: LCD_PCLK, divided from LCD_CLK

HP_SYS_CLKRST_LCD_CLK_EN is used to enable LCD_CLK_SRC (the clock source), and HP_SYS_CLKRST_LCD_CLK_SRC_SEL is used to select LCD_CLK_SRC from one of the following clock sources:

- 0: XTAL_CLK
- 1: PLL_F160M_CLK
- 2: APLL_CLK
- 3: Disable LCD clock source

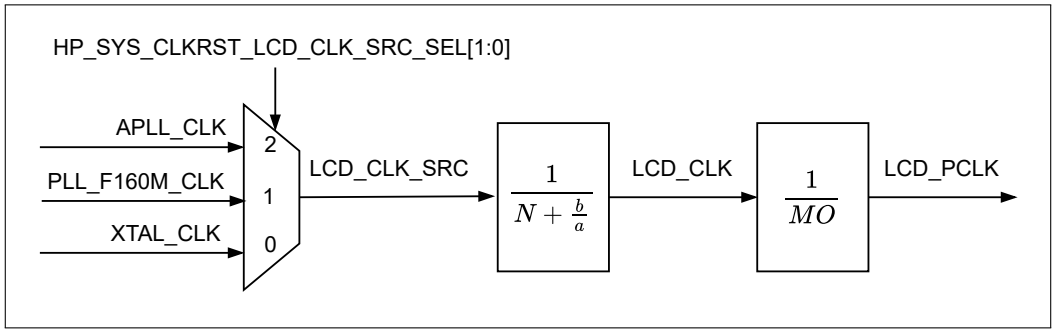


Figure 40.3-2. LCD Clock

The following formula shows the relation between the frequency of LCD_CLK ($f_{\text{LCD_CLK}}$) and LCD_CLK_SRC ($f_{\text{LCD_CLK_SRC}}$):

$$f_{\text{LCD_CLK}} = \frac{f_{\text{LCD_CLK_SRC}}}{N + \frac{b}{a}}$$

The values of *N*, *a*, and *b* are related to HP_SYS_CLKRST_LCD_CLK_DIV_NUM, HP_SYS_CLKRST_LCD_CLK_DIV_NUMERATOR, and HP_SYS_CLKRST_LCD_CLK_DIV_DENOMINATOR. Specifically,

- When HP_SYS_CLKRST_LCD_CLK_DIV_NUM = 0, *N* = 1. The values of *a* and *b* do not take effect. The divider is always 1.
- When HP_SYS_CLKRST_LCD_CLK_DIV_NUM >=1, *N* = HP_SYS_CLKRST_LCD_CLK_DIV_NUM + 1.
  - For integer divider, please clear HP_SYS_CLKRST_LCD_CLK_DIV_NUMERATOR and HP_SYS_CLKRST_LCD_CLK_DIV_DENOMINATOR.
  - For fractional divider, *b* = HP_SYS_CLKRST_LCD_CLK_DIV_NUMERATOR, *a* = HP_SYS_CLKRST_LCD_CLK_DIV_DENOMINATOR. The value of HP_SYS_CLKRST_LCD_CLK_DIV_NUMERATOR should be smaller than the value of HP_SYS_CLKRST_LCD_CLK_DIV_DENOMINATOR.

The following formula shows the relation between the frequencies of LCD_PCLK ($f_{\text{LCD_PCLK}}$) and LCD_CLK ($f_{\text{LCD_CLK}}$):

$$f_{\text{LCD_PCLK}} = \frac{f_{\text{LCD_CLK}}}{\text{MO}}$$

MO is determined by LCD_CAM_LCD_CLK_EQU_SYSCLK and LCD_CAM_LCD_CLKCNT_N, specifically:

- When LCD_CAM_LCD_CLK_EQU_SYSCLK = 1, MO = 1.

- When LCD_CAM_LCD_CLK_EQU_SYSCLK = 0, MO = LCD_CAM_LCD_CLKCNT_N + 1.

Notes:

- LCD_CAM_LCD_CLKCNT_N must not be configured as 0.
- Using fractional divider may introduce clock jitters. In case LCD_CLK and LCD_PCLK can not be generated from PLL_F160M_CLK by integer divider, APLL_CLK can be used as the clock source. For more information, please refer to Chapter 11 *Reset and Clock*.

40.3.3.2 Camera Clock

The clocks used in the Camera module are generated from clock sources by the CAM_Clock Generator, see Figure 40.3-3. The clocks include:

- Master clock: CAM_CLK, master clock output from the Camera module, divided from the clock sources.
- Pixel clock: CAM_PCLK, clock input from camera slave.

HP_SYS_CLKRST_CAM_CLK_EN is used to enable the CAM_CLK_SRC (the clock source), and HP_SYS_CLKRST_CAM_CLK_SRC_SEL is used to select CAM_CLK_SRC from one of the following clock sources:

- 0: XTAL_CLK
- 1: PLL_F160M_CLK
- 2: APLL_CLK
- 3: Disable camera clock source

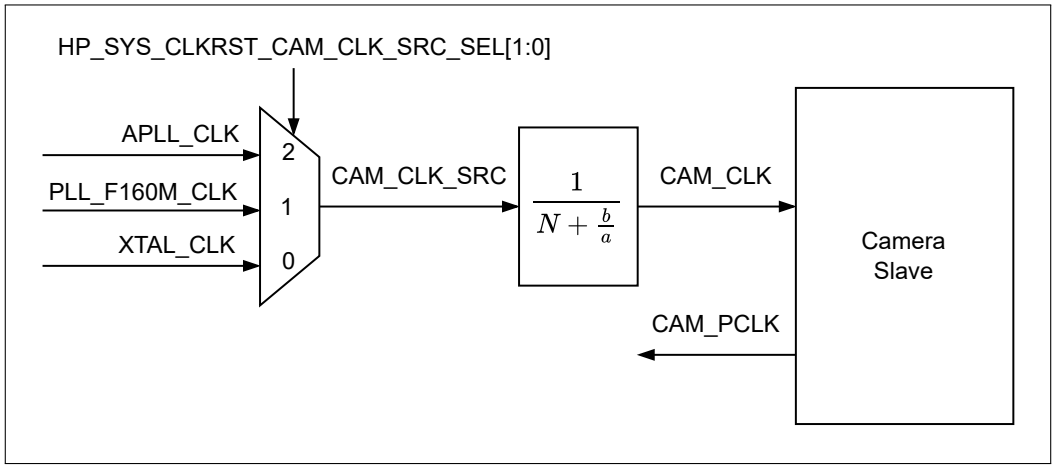

Figure 40.3-3. Camera Clock

The following formula shows the relation between the frequencies of CAM_CLK (f_{CAM_CLK}) and the divider's clock source ($f_{CAM_CLK_SRC}$):

$$f_{CAM_CLK} = \frac{f_{CAM_CLK_SRC}}{N + \frac{b}{a}}$$

N is an integer value between 2 and 256. The value of *N* corresponds to the value of HP_SYS_CLKRST_CAM_CLK_DIV_NUM as follows:

- When HP_SYS_CLKRST_CAM_CLK_DIV_NUM = 0, *N* = 256.

- When HP_SYS_CLKRST_CAM_CLK_DIV_NUM = 1, *N* = 2.
- When HP_SYS_CLKRST_CAM_CLK_DIV_NUM = other value, *N* = HP_SYS_CLKRST_CAM_CLK_DIV_NUM.

b corresponds to the value of HP_SYS_CLKRST_CAM_CLK_DIV_NUMERATOR, and *a* to the value of HP_SYS_CLKRST_CAM_CLK_DIV_DENOMINATOR.

- For integer divider, please clear HP_SYS_CLKRST_CAM_CLK_DIV_NUMERATOR and HP_SYS_CLKRST_CAM_CLK_DIV_DENOMINATOR.
- For fractional divider, the value of HP_SYS_CLKRST_CAM_CLK_DIV_NUMERATOR should be smaller than the value of HP_SYS_CLKRST_CAM_CLK_DIV_DENOMINATOR.

40.3.4 LCD_CAM Reset

LCD_CAM module has the following reset registers that can reset different parts of the module:

- HP_SYS_CLKRST_RST_EN_LCDCAM: Setting this register will reset the whole LCD_CAM module.
- LCD_CAM_LCD_RESET: Setting this register will reset the whole LCD module, including the LCD control unit (LCD_Ctrl), the RGB/YUV Converter, and Async TX FIFO. Configuring this register will not affect the Camera module.
- LCD_CAM_CAM_RESET: Setting this register will reset the whole Camera module, including the Camera control unit (Camera_Ctrl), the RGB/YUV Converter, and Async RX FIFO. Configuring this register will not affect the LCD module.
- LCD_CAM_LCD_AFIFO_RESET: Setting this register will reset the Async TX FIFO without affecting other parts in the module. For example, setting this reset register every time the LCD finishes sending a frame can prevent transmission errors of the previous frame from affecting the transmission of the next frame.
- LCD_CAM_CAM_AFIFO_RESET: Setting this register will reset the Async RX FIFO without affecting other parts in the module. For example, setting this reset register every time the Camera finishes receiving a frame can prevent transmission errors of the previous frame from affecting the receiving of the next frame.

Notes:

- The reset register HP_SYS_CLKRST_RST_EN_LCDCAM is not self-clearing, meaning writing 1 enables the reset, and writing 0 releases the reset.
- All the above reset registers, except for HP_SYS_CLKRST_RST_EN_LCDCAM, are self-clearing, meaning that after writing 1, the hardware will generate a reset pulse and automatically clear the register.
- The module clocks LCD_CLK and CAM_CLK must be configured first before the module and FIFO are reset.

40.3.5 LCD_CAM Data Format Control

40.3.5.1 LCD Data Format Control

When the data is transmitted by the LCD module, it undergoes three stages of processing:

1. Stage One: Data preprocessing
   The LCD module processes the input data from GDMA and sends it to the YUV-RGB converter.

2. Stage Two: Data color space conversion
   The YUV-RGB converter processes the data. If the YUV-RGB converter is disabled, the data remains unchanged at this stage.
3. Stage Three: Data post-processing
   The LCD module gets data from the YUV-RGB converter for post-processing and then transmits the data to GPIO.

Note:
The output data from the previous stage is the input data for the subsequent stage.

The detailed configuration of each stage is described below.

Stage One: Data Preprocessing

At this stage, configure the following registers to adjust the bit width, bit order, and byte order of the data from GDMA.

- LCD_CAM_LCD_BYTE_MODE
  - 0: The data width of the LCD input from GDMA is 8 bits.
  - 1: The data width of the LCD input from GDMA is 16 bits.
  - 2: The data width of the LCD input from GDMA is 24 bits.
- LCD_CAM_LCD_BIT_ORDER
  - 0: Do not invert.
  - 1: Invert the input data bit order.
- LCD_CAM_LCD_BYTE_ORDER
  - 0: Do not invert.
  - 1: Invert data byte order, only valid in 16/24-bit modes.

For the detailed configuration, see Table 40.3-2.

Table 40.3-2. LCD Data Format Control – Stage One

GDMA Data Order[1]	LCD_CAM_LCD_BYTE_MODE	LCD_CAM_LCD_BIT_ORDER	LCD_CAM_LCD_BYTE_ORDER[2]	Output Data Order[3,4]
B0,B1,B2,B3,B4,B5	0	0	0	{B0}{B1}{B2}{B3}{B4}{B5}
		1	0	{B0'}{B1'}{B2'}{B3'}{B4'}{B5'}
	1	0	0	{B1,B0}{B3,B2}{B5,B4}
			1	{B0,B1}{B2,B3}{B4,B5}
		1	0	{B1',B0'}{B3',B2'}{B5',B4'}
			1	{B0',B1'}{B2',B3'}{B4',B5'}
	2	0	0	{B2,B1,B0}{B5,B4,B3}
			1	{B0,B1,B2}{B3,B4,B5}
		1	0	{B2',B1',B0'}{B5',B4',B3'}
			1	{B0',B1',B2'}{B3',B4',B5'}

[1] B0 ~ B5 represent the bytes of the data from GDMA, from low address to high address.

[2] Only the configuration listed in the table is valid. Other configurations may cause unexpected data errors.

[3] In output data, the bits in {} are in big-endian, and are in parallel with each other, while the data of {} is in serial with the data of other {}. Data is sent out from left to right. Take {B0}{B1}{B2}{B3} as an example. The bits in {B0} are in parallel with each other, but are in serial with the bits in {B1}{B2}{B3}. {B0} is sent out first.

[4] In output data, Bn'[7:0] = Bn[0:7] (n = 0,1,2,3,4,5).

Stage Two: Data Color Space Conversion

At this stage, the data undergoes color space conversion. For detailed configurations, please refer to Section 40.3.6.

> **Note:**
> Users can skip Stage Two by configuring LCD_CAM_LCD_CONV_ENABLE as 0, in which case the output of Stage One will directly become the input of Stage Three.

Stage Three: Data Post-processing

At this stage, configure the following registers to adjust the bit and byte order of the output data.

- LCD_CAM_LCD_WIRE_MODE
  - 0: The bit width of the data transmitted to GPIO is 8 bits.
  - 1: The bit width of the data transmitted to GPIO 16 bits.
  - 2: The bit width of the data transmitted to GPIO is 24 bits.
- LCD_CAM_LCD_DOUT_BIT_ORDER
  - 0: Do not invert.
  - 1: Invert the output data bit order.
- LCD_CAM_LCD_DOUT_BYTE_SWIZZLE_ENABLE
  - 0: Disable LCD output data byte reordering.
  - 1: Enable LCD output data byte reordering by configuring LCD_CAM_LCD_DOUT_BYTE_SWIZZLE_MODE. For the reordering results see Table 40.3-3.

Table 40.3-3. LCD Output Data Reordering

Stage Three Input Data Byte Order[1]	LCD_CAM_LCD_DOUT_BYTE_SWIZZLE_MODE[2]	Stage Three Output Data Byte Order[3]
B0,B1,B2,B3,B4,B5	0	B1,B0,B3,B2,B5,B4
	1	B0,B2,B1,B3,B5,B4
	2	B1,B0,B2,B4,B3,B5
	3	B1,B2,B0,B4,B5,B3
	4	B2,B0,B1,B5,B3,B4
	5	B2,B1,B0,B5,B4,B3

[1] B0 ~ B5 represent the bytes of the input data in stage three, i.e., the input data is arranged in a little-endian byte sequence. For example, when the valid data width of the input data is 16 bits, the original input data sequence B1,B0B3,B2B5,B4 is converted to B0,B1,B2,B3,B4,B5.

[2] Only the values listed in the table are valid. Other values may cause unexpected data errors.

[3] The byte order of data that is ultimately transmitted to GPIO is determined by the "Stage Three Output Data Byte Order" and the bit width. For example, if the "Stage Three Output Data Byte Order" is B1,B0,B2,B4,B3,B5 and the transmitted data width is 16 bits, then the transmitted data byte order would be {B0,B1}{B4,B2}{B5,B3}. In this sequence, the data within each {} is in big-endian parallel format, and the data in each {} is in serial with the data in other {}. Data is transmitted from left to right. In this particular example, the data in {B0,B1} are in parallel with each other, while the data in {B0,B1} is in serial with the data in {B4,B2} and {B5,B3}. {B0,B1} is transmitted first.

40.3.5.2 Camera Data Format Control

When the Camera module receives data, configure the following registers to adjust the bit/byte order of the data sent to GDMA.

- LCD_CAM_CAM_2BYTE_EN
  - 0: The data width of the Camera input is 8 bits.
  - 1: The data width of the Camera input is 16 bits.
- LCD_CAM_CAM_BIT_ORDER
  - 0: Do not invert.
  - 1: Invert data bit order.
    - Invert CAM_DATA_in[7:0] to CAM_DATA_in[0:7] in 8-bit mode.
    - Invert CAM_DATA_in[15:0] to CAM_DATA_in[0:15] in 16-bit mode.
- LCD_CAM_CAM_BYTE_ORDER
  - 0: Do not invert.
  - 1: Invert data byte order, only valid in 16-bit mode.

For the detailed configuration, see Table 40.3-4.

Table 40.3-4. Camera Data Format Control

RX Data Order[1]	LCD_CAM_CAM_2BYTE_EN	LCD_CAM_CAM_BIT_ORDER[2]	LCD_CAM_CAM_BYTE_ORDER[2]	GDMA Data Order[3,4]
{B0}{B1}{B2}{B3}	0	0	0	B0,B1,B2,B3
		1	0	B0',B1',B2',B3'
{B1,B0}{B3,B2}	1	0	0	B0,B1,B2,B3
			1	B1,B0,B3,B2
		1	0	B0',B1',B2',B3'
			1	B1',B0',B3',B2'

[1] In RX data, the bits in {} are in big-endian, and are in parallel with each other, while the data in {} is in serial with the data in other {}. Data is received from left to right. Take {B0}{B1}{B2}{B3} as an example. The bits in {B0} are in parallel with each other, but are in serial with the bits in {B1}{B2}{B3}. {B0} is received first.

[2] Only the configuration listed in the table is valid. Other configurations may cause unexpected data errors.

[3] B0 ~ B3 represent the bytes of the data to GDMA, from low address to high address.

[4] In the data to GDMA, Bn'[7:0] = Bn[0:7] (n = 0,1,2,3).

Note:
If only one byte is received each time, CAM_Data_in[7:0] is valid data. For such case, users must connect CAM_Data_in[7:0] with the master.

40.3.6 YUV-RGB Data Format Conversion

LCD_CAM is capable of converting data formats between YUV and RGB. The LCD module and Camera module each have a data format converter. The converters support format conversion:

- under BT601 and BT709 standards
- from RGB565 to YUV422/420/411 (full/limited range)
- from YUV422/YUV411 (full/limited range) to RGB565
- between YUV422/411 (full/limited range) formats

The converter in the LCD module also supports conversion:

- from YUV422/411 (full/limited range) to RGB888 (full/limited range)
- from RGB565 to YUV444 (full/limited range)
- between RGB888 (full/limited range) and RGB565
- from YUV422/411 (full/limited range) to YUV444 (full/limited range)

40.3.6.1 YUV Formats

In LCD_CAM module, assume that there are 8 pixels to be transmitted, corresponding to YUV data [Y_i, U_i, V_i] (i = 1 ~ 8). Then:

- In YUV422 mode, the LCD sends (or the camera receives) the data as follows:

Y_1	U_1	Y_2	V_2	Y_3	U_3	Y_4	V_4	Y_5	U_5	Y_6	V_6	Y_7	U_7	Y_8	V_8

- In YUV420 mode, the LCD and the camera do not participate in format conversion.
- In YUV411 mode, the LCD sends (or the camera receives) the data as follows:

Y_1	U_1	Y_2	Y_3	V_3	Y_4	Y_5	U_5	Y_6	Y_7	V_7	Y_8

40.3.6.2 Format Conversion Configuration

The configuration process for the format conversion in the Camera module is almost identical to that in the LCD module. Therefore, we will illustrate the process using the example of format conversion in the LCD module.

1. Enable YUV-RGB format converter by setting LCD_CAM_LCD_CONV_ENABLE.
2. Configure the valid bit width of the input data by configuring LCD_CAM_LCD_CONV_MODE_8BITS_ON:
   - 0: The valid bit width is 16 bits.
   - 1: The valid bit width is 8 bits.
3. Configure the valid bit width of the output data:
   - For the format conversion in the Camera module, the valid bit width of the output data is equal to that of the input data.
   - For the format conversion in the LCD module, when LCD_CAM_LCD_WIRE_MODE is:
     - 2: The valid bit width of the format converter's output data is 24 bits.
     - Other value: The valid bit width of the format converter's output data is equal to that of the input data.
4. Select the standard by configuring LCD_CAM_LCD_CONV_PROTOCOL_MODE:
   - 0: BT601 standard
   - 1: BT709 standard
5. Configure the conversion mode:
   - In 24-bit output mode:

Table 40.3-5. Conversion Mode Control in 24-bit Mode

Conversion Mode	TRANS_MODE[1]	YUV_MODE[2]	YUV2YUV_MODE[3]	RGB2RGB_MODE[4]
RGB565 → YUV444	1	-	3	-
RGB565 → RGB888	0	-	-	1
YUV422 → RGB888	0	0	3	-
YUV411 → RGB888	0	2	3	-
YUV422 → YUV444	1	0	0/1/2	-
YUV411 → YUV444	1	2	0/1/2	-

[1] The value of LCD_CAM_LCD_CONV_TRANS_MODE
[2] The value of LCD_CAM_LCD_CONV_YUV_MODE
[3] The value of LCD_CAM_LCD_CONV_YUV2YUV_MODE
[4] The value of LCD_CAM_LCD_CONV_RGB2RGB_MODE

- In other output modes:

Table 40.3-6. Conversion Mode Control in Other Modes

Conversion Mode	TRANS_MODE[1]	YUV_MODE[2]	YUV2YUV_MODE[3]	RGB2RGB_MODE[4]
RGB565 → YUV422	1	0	3	-
RGB565 → YUV420	1	1	3	-
RGB565 → YUV411	1	2	3	-
RGB888 → RGB565	0	-	-	1
YUV422 → RGB565	0	0	3	-
YUV411 → RGB565	0	2	3	-
YUV422 → YUV420	1	0	1	-
YUV422 → YUV411	1	0	2	-
YUV411 → YUV422	1	2	0	-
YUV411 → YUV420	1	2	1	-

[1] The value of LCD_CAM_LCD_CONV_TRANS_MODE
[2] The value of LCD_CAM_LCD_CONV_YUV_MODE
[3] The value of LCD_CAM_LCD_CONV_YUV2YUV_MODE
[4] The value of LCD_CAM_LCD_CONV_RGB2RGB_MODE

6. Configure the color range for the input data by configuring LCD_CAM_LCD_CONV_DATA_IN_MODE:
   - 0: limited color range[1]
   - 1: full color range[2]
7. Configure the color range for the output data by configuring LCD_CAM_LCD_CONV_DATA_OUT_MODE:
   - 0: limited color range[1]
   - 1: full color range[2]

Note:

1. If the limited color range is selected,

- the color range of RGB is: 16 ~ 240.
- the color range of YUV is:
  - Y: 16 ~ 240.
  - U-V: 16 ~ 235.

2. If the full color range is selected, the color range of RGB or YUV is 0 ~ 255.

40.3.7 LCD_CAM Timing

40.3.7.1 LCD Timing (RGB Format)

Figure 40.3-4 shows the LCD frame structure.

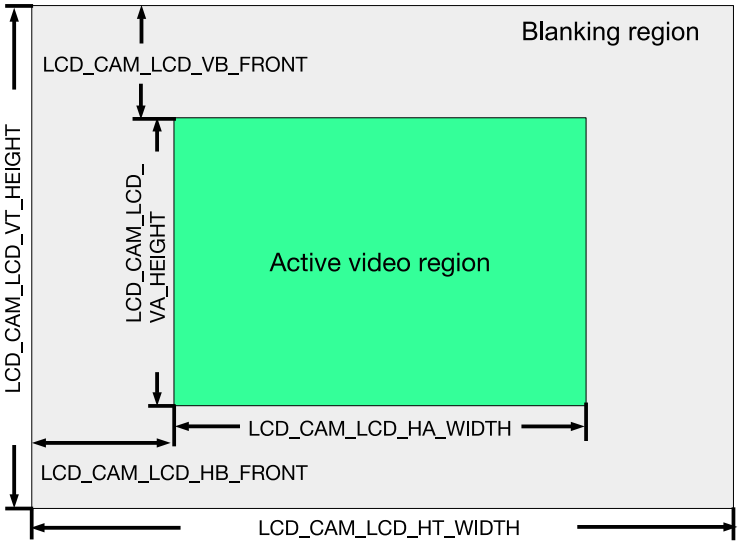

Figure 40.3-4. LCD Frame Structure

As depicted in the figure, the frame structure can be set up with the following registers:

- LCD_CAM_LCD_VT_HEIGHT
- LCD_CAM_LCD_VA_HEIGHT
- LCD_CAM_LCD_HB_FRONT
- LCD_CAM_LCD_HT_WIDTH
- LCD_CAM_LCD_HA_WIDTH
- LCD_CAM_VB_FRONT

Figure 40.3-5 shows the timing of an LCD full frame.

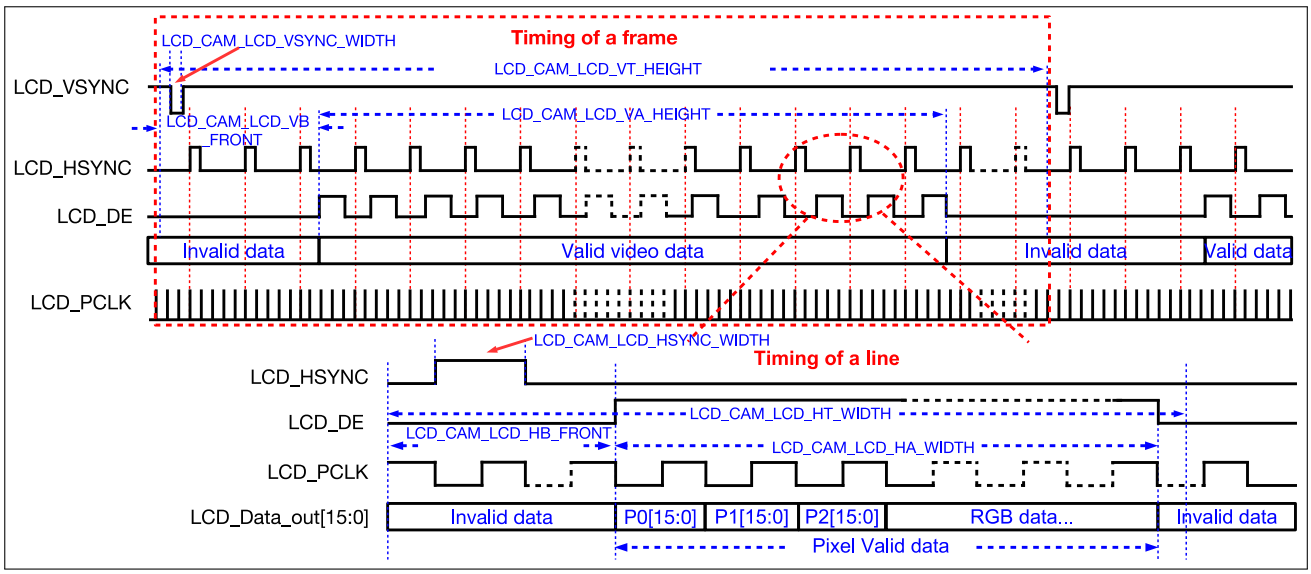

Figure 40.3-5. LCD Timing (RGB Format)

Note:

When configuring the parameters shown in the figures above, please note that the parameter is equal to the register value + 1. For example, if the expected VSYNC width is 1, then please configure LCD_CAM_LCD_VSYNC_WIDTH to 0. For more information, see the register description.

40.3.7.2 LCD Timing (I8080/MOTO6800 Format)

Figure 40.3-6 shows the LCD timing sequence in I8080/MOTO6800 format.

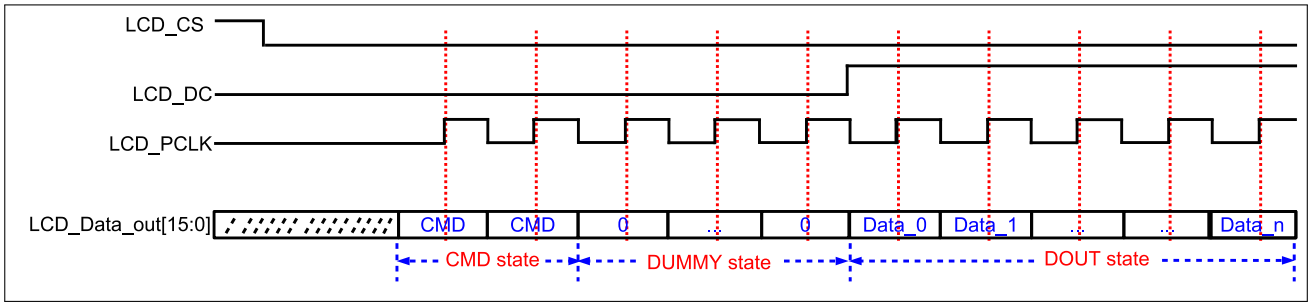

Figure 40.3-6. LCD Timing (I8080/MOTO6800 Format)

40.4 Interrupts

ESP32-P4's LCD_CAM can generate the following interrupt signal that will be sent to the Interrupt Matrix.

- LCD_CAM_INTR

The following internal interrupt sources from LCD_CAM can generate LCD_CAM_INTR:

- LCD_CAM_CAM_HS_INT: Triggered when the Camera module receives lines more than or equal to the value of LCD_CAM_CAM_LINE_INT_NUM + 1.
- LCD_CAM_CAM_VSYNC_INT: Triggered when the Camera module receives a whole frame.

- LCD_CAM_LCD_TRANS_DONE_INT: Triggered when the LCD module finishes the transmission.
- LCD_CAM_LCD_VSYNC_INT: Triggered when the LCD module transmits a whole frame.

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

40.5 Software Configuration Process

Note:
Updating the configurations of the LCD module or the Camera module requires setting the LCD_CAM_LCD_UPDATE and LCD_CAM_CAM_UPDATE respectively to synchronize registers from the APB clock domain to the LCD/camera clock domain. Check the configuration examples below for more details.

40.5.1 Configure LCD (RGB Format) as TX Mode

Follow the steps below to configure LCD (RGB format) as TX mode via software:

1. Configure clock according to Section 40.3.3.
2. Configure signal pins according to Table 40.3-1 and Chapter 10 *GPIO Matrix and IO MUX*.
3. Enable corresponding interrupts, see Section 40.4.
4. Enable RGB format by setting LCD_CAM_LCD_RGB_MODE_EN.
5. Configure frame structure according to Section 40.3.7.1.
6. Set LCD_CAM_LCD_UPDATE so that the configurations take effect.
7. Reset TX control unit (LCD_Ctrl) and Async TX FIFO as described in Section 40.3.4.
8. Configure GDMA outlink, see Chapter 7 *VDMA Controller (VDMA)*.
9. Start transmitting data:
   - Wait till LCD slave gets ready.
   - Set LCD_CAM_LCD_START to start transmitting data.
10. Wait for the interrupt signals set in Step 3.
11. In frame intervals during data transmission, check if LCD_CAM_LCD_NEXT_FRAME_EN is set:
    - If yes, set LCD_CAM_LCD_UPDATE (repeating the steps above) to continue transmitting next frame.
    - If not, LCD stops transmitting data.
12. Clear LCD_CAM_LCD_START if data transmission is done.

40.5.2 Configure LCD (I8080/MOTO6800 Format) as TX Mode

Follow the steps below to configure LCD (I8080/MOTO6800 format) as TX mode via software:

1. Configure clock according to Section 40.3.3.

2. Configure signal pins according to Table 40.3-1 and Chapter 10 *GPIO Matrix and IO MUX*.
3. Enable corresponding interrupts, see Section 40.4.
4. Clear LCD_CAM_LCD_RGB_MODE_EN to disable RGB format.
5. Configure CMD phase with LCD_CAM_LCD_CMD, LCD_CAM_LCD_CMD_2_CYCLE_EN, and LCD_CAM_LCD_LATTER_CMD_VALUE.
6. Configure DUMMY phase with LCD_CAM_LCD_DUMMY and LCD_CAM_LCD_DUMMY_CYCLELEN.
7. Configure DOUT phase with LCD_CAM_LCD_DOUT, depending on the output mode:
   - In a fixed-length output[1], configure data length in LCD_CAM_LCD_DOUT_CYCLELEN.
   - In a continuous output[2], set LCD_CAM_LCD_ALWAYS_OUT_EN. Users do not need to configure LCD_CAM_LCD_DOUT_CYCLELEN.

   Note:

   (a) In a fixed-length output, the LCD module stops sending data once the data length reaches the value set in LCD_CAM_LCD_DOUT_CYCLELEN.

   (b) In a continuous output, LCD module keeps sending data till:

   - LCD_CAM_LCD_START is cleared;
   - or LCD_CAM_LCD_RESET is set;
   - or all the data in GDMA is sent out.

8. Configure the CD signal mode, including the default value of the CD signal and the values at each phase, see the description of LCD_CAM_LCD_MISC_REG.
9. Set LCD_CAM_LCD_UPDATE so that the configurations take effect.
10. Reset TX control unit (LCD_Ctrl) and Async TX FIFO as described in Section 40.3.4.
11. Configure GDMA outlink, see Chapter 7 *VDMA Controller (VDMA)*.
12. Start transmitting data:
    - Wait till LCD slave gets ready.
    - Set LCD_CAM_LCD_START to start transmitting data.
13. Wait for the interrupt signals set in Step 2.
14. Clear LCD_CAM_LCD_START if data transmission is done.

Notes:

No matter in which format, RGB or I8080/MOTO6800, the rules below must be followed when accessing internal and external memory via GDMA:

- If LCD data bus is configured to 8-bit parallel output mode, then
  - The pixel clock frequency must be less than 80 MHz.
  - If YUV-RGB format conversion is being used at the same time, the pixel clock frequency must be less than 60 MHz.
- If LCD data bus is configured to 16-bit parallel output mode, then

- The pixel clock frequency must be less than 40 MHz.
- If YUV-RGB format conversion is being used at the same time, the pixel clock frequency must be less than 30 MHz.

40.5.3 Configure Camera as RX Mode

Follow the steps below to configure the Camera as RX mode via software:

1. Configure clock according to Section 40.3.3. Note that in slave mode, the module clock frequency should be twice as fast as the PCLK frequency of the image sensor.
2. Configure signal pins according to Table 40.3-1 and Chapter 10 *GPIO Matrix and IO MUX*.
3. Set or clear LCD_CAM_CAM_VH_DE_MODE_EN according to the control signal HSYNC.
4. Set needed RX data format according to Section 40.3.5.2.
5. Set LCD_CAM_CAM_UPDATE so that the configurations take effect.
6. Reset RX control unit (Camera_Ctrl) and Async RX FIFO as described in Section 40.3.4.
7. Enable corresponding interrupts, see Section 40.4.
8. Configure GDMA inlink, and set the length of RX data in LCD_CAM_CAM_REC_DATA_BYTELEN.
9. Start receiving data:
   - In master mode, when the slave is ready, set LCD_CAM_CAM_START to start receiving data.
   - In slave mode, set LCD_CAM_CAM_START. Receiving data starts after the master provides clock signal and control signal.
10. Receive data and store the data to GDMA. Then corresponding interrupts set in Step 7 will be generated.

Notes:

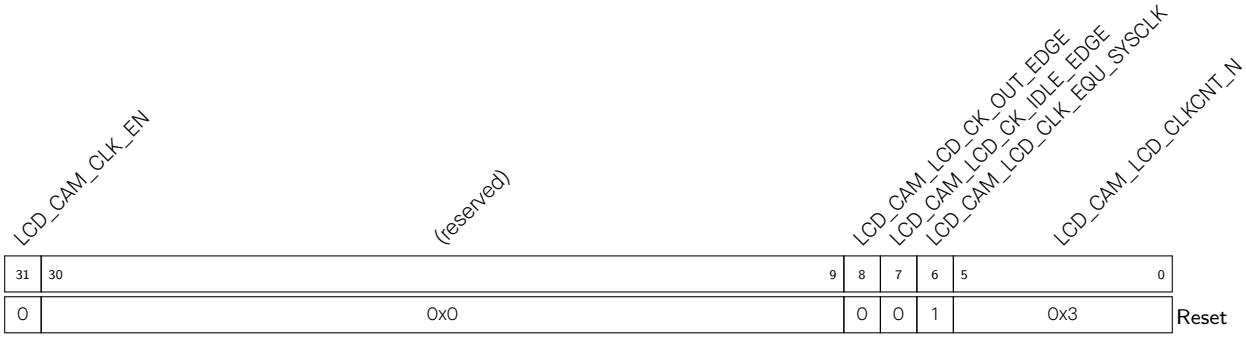
- No matter in which operation mode, camera master RX mode or camera slave RX mode, the rules below must be followed when accessing internal memory via GDMA:
  - If 8-bit parallel data input mode is selected, then
    * The pixel clock frequency must be less than 80 MHz.
    * If YUV-RGB format is being used at the same time, the pixel clock frequency must be less than 60 MHz.
  - If 16-bit parallel data input mode is selected, then
    * The pixel clock frequency must be less than 40 MHz.
    * If YUV-RGB format conversion is being used at the same time, the pixel clock frequency must be less than 30 MHz.

Note:
If both LCD and camera are connected externally at the same time, it is necessary to ensure that the maximum data throughput on the interface is less than the total data bandwidth of GDMA when accessing internal/external storage. The default frequency of APB_CLK is 80 MHz in this scenario. For more information about APB_CLK, see Chapter 11 *Reset and Clock*.

40.6 Register Summary

The addresses in this section are relative to LCD_CAM base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



Name	Description	Address	Access
LCD Module Configuration Registers			
LCD_CAM_LCD_CLOCK_REG	LCD clock configuration register	0x0000	R/W
LCD_CAM_LCD_RGB_YUV_REG	LCD data format conversion register	0x0010	R/W
LCD_CAM_LCD_USER_REG	LCD user configuration register	0x0014	varies
LCD_CAM_LCD_MISC_REG	LCD MISC configuration register	0x0018	varies
LCD_CAM_LCD_CTRL_REG	LCD signal configuration register	0x001C	R/W
LCD_CAM_LCD_CTRL1_REG	LCD signal configuration register 1	0x0020	R/W
LCD_CAM_LCD_CTRL2_REG	LCD signal configuration register 2	0x0024	R/W
LCD_CAM_LCD_FIRST_CMD_VAL_REG	LCD command value configuration register	0x0028	R/W
LCD_CAM_LCD_LATTER_CMD_VAL_REG	LCD command value configuration register	0x002C	R/W
LCD_CAM_LCD_DLY_MODE_CFG1_REG	LCD data/signal delay configuration register	0x0030	R/W
LCD_CAM_LCD_DLY_MODE_CFG2_REG	LCD signal delay mode configuration register	0x0038	R/W
Camera Module Configuration Registers			
LCD_CAM_CAM_CTRL_REG	Camera clock configuration	0x0004	R/W
LCD_CAM_CAM_CTRL1_REG	Camera control register	0x0008	varies
LCD_CAM_CAM_RGB_YUV_REG	Camera data format conversion register	0x000C	R/W
Interrupt Registers			
LCD_CAM_LC_DMA_INT_ENA_REG	LCD_CAM GDMA interrupt enable register	0x0064	R/W
LCD_CAM_LC_DMA_INT_RAW_REG	LCD_CAM GDMA raw interrupt status register	0x0068	RO
LCD_CAM_LC_DMA_INT_ST_REG	LCD_CAM GDMA masked interrupt status register	0x006C	RO
LCD_CAM_LC_DMA_INT_CLR_REG	LCD_CAM GDMA interrupt clear register	0x0070	WO
Version Control Register			
LCD_CAM_LC_DATE_REG	Version control register	0x00FC	R/W

40.7 Registers

The addresses in this section are relative to LCD_CAM base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 40.1. LCD_CAM_LCD_CLOCK_REG (0x0000)

LCD_CAM_LCD_CLKCNT_N Determines the frequency of the LCD pixel clock LCD_PCLK together with LCD_CAM_LCD_CLK_EQU_SYSCLK.

When LCD_CAM_LCD_CLK_EQU_SYSCLK = 0,

$f_{LCD_PCLK} = f_{LCD_CLK}/$(LCD_CAM_LCD_CLKCNT_N + 1)

Note: this field must not be configured to 0.

(R/W)

LCD_CAM_LCD_CLK_EQU_SYSCLK Determines the frequency of the LCD pixel clock LCD_PCLK together with LCD_CAM_LCD_CLK_EQU_SYSCLK.

0: $f_{LCD_PCLK} = f_{LCD_CLK}/$(LCD_CAM_LCD_CLKCNT_N + 1)

1: $f_{LCD_PCLK} = f_{LCD_CLK}$

(R/W)

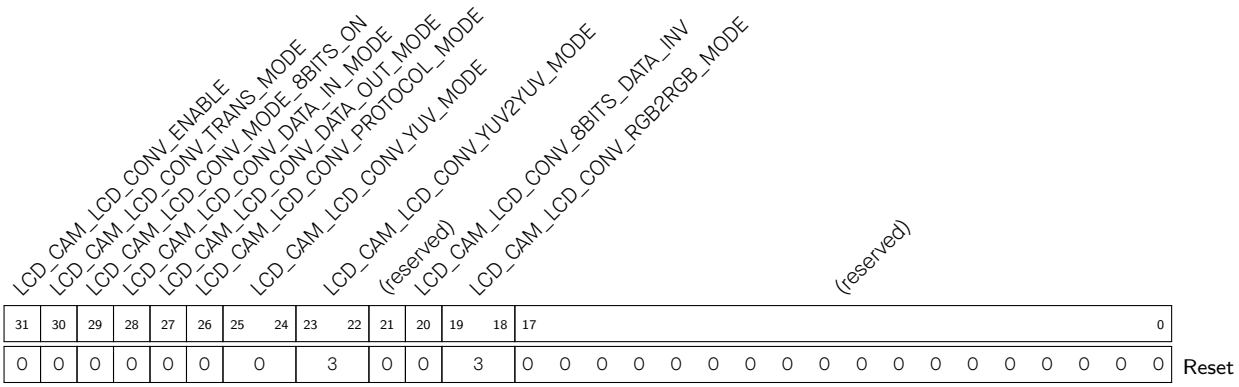
LCD_CAM_LCD_CK_IDLE_EDGE Indicates the level of LCD_PCLK in idle state.

0: LCD_PCLK is low.

1: LCD_PCLK is high.

(R/W)

LCD_CAM_LCD_CK_OUT_EDGE Indicates the level of LCD_PCLK in the first half clock cycle.



0: LCD_PCLK is low.

1: LCD_PCLK is high.

(R/W)

LCD_CAM_CLK_EN Set this bit to force enable the clock for all configuration registers. Clock gate is not used. (R/W)

Register 40.2. LCD_CAM_LCD_RGB_YUV_REG (0x0010)

LCD_CAM_LCD_CONV_RGB2RGB_MODE Configures data format conversion in RGB-to-RGB mode.

0: Data is converted to RGB565 format.

1: Data is converted to RGB888 format.

2/3: Data format conversion is disabled.

(R/W)

LCD_CAM_LCD_CONV_8BITS_DATA_INV Configures whether to swap every two 8-bit GDMA input data.

0: Do not swap.

1: Swap.

(R/W)

LCD_CAM_LCD_CONV_YUV2YUV_MODE Configures data format conversion in YUV-to-YUV mode.

0: Data is converted to YUV422 format.

1: Data is converted to YUV420 format.

2: Data is converted to YUV411 format.

3: Data format conversion is disabled.

Only valid when LCD_CAM_LCD_CONV_TRANS_MODE = 1.

(R/W)

LCD_CAM_LCD_CONV_YUV_MODE Configures the YUV format of input data in YUV-to-YUV mode and YUV-to-RGB mode.

0: Input data is in YUV422 format.

1: Input data is in YUV420 format.

2: Input data is in YUV411 format.

(R/W)

LCD_CAM_LCD_CONV_PROTOCOL_MODE Configures the data format conversion standard.

0: BT601.

1: BT709.

(R/W)

LCD_CAM_LCD_CONV_DATA_OUT_MODE Configures the color range for output data.

0: Limited color range.

1: Full color range.

(R/W)

Continued on the next page...

Register 40.2. LCD_CAM_LCD_RGB_YUV_REG (0x0010)

Continued from the previous page...

LCD_CAM_LCD_CONV_DATA_IN_MODE Configures the color range for input data.

0: Limited color range.

1: Full color range.

(R/W)

LCD_CAM_LCD_CONV_MODE_8BITS_ON Configures the valid bit width of the YUV-RGB converter's input data.

0: 16 bits.

1: 8 bits.

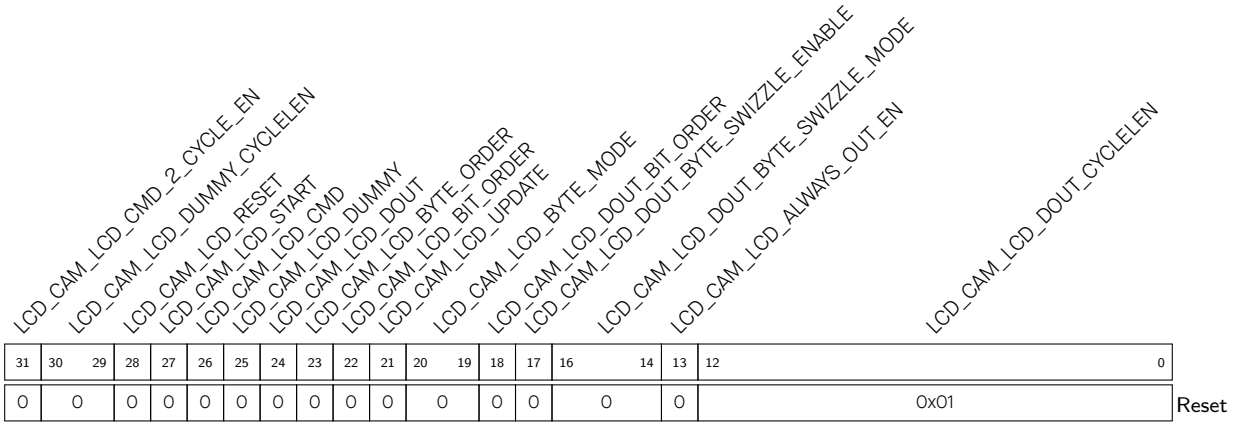
(R/W)

LCD_CAM_LCD_CONV_TRANS_MODE Configures the RGB or YUV format for data conversion.

0: Converted to RGB format.

1: Converted to YUV format.

(R/W)



LCD_CAM_LCD_CONV_ENABLE Configures whether to enable YUV-RGB converter.

0: Bypass the converter.

1: Enable the converter.

(R/W)

Register 40.3. LCD_CAM_LCD_USER_REG (0x0014)

LCD_CAM_LCD_DOUT_CYCLELEN Configures the period of the LCD module's data output phase (DOUT). The actual period duration = the value of this field + 1. (R/W)

LCD_CAM_LCD_ALWAYS_OUT_EN Enables continuous output of the LCD module. In this mode, the LCD module continuously outputs data during the DOUT phase, until LCD_CAM_LCD_START is cleared or LCD_CAM_LCD_RESET is set. (R/W)

LCD_CAM_LCD_DOUT_BYTE_SWIZZLE_MODE Configures LCD output data byte reordering. For details please refer to Table 40.3-3. (R/W)

LCD_CAM_LCD_DOUT_BYTE_SWIZZLE_ENABLE Configures whether to enable LCD output data byte reordering.

0: Disable

1: Enable

(R/W)

LCD_CAM_LCD_DOUT_BIT_ORDER Configures whether to invert the LCD output data bit order.

0: Do not invert.

1: Invert the bit order. In n-bit mode, LCD_DATA_in[n-1:0] is inverted to LCD_DATA_in[0:n-1].

(R/W)

LCD_CAM_LCD_BYTE_MODE Configures the data bit width from GDMA.

0: 8-bit

1: 16-bit

2: 24-bit

(R/W)

LCD_CAM_LCD_UPDATE Configures whether to update the LCD register configurations.

0: Do not update.

1: Update configurations. This bit is cleared by hardware.

(R/W)

LCD_CAM_LCD_BIT_ORDER Configures whether to invert the bit order of the LCD input data.

0: Do not invert.

1: Invert the bit order. In n-bit mode, LCD_DATA_in[n-1:0] is invertd to LCD_DATA_in[0:n-1].

(R/W)

Continued on the next page...

Register 40.3. LCD_CAM_LCD_USER_REG (0x0014)

Continued from the previous page...

LCD_CAM_LCD_BYTE_ORDER Configures whether to invert the byte order of the LCD input data.

0: Do not invert.

1: Invert data byte order, only valid in 16/24-bit mode.

(R/W)

LCD_CAM_LCD_DOUT Configures the LCD DOUT phase.

0: Disable.

1: The LCD module sends data in RGB/I8080 format.

(R/W)

LCD_CAM_LCD_DUMMY Configures the LCD DUMMY phase.

0: Disable.

1: Enable the DUMMY phase when LCD initiates.

(R/W)

LCD_CAM_LCD_CMD Configures the LCD CMD phase.

0: Disable.

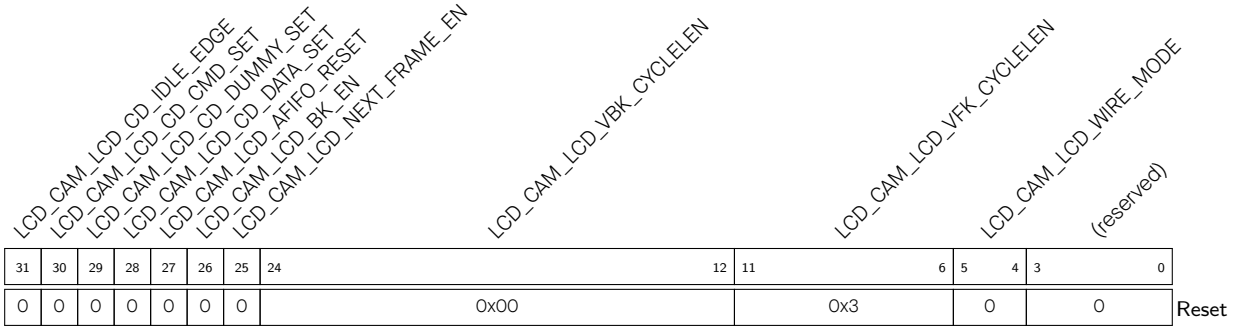
1: The LCD module sends commands.

(R/W)

LCD_CAM_LCD_START When set to 1, the LCD module starts transmitting data. (R/W)

LCD_CAM_LCD_RESET When set to 1, the LCD module is reset. (WO)

LCD_CAM_LCD_DUMMY_CYCLELEN Configures DUMMY cycles. DUMMY cycles = this value + 1. (R/W)



LCD_CAM_LCD_CMD_2_CYCLE_EN Configures the number of cycles of the Command phase.

0: One cycle.

1: Two cycles.

(R/W)

Register 40.4. LCD_CAM_LCD_MISC_REG (0x0018)

LCD_CAM_LCD_WIRE_MODE Configures the bit width of LCD output data to GPIO.

0: 8-bit

1: 16-bit

2: 24-bit

(R/W)

LCD_CAM_LCD_VFK_CYCLELEN Configures the clock cycles of the setup time in LCD non-RGB mode. Setup clock cycles = this value + 1. (R/W)

LCD_CAM_LCD_VBK_CYCLELEN Configures the clock cycles of the hold time in LCD non-RGB mode. Hold clock cycles = this value + 1. (R/W)

LCD_CAM_LCD_NEXT_FRAME_EN Configures whether to send the next frame.

0: The LCD module stops when the current frame is sent out.

1: The LCD module continues sending the next frame when the current frame is sent out.

(R/W)

LCD_CAM_LCD_BK_EN Configures whether to enable blanking region when LCD sends data.

0: No blanking region.

1: Enable blanking region.

(R/W)

LCD_CAM_LCD_AFIFO_RESET When set to 1, Async TX FIFO is reset. (WO)

LCD_CAM_LCD_CD_DATA_SET Configures LCD_CD value in DOUT phase for LCD I8080 mode.

0: LCD_CD = LCD_CAM_LCD_CD_IDLE_EDGE

1: LCD_CD = !LCD_CAM_LCD_CD_IDLE_EDGE

(R/W)

LCD_CAM_LCD_CD_DUMMY_SET Configures LCD_CD value in DUMMY phase for LCD I8080 mode.

0: LCD_CD = LCD_CAM_LCD_CD_IDLE_EDGE

1: LCD_CD = !LCD_CAM_LCD_CD_IDLE_EDGE

(R/W)

LCD_CAM_LCD_CD_CMD_SET Configures LCD_CD value in CMD phase for LCD I8080 mode.

0: LCD_CD = LCD_CAM_LCD_CD_IDLE_EDGE

1: LCD_CD = !LCD_CAM_LCD_CD_IDLE_EDGE

(R/W)

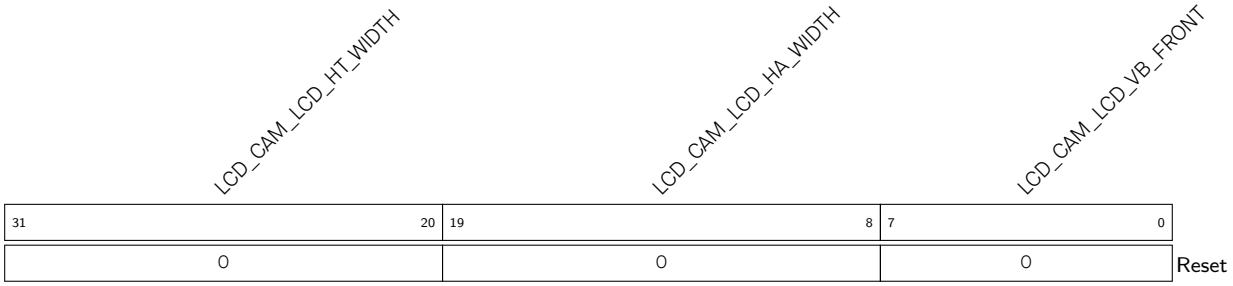
LCD_CAM_LCD_CD_IDLE_EDGE The default value of LCD_CD. (R/W)

Register 40.5. LCD_CAM_LCD_CTRL_REG (0x001C)

LCD_CAM_LCD_HB_FRONT Configures the value of (HSYNC_POSITION + HSYNC_WIDTH + horizontal back porch). (R/W)

LCD_CAM_LCD_VA_HEIGHT Configures the vertical active height of a frame. (R/W)

LCD_CAM_LCD_VT_HEIGHT Configures the vertical total height of a frame. (R/W)



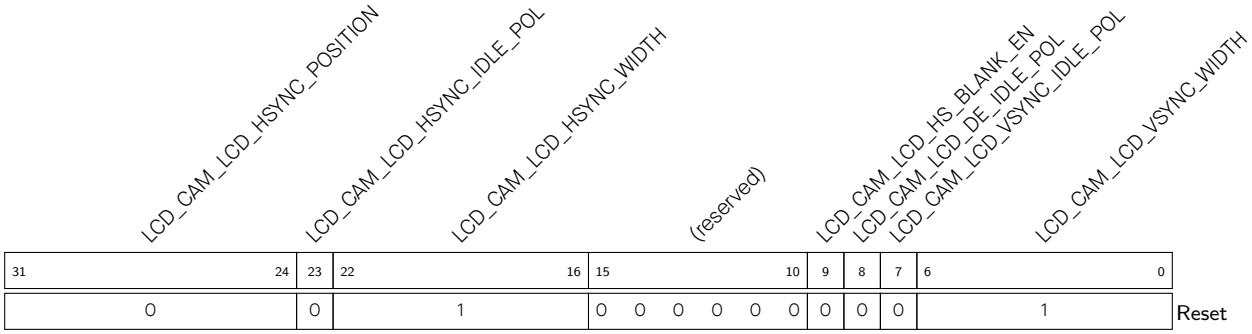
LCD_CAM_LCD_RGB_MODE_EN Configures whether to enable RGB mode.

0: Disable RGB mode.

1: Enable RGB mode and input VSYNC, HSYNC, and DE signals.

(R/W)

Register 40.6. LCD_CAM_LCD_CTRL1_REG (0x0020)



LCD_CAM_LCD_VB_FRONT Configures the value of (VSYNC_WIDTH + vertical back porch). (R/W)

LCD_CAM_LCD_HA_WIDTH Configures the horizontal active width of a frame. (R/W)

LCD_CAM_LCD_HT_WIDTH Configures the horizontal total width of a frame. (R/W)

Register 40.7. LCD_CAM_LCD_CTRL2_REG (0x0024)

LCD_CAM_LCD_VSYNC_WIDTH Configures the width of LCD_VSYNC active pulse in a line. Expected width = this value + 1. (R/W)

LCD_CAM_LCD_VSYNC_IDLE_POL Configures the idle value of LCD_VSYNC.

0: The idle value is low.

1: The idle value is high.

(R/W)

LCD_CAM_LCD_DE_IDLE_POL Configures the idle value of LCD_DE.

0: The idle value is low.

1: The idle value is high.

(R/W)

LCD_CAM_LCD_HS_BLANK_EN Configures the LCD_HSYNC output in RGB mode.

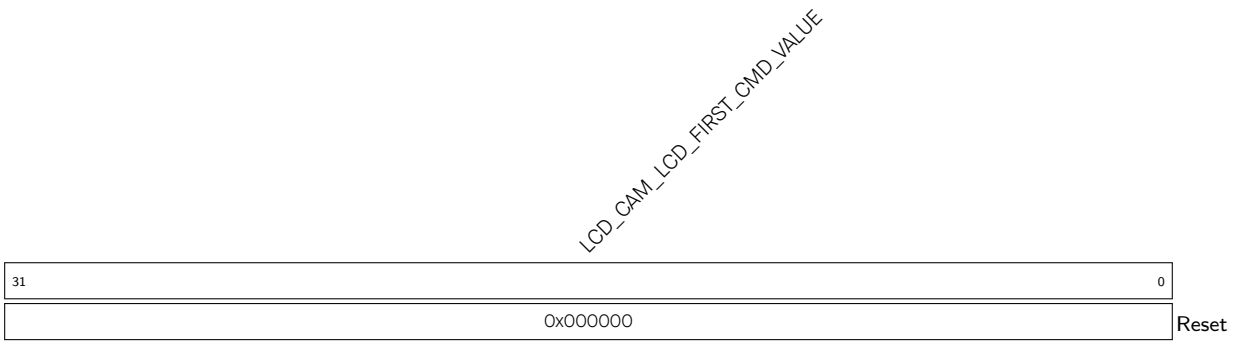
0: LCD_HSYNC is output only in active video lines.

1: LCD_HSYNC can be output in vertical blanking intervals.

(R/W)

LCD_CAM_LCD_HSYNC_WIDTH Configures the width of LCD_HSYNC active pulse. Expected width = this value +1. (R/W)

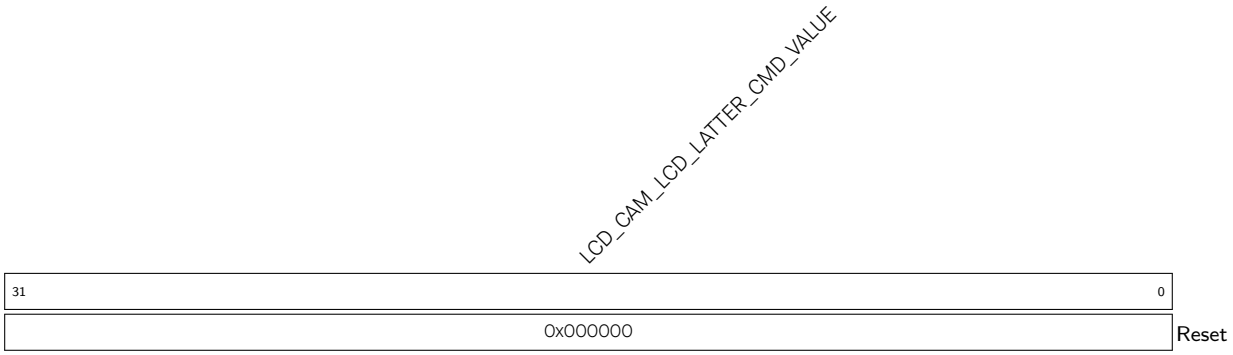
LCD_CAM_LCD_HSYNC_IDLE_POL Configures the idle value of LCD_HSYNC.



0: The idle value is low.

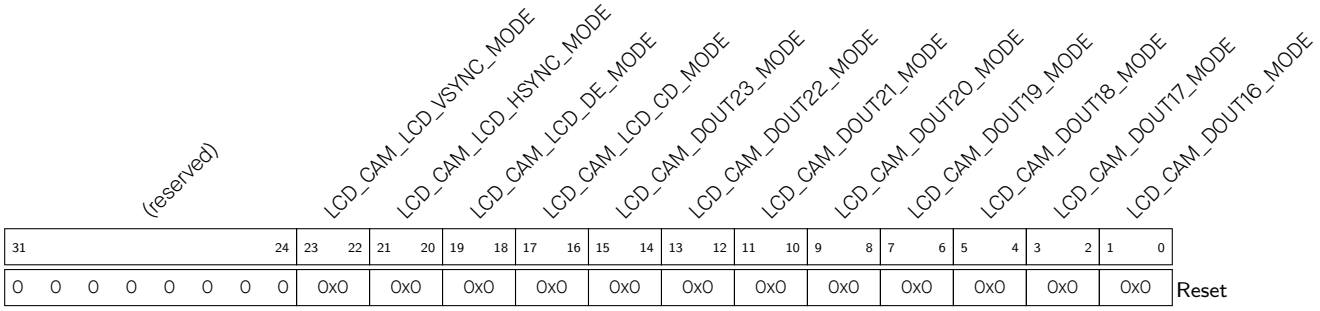
1: The idle value is high.

(R/W)



LCD_CAM_LCD_HSYNC_POSITION Configures the position of LCD_HSYNC active pulse. Expected position = this value + 1. Unit is a pixel. (R/W)

Register 40.8. LCD_CAM_LCD_FIRST_CMD_VAL_REG (0x0028)



LCD_CAM_LCD_FIRST_CMD_VALUE Configures the value of the transmitted command when the LCD module is in the first cycle of the CMD phase. (R/W)

Register 40.9. LCD_CAM_LCD_LATTER_CMD_VAL_REG (0x002C)

LCD_CAM_LCD_LATTER_CMD_VALUE Configures the value of the transmitted command when the LCD module is in the second cycle of the CMD phase. (R/W)

Register 40.10. LCD_CAM_LCD_DLY_MODE_CFG1_REG (0x0030)

LCD_CAM_DOUT*n*_MODE (*n*: 16 - 23) Configures the delay of the output data bit (*n*).

0: No delay.

1: Delayed at the rising edge of LCD_CLK.

2: Delayed at the falling edge of LCD_CLK.

(R/W)

LCD_CAM_LCD_CD_MODE Configures the delay of LCD_CD output signal.

0: No delay.

1: Delayed at the rising edge of LCD_CLK.

2: Delayed at the falling edge of LCD_CLK.

(R/W)

LCD_CAM_LCD_DE_MODE Configures the delay of LCD_DE output signal.

0: No delay.

1: Delayed at the rising edge of LCD_CLK.

2: Delayed at the falling edge of LCD_CLK.

(R/W)

LCD_CAM_LCD_HSYNC_MODE Configures the delay of LCD_HSYNC output signal.

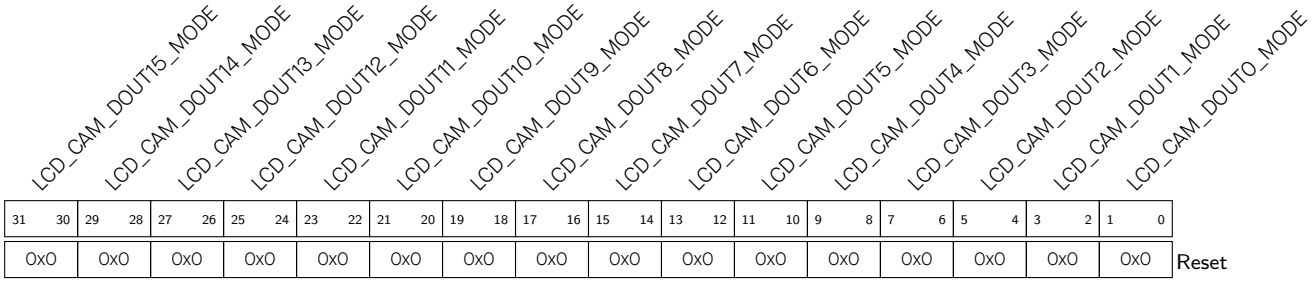
0: No delay.

1: Delayed at the rising edge of LCD_CLK.

2: Delayed at the falling edge of LCD_CLK.

(R/W)

LCD_CAM_LCD_VSYNC_MODE Configures the delay of LCD_VSYNC output signal.



0: No delay.

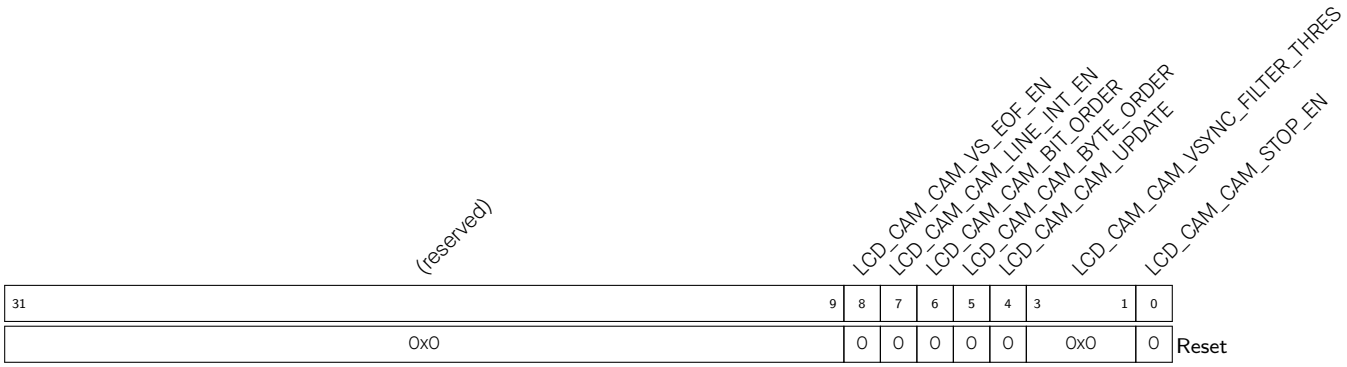
1: Delayed at the rising edge of LCD_CLK.

2: Delayed at the falling edge of LCD_CLK.

(R/W)

Register 40.11. LCD_CAM_LCD_DLY_MODE_CFG2_REG (0x0038)

LCD_CAM_DOUT*n*_MODE (*n*: 0 - 15) Configures the delay of the output data bit *n*.



0: No delay.

1: Delayed at the rising edge of LCD_CLK.

2: Delayed at the falling edge of LCD_CLK.

(R/W)

Register 40.12. LCD_CAM_CAM_CTRL_REG (0x0004)

LCD_CAM_CAM_STOP_EN Configures whether to stop the Camera module.

0: Do not stop.

1: The Camera module stops when GDMA RX FIFO is full.

(R/W)

LCD_CAM_CAM_VSYNC_FILTER_THRES Configures the filter threshold value for CAM_VSYNC signal. (R/W)

LCD_CAM_CAM_UPDATE Configures whether to update the Camera register configurations.

0: No effect.

1: Update configurations. This bit is cleared by hardware.

(R/W)

LCD_CAM_CAM_BYTE_ORDER Configures whether to invert the byte order of the Camera's input data.

0: Do not invert.

1: Invert data byte order, only valid in 16-bit mode.

(R/W)

LCD_CAM_CAM_BIT_ORDER Configures whether to invert the bit order of the Camera's input data.

0: Do not invert.

1: Invert the bit order. In n-bit mode, CAM_DATA_in[n-1:0] is invertd to CAM_DATA_in[0:n-1]. n = 8 or 15.

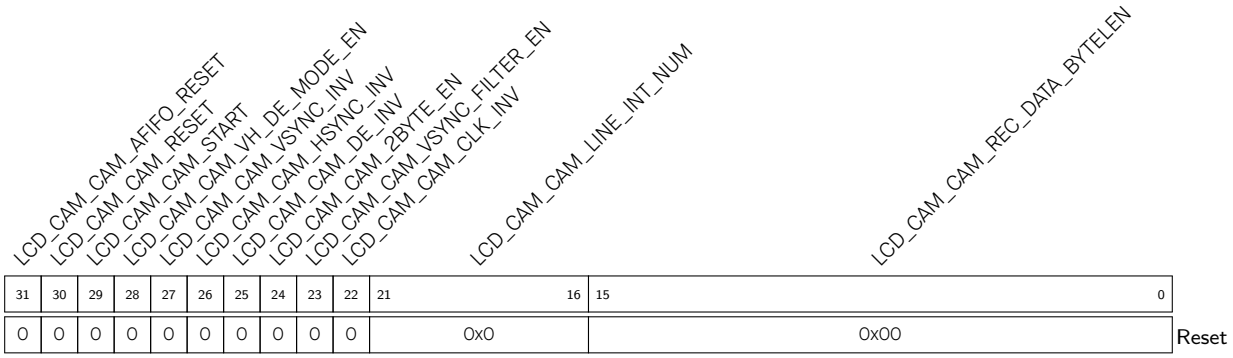
(R/W)

LCD_CAM_CAM_LINE_INT_EN Configures whether the RAW bit of LCD_CAM_CAM_HS_INT can generate.

0: Disable the interrupt, i.e., LCD_CAM_CAM_HS_INT_RAW cannot generate.

1: Enable the interrupt, i.e., LCD_CAM_CAM_HS_INT_RAW can generate.

(R/W)



LCD_CAM_CAM_VS_EOF_EN Configures whether to enable CAM_VSYNC to generate in_suc_eof.

0: in_suc_eof is controlled by LCD_CAM_CAM_REC_DATA_BYTELEN.

1: in_suc_eof is controlled by CAM_VSYNC.

(R/W)

Register 40.13. LCD_CAM_CAM_CTRL1_REG (0x0008)

LCD_CAM_CAM_REC_DATA_BYTELEN Configures the data byte length received by the Camera module. When the length of received data reaches this value + 1, GDMA in_suc_eof_int is triggered. (R/W)

LCD_CAM_CAM_LINE_INT_NUM Configures the number of video lines. When the number of video lines reaches this value + 1, LCD_CAM_CAM_HS_INT is triggered. (R/W)

LCD_CAM_CAM_CLK_INV Configures whether to invert the input signal CAM_PCLK.

0: Do not invert.

1: Invert.

(R/W)

LCD_CAM_CAM_VSYNC_FILTER_EN Configures whether to enable CAM_VSYNC filter function.

0: Bypass.

1: Enable.

(R/W)

LCD_CAM_CAM_2BYTE_EN Configures the width of input data.

0: 8 bits.

1: 16 bits.

(R/W)

LCD_CAM_CAM_DE_INV Configures whether to invert the input signal CAM_DE.

0: Do not invert.

1: Invert.

(R/W)

LCD_CAM_CAM_HSYNC_INV Configures whether to invert the input signal CAM_HSYNC.

0: Do not invert.

1: Invert.

(R/W)

LCD_CAM_CAM_VSYNC_INV Configures whether to invert the input signal CAM_VSYNC.

0: Do not invert.

1: Invert.

(R/W)

Continued on the next page...

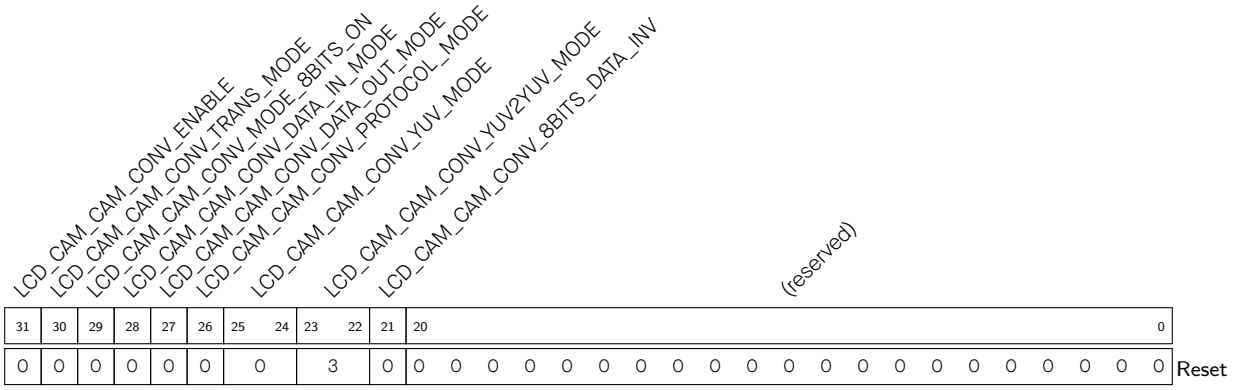
Register 40.13. LCD_CAM_CAM_CTRL1_REG (0x0008)

Continued from the previous page...

LCD_CAM_CAM_VH_DE_MODE_EN Configures the input control signals.

0: VSYNC and DE signals control the data. In this case, wiring HSYNC signal line is not a must. But in this case, the YUV-RGB conversion function of the camera module is not available.

1: VSYNC, HSYNC, and DE signals control the data. In this case, users need to wire the three signal lines.



(R/W)

LCD_CAM_CAM_START Camera module start signal. (R/W)

LCD_CAM_CAM_RESET When set to 1, the Camera module is reset. (WO)

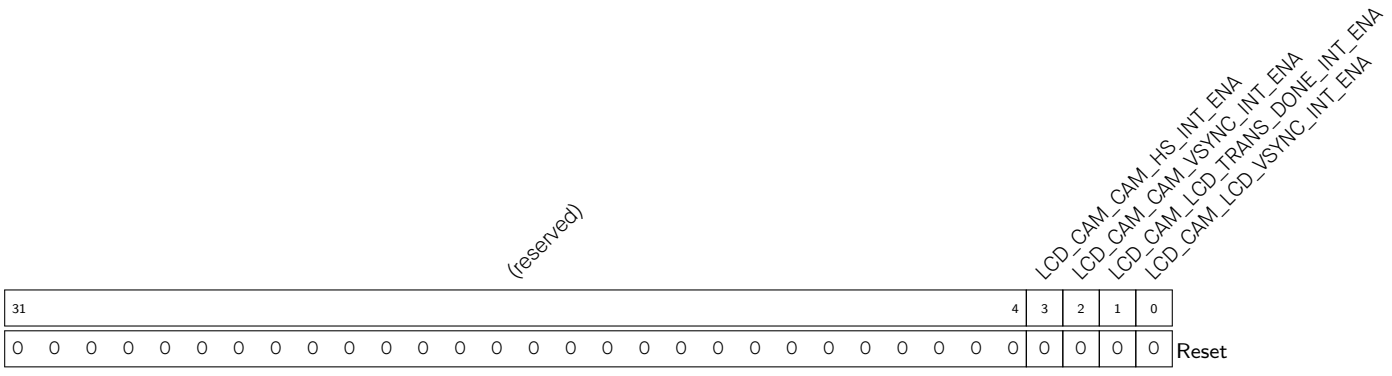
LCD_CAM_CAM_AFIFO_RESET When set to 1, the Camera Async RX FIFO is reset. (WO)

Register 40.14. LCD_CAM_CAM_RGB_YUV_REG (0x000C)

LCD_CAM_CAM_CONV_ENABLE
LCD_CAM_CAM_CONV_TRANS_MODE
LCD_CAM_CAM_CONV_MODE_8BITS_ON
LCD_CAM_CAM_CONV_DATA_IN_MODE
LCD_CAM_CAM_CONV_DATA_OUT_MODE
LCD_CAM_CAM_CONV_PROTOCOL_MODE
LCD_CAM_CAM_CONV_YUV_MODE
LCD_CAM_CAM_CONV_YUV2YUV_MODE
LCD_CAM_CAM_CONV_8BITS_DATA_INV
(reserved)
31 30 29 28 27 26 25 24 23 22 21 20 0
0 0 0 0 0 0 0 3 0 0 0 0 0 0

Register 40.14. LCD_CAM_CAM_RGB_YUV_REG (0x000C)

Continued from the previous page...



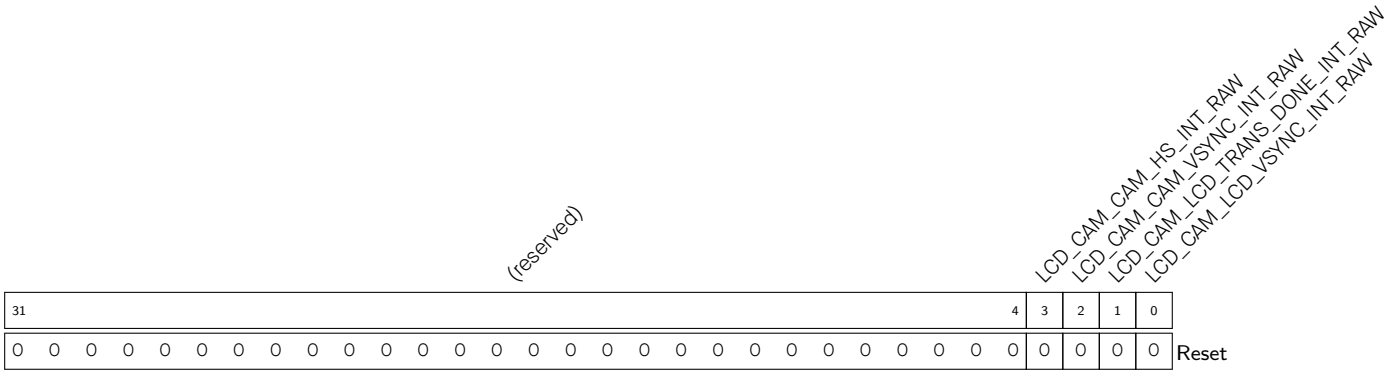
LCD_CAM_CAM_CONV_DATA_IN_MODE Configures the color range for the YUV-RGB converter's input data.
0: Limited color range.
1: Full color range.
(R/W)

LCD_CAM_CAM_CONV_MODE_8BITS_ON Configures the bit width of the YUV-RGB converter's input data.
0: 16-bit mode.
1: 8-bit mode.
(R/W)

LCD_CAM_CAM_CONV_TRANS_MODE Configures the data conversion format.
0: Data is converted to RGB format.
1: Data is converted to YUV format.
(R/W)

LCD_CAM_CAM_CONV_ENABLE Configures whether to enable the YUV-RGB converter.
0: Bypass.
1: Enable.
(R/W)

Register 40.15. LCD_CAM_LC_DMA_INT_ENA_REG (0x0064)



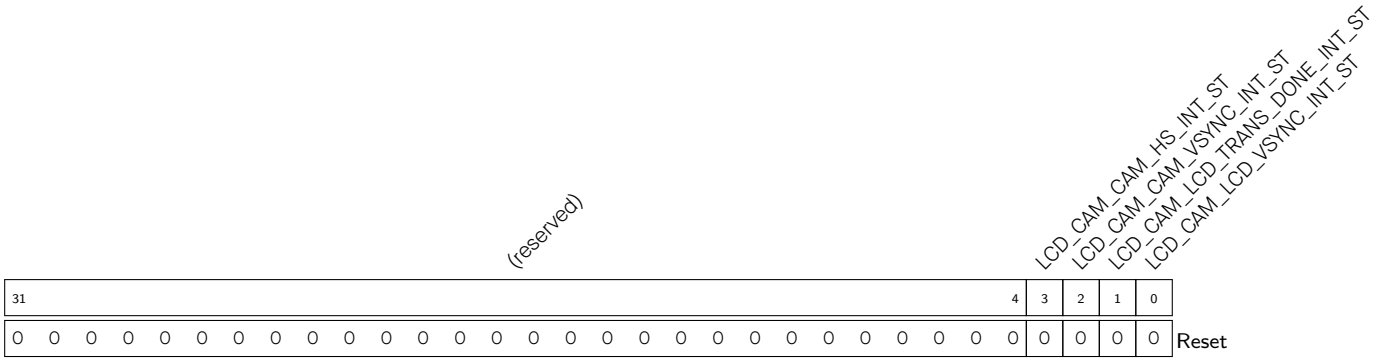
LCD_CAM_LCD_VSYNC_INT_ENA Write 1 to enable LCD_CAM_LCD_VSYNC_INT. (R/W)

LCD_CAM_LCD_TRANS_DONE_INT_ENA Write 1 to enable LCD_CAM_LCD_TRANS_DONE_INT. (R/W)

LCD_CAM_CAM_VSYNC_INT_ENA Write 1 to enable LCD_CAM_CAM_VSYNC_INT. (R/W)

LCD_CAM_CAM_HS_INT_ENA Write 1 to enable LCD_CAM_CAM_HS_INT. (R/W)

Register 40.16. LCD_CAM_LC_DMA_INT_RAW_REG (0x0068)



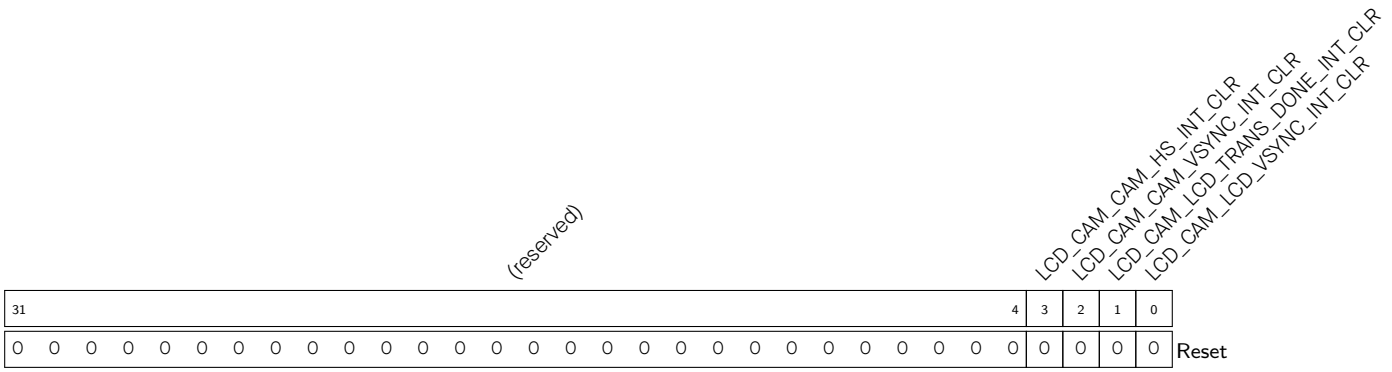
LCD_CAM_LCD_VSYNC_INT_RAW The raw interrupt status of LCD_CAM_LCD_VSYNC_INT. (RO)

LCD_CAM_LCD_TRANS_DONE_INT_RAW The raw interrupt status of LCD_CAM_LCD_TRANS_DONE_INT. (RO)

LCD_CAM_CAM_VSYNC_INT_RAW The raw interrupt status of LCD_CAM_CAM_VSYNC_INT. (RO)

LCD_CAM_CAM_HS_INT_RAW The raw interrupt status of LCD_CAM_CAM_HS_INT. (RO)

Register 40.17. LCD_CAM_LC_DMA_INT_ST_REG (0x006C)



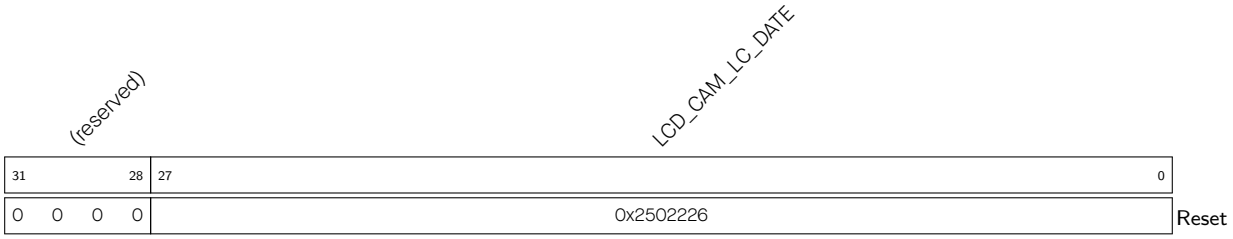
LCD_CAM_LCD_VSYNC_INT_ST The masked interrupt status of LCD_CAM_LCD_VSYNC_INT. (RO)

LCD_CAM_LCD_TRANS_DONE_INT_ST The masked interrupt status of LCD_CAM_LCD_TRANS_DONE_INT. (RO)

LCD_CAM_CAM_VSYNC_INT_ST The masked interrupt status of LCD_CAM_CAM_VSYNC_INT. (RO)

LCD_CAM_CAM_HS_INT_ST The masked interrupt status of LCD_CAM_CAM_HS_INT. (RO)

Register 40.18. LCD_CAM_LC_DMA_INT_CLR_REG (0x0070)



LCD_CAM_LCD_VSYNC_INT_CLR Write 1 to clear LCD_CAM_LCD_VSYNC_INT. (WO)

LCD_CAM_LCD_TRANS_DONE_INT_CLR Write 1 to clear LCD_CAM_LCD_TRANS_DONE_INT. (WO)

LCD_CAM_CAM_VSYNC_INT_CLR Write 1 to clear LCD_CAM_CAM_VSYNC_INT. (WO)

LCD_CAM_CAM_HS_INT_CLR Write 1 to clear LCD_CAM_CAM_HS_INT. (WO)

Register 40.19. LCD_CAM_LC_REG_DATE_REG (0x00FC)

LCD_CAM_LC_DATE Version control register. (R/W)

Chapter 41

H264 Encoder

41.1 Overview

The H264 encoder is based on the H264 standard. It is used for real-time compression of video sequences, which can significantly reduce the total amount of data with minimal loss of video quality.

41.2 Terminology

bitstream	A sequence of bits that forms the representation of one or more coded video sequences.
profile	A subset of the entire bitstream syntax that is specified by the H264 standard.
level	Specified within each profile. A specified set of constraints imposed on values of the syntax elements in the bitstream.
MB	The full name is macroblock. It is a 16 × 16 block of luma samples and two corresponding blocks of chroma samples of a picture that has three sample arrays.
slice	An integer number of MBs.
I frame	Intra frame.
P frame	Inter frame.
I slice	Slice in I frame.
P slice	Slice in P frame.
P-skip MBs	MBs in P frame that skip the encoding.
CAVLC	Context-based adaptive variable length coding.
MV	Motion vector.
GOP	Group of pictures. In a GOP, the first frame is an I frame, and subsequent frames are P frames.
QP	Quantization parameter.
ROI	Region of interest.
AXI	Advanced extensible interface.
TX	Transmit.
RX	Receive.
DB	Deblocking filter.
NUM_H_MB	Number of horizontal MBs in a picture.

41.3 Features

The H264 encoder supports the following features:

- Baseline profile and level 4.1.
- Encoded video color space: 8-bit YUV420.
- Original video color space: RGB888/RGB565/8-bit YUV444/8-bit YUV422/8-bit YUV420(hardware can convert it to 8-bit YUV420 for encoding).
- Progressive video with a maximum resolution of 1920 × 1088 @ 30 fps.
- I and P frames.
- Two working modes: GOP mode and dual stream mode. In dual stream mode, the total bandwidth of the two video sequences to be encoded should not exceed 1920 × 1088 @ 30 fps.
- 4 × 4 and 16 × 16 intra frame luma MB segmentation.
- All nine prediction modes for intra 4 × 4 luma MBs, and all four prediction modes for intra 16 × 16 luma MBs.
- All four prediction modes for intra chroma MBs.
- All partition size for inter luma MBs: 4 × 4, 4 × 8, 8 × 4, 8 × 8, 8 × 16, 16 × 8, 16 × 16.
- One-half and one-quarter pixel precision motion estimation.
- Horizontal motion search range [-29.75, +16.75] and vertical motion search range [-13.75, +13.75].
- Deblocking filter.
- CAVLC.
- P-skip MBs.
- I MB in P slices.
- Decimation operation of luma and chroma component quantization results.
- Fixed QP and MB level rate control.
- MV merge function. If the MV of MB is greater than 0, it can be output to memory.
- ROI function, with up to eight rectangular ROI configurable at any position (allowing overlap, fixed priority). Each ROI can be configured with a constant QP or QP offset, and non-ROI can be configured with a QP offset.
- Debug function: the original video pixel data, the MV merge result data, the bitstream data, the deblocking filter intermediate data and the deblocking filter result data can be replaced by configuration register value.

41.4 Architecture

The architecture of H264 is shown in Figure 41.4-1.

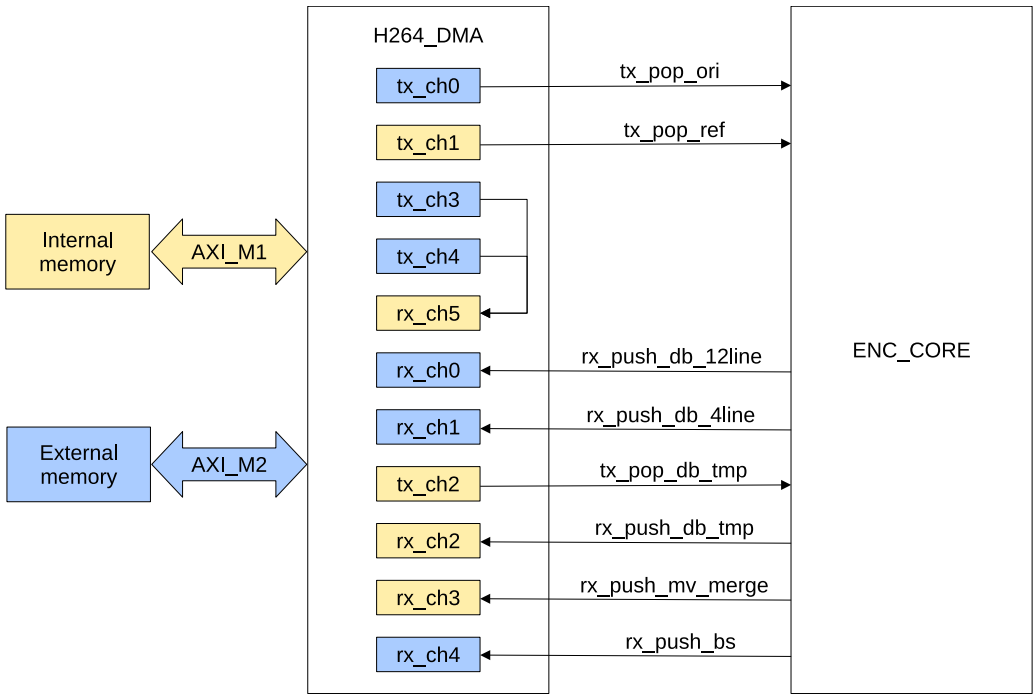


Figure 41.4-1. H264 Video Encoder Architecture

The H264 encoder can be divided into two parts, H264 dedicated DMA (H264_DMA) and encoder algorithm core (ENC_CORE). H264_DMA is used for data transfer, and is connected to the internal/external memory through two sets of AXI buses. Meanwhile, it is connected to the ENC_CORE through multiple DMA sending/receiving channels (H264_DMA has five sending channels (TX channel *n*) and six receiving channels (RX channel *n*)). TX channel 3, TX channel 4, and RX channel 5 are the internal channels of H264_DMA, which are not connected to the ENC_CORE. The ENC_CORE is used to compress video sequences.

The function of each H264_DMA sending and receiving channel is as follows:

- **TX channel 0** sends the original picture to ENC_CORE.
- **TX channel 1** sends the reference picture to ENC_CORE.
- **TX channel 2** sends the deblocking filter intermediate data to ENC_CORE.
- Sending channel **TX channel 3** and TX channel 4 send the reference picture (i.e., the previous deblocking filtered picture) to receiving channel **RX channel 5**.
- **RX channel 0** and **RX channel 1** send the result of the deblocking filter (i.e., reference picture) to external memory.
- **RX channel 2** sends the deblocking filter intermediate data to internal memory.
- **RX channel 3** sends the MV merge result to internal memory.
- **RX channel 4** sends the encoded bitstream to external memory.
- **RX channel 5** sends the reference picture (i.e., the previous deblocking filtered picture) to internal memory.

From the provided description, the H264_DMA channels can be divided into two types:

- Reading or writing internal memory (through AXI_M1 bus): TX channel 1/2, RX channel 2/3/5

- Reading or writing external memory (through AXI_M2 bus): TX channel 0/3/4, RX channel 0/1/4

41.5 Functional Description

41.5.1 Encoder Algorithm Core (ENC_CORE)

The function of the ENC_CORE is to compress and encode the video sequences according to the software configuration.

41.5.1.1 Architecture

The architecture of the encoder algorithm core is shown in Figure 41.5-1 *ENC_CORE Architecture*.

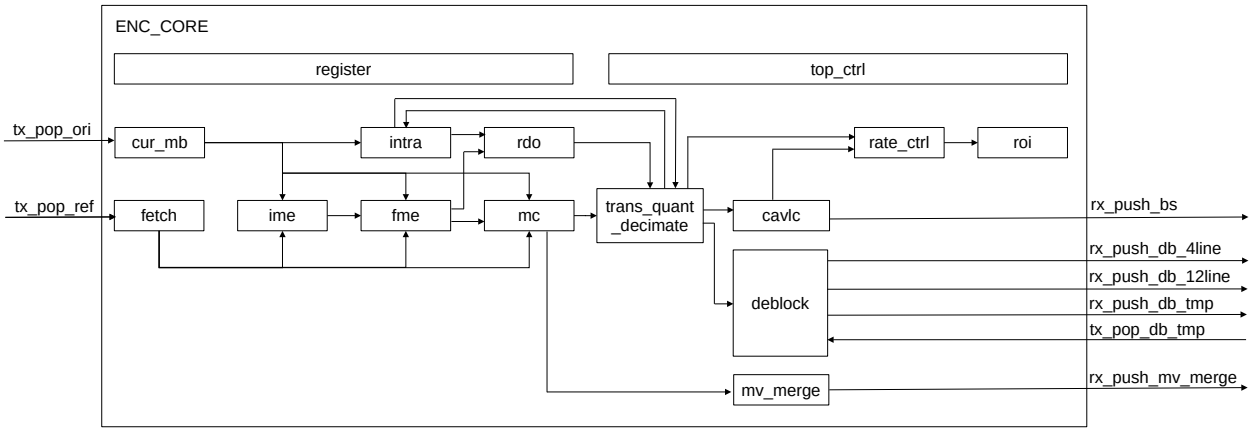

Figure 41.5-1. ENC_CORE Architecture

The functions of each module are as follows:

- register: Implements register configuration and selection.
- top_ctrl: Realizes the control and scheduling of each module of the encoder algorithm core.
- cur_mb: Reads the original picture MB from the TX channel 0 (tx_pop_ori) of H264_DMA, converts its color space to 8-bit YUV420, and distributes it to the intra, ime, fme, and mc modules.
- intra: Uses the reconstruction result calculated by the trans_quant_decimate module to perform intra-frame prediction of the MB, sends the intra-frame prediction and residual results to the trans_quant_decimate module, and sends the intra-frame prediction cost to the rdo module.
- fetch: Reads reference picture MBs within the search range from the TX channel 1 channel (tx_pop_ref) of H264_DMA, and distributes them to the ime, fme, and mc modules.
- ime: Receives the original picture MB from the cur_mb module, receives the reference picture MB from the fetch module, performs integer motion estimation within the search range, and sends the integer motion estimation result to the fme module.
- fme: Receives the original picture MB from the cur_mb module, receives the reference picture MB from the fetch module, receives the integer motion estimation result from the ime module, and performs

fractional motion estimation on the basis of the integer motion estimation. The fractional motion estimation result is sent to the mc module, and the inter prediction cost is sent to the rdo module.

- mc: Receives the original picture MB from the cur_mb module, receives the reference picture MB from the fetch module, receives the fractional motion estimation result from the fme module, performs motion compensation according to the fractional motion estimation result. The inter-frame prediction and the sum of the residual results are sent to the trans_quant_decimate module, and the motion vector is sent to the mv_merge module.
- rdo: Receives the intra-frame prediction cost from the intra module, receives the inter-frame prediction cost from the fme module, selects the final type of the current MB, implements the P slice to support the I MB function, and sends the final MB type to trans_quant_decimate module.
- trans_quant_decimate: Receives the final MB type from the rdo module, receives the intra prediction and residual results from the intra module, receives the inter prediction and residual results from the mc module. Then, it performs DCT, quantization, inverse quantization, and inverse DCT, and quantization result decimation, sends the residual information to the rate_ctrl module, sends the reduced quantization result to the cavlc module, and sends the reconstruction result to the deblock module.
- cavlc: Receives the quantization result from the trans_quant_decimate module and the prediction information of the current MB, performs context adaptive variable length coding (CAVLC), and writes the coded stream to the RX channel 4 of H264_DMA.
- deblock: Receives reconstruction result from the trans_quant_decimate module and the prediction information of the current MB, performs deblocking filtering, and writes the deblocking filter result (i.e., the reference picture) to the RX channel 0 (rx_push_db_12line) and RX channel 1 (rx_push_db_4line). This module reads and writes the deblocking filter intermediate data through the TX channel 2 channel (tx_pop_db_tmp) and RX channel 2 channel (rx_push_db_tmp) of H264_DMA.
- mv_merge: Receives the motion vector from the mc module, performs MV merging, and writes the merging result (MB motion information) to the RX channel 3 channel (rx_push_mv_merge) of H264_DMA.
- rate_ctrl: Receives the residual information from the trans_quant_decimate module, receives the encoding information from the cavlc module, receives the frame-level information configured by the register module, performs MB level rate control, and converts the calculated quantization parameter (QP) to the roi module.
- roi: Receives QPs from the rate_ctrl module, receives the ROI information configured by the register module, adjusts the QPs, and uses the adjusted QPs to process the current MB.

41.5.1.2 Original Video Color Space Convert

Because the original video color space can be RGB888/RGB565/8-bit YUV444/8-bit YUV422/8-bit YUV420 and the ENC_CORE can only encode 8-bit YUV420 video, the ENC_CORE should convert it to 8-bit YUV420.

The convert steps are as follows:

- convert to RGB888 by padding zeros at lower bits(only for RGB565 original video, for RGB888/8-bit YUV444/8-bit YUV422/8-bit YUV420 original video, skip this step):

RGB888_R={RGB565_R,3-bit 0}

RGB888_G={RGB565_G,2-bit 0}

RGB888_B={RGB565_B,3-bit 0}

- convert to 8-bit YUV444 by the equation below (only for RGB565/RGB888 original video, for 8-bit YUV444/8-bit YUV422/8-bit YUV420 original video, skip this step):

YUV444_Y=(RGB888_R × 4899 + RGB888_G × 9617 + RGB888_B × 1868)»14

YUV444_U=(128 × 16384 + RGB888_B × 8192 - RGB888_R × 2764 - RGB888_G × 5428)»14

YUV444_V=(128 × 16384 + RGB888_R × 8192 - RGB888_G × 6860 - RGB888_B × 1332)»14

- subsample 8-bit YUV444/8-bit YUV422 to 8-bit YUV420(only for RGB565/RGB888/8-bit YUV444/8-bit YUV422 original video, for 8-bit YUV420 original video, skip this step)

The original video color space is configured by register H264_*x*_ORI_COLOR_SPACE. *x* can be A or B, indicating the register corresponding to video sequence A or B.

41.5.1.3 Quantization Result Decimation

The ENC_CORE calculates the score of each MB based on the magnitude of its final quantization result, and then compares the score with the configurable threshold register. If it is below the threshold, the quantization result will be set to 0. Otherwise, the quantization result will remain unchanged, so as to further improve the compression ratio. For each MB, its luma and chroma component carry out the above process independently. Different types of MBs have different comparison methods, as follows:

- luma component I MB with 16 × 16 partition:

$$\text{I_score_mb_cmp} + \text{H264_}x\text{_I16×16_DECI_SCORE_OFFSET} < \text{H264_}x\text{_L_DECI_SCORE}$$

  Among them, I_score_mb_cmp is the score of the luma component of the current MB calculated by ENC_CORE. H264_*x*_I16×16_DECI_SCORE_OFFSET is the configurable offset register. H264_*x*_L_DECI_SCORE is the configurable threshold register. *x* can be A or B, indicating the register corresponding to video sequence A or B. When the above requirement is met, the quantization result of the current luma component MB will be decimated to 0.

- luma component I MB with 4 × 4 partition: Current luma component MB quantization result will not be decimated to 0.

- chroma component I MB:

$$\text{c_score_mb_cmp} + \text{H264_}x\text{_I_chroma_DECI_SCORE_OFFSET} < \text{H264_}x\text{_C_DECI_SCORE}$$

  Among them, c_score_mb_cmp is the score of current chroma component MB calculated by ENC_CORE. H264_*x*_I_chroma_DECI_SCORE_OFFSET is the configurable offset register. H264_*x*_C_DECI_SCORE is the configurable threshold register. *x* can be A or B, indicating the register corresponding to video sequence A or B. When the above requirement is met, the quantization result of the current chroma component MB will be decimated to 0.

- luma component P MB:

$$\text{I_score_mb_cmp} + \text{H264_}x\text{_P16×16_DECI_SCORE_OFFSET} < \text{H264_}x\text{_L_DECI_SCORE}$$

  Among them, I_score_mb_cmp is the score of current luma component MB calculated by ENC_CORE. H264_*x*_P16×16_DECI_SCORE_OFFSET is the configurable offset register. H264_*x*_L_DECI_SCORE is the configurable threshold register. *x* can be A or B, indicating the register corresponding to video

sequence A or B. When the above requirement is met, the quantization result of the current luma component MB will be decimated to 0.

- chroma component P MB:

  $$c_score_mb_cmp + H264_x_P_chroma_DECI_SCORE_OFFSET < H264_x_C_DECI_SCORE$$

  Among them, c_score_mb_cmp is the score of current chroma component MB calculated by ENC_CORE. H264_*x*_P_chroma_DECI_SCORE_OFFSET is the configurable offset register. H264_*x*_C_DECI_SCORE is the configurable threshold register. *x* can be A or B, indicating the register corresponding to video sequence A or B. When the above requirement is met, the quantization result of the current chroma component MB will be decimated to 0.

41.5.1.4 Motion Vector (MV) Merging

The ENC_CORE merges the MVs of the luma MB according to the configuration of the registers related to MV merging, and writes it out to the RX channel 3 channel (rx_push_mv_merge) of H264_DMA, and finally stores it in the internal memory for the upper layer application use, such as motion detection.

The registers related to MV merging are as follows:

- H264_*x*_MV_MERGE_EN: This register controls the enablement of MV merging. Setting this register to 1 means enabling the MV merging function of the corresponding video sequence. Setting this register to 0 means turning off the MV merging function of the corresponding video sequence. *x* can be A or B, indicating the register corresponding to video sequence A or B. Even if the MV merging function is enabled, the I MB will not output any data to the memory because the I MB has no MV.
- H264_MV_MERGE_TYPE: This register controls the type of MV merging. Configuring this register to 0 means only retaining the MV of the MB whose final type is P MB and the partition of luma component is 16 × 16. Configuring this register to 1 means only retaining the MV with the minimum modulus of the MB whose final type is P MB. Configuring this register to 2 means only retaining the MV with the maximum modulus of the MB whose final type is P MB. 3 is an invalid value. When the register H264_*x*_MV_MERGE_EN is set to 1, the configuration of this register will take effect.
- H264_INT_MV_OUT_EN: This register controls the type of merged MV ultimately stored in memory. Setting this register to 0 means that if the reserved merged MV is not 0, it will be stored in memory. Otherwise, it will be discarded. Setting this register to 1 means that if the integer part of the reserved merged MV is not 0, it will be stored in memory, otherwise discarded. When the register H264_*x*_MV_MERGE_EN is set to 1, the configuration of this register will take effect.
- H264_MB_VALID_NUM: This register represents the number of MV merging results stored in the memory in the current picture. One MB corresponds to one MV merging result. When the register H264_*x*_MV_MERGE_EN is set to 1, the value of this register is meaningful, otherwise the value of this register is meaningless and remains 0.

41.5.1.5 MB Level Rate Control

The ENC_CORE calculates the QP adjustment amount of each MB based on the configuration of the rate control related registers, the number of encoding bits of the current MB, and the mean absolute value of the residual (MAD). Then it uses the frame-level QP configured in the register and the QP adjustment amount to calculate the QP of each MB, thereby adjusting the number of coded bits.

The MB level rate control related registers are as follows:

- H264_*x*_MB_RATE_CTRL_EN: This register controls the enablement of MB level rate control. Setting this register to 1 means enabling the MB level rate control function of the corresponding video sequence. Setting this register to 0 means turning off the MB level rate control function of the corresponding video sequence. *x* can be A or B, indicating the register corresponding to video sequence A or B. Since the I frame uses a constant QP encoding method, the QP of each macro block of the I frame will not change even if the MB level rate control function is enabled.
- H264_*x*_RATE_CTRL_U: The value of this register is configured by the parameters calculated by the frame-level rate control in the software. ENC_CORE needs this value to calculate the QP adjustment amount of each macro block. *x* can be A or B, indicating the register corresponding to video sequence A or B. The calculation method of the configuration value of this register belongs to the category of the frame-level rate control algorithm in the software, which is beyond the scope of this chapter and will not be described.
- H264_*x*_MAD_FRAME_PRED: This register is the predicted value of frame-level MAD, which is configured by the frame-level rate control in the software. ENC_CORE needs this value to calculate the QP adjustment amount of each MB, *x* can be A or B, indicating the register corresponding to video sequence A or B. The calculation method of the configuration value of this register belongs to the category of the frame-level rate control algorithm in the software, which is beyond the scope of this chapter and will not be described.
- H264_*x*_QP: This register is the frame-level QP value, and the value range is 10 to 51. It is configured by the frame-level rate control in the software. ENC_CORE will adjust the QP value of each MB based on it, so as to realize the MB level rate control, *x* can be A or B, indicating the register corresponding to video sequence A or B. The calculation method of the configuration value of this register belongs to the category of the frame-level rate control algorithm in the software, which is beyond the scope of this chapter and will not be described.
- H264_*x*_QP_MAX: This register is used to limit the maximum value of the QP finally calculated by the MB level rate control, and the value range is from 10 to 51. If the QP value finally calculated by the MB level rate control is greater than the configuration value of this register, it will be limited to the configured value of this register, otherwise the original value is retained. *x* can be A or B, indicating the register corresponding to video sequence A or B.
- H264_*x*_QP_MIN: This register is used to limit the minimum value of the QP finally calculated by the MB level rate control, and the value range is from 10 to 51. If the QP value finally calculated by the MB level rate control is smaller than the configuration value of this register, it will be limited to the configured value of this register, otherwise it remains the original value, *x* can be A or B, indicating the register corresponding to video sequence A or B.
- H264_FRAME_MAD_SUM: This register represents the cumulative sum of the MADs of all MBs in the current frame. The software needs to read the value of this register after the encoding of a frame of video is completed for calculation of frame-level rate control. The frame-level rate control algorithm in the software is beyond the scope of this chapter and will not be described.
- H264_FRAME_ENC_BITS: This register represents the sum of the number of encoding bits of all MBs in the current frame. The software needs to read the value of this register after completely encoding a frame of video to perform frame-level rate control. The frame-level rate control algorithm in the software is beyond the scope of this chapter and will not be described.
- H264_FRAME_QP_SUM: This register represents the sum of QP of all MBs in the current frame. The

software needs to read the value of this register after completely encoding of a frame of video to perform frame-level rate control. The frame-level rate control algorithm in the software is beyond the scope of this chapter and will not be described.

41.5.1.6 Region of Interest (ROI)

ENC_CORE can have up to eight overlapping fixed-priority rectangular ROI in a frame of video according to the configuration of the relevant registers. The QP (calculated by MB level rate control) is adjusted, so that each ROI has different encoded picture quality.

The registers related to the ROI are as follows:

- H264_*x*_ROI_EN: This register is used to control the switch of the ROI function. Set it to 1 to enable the ROI function, and set it to 0 to disable the ROI function. *x* can be A or B, indicating the register corresponding to video sequence A or B.
- H264_*x*_ROI_MODE: This register is used to specify the working mode of ROI. If it is configured as 0, ROI will work in fixed QP mode. If it is configured as 1, ROI will work in QP offset mode. *x* can be A or B, indicating the register corresponding to video sequence A or B.
- H264_*x*_ROI_REGION*n*_REG: This register is used to configure the enable and position information of each rectangular ROI. *x* can be A or B, indicating the register corresponding to video sequence A or B. *n* can be 0 to 7, indicating 8 ROI. From ROI 0 to ROI 7, the priority decreases in order. When there are overlapping areas, the configuration of the ROI with the highest priority takes effect. This register contains the following fields:
  - H264_*x*_ROI_REGION*n*_EN: Set to 1 to enable ROI *n*, set it to 0 to close the ROI *n*. When the register H264_*x*_ROI_EN set to 1, this register can control the ROI *n* switch, otherwise, this register has no effect.
  - H264_*x*_ROI_REGION*n*_X: Configure the horizontal starting MB coordinates of the ROI *n* in a frame of video.
  - H264_*x*_ROI_REGION*n*_Y: Configure the vertical starting MB coordinates of the ROI *n* in a frame of video.
  - H264_*x*_ROI_REGION*n*_X_LEN: Configure the number of horizontal MBs in the ROI *n* in a frame of video.
  - H264_*x*_ROI_REGION*n*_Y_LEN: Configure the number of vertical MBs in the ROI *n* in a frame of video.
- H264_*x*_ROI_REGION*n*_QP: This register is used to configure the QP adjustment amount of the MBs in each rectangular ROI. *x* can be A or B, indicating the register corresponding to video sequence A or B. *n* can be 0 to 7, representing 8 ROI. The configuration method of this register is related to the configuration value of the H264_*x*_ROI_MODE register:
  - When H264_*x*_ROI_MODE is set to 0: The ROI mode is fixed QP mode. The value of the H264_*x*_ROI_REGION*n*_QP register directly specifies the QP value for MBs in the corresponding ROI and ranges from 10 to 51.
  - When H264_*x*_ROI_MODE is set to 1: It indicates that the ROI mode is QP offset mode. At this time, bit 0 to bit 5 of the H264_*x*_ROI_REGION*n*_QP register indicates the QP offset, and the value range

is 0 to 51. Bit 6 indicates the sign of the offset, where 0 indicates a positive offset, and 1 indicates a negative offset.

- H264_*x*_NO_ROI_REGION_QP: This register is used to configure the QP offset of the MB in the non-ROI. Bit 0 to bit 5 represent the QP offset, and the value range is 0 to 51. Bit 6 represents the sign of the offset, where 0 represents a positive offset, and 1 indicates a negative offset. *x* can be A or B, indicating the register corresponding to video sequence A or B. When the ROI function is disabled, that is, when the H264_*x*_ROI_EN register is set to 0, this register will not take effect, and the QP of the MB in the non-ROI will not be changed.

Please note that the adjusted QP value of any ROI should not be less than 10.

Regardless of whether the MB is in the ROI or non-ROI, its final adjusted QP value will be limited to 10 to 51 to ensure that it does not exceed the value range in the H264 standard.

41.5.1.7 Data Replace For Debug Function

For debug which part of data is wrong in ENC_CORE processing flow, the original video pixel data, the MV merge result data, the bitstream data, the deblocking filter intermediate data and the deblocking filter result data can be replaced by configuration register value(H264_*x*_DBG_REPLACE_ORI_DATA, H264_*x*_DBG_REPLACE_MV_MERGE_DATA, H264_*x*_DBG_REPLACE_WR_BS_DATA, H264_*x*_DBG_REPLACE_WR_DB_TEMP_DATA, H264_*x*_DBG_REPLACE_RD_DB_TEMP_DATA, H264_*x*_DBG_REPLACE_WR_DB_DATA, H264_*x*_DBG_REPLACE_REF_DATA).

- original video pixel data replace: Set register H264_*x*_DBG_REPLACE_ORI_DATA_EN to 1 to enable this function. The original video pixel data which is read from H264_DMA will be replaced by H264_*x*_DBG_REPLACE_ORI_DATA.
- MV merge result data replace: Set register H264_*x*_DBG_REPLACE_MV_MERGE_DATA_EN to 1 to enable this function. The MV merge data which is written to H264_DMA will be replaced by H264_*x*_DBG_REPLACE_MV_MERGE_DATA.
- bitstream data replace: Set register H264_*x*_DBG_REPLACE_WR_BS_DATA_EN to 1 to enable this function. The bitstream data which is written to H264_DMA will be replaced by H264_*x*_DBG_REPLACE_WR_BS_DATA.
- deblocking filter intermediate data replace: Set register H264_*x*_DBG_REPLACE_WR_DB_TEMP_DATA_EN to 1 to enable the function that the deblocking filter intermediate data which is written to H264_DMA will be replaced by H264_*x*_DBG_REPLACE_WR_DB_TEMP_DATA. Set register H264_*x*_DBG_REPLACE_RD_DB_TEMP_DATA_EN to 1 to enable the function that the deblocking filter intermediate data which is read from H264_DMA will be replaced by H264_*x*_DBG_REPLACE_RD_DB_TEMP_DATA.
- deblocking filter result data replace: Set register H264_*x*_DBG_REPLACE_WR_DB_DATA_EN to 1 to enable the function that the deblocking filter result data which is written to H264_DMA will be replaced by H264_*x*_DBG_REPLACE_WR_DB_DATA. Set register H264_*x*_DBG_REPLACE_REF_DATA_EN to 1 to enable the function that the reference picture pixel data(i.e. deblocking filter result data) which is read from H264_DMA will be replaced by H264_*x*_DBG_REPLACE_REF_DATA.

41.5.2 H264 Dedicated DMA

The H264 dedicated DMA controls the data transfers between encoder algorithm core and memory based on the software configuration.

41.5.2.1 Architecture

H264_DMA architecture is shown in the figure 41.5-2:

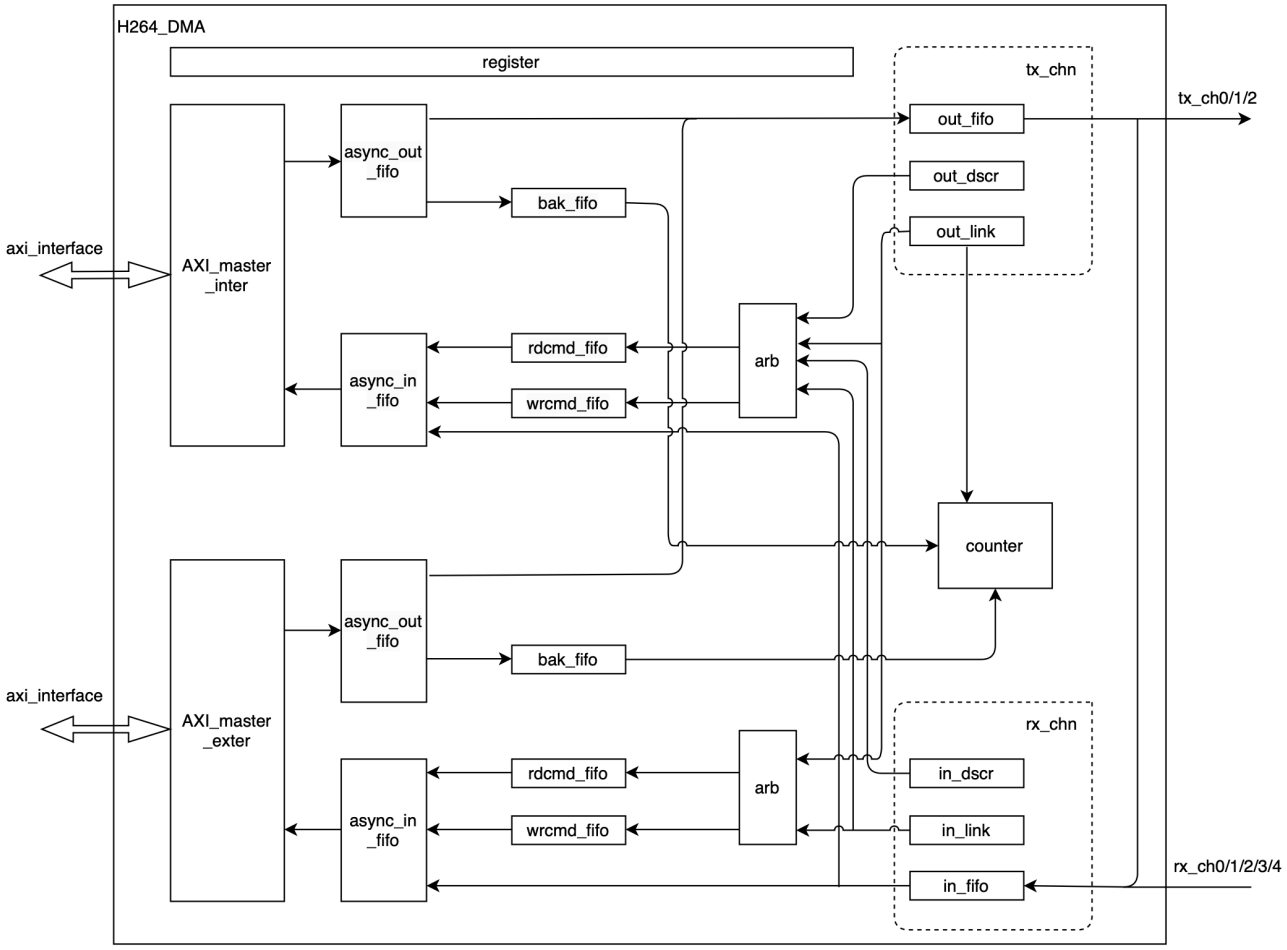

Figure 41.5-2. H264_DMA Architecture

The functions of each module are:

- register: This module implements register configuration and selection.
- in_dscr: This module initiates an AXI read request to internal memory, obtains the RX channel's linked list descriptor, and sends the descriptor to the in_link module of the corresponding RX channel.
- in_link: This module receives the descriptor of the corresponding channel in_dscr module and splits it into multiple AXI write data requests to guide the corresponding in_fifo module to write data to internal memory or external memory. RX channel 0/1/4 is designed for writing data to external memory, while RX channel 2/3/5 is for writing data to internal memory.
- out_dscr: This module initiates an AXI read internal memory request, obtains the TX channel linked list descriptor, and sends the descriptor to the out_link module of corresponding TX channel.

- out_link: This module receives the descriptor of the corresponding channel out_dscr module and divides it into multiple AXI read data requests to obtain data from internal memory or external memory. TX channel 0/3/4 reads data from external memory and TX channel 1/2 reads data from internal memory.
- out_fifo: This module receives the data returned by the AXI read request and waits for h264 to read, or RX channel 5 to read. TX channel 0/1/2 is for h264 to read, and TX channel 3/4 is for RX channel 5 to read.
- arb: This module receives read/write requests for external or internal memory, and arbitrates the read/write requests. The requests are sent to the rdcmd_fifo and wrcmd_fifo modules of external memory, and the rdcmd_fifo and wrcmd_fifo modules of internal memory respectively.
- wrcmd_fifo: This module caches the AXI write request arbitrated by the arb module, and cuts the write request and data into multiple 8-byte data chunks before sending them to the async_in_fifo module.
- rdcmd_fifo: This module caches the AXI read request arbitrated by the arb module and sends the read request to the async_in_fifo module.
- bak_fifo: This module caches the read/write request information arbitrated by the arb module, including channel id, AXI_id, read/write request data length, read/write request source and read request starting address. The module finds the information corresponding to the request based on the AXI_id returned by the async_out_fifo module, and sends the completion information of the request and the read data in the async_out_fifo module to the corresponding channel.
- async_in_fifo: This module is used to receive AXI requests from the wrcmd_fifo module and rdcmd_fifo module, and synchronize the request from H264_DMA core clock domain to the AXI clock domain, waiting for the AXI master to read.
- async_out_fifo: This module is used to receive the read data returned by the AXI_master_inter/AXI_master_exter module and the completion of the read/write request, and synchronize it from the AXI clock domain to the H264_DMA core clock domain.
- AXI_master_inter/AXI_master_exter: This module reads the read/write request in the async_in_fifo module and converts it into an AXI bus protocol format output. The module receives the read data and read/write completion returned by the AXI slave and converts it into an internal private interface. The resulting format is written to the async_out_fifo module. The AXI_master_inter module is used to access the internal memory space, and the AXI_master_exter module is used to access the external memory space.

41.5.2.2 Linked List Descriptor

H264_DMA linked list descriptor is shown in the figure 41.5-3:

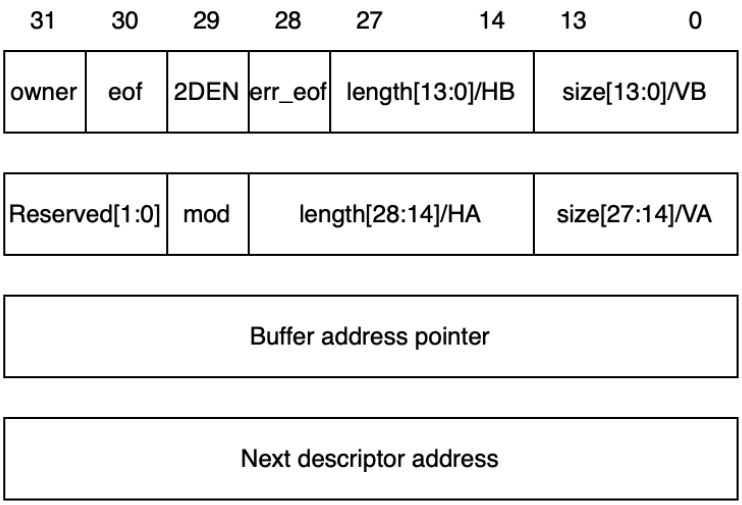

Figure 41.5-3. H264_DMA Linked List Descriptor

- owner: Indicates the operators allowed by the buffer corresponding to the current descriptor.
  - 0: Allow the operator to be CPU.
  - 1: The operator is allowed to be H264_DMA. H264_DMA will clear this bit after using the descriptor.
  - For transmit descriptors, since a descriptor will not be written back by default, the default owner will not be cleared. Configure H264_DMA_OUT_AUTO_WRBACK to enable writeback.
- suc_eof: end flag.
  - 0: The current descriptor is not the last descriptor.
  - 1: The current descriptor is the last descriptor.
- mod: Data block read mode.
  - 0: H264_DMA read/write a picture block with a horizontal width of hb and a vertical height of vb only once.
  - 1: H264_DMA read/write multiple times the picture block with a horizontal width of hb and a vertical height of vb until the picture data with a horizontal width of HA and a vertical height of VA is read/written. Note: The unit of hb/vb/HA/VA is pixel.
  - In 1D mode, this field must be 0.
- err_eof: Receive end error flag.
  - For the receive descriptor, the hardware will set this bit to 1 after receiving a packet and detecting a received data error.
  - For transmit descriptors, this bit is fixed to 0.
- 2DEN: 2D function enable signal.
  - 0: The function of H264_DMA is the same as the general DMA function. At this time, it can be used to transfer continuous data segments.
  - 1: The H264_DMA function is enabled and data is transferred according to the configured picture blocks.

- length[13:0]/HB:
  - When 2DEN = 0, this field represents the length of the data being transferred (least significant 14 bits). For data reception, this field is filled in after the hardware receives a frame of data. For data transmission, this field indicates the length of the data to be sent. The unit is byte.
  - When 2DEN = 1, this field represents the horizontal width of the picture block (HB). The unit is pixel.
- size[13:0]/VB:
  - When 2DEN = 0, this field represents the size of the memory space allocated for transferring data (least significant 14 bits). The unit is byte.
  - When 2DEN = 1, this field represents the vertical height of the picture block (VB). The unit is pixel.
- length[28:14]/HA:
  - WHen 2DEN = 0, this field represents the length of the transferred data (most significant 14 bits, only bit14-bit27 is used). For data reception, this field is filled after the hardware receives a frame of data. For data transmission, this field indicates the length of the data to be sent. The unit is byte.
  - When 2DEN = 1, this field represents the horizontal width of the picture corresponding to the descriptor (HA). The unit is pixel.
- size[27:14]/VA:
  - When 2DEN = 0, this field represents the size of the memory space for transferring data (most significant 14 bits). The unit is byte.
  - When 2DEN = 1, this field represents the vertical height of the picture corresponding to the descriptor (VA). The unit is pixel.
- Buffer address pointer:
  - When 2DEN = 0, it is the buffer address pointer.
  - When 2DEN = 1, it is the address pointer of the origin coordinates of the HA × VA picture block in the buffer.
- Next descriptor address: Next descriptor address pointer.

41.5.2.3 Transfer Initialization

H264_DMA will read the linked list from the internal memory to the local according to the configuration of the registers related to each channel linked list descriptor, so that it can be used by the corresponding channel to transfer data, thereby start the corresponding channel.

The registers associated with each linked list descriptor are as follows:

- H264_DMA_OUTLINK/INLINK_START_CH*x*: This register controls whether the corresponding channel of H264_DMA starts to obtain descriptors. Setting this register to 1 means that the corresponding channel starts to obtain the descriptor. After obtaining the descriptor, the hardware automatically sets this register to 0, and then automatically obtain subsequent descriptors. *x* can be 0, 1, 2, 3, and 4, indicating the registers corresponding to channels 0, 1, 2, 3, and 4.
- H264_DMA_OUTLINK/INLINK_ADDR_CH*x*: This register represents the memory address where the first descriptor is stored, and the address requires 8-byte alignment.

41.5.2.4 Transfer Reset

In order to ensure the safe reset of H264_DMA and prevent channel from being stuck, the reset of H264_DMA channel must be carried out according to the following procedure:

1. Write 1 to register H264_DMA_OUT/IN_CMD_DISABLE_CH*x* of the corresponding channel.
2. Wait for H264_DMA_OUT/IN_RESET_AVAIL_CH*x* of the corresponding channel to be set.
3. Write 1 to register H264_DMA_OUT/IN_RST_CH*x* of the corresponding channel.
4. Write 0 to register H264_DMA_OUT/IN_RST_CH*x* of the corresponding channel.

The registers related to channel reset are as follows:

- H264_DMA_OUT/IN_CMD_DISABLE_CH*x*: This register controls whether the corresponding channel of H264_DMA stops initiating read/write requests to AXI. Setting this register to 1 means that the corresponding channel stops initiating read/write requests to AXI. Setting this register to 0 means that the corresponding channel can initiate read/write requests to AXI. *x* can be 0, 1, and 2 in TX channel, indicating the registers corresponding to channels 0, 1, and 2. In RX channel, they can be 0, 1, 2, 3, 4, and 5, indicating the registers corresponding to channels 0, 1, 2, 3, 4, and 5.
- H264_DMA_OUT/IN_RESET_AVAIL_CH*x*: This register indicates whether the channel corresponding to H264_DMA can be safely reset. If this register is 1, it means that the corresponding channel can be safely reset. If this register is 0, it means that the corresponding channel cannot be safely reset.
- H264_DMA_OUT/IN_RST_CH*x*: This register controls whether the corresponding channel of H264_DMA performs soft reset. Setting this register to 1 means that the corresponding channel performs a soft reset. Setting this register to 0 means that the corresponding channel does not perform a soft reset.

Notes:

- Since TX channel 3, TX channel 4, and RX channel 5 are bound, these three channels only have one set of H264_DMA_OUT/IN_CMD_DISABLE_CH5, H264_DMA_OUT/IN_RESET_AVAIL_CH5, and H264_DMA_OUT/IN_RST_CH5 registers. When resetting these three channels, you only need to operate this group of registers to realize the safe reset of the three H264_DMA channels.
- In order to ensure the completion of data transmission, before resetting RX channel 0, RX channel 1, RX channel 3, and RX channel 4, you need to check whether the corresponding channel linked list descriptor is written back successfully. Only after the linked list descriptor of the channel is written back successfully, which means all data transmission of the channel is completed, can the channel be reset. If the MV merging function is not enabled or the number of video frames in a GOP is 1, which means the register H264_GOP_NUM is configured as 1, there is no need to check whether the linked list descriptor of RX channel 3 is written back successfully.

41.5.2.5 Data Replace For Debug Function

H264_DMA module supports replacing the original data of each channel with debug data.

- Register H264_DMA_CH_DBG_EN_REG controls whether to enable debug data replace for each channel
- After debug-data replacement is enabled, the original data of each channel is replaced with the data configured by H264_DMA_IN/OUT_CHx_DBG_DATA_H/L_REG. Except for TX channel 0, all channels are

replaced directly with the 64-bit debug data. According to the pbyte configuration, the replacement for TX channel 0 is as follows:

- H264_DMA_ORI_PBYTE=0, bit 3:0 of H264_OUT_CH0_DBG_DATA_L is valid
- H264_DMA_ORI_PBYTE=1, bit 7:0 of H264_OUT_CH0_DBG_DATA_L is valid
- H264_DMA_ORI_PBYTE=2, bit 23:0 of H264_OUT_CH0_DBG_DATA_L is valid
- H264_DMA_ORI_PBYTE=3, bit 15:0 of H264_OUT_CH0_DBG_DATA_L is valid
- H264_DMA_ORI_PBYTE=4, bit 23:0 of H264_OUT_CH0_DBG_DATA_L is valid

41.5.2.6 Channel Configuration

Before the software starts H264_DMA, it needs to configure H264_DMA first. The configuration consists of register configuration and linked list descriptor configuration.

Linked list descriptor configuration: The channels that need to be configured with descriptors are TX channel 0 ~ TX channel 4 and RX channel 0 ~ RX channel 4. The linked list descriptors are all circular linked lists.

1. Configure the channel of reading the original picture (TX channel 0):
   - mode: 2D, mode1.
   - length/size: HA is the number of horizontal pixels of the picture. VA is the number of vertical pixels of the picture, HB is 16 × 4, and VB is 16.
2. Configure the channel of reading reference picture (TX channel 1):
   - mode: 2D, mode1.
   - length/size: HA is NUM_H_MB × 16 × 16, VA is 3, HB is 16 × 16, and VB is 3.
3. Configure the channel of reading DB intermediate data (TX channel 2):
   - mode: 1D.
   - length/size: The read space size is NUM_H_MB × (16 × 4 + 8 × 4 × 2).
4. Configure the channel of reading first 12 lines of DB data (TX channel 3):
   - mode: 1D.
   - length/size: The read space size is (NUM_H_MB × (number of vertical macro block lines in the picture - 1) × (16 × 12 + 8 × 4 × 2)) + (NUM_H_MB × 16 × 16 × 1.5).
5. Configure the channel of reading last 4 lines DB data (TX channel 4):
   - mode: 1D.
   - length/size: The read space size is (NUM_H_MB × (number of vertical MB lines in the picture - 1) × (16 × 4 + 8 × 4 × 2)).
6. Configure the channel of writing first 12 lines of DB data (RX channel 0):
   - mode: 1D.
   - length/size: The size of the writing space is the same as the size of TX channel 3.
7. Configure the channel of writing last 4 lines of DB data (RX channel 1):

- mode: 1D.
- length/size: The size of the writing space is the same as the size of TX channel 4.

8. Configure the channel of writing DB intermediate data (RX channel 2):
   - mode: 1D.
   - length/size: The size of the writing space is the same as the size of TX channel 2.
9. Configure the channel of writing MV merge data (RX channel 3):
   - mode: 1D.
   - length/size: The writing space size is NUM_H_MB × the number of vertical MB lines × 4.
10. Configure the channel of writing bit stream data (RX channel 4):
    - mode: 1D.
    - length/size: The size of the writing space is the number of horizontal pixels of the picture × the number of vertical pixel lines × 1.5.

Register configuration:

- H264_DMA_ORI_PBYTE: This register configures the bytes number of each pixel in original picture.
- H264_DMA_OUT/IN_MEM_BURST_LENGTH_CH*x*: This register controls the AXI burst length of the corresponding channel.
  - 0: 8 bytes. 1: 16 bytes. 2: 32 bytes. 3: 64 bytes. 4: 128 bytes.
  - In TX channel, *x* can be 0 ~ 4. In RX channel, *x* can be 0 ~ 5.
  - The burst length of TX channel 2 and RX channel 2 must be configured the same.
- H264_DMA_OUT_REORDER_EN_CH0: This register controls the TX channel 0 reorder enable. When the linked list descriptor configuration HB is not 16 in TX channel 0, this register must be configured as 1.
- H264_DMA_BLOCK_START_ADDR_CH5: This register controls the data starting address of the RX channel 5. The register configuration must be consistent with the data buffer address in the linked list descriptor of the TX channel 1.
- H264_DMA_BLOCK_ROW_LENGTH_4LINE_CH5: This register specifies the number of bytes contained in a row block of 4 lines. The data size is (NUM_H_MB × (16 × 4 + 8 × 4 × 2)).
- H264_DMA_BLOCK_ROW_LENGTH_12LINE_CH5: This register specifies the number of bytes contained in a row block of 12 lines. The data size is (NUM_H_MB × (16 × 12 + 8 × 4 × 2)).
- H264_DMA_BLOCK_LENGTH_4LINE_CH5: This register specifies the number of bytes contained in a block of 4 lines. The data size is (16 × 4 + 8 × 4 × 2).
- H264_DMA_BLOCK_LENGTH_12LINE_CH5: This register specifies the number of bytes contained in a block of 12 lines. The data size is (16 × 12 + 8 × 4 × 2).

41.6 Interrupts

ESP32-P4's H264 Encoder can generate the following interrupt signals, which are then sent to the Interrupt Matrix.

- H264_REG_INT
- H264_DMA_IN_CH0_INT
- H264_DMA_IN_CH1_INT
- H264_DMA_IN_CH2_INT
- H264_DMA_IN_CH3_INT
- H264_DMA_IN_CH4_INT
- H264_DMA_IN_CH5_INT
- H264_DMA_OUT_CH0_INT
- H264_DMA_OUT_CH1_INT
- H264_DMA_OUT_CH2_INT
- H264_DMA_OUT_CH3_INT
- H264_DMA_OUT_CH4_INT

There are several internal interrupt sources from H264 Encoder that can generate the above interrupt signals.

Interrupt signal H264_REG_INT can be generated by the following internal interrupt sources:

- H264_BS_BUFFER_OVERFLOW_INT: When the number of encoded bytes of a 4 × 4 sub-block of ENC_CORE exceeds H264_BS_BUFFER_THRESHOLD, the interrupt is triggered.
- H264_DMA_MOVE_2MB_LINE_DONE_INT: When H264_DMA completes moving the reference pictures of two MB rows from external memory to internal memory, the interrupt is triggered.
- H264_FRAME_DONE_INT: When ENC_CORE finishes compressing and encoding a frame of video, the interrupt is triggered.
- H264_REC_READY_INT: When ENC_CORE writes the deblocking filter result (i.e., the reference picture) of H264_*x*_REC_READY_TRIGGER_MB_LINES lines of MBs to the external memory, the interrupt is triggered. *x* can be A or B, indicating the register corresponds to video sequence A or B.
- H264_DB_TMP_READY_INT: When ENC_CORE writes the deblocking filter intermediate data of H264_*x*_DB_TMP_READY_TRIGGER_MB_NUM MBs to the internal memory, the interrupt is triggered. *x* can be A or B indicates the register corresponds to video sequence A or B.

The above interrupt sources can only be triggered when the interrupt enable register *XXX*_ENA is set to 1. Write 1 to *XXX*_CLR will clear the interrupt (*XXX* is the interrupt source name).

The H264_DMA_IN_CH*n*_INT (*n* is 0 ~ 5) signals are generated by the following interrupt sources:

- H264_DMA_IN_DONE_CH*n*_INT: Triggered when all data corresponding to a receive descriptor has been received via RX channel *n* (*n* is 0 ~ 5).
- H264_DMA_IN_SUC_EOF_CH*n*_INT: Triggered when the suc_eof bit in a receive descriptor is 1 and the data corresponding to this receive descriptor has been received (i.e. when the data frame or packet corresponding to an inlink has been received) via RX channel *n* (*n* is 0 ~ 5).
- H264_DMA_IN_ERR_EOF_CH*n*_INT: Triggered when an error is detected in the data frame or packet received via RX channel *n* (*n* is 0 ~ 4).

- H264_DMA_IN_DSCR_EMPTY_CH*n*_INT: Triggered when the size of the buffer pointed by receive descriptors is smaller than the length of data to be received via RX channel *n* (*n* is 0 ~ 4).
- H264_DMA_IN_DSCR_ERR_CH*n*_INT: Triggered when a receive descriptor on RX channel *n* (*n* is 0 ~ 4) fails any of the two descriptor checks.
- H264_DMA_INFIFO_OVF_L1_CH*n*_INT: Triggered when the L1 RX FIFO of RX channel *n* (*n* is 0 ~ 5) overflows.
- H264_DMA_INFIFO_OVF_L2_CH*n*_INT: Triggered when the L2 RX FIFO of RX channel *n* (*n* is 0 ~ 4) overflows.
- H264_DMA_INFIFO_UDF_L1_CH*n*_INT: Triggered when the L1 RX FIFO of RX channel *n* (*n* is 0 ~ 5) underflows.
- H264_DMA_INFIFO_UDF_L2_CH*n*_INT: Triggered when the L2 RX FIFO of RX channel *n* (*n* is 0 ~ 4) underflows.
- H264_DMA_IN_DSCR_TASK_OVF_CH*n*_INT: Triggered when descriptor ready task FIFO of RX channel *n* (*n* is 0 ~ 4) overflows.
- H264_DMA_FETCH_MB_COL_CNT_OVF_CH*n*_INT: Triggered when fetch MB columns cnt of RX channel *n* (*n* is 5) overflows.

The H264_DMA_OUT_CH*n*_INT (*n* is 0 ~ 4) signals are generated by the following interrupt sources:

- H264_DMA_OUT_DONE_CH*n*_INT: Triggered when all data corresponding to a transmit descriptor has been sent via TX channel *n*.
- H264_DMA_OUT_EOF_CH*n*_INT: Triggered when the suc_eof bit in a transmit descriptor is 1 and data corresponding to this descriptor has been sent via TX channel *n*. If H264_DMA_OUT_EOF_MODE_CH*n* is 0, this interrupt will be triggered when the last byte of data corresponding to this descriptor enters H264_DMA's TX channel; if H264_DMA_OUT_EOF_MODE_CH*n* is 1, this interrupt is triggered when the last byte of data is taken from H264_DMA's TX channel.
- H264_DMA_OUT_DSCR_ERR_CH*n*_INT: Triggered when a transmit descriptor on TX channel *n* fails any of the two descriptor checks.
- H264_DMA_OUT_TOTAL_EOF_CH*n*_INT: Triggered when all data corresponding to a linked list (including multiple descriptors) has been sent via TX channel *n*.
- H264_DMA_OUTFIFO_OVF_L1_CH*n*_INT: Triggered when the L1 TX FIFO of H264_DMA overflows.
- H264_DMA_OUTFIFO_OVF_L2_CH*n*_INT: Triggered when the L2 TX FIFO of H264_DMA overflows.
- H264_DMA_OUTFIFO_UDF_L1_CH*n*_INT: Triggered when the L1 TX FIFO of H264_DMA underflows.
- H264_DMA_OUTFIFO_UDF_L2_CH*n*_INT: Triggered when the L2 TX FIFO of H264_DMA underflows.
- H264_DMA_OUT_DSCR_TASK_OVF_CH*n*_INT: Triggered when descriptor ready task FIFO of TX channel *n* overflows.

41.7 Programming Procedures

The H264 encoder can work in two modes. In GOP mode, it periodically inserts an I frame into a specified number (configurable) of P frame intervals. In dual stream mode, it takes turns to process two video

sequences, and the hardware automatically switches the ENC_CORE configurations.

41.7.1 GOP Mode

In GOP mode, a single video sequence A is encoded. Take a GOP containing three pictures as an example, the encoding sequence of pictures is shown in Figure 41.7-1:

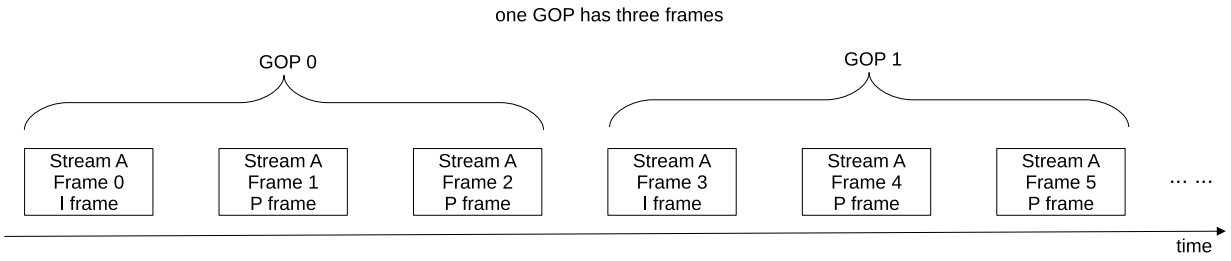

Figure 41.7-1. Coding Order of Pictures in GOP Mode

In GOP mode, the register with the prefix H264_A_ is valid, and the register with the prefix H264_B_ is invalid.

The GOP mode configuration process is as follows:

1. Refer to the description in chapter 41.5.2.6 to configure each H264_DMA channel:
   (a) Configure H264_DMA TX channel 0.
   (b) Configure H264_DMA TX channel 1.
   (c) Configure H264_DMA TX channel 2.
   (d) Configure H264_DMA TX channel 3 and TX channel 4.
   (e) Configure H264_DMA RX channel 0 and RX channel 1.
   (f) Configure H264_DMA RX channel 2.
   (g) Configure H264_DMA RX channel 3.
   (h) Configure H264_DMA RX channel 4.
   (i) Configure H264_DMA RX channel 5.
2. Configure ENC_CORE according to the required functions:
   (a) Configure GOP mode: Set register H264_FRAME_MODE to 0 and register H264_DUAL_STREAM_MODE to 0.
   (b) Configure the number of pictures in a GOP: Configure the register H264_GOP_NUM as n, indicating that a GOP contains n pictures. When the register is configured as 0, the first frame of a GOP is an I frame, and the subsequent frames of a GOP are always P frame until the encoder is reset.
   (c) Configure the MB resolution of a picture: configure the register H264_A_SYS_TOTAL_MB_X as the number of MBs in the horizontal direction of the picture, and configure the register H264_A_SYS_TOTAL_MB_Y as the number of MBs in the vertical direction of the picture. The number of MBs in the horizontal direction is equal to the width of the video divided by 16 and

rounded up. And the number of MBs in the vertical direction is equal to the height of the video divided by 16 and rounded up.

(d) Configure the initial QP value of a picture: configure the register H264_A_QP as the initial QP value, ranging from 10 to 51.

(e) Configure deblocking filter: Set register H264_A_BYPASS_DB_FILTER to 0 to enable the deblocking filter, set register H264_A_BYPASS_DB_FILTER to 1 to disable the deblocking filter.

(f) Configure slice header information: According to the information required to be included in the slice header in the H264 standard, configure the relevant registers H264_SLICE_REMAIN_BIT, H264_SLICE_REMAIN_BITLENGTH, H264_SLICE_BYTE_LENGTH, H264_SLICE_BYTE_LSB, and H264_SLICE_BYTE_MSB. For example, if the slice header is a variable with 41 bits and the most significant bit is the first bit of the slice header, these registers should be set in the following ways.

- H264_SLICE_BYTE_MSB: From bit 41 to bit 10 of the slice header
- H264_SLICE_BYTE_LSB: From bit 9 to bit 2 of the slice header
- H264_SLICE_REMAIN_BIT: Bit 1 of the slice header
- H264_SLICE_BYTE_LENGTH: 5
- H264_SLICE_REMAIN_BITLENGTH: 1

(g) Configure original video color space: Configure the register H264_A_ORI_COLOR_SPACE as the corresponding original video color space.

(h) To use the quantization result decimation function, configure its related registers referring to the description in section 41.5.1.3.

(i) To use the MB level rate control function, configure its related registers referring to the description in section 41.5.1.5.

(j) To use the ROI function, configure its related registers referring to the description in chapter 41.5.1.6.

(k) To use the MV merge function, configure its related registers referring to the description in section 41.5.1.4.

(l) To use the debug function, configure its related registers referring to the description in section 41.5.1.7.

3. Perform the corresponding operations based on the type of video frame to be encoded (In a GOP, the first frame is an I frame, and subsequent frames are P frames):

- The video frame to be encoded is an I frame:

(a) Start H264_DMA TX channel 0: Refer to chapter 41.5.2.3 for the configuration.

(b) Start H264_DMA RX channel 0 and RX channel 1: Refer to chapter 41.5.2.3 for the configuration.

(c) Start H264_DMA RX channel 2: Refer to chapter 41.5.2.3 for the configuration.

(d) To use the MV merge function, start H264_DMA RX channel 3. Refer to chapter 41.5.2.3 for the configuration.

(e) Start H264_DMA RX channel 4: Refer to chapter 41.5.2.3 for the configuration.

(f) Clear H264 interrupts and enable interrupts.

(g) Start the encoding of a picture: Write 1 to register H264_FRAME_START.

(h) Wait for the H264_DB_TMP_READY_INT interrupt. When the interrupt is triggered, start H264_DMA TX channel 2. Refer to chapter 41.5.2.3 for the configuration.

(i) Wait for the H264_REC_READY_INT interrupt. When the interrupt is triggered, start H264_DMA RX channel 5, H264_DMA TX channel 3, and TX channel 4. Refer to section 41.5.2.3 for the configuration.

(j) Start H264_DMA to move the reference picture from external memory to internal memory: Write 1 to register H264_DMA_MOVE_START.

(k) Wait for the H264_DMA_MOVE_2MB_LINE_DONE_INT interrupt. When the interrupt is triggered, start H264_DMA TX channel 1. Refer to chapter 41.5.2.3 for the configuration.

(l) Wait for the H264_FRAME_DONE_INT interrupt. When the interrupt is triggered, it indicates that the picture encoding is completed.

(m) Reset H264_DMA TX channel 2 and RX channel 2: Refer to chapter 41.5.2.4 for the configuration.

(n) Reset the read and write time counter of the deblocking filter intermediate data in H264_DMA: Set register H264_DMA_RX_CH2_INTER_COUNTER_RST to 1, then set to 0.

- The video frame to be encoded is P frame:

  (a) Clear H264 interrupts and enable interrupts.

  (b) Start H264_DMA RX channel 2: Refer to chapter 41.5.2.3 for the configuration.

  (c) Start encoding a picture: Write 1 to register H264_FRAME_START.

  (d) Wait for the H264_DB_TMP_READY_INT interrupt. When the interrupt is triggered, start H264_DMA TX channel 2. Refer to chapter 41.5.2.3 for the configuration.

  (e) Wait for the H264_FRAME_DONE_INT interrupt. When the interrupt is triggered, it indicates that the picture encoding is completed.

  (f) Reset H264_DMA TX channel 2 and RX channel 2: Refer to chapter 41.5.2.4 for the configuration.

  (g) Reset the read and write time counter of deblocking filter intermediate data in H264_DMA: Set register H264_DMA_RX_CH2_INTER_COUNTER_RST to 1, then set to 0.

- After any frame ends, the following registers can be reconfigured:
  - Registers related to the quantization result decimation function. Refer to chapter 41.5.1.3 for details.
  - Registers related to the MB level rate control function. Refer to chapter 41.5.1.5 for details.
  - Deblocking filter enable register: H264_A_BYPASS_DB_FILTER.
  - ROI function related registers. Refer to chapter 41.5.1.6 for details.
  - Registers related to slice header information: H264_SLICE_REMAIN_BIT, H264_SLICE_REMAIN_BITLENGTH, H264_SLICE_BYTE_LENGTH, H264_SLICE_BYTE_LSB, H264_SLICE_BYTE_MSB.

- Registers related to the MV merge function. Refer to chapter 41.5.1.4 for details.
- Registers related to the debug function. Refer to chapter 41.5.1.7 for details.

4. Repeat step 3 until all video frames in a GOP are encoded.
5. Make sure the data is written completely. Refer to chapter 41.5.2.4 for the method.
6. Reset each sending and receiving channel of H264_DMA referring to chapter 41.5.2.4.
7. Reset the read and write times counter of deblocking filter result data, and the read and write times counter of reference picture data in H264_DMA. To be specific, set register H264_DMA_RX_CH0_EXTER_COUNTER_RST to 1, then set it to 0; Set register H264_DMA_RX_CH1_EXTER_COUNTER_RST to 1, then set it to 0; Set register H264_DMA_RX_CH5_INTER_COUNTER_RST to 1, then set it to 0.
8. Reconfigure from step 2 and start encoding the next GOP.

41.7.2 Dual Stream Mode

In the dual stream mode, two video sequences A and B are encoded. The encoding sequence of pictures is shown in Figure 41.7-2 (a GOP contains three pictures).

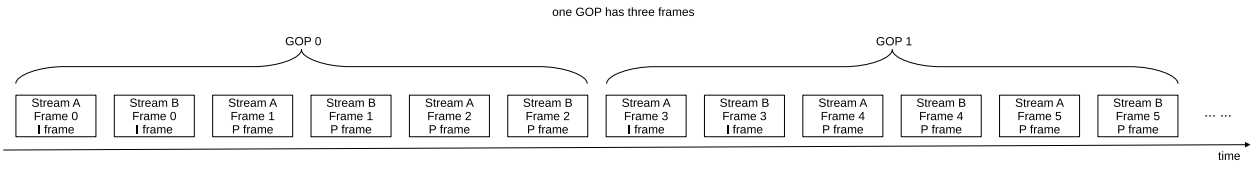

Figure 41.7-2. Coding Order of Pictures in Dual Stream Mode

In dual stream mode, the frame order of H264 processing is fixed as A1, B1, A2, B2, A3, B3... When processing frames in video sequence A, registers with the prefix H264_A_ will be automatically applied. When processing frames in video sequence B, registers with the prefix H264_B_ will be automatically applied. The registers with other prefixes are valid for both video sequence frames.

The configuration process of dual stream mode is as follows:

1. Configure ENC_CORE according to the required function:
   (a) Configure dual stream mode: Set register H264_FRAME_MODE to 1, and set register H264_DUAL_STREAM_MODE to 1.
   (b) Configure GOP (the GOP configuration of video sequence A and B must be the same): Configure the register H264_GOP_NUM as n, indicating that a GOP contains n pictures. When the register is configured as 0, the first frame of a GOP is an I frame, and the subsequent frames of a GOP are always P frames until the encoder is reset.
   (c) Configure the MB resolution of a picture: Configure the register H264_A_SYS_TOTAL_MB_X as the number of MBs in the horizontal direction of the video sequence A, and configure the register H264_A_SYS_TOTAL_MB_Y as the number of MBs in the vertical direction of the video sequence A. Configure the register H264_B_SYS_TOTAL_MB_X as the number of MBs in the horizontal direction of the video sequence B, and configure the register H264_B_SYS_TOTAL_MB_Y as the number of MBs in the vertical direction of the video sequence B. The number of MBs in the horizontal

direction is equal to the width of the video divided by 16 and rounded up. And the number of MBs in the vertical direction is equal to the height of the video divided by 16 and rounded up.

(d) Configure the initial QP of a picture: Configure the register H264_A_QP as the initial QP of video sequence A, ranging from 10 to 51. Configure the register H264_B_QP as the initial QP of video sequence B, ranging from 10 to 51.

(e) Configure the deblocking filter: Set the register H264_A_BYPASS_DB_FILTER to 0 to enable the deblocking filter of video sequence A. Set the register H264_A_BYPASS_DB_FILTER to 1 to disable the deblocking filter of video sequence A. Set the register H264_B_BYPASS_DB_FILTER to 0 to enable the deblocking filter of video sequence B. Set the register H264_B_BYPASS_DB_FILTER to 1 to disable the deblocking filter of video sequence B.

(f) Configure slice header information: According to the information required to be included in the slice header in the H264 standard, configure the relevant registers H264_SLICE_REMAIN_BIT, H264_SLICE_REMAIN_BITLENGTH, H264_SLICE_BYTE_LENGTH, H264_SLICE_BYTE_LSB, and H264_SLICE_BYTE_MSB. For example, if the slice header is a variable with 41 bits and the most significant bit is the first bit of the slice header, these registers should be set in the following ways.

- H264_SLICE_BYTE_MSB: From bit 41 to bit 10 of the slice header
- H264_SLICE_BYTE_LSB: From bit 9 to bit 2 of the slice header
- H264_SLICE_REMAIN_BIT: Bit 1 of the slice header
- H264_SLICE_BYTE_LENGTH: 5
- H264_SLICE_REMAIN_BITLENGTH: 1

(g) Configure original video color space: Configure the register H264_A_ORI_COLOR_SPACE as the corresponding original video color space of video sequence A. Configure the register H264_B_ORI_COLOR_SPACE as the corresponding original video color space of video sequence B.

(h) To use the quantization result decimation function, configure its related registers referring to section 41.5.1.3.

(i) To use the MB level rate control function, configure its related registers referring to chapter 41.5.1.5.

(j) To use the ROI function, configure its related registers referring to chapter 41.5.1.6.

(k) To use the MV merge function, configure its related registers referring to chapter 41.5.1.4.

(l) To use the debug function, configure its related registers referring to the description in section 41.5.1.7.

2. According to whether the frame to be encoded belongs to video sequence A or B, use the information corresponding to the video sequence and configure each H264_DMA channel referring to section 41.5.2.6:

(a) Configure H264_DMA TX channel 0.

(b) Configure H264_DMA TX channel 1.

(c) Configure H264_DMA TX channel 2.

(d) Configure H264_DMA TX channel 3 and TX channel 4.

(e) Configure H264_DMA RX channel 0 and RX channel 1.

(f) Configure H264_DMA RX channel 2.

(g) Configure H264_DMA RX channel 3.

(h) Configure H264_DMA RX channel 4.

(i) Configure H264_DMA RX channel 5.

3. Perform the corresponding operations based on the type of video frame to be encoded. Video sequence A and B are encoded alternately, i.e., first a picture in video sequence A is encoded, and then a picture in video sequence B, etc. In a GOP, the first frame is an I frame, and the subsequent frames are P frames for any video sequence.

   - The video frame to be encoded is an I frame:

     (a) Start H264_DMA TX channel 0: Refer to section 41.5.2.3 for the configuration.

     (b) Start H264_DMA RX channel 0 and RX channel 1: Refer to section 41.5.2.3 for the configuration.

     (c) Start H264_DMA RX channel 2: Refer to section 41.5.2.3 for the configuration.

     (d) Start H264_DMA RX channel 4: Refer to section 41.5.2.3 for the configuration.

     (e) Clear H264 interrupts and enable interrupts.

     (f) Start encoding a picture: Write 1 to register H264_FRAME_START.

     (g) Wait for the H264_DB_TMP_READY_INT interrupt. When the interrupt is triggered, start H264_DMA TX channel 2. Refer to section 41.5.2.3 for the configuration.

     (h) Wait for the H264_FRAME_DONE_INT interrupt. When the interrupt is triggered, it means that the picture encoding is completed.

     (i) Make sure the data is written completely. Refer to section 41.5.2.4 for the method.

     (j) Reset each sending and receiving channel of H264_DMA referring to section 41.5.2.4.

     (k) Reset the read and write counter of the deblocking filter intermediate data, and the read and write counter of the reference picture data in H264_DMA. To be specific, set register H264_DMA_RX_CH2_INTER_COUNTER_RST to 1, and then set it to 0. Then set H264_DMA_RX_CH5_INTER_COUNTER_RST to 1 and then to 0.

   - The video frame to be encoded is P frame:

     (a) Clear H264 interrupts and enable interrupts.

     (b) Start H264_DMA TX channel 0: Refer to section 41.5.2.3 for the configuration.

     (c) Start H264_DMA RX channel 0 and RX channel 1: Refer to section 41.5.2.3 for the configuration.

     (d) Start H264_DMA RX channel 2: Refer to section 41.5.2.3 for the configuration.

     (e) Start H264_DMA RX channel 4: Refer to section 41.5.2.3 for the configuration.

     (f) Start H264_DMA RX channel 5: Refer to section 41.5.2.3 for the configuration.

     (g) Start H264_DMA TX channel 3 and TX channel 4: Refer to section 41.5.2.3 for the configuration.

     (h) To use the MV merge function, start H264_DMA RX channel 3: Refer to section 41.5.2.3 for the configuration.

(i) Start H264_DMA to move the reference picture from external memory to internal memory: Write 1 to register H264_DMA_MOVE_START.

(j) Wait for H264_DMA_MOVE_2MB_LINE_DONE_INT interrupt. When the interrupt is triggered, start H264_DMA TX channel 1. Refer to section 41.5.2.3 for the configuration.

(k) Start encoding of a picture: Write 1 to register H264_FRAME_START.

(l) Wait for the H264_DB_TMP_READY_INT interrupt. When the interrupt is triggered, start H264_DMA TX channel 2. Refer to section 41.5.2.3 for the configuration.

(m) Wait for the H264_FRAME_DONE_INT interrupt. When the interrupt is triggered, it indicates that the picture encoding is completed.

(n) Make sure the data is written completely referring to section 41.5.2.4.

(o) Reset each sending and receiving channel of H264_DMA referring to section 41.5.2.4.

(p) Reset the read and write counter of the deblocking filter intermediate data and the read and write counter of the reference picture data in H264_DMA. To be specific, set the register H264_DMA_RX_CH2_INTER_COUNTER_RST to 1, and then set it to 0; Set the register H264_DMA_RX_CH5_INTER_COUNTER_RST to 1 and then set it to 0.

- After any frame ends, the following registers corresponding to the currently encoded video sequence can be reconfigured:
  - Registers related to the quantization result decimation function, refer to the description in chapter 41.5.1.3.
  - Registers related to the MB level rate control function, refer to the description in chapter 41.5.1.5.
  - Deblocking filter enable register: H264_A_BYPASS_DB_FILTER.
  - ROI function related registers, refer to the description in chapter 41.5.1.6.
  - Registers related to the slice header information: H264_SLICE_REMAIN_BIT, H264_SLICE_REMAIN_BITLENGTH, H264_SLICE_BYTE_LENGTH, H264_SLICE_BYTE_LSB, and H264_SLICE_BYTE_MSB.
  - Registers related to the MV merge function, refer to the description in chapter 41.5.1.4.
  - Registers related to the debug function. Refer to chapter 41.5.1.7 for details.

4. Repeat steps 2 and 3 until one GOP of each of the two video sequences is encoded.
5. Reset the read and write times counter of the deblocking filter result data in H264_DMA. To be specific, set the register H264_DMA_RX_CHO_EXTER_COUNTER_RST to 1, then set to 0. Set the register H264_DMA_RX_CH1_EXTER_COUNTER_RST to 1, then set to 0.
6. Reconfigure from step 1 to start the encoding of the next GOP.

41.7.3 Soft Reset

No matter what working mode H264 is in, reset it according to the following process can stop encoding at any time.

1. Reset ENC_CORE: Write 1 to register H264_SYS_RST_PULSE.

2. Reset each sending and receiving channel of H264_DMA referring to section 41.5.2.4.
3. Reset each read and write time counter in H264_DMA. To be specific, set register H264_DMA_RX_CH0_EXTER_COUNTER_RST to 1, then set it to 0; Set register H264_DMA_RX_CH1_EXTER_COUNTER_RST to 1, then set it to 0; Set the register H264_DMA_RX_CH2_INTER_COUNTER_RST to 1, and then set it to 0; Set the register H264_DMA_RX_CH5_INTER_COUNTER_RST to 1, and then set it to 0.
4. H264 returns to the initial state and can be reconfigured as needed.

41.8 Register Summary

The addresses in this section are relative to **H264 Encoder** base address and **H264 DMA** base address. These base addresses are provided in Table 9.3-2 *Module/Peripheral Address Mapping* in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

41.8.1 H264 Encoder Register Summary

Name	Description	Address	Access
Configuration Registers			
H264_SYS_CTRL_REG	H264 system level control register	0x0000	varies
H264_GOP_CONF_REG	GOP related configuration register	0x0004	R/W
H264_SLICE_HEADER_REMAIN_REG	Frame slice header remain bit register	0x00AC	R/W
H264_SLICE_HEADER_BYTE_LENGTH_REG	Frame slice header byte length register	0x00B0	R/W
H264_BS_THRESHOLD_REG	Bitstream buffer overflow threshold register	0x00B4	R/W
H264_SLICE_HEADER_BYTE0_REG	Frame slice header byte low 32 bit register	0x00B8	R/W
H264_SLICE_HEADER_BYTE1_REG	Frame slice header byte high 32 bit register	0x00BC	R/W
H264_CONF_REG	General configuration register	0x00D0	R/W
H264_MV_MERGE_CONFIG_REG	MV merge configuration register	0x00D4	varies
Video Sequence A Configuration Registers			
H264_A_SYS_MB_RES_REG	Video sequence A horizontal and vertical MB resolution register	0x0008	R/W
H264_A_SYS_CONF_REG	Video sequence A system level configuration register	0x000C	R/W
H264_A_DECI_SCORE_REG	Video sequence A luma and chroma MB decimate score register	0x0010	R/W
H264_A_DECI_SCORE_OFFSET_REG	Video sequence A luma and chroma MB decimate score offset register	0x0014	R/W
H264_A_RC_CONF0_REG	Video sequence A rate control configuration register0	0x0018	R/W
H264_A_RC_CONF1_REG	Video sequence A rate control configuration register1	0x001C	R/W
H264_A_DB_BYPASS_REG	Video sequence A Deblocking bypass register	0x0020	R/W
H264_A_ROI_REGION0_REG	Video sequence A H264 ROI0 range configure register	0x0024	R/W
H264_A_ROI_REGION1_REG	Video sequence A H264 ROI1 range configure register	0x0028	R/W
H264_A_ROI_REGION2_REG	Video sequence A H264 ROI2 range configure register	0x002C	R/W

Name	Description	Address	Access
H264_A_ROI_REGION3_REG	Video sequence A H264 ROI3 range configure register	0x0030	R/W
H264_A_ROI_REGION4_REG	Video sequence A H264 ROI4 range configure register	0x0034	R/W
H264_A_ROI_REGION5_REG	Video sequence A H264 ROI5 range configure register	0x0038	R/W
H264_A_ROI_REGION6_REG	Video sequence A H264 ROI6 range configure register	0x003C	R/W
H264_A_ROI_REGION7_REG	Video sequence A H264 ROI7 range configure register	0x0040	R/W
H264_A_ROI_REGION0_3_QP_REG	Video sequence A H264 ROI0-3 QP register	0x0044	R/W
H264_A_ROI_REGION4_7_QP_REG	Video sequence A H264 ROI4-7 QP register	0x0048	R/W
H264_A_NO_ROI_REGION_QP_OFFSET_REG	Video sequence A H264 no ROI QP register	0x004C	R/W
H264_A_ROI_CONFIG_REG	Video sequence A H264 ROI configure register	0x0050	R/W
Video Sequence B Configuration Registers			
H264_B_SYS_MB_RES_REG	Video sequence B horizontal and vertical MB resolution register	0x0054	R/W
H264_B_SYS_CONF_REG	Video sequence B system level configuration register	0x0058	R/W
H264_B_DECI_SCORE_REG	Video sequence B luma and chroma MB decimate score register	0x005C	R/W
H264_B_DECI_SCORE_OFFSET_REG	Video sequence B luma and chroma MB decimate score offset register	0x0060	R/W
H264_B_RC_CONF0_REG	Video sequence B rate control configuration register0.	0x0064	R/W
H264_B_RC_CONF1_REG	Video sequence B rate control configuration register1.	0x0068	R/W
H264_B_DB_BYPASS_REG	Video sequence B Deblocking bypass register	0x006C	R/W
H264_B_ROI_REGION0_REG	Video sequence B H264 ROI0 range configure register	0x0070	R/W
H264_B_ROI_REGION1_REG	Video sequence B H264 ROI1 range configure register	0x0074	R/W
H264_B_ROI_REGION2_REG	Video sequence B H264 ROI2 range configure register	0x0078	R/W
H264_B_ROI_REGION3_REG	Video sequence B H264 ROI3 range configure register	0x007C	R/W
H264_B_ROI_REGION4_REG	Video sequence B H264 ROI4 range configure register	0x0080	R/W

Name	Description	Address	Access
H264_B_ROI_REGION5_REG	Video sequence B H264 ROI5 range configure register	0x0084	R/W
H264_B_ROI_REGION6_REG	Video sequence B H264 ROI6 range configure register	0x0088	R/W
H264_B_ROI_REGION7_REG	Video sequence B H264 ROI7 range configure register	0x008C	R/W
H264_B_ROI_REGION0_3_QP_REG	Video sequence B H264 ROI0-3 QP register	0x0090	R/W
H264_B_ROI_REGION4_7_QP_REG	Video sequence B H264 ROI4-7 QP register	0x0094	R/W
H264_B_NO_ROI_REGION_QP_OFFSET_REG	Video sequence B H264 no ROI QP register	0x0098	R/W
H264_B_ROI_CONFIG_REG	Video sequence B H264 ROI configure register	0x009C	R/W
H264_A_ORI_CONF_REG	Original picture configuration register of video sequence A	0x00F4	R/W
H264_B_ORI_CONF_REG	Original picture configuration register of video sequence B	0x00F8	R/W
H264_ORI_DEBUG_CONF_REG	Original picture debug configuration register	0x00FC	R/W
H264_MV_MERGE_DEBUG_CONF_REG	MV merge debug configuration register	0x0100	R/W
H264_BS_DEBUG_CONG_REG	Encoded bitstream debug configuration register	0x0104	R/W
H264_DB_WR_TEMP_DEBUG_CONG_REG	Deblocking filter write temporary data debug configuration register	0x0108	R/W
H264_DB_RD_TEMP_DEBUG_CONG_REG	Deblocking filter read temporary data debug configuration register	0x010C	R/W
H264_DB_WR_DEBUG_CONG_REG	Deblocking filter final data debug configuration register	0x0110	R/W
H264_REF_DEBUG_CONG_REG	Reference frame debug configuration register	0x0114	R/W
Status Registers			
H264_RC_STATUS0_REG	Rate control status register0	0x00A0	RO
H264_RC_STATUS1_REG	Rate control status register1	0x00A4	RO
H264_RC_STATUS2_REG	Rate control status register2	0x00A8	RO
H264_SYS_STATUS_REG	System status register	0x00DC	RO

41.9 Registers

The addresses in this section are relative to **H264 Encoder** base address and **H264 DMA** base address. These base addresses are provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

41.9.1 H264 Encoder Registers

Register 41.1. H264_SYS_CTRL_REG (0x0000)

H264_FRAME_START Configures whether to start encoding of a picture.

0: Invalid. No effect

1: Start encoding of a picture

(WT)

H264_DMA_MOVE_START Configures whether to start moving reference data from external mem.

0: Invalid. No effect

1: H264 start moving two MB lines of reference frame from external mem to internal mem

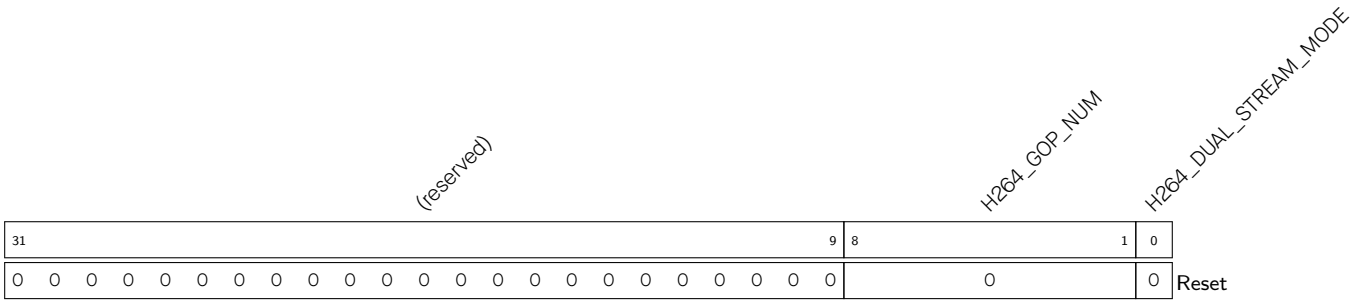
(WT)

H264_FRAME_MODE Configures H264 running mode. When field H264_DUAL_STREAM_MODE is set to 1, this field must be set to 1 too.

0: GOP mode. Before the start of every GOP, the H264_DMA needs to be reconfigured

1: Frame mode. Before the start of every frame, the H264_DMA needs to be reconfigured

(R/W)



H264_SYS_RST_PULSE Configures whether to reset H264 encoder.

0: Invalid. No effect

1: Reset H264 encoder

(WT)

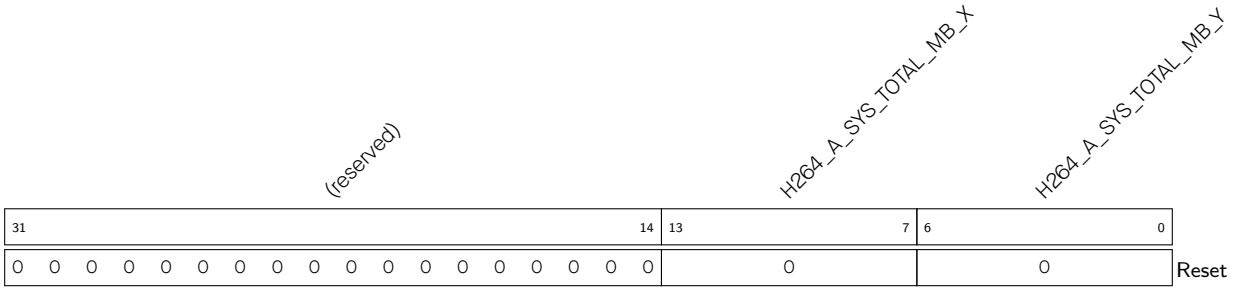
Register 41.2. H264_GOP_CONF_REG (0x0004)

H264_DUAL_STREAM_MODE Configures whether to enable dual stream mode. When this field is set to 1, H264_FRAME_MODE field must be set to 1 too.

0: GOP mode

1: Dual stream mode

(R/W)

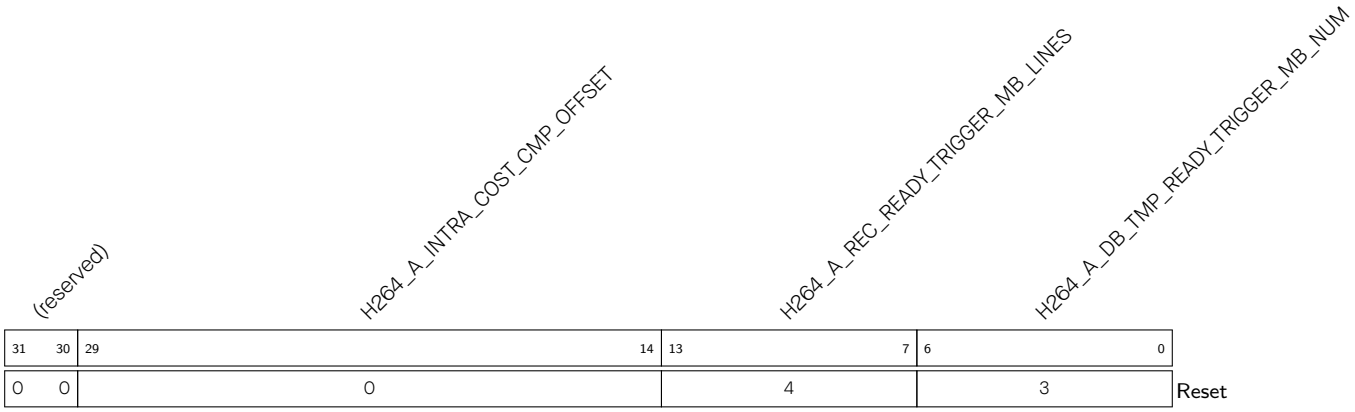


H264_GOP_NUM Configures the frame number of one GOP.

0: The frame number of one GOP is infinite

Others: Actual frame number of one GOP

(R/W)

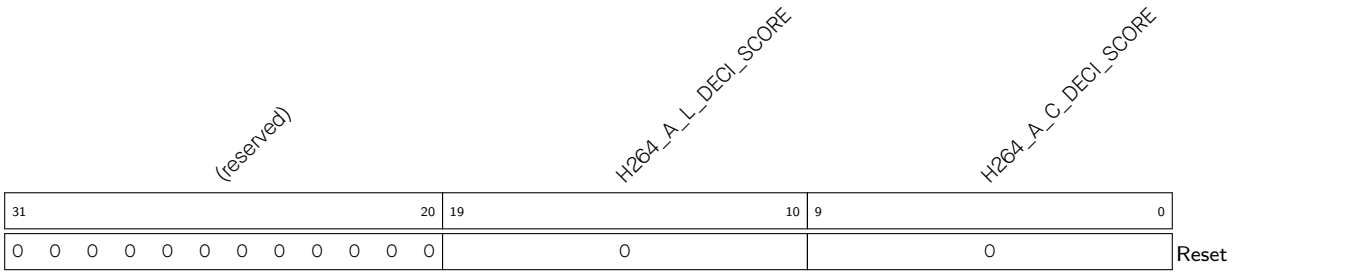


Register 41.3. H264_A_SYS_MB_RES_REG (0x0008)

H264_A_SYS_TOTAL_MB_Y Configures video sequence A vertical MB resolution. (R/W)

H264_A_SYS_TOTAL_MB_X Configures video sequence A horizontal MB resolution. (R/W)

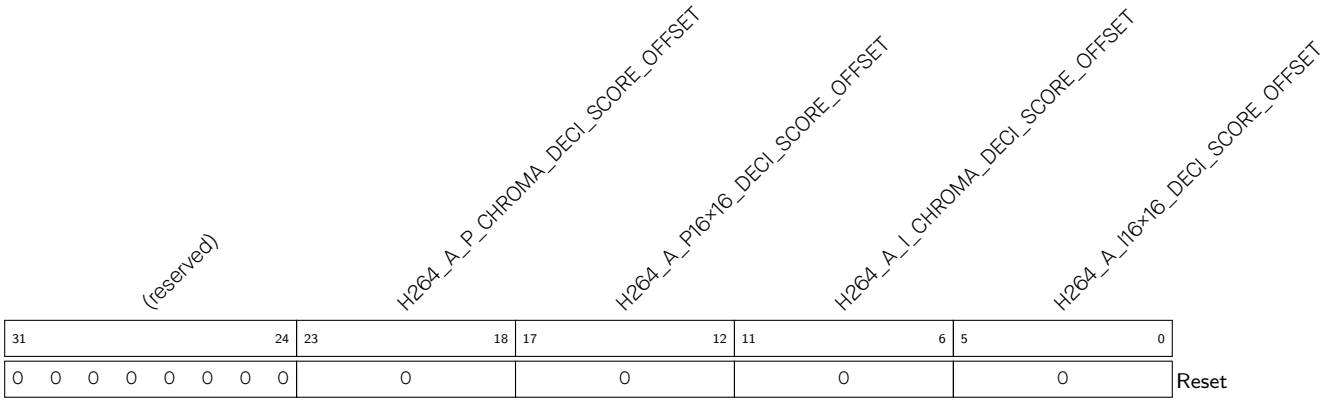
Register 41.4. H264_A_SYS_CONF_REG (0x000C)



H264_A_DB_TMP_READY_TRIGGER_MB_NUM Configures when to trigger video sequence A H264_DB_TMP_READY_INT. When the (MB number of written db temp+1) is greater than this field in first MB line, trigger H264_DB_TMP_READY_INT. Min is 3. (R/W)

H264_A_REC_READY_TRIGGER_MB_LINES Configures when to trigger video sequence A H264_REC_READY_INT. When the MB line number of generated reconstruct pixel is greater than this field, trigger H264_REC_READY_INT. Min is 4. (R/W)

H264_A_INTRA_COST_CMP_OFFSET Configures video sequence A intra cost offset when I MB compared with P MB. (R/W)

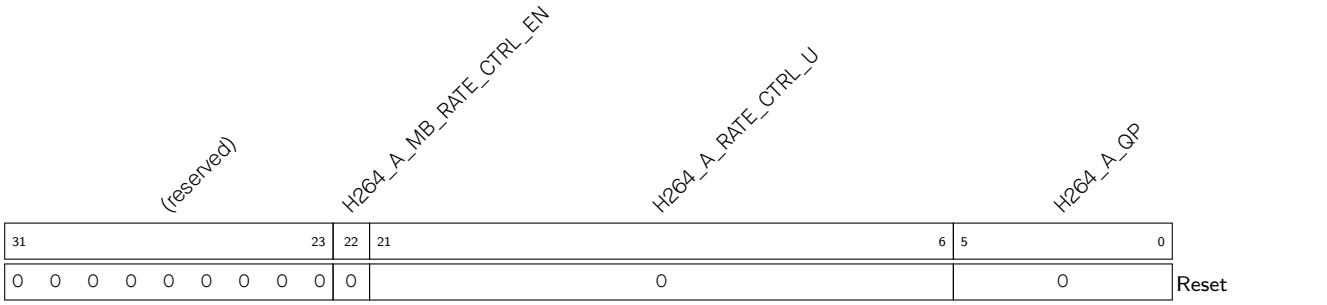


Register 41.5. H264_A_DECI_SCORE_REG (0x0010)

H264_A_C_DECI_SCORE Configures video sequence A chroma MB decimate score. When chroma score is smaller than it, chroma decimate will be enabled. (R/W)

H264_A_L_DECI_SCORE Configures video sequence A luma MB decimate score. When luma score is smaller than it, luma decimate will be enabled. (R/W)

Register 41.6. H264_A_DECI_SCORE_OFFSET_REG (0x0014)



H264_A_I16×16_DECI_SCORE_OFFSET Configures video sequence A i16 × 16 MB decimate score offset. This offset will be added to i16 × 16 MB score. (R/W)

H264_A_I_CHROMA_DECI_SCORE_OFFSET Configures video sequence A I chroma MB decimate score offset. This offset will be added to I chroma MB score. (R/W)

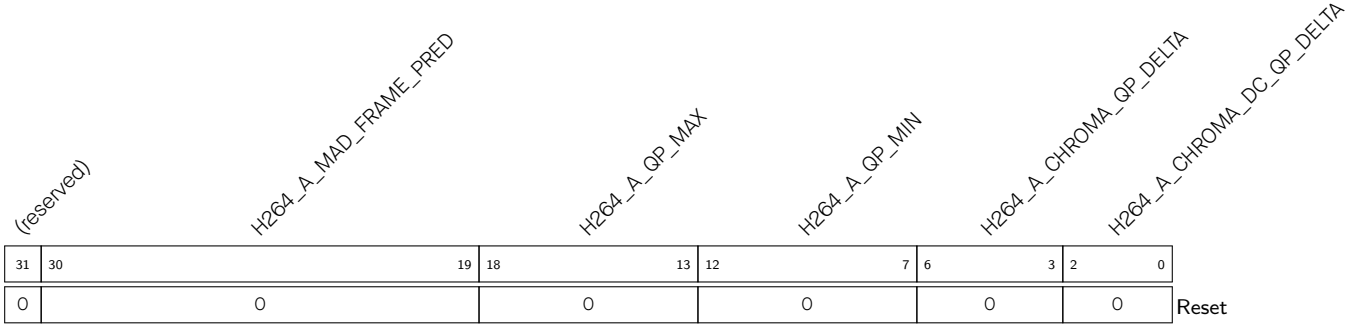
H264_A_P16×16_DECI_SCORE_OFFSET Configures video sequence A p16 × 16 MB decimate score offset. This offset will be added to p16 × 16 MB score. (R/W)

H264_A_P_CHROMA_DECI_SCORE_OFFSET Configures video sequence A p chroma MB decimate score offset. This offset will be added to p chroma MB score. (R/W)

Register 41.7. H264_A_RC_CONF0_REG (0x0018)

H264_A_QP Configures video sequence A frame level initial luma QP value. (R/W)

H264_A_RATE_CTRL_U Configures video sequence A parameter U value. U = `(int)((float)u « 8)`. (R/W)



H264_A_MB_RATE_CTRL_EN Configures video sequence A whether to enable the MB level rate ctrl.

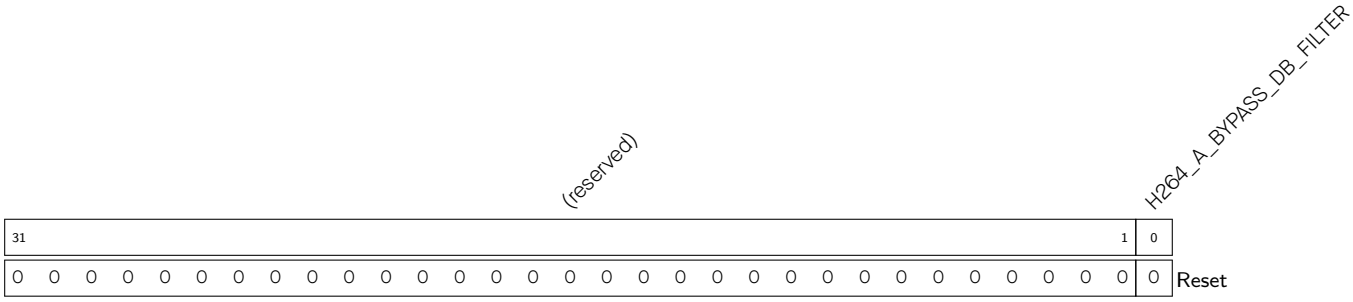
0: Disable the MB level rate ctrl

1: Enable the MB level rate ctrl

(R/W)

Register 41.8. H264_A_RC_CONF1_REG (0x001C)

H264_A_CHROMA_DC_QP_DELTA Configures video sequence A chroma DC QP offset based on Chroma QP. Chroma DC QP = Chroma QP(after map) + reg_chroma_dc_QP_delta. (R/W)



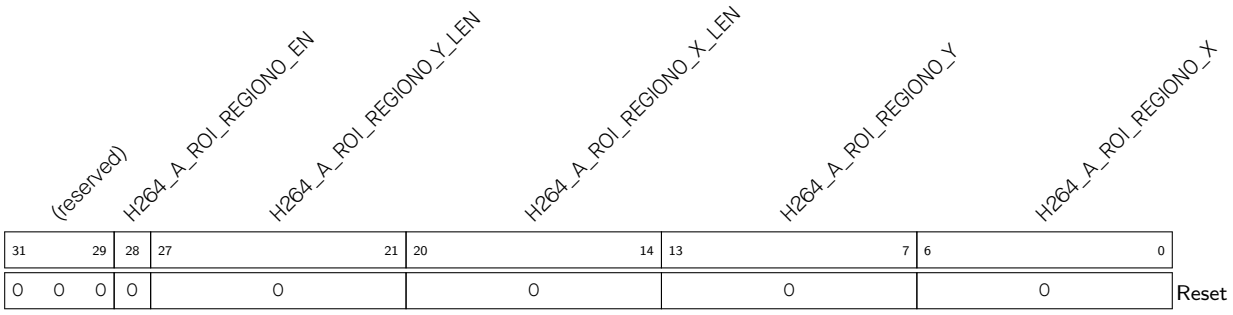
H264_A_CHROMA_QP_DELTA Configures video sequence A chroma QP offset based on luma QP. Chroma QP(before map) = Luma QP + reg_chroma_QP_delta. (R/W)

H264_A_QP_MIN Configures video sequence A allowed luma QP min value. (R/W)

H264_A_QP_MAX Configures video sequence A allowed luma QP max value. (R/W)

H264_A_MAD_FRAME_PRED Configures video sequence A frame level predicted MB MAD value. (R/W)

Register 41.9. H264_A_DB_BYPASS_REG (0x0020)



H264_A_BYPASS_DB_FILTER Configures whether to bypass video sequence A deblocking filter.

0: Do not bypass the deblocking filter

1: Bypass the deblocking filter

(R/W)

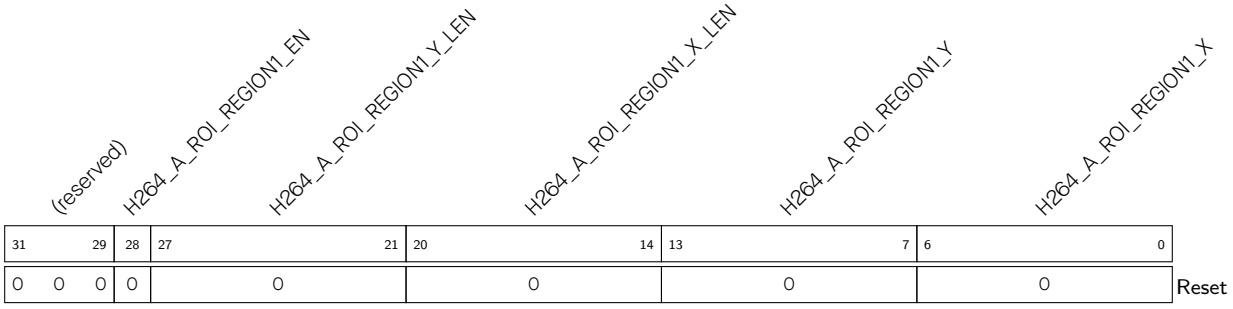
Register 41.10. H264_A_ROI_REGION0_REG (0x0024)

H264_A_ROI_REGION0_X Configures the horizontal start MBs of ROI 0 in video sequence A. (R/W)

H264_A_ROI_REGION0_Y Configures the vertical start MBs of ROI 0 in video sequence A. (R/W)

H264_A_ROI_REGION0_X_LEN Configures the number of MBs in horizontal direction of ROI 0 in video sequence A. (R/W)

H264_A_ROI_REGION0_Y_LEN Configures the number of MBs in vertical direction of ROI 0 in video sequence A. (R/W)



H264_A_ROI_REGION0_EN Configures whether to enable ROI 0 in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

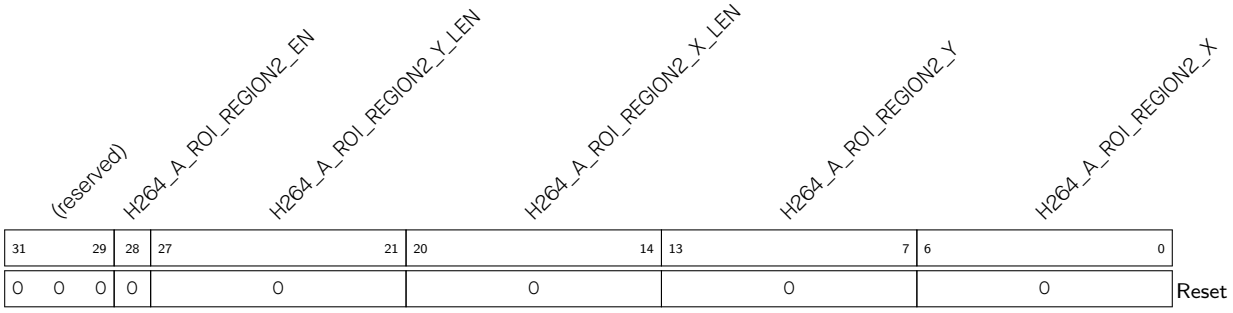
Register 41.11. H264_A_ROI_REGION1_REG (0x0028)

H264_A_ROI_REGION1_X Configures the horizontal start MBs of ROI 1 in video sequence A. (R/W)

H264_A_ROI_REGION1_Y Configures the vertical start MBs of ROI 1 in video sequence A. (R/W)

H264_A_ROI_REGION1_X_LEN Configures the number of MBs in horizontal direction of ROI 1 in video sequence A. (R/W)

H264_A_ROI_REGION1_Y_LEN Configures the number of MBs in vertical direction of ROI 1 in video sequence A. (R/W)



H264_A_ROI_REGION1_EN Configures whether to enable ROI 1 in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

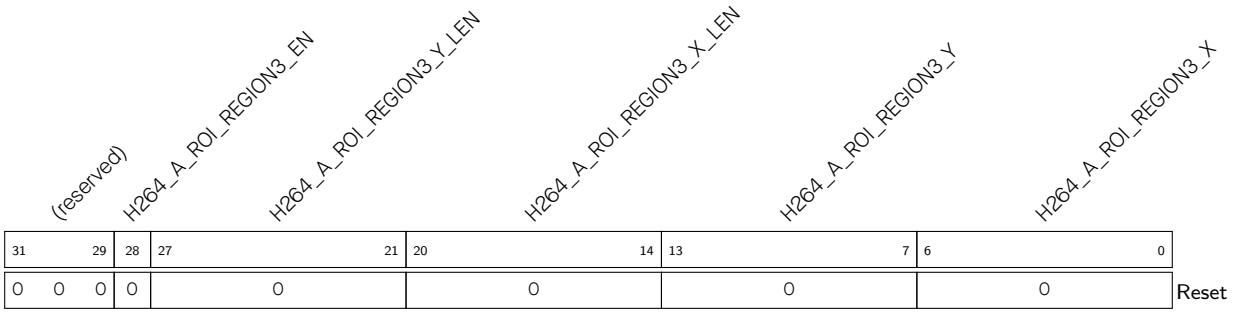
Register 41.12. H264_A_ROI_REGION2_REG (0x002C)

H264_A_ROI_REGION2_X Configures the horizontal start MBs of ROI 2 in video sequence A. (R/W)

H264_A_ROI_REGION2_Y Configures the vertical start MBs of ROI 2 in video sequence A. (R/W)

H264_A_ROI_REGION2_X_LEN Configures the number of MBs in horizontal direction of ROI 2 in video sequence A. (R/W)

H264_A_ROI_REGION2_Y_LEN Configures the number of MBs in vertical direction of ROI 2 in video sequence A. (R/W)



H264_A_ROI_REGION2_EN Configures whether to enable ROI 2 in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

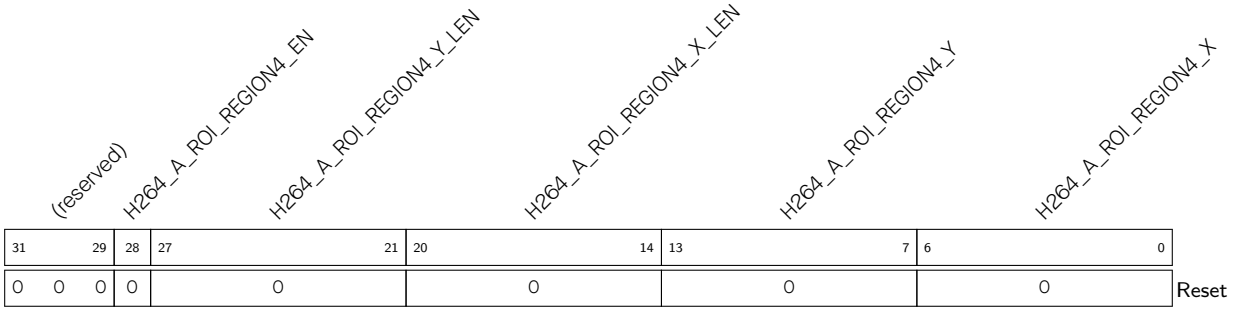
Register 41.13. H264_A_ROI_REGION3_REG (0x0030)

H264_A_ROI_REGION3_X Configures the horizontal start MBs of ROI 3 in video sequence A. (R/W)

H264_A_ROI_REGION3_Y Configures the vertical start MBs of ROI 3 in video sequence A. (R/W)

H264_A_ROI_REGION3_X_LEN Configures the number of MBs in horizontal direction of ROI 3 in video sequence A. (R/W)

H264_A_ROI_REGION3_Y_LEN Configures the number of MBs in vertical direction of ROI 3 in video sequence A. (R/W)



H264_A_ROI_REGION3_EN Configures whether to enable ROI 3 in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

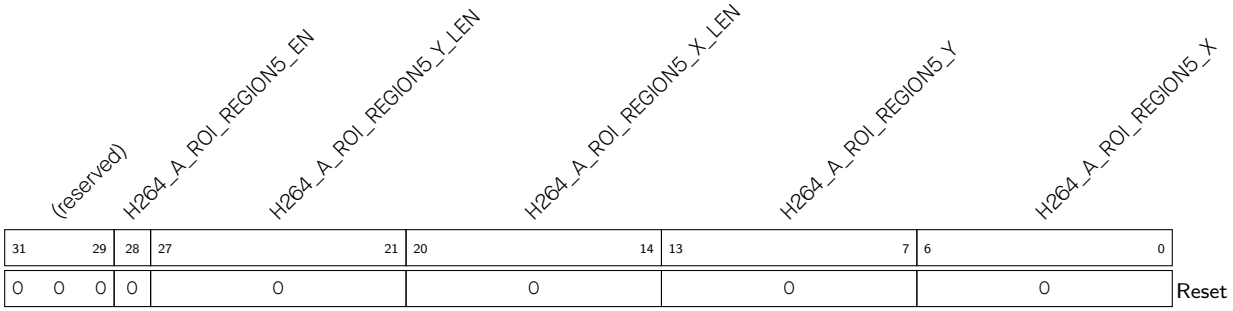
Register 41.14. H264_A_ROI_REGION4_REG (0x0034)

H264_A_ROI_REGION4_X Configures the horizontal start MBs of ROI 4 in video sequence A. (R/W)

H264_A_ROI_REGION4_Y Configures the vertical start MBs of ROI 4 in video sequence A. (R/W)

H264_A_ROI_REGION4_X_LEN Configures the number of MBs in horizontal direction of ROI 4 in video sequence A. (R/W)

H264_A_ROI_REGION4_Y_LEN Configures the number of MBs in vertical direction of ROI 4 in video sequence A. (R/W)



H264_A_ROI_REGION4_EN Configures whether to enable ROI 4 in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

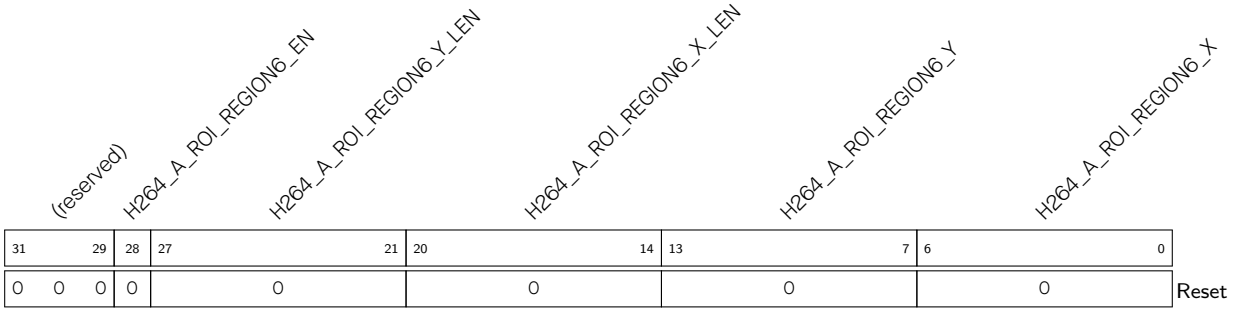
Register 41.15. H264_A_ROI_REGION5_REG (0x0038)

H264_A_ROI_REGION5_X Configures the horizontal start MBs of ROI 5 in video sequence A. (R/W)

H264_A_ROI_REGION5_Y Configures the vertical start MBs of ROI 5 in video sequence A. (R/W)

H264_A_ROI_REGION5_X_LEN Configures the number of MBs in horizontal direction of ROI 5 in video sequence A. (R/W)

H264_A_ROI_REGION5_Y_LEN Configures the number of MBs in vertical direction of ROI 5 in video sequence A. (R/W)



H264_A_ROI_REGION5_EN Configures whether to enable ROI 5 in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

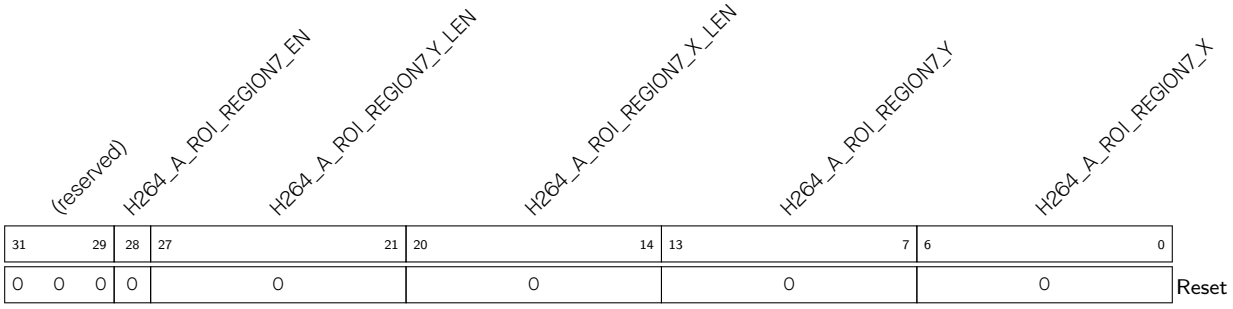
Register 41.16. H264_A_ROI_REGION6_REG (0x003C)

H264_A_ROI_REGION6_X Configures the horizontal start MBs of ROI 6 in video sequence A. (R/W)

H264_A_ROI_REGION6_Y Configures the vertical start MBs of ROI 6 in video sequence A. (R/W)

H264_A_ROI_REGION6_X_LEN Configures the number of MBs in horizontal direction of ROI 6 in video sequence A. (R/W)

H264_A_ROI_REGION6_Y_LEN Configures the number of MBs in vertical direction of ROI 6 in video sequence A. (R/W)



H264_A_ROI_REGION6_EN Configures whether to enable ROI 6 in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

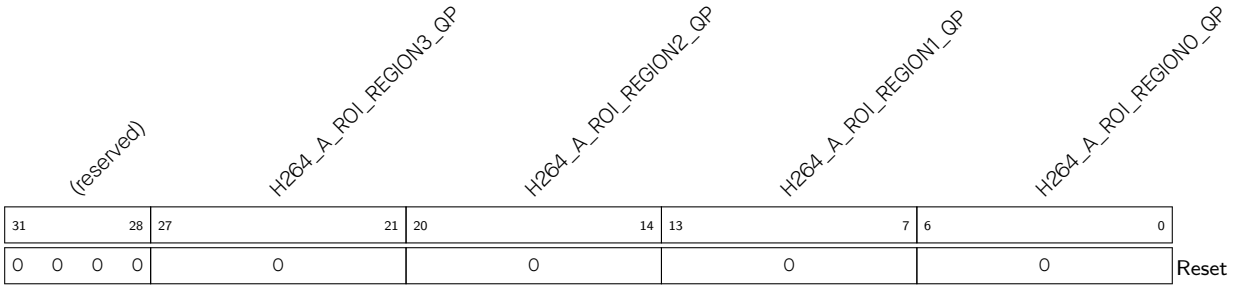
Register 41.17. H264_A_ROI_REGION7_REG (0x0040)

H264_A_ROI_REGION7_X Configures the horizontal start MBs of ROI 7 in video sequence A. (R/W)

H264_A_ROI_REGION7_Y Configures the vertical start MBs of ROI 7 in video sequence A. (R/W)

H264_A_ROI_REGION7_X_LEN Configures the number of MBs in horizontal direction of ROI 7 in video sequence A. (R/W)

H264_A_ROI_REGION7_Y_LEN Configures the number of MBs in vertical direction of ROI 7 in video sequence A. (R/W)



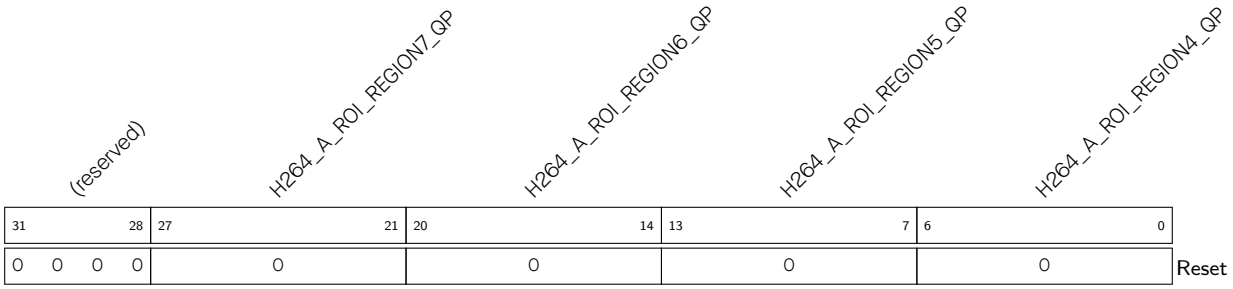
H264_A_ROI_REGION7_EN Configures whether to enable ROI 7 in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

Register 41.18. H264_A_ROI_REGION0_3_QP_REG (0x0044)



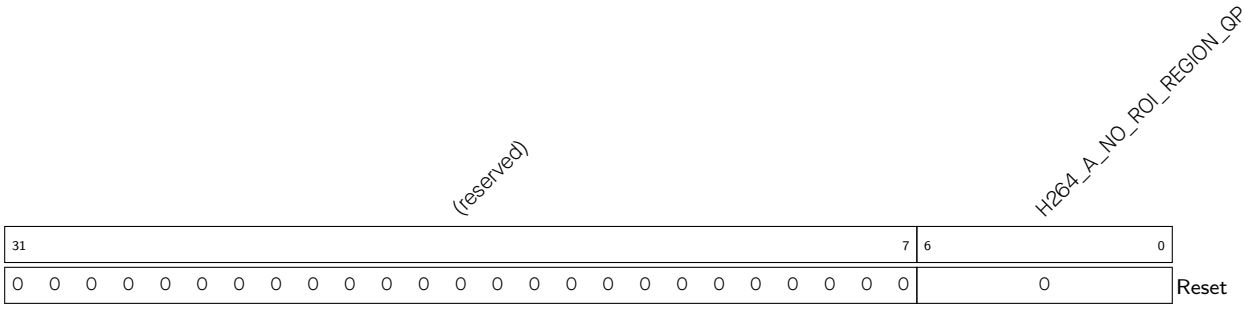
H264_A_ROI_REGION0_QP Configures H264 ROI 0 QP adjustment amount in video sequence A. (R/W)

H264_A_ROI_REGION1_QP Configures H264 ROI 1 QP adjustment amount in video sequence A. (R/W)

H264_A_ROI_REGION2_QP Configures H264 ROI 2 QP adjustment amount in video sequence A. (R/W)

H264_A_ROI_REGION3_QP Configures H264 ROI 3 QP adjustment amount in video sequence A. (R/W)

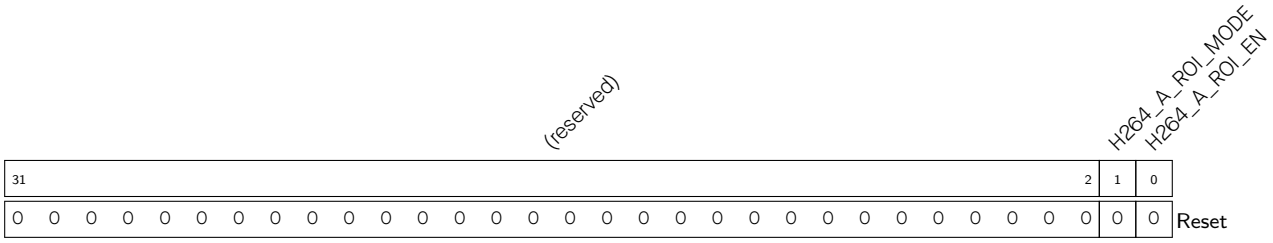
Register 41.19. H264_A_ROI_REGION4_7_QP_REG (0x0048)



H264_A_ROI_REGION4_QP Configures H264 ROI 4 QP adjustment amount in video sequence A. (R/W)

H264_A_ROI_REGION5_QP Configures H264 ROI 5 QP adjustment amount in video sequence A. (R/W)

H264_A_ROI_REGION6_QP Configures H264 ROI 6 QP adjustment amount in video sequence A. (R/W)



H264_A_ROI_REGION7_QP Configures H264 ROI 7 QP adjustment amount in video sequence A. (R/W)

Register 41.20. H264_A_NO_ROI_REGION_QP_OFFSET_REG (0x004C)

H264_A_NO_ROI_REGION_QP Configures H264 non-ROI QP in video sequence A, delta QP. (R/W)

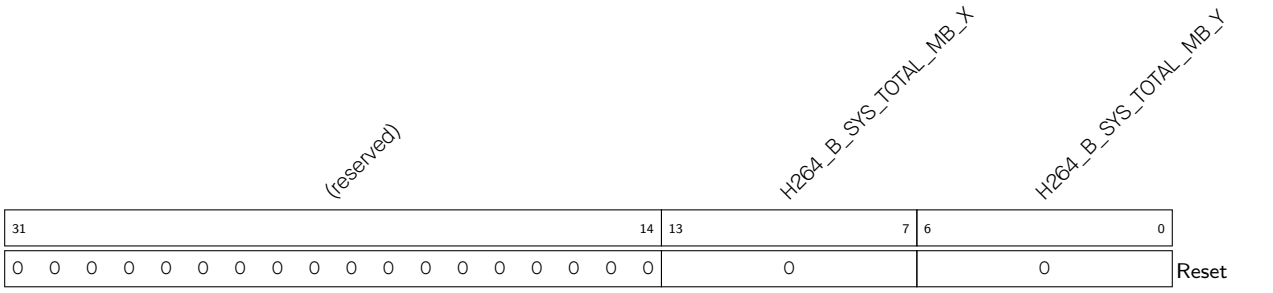
Register 41.21. H264_A_ROI_CONFIG_REG (0x0050)

H264_A_ROI_EN Configures whether to enable ROI in video sequence A.

0: Disable ROI

1: Enable ROI

(R/W)

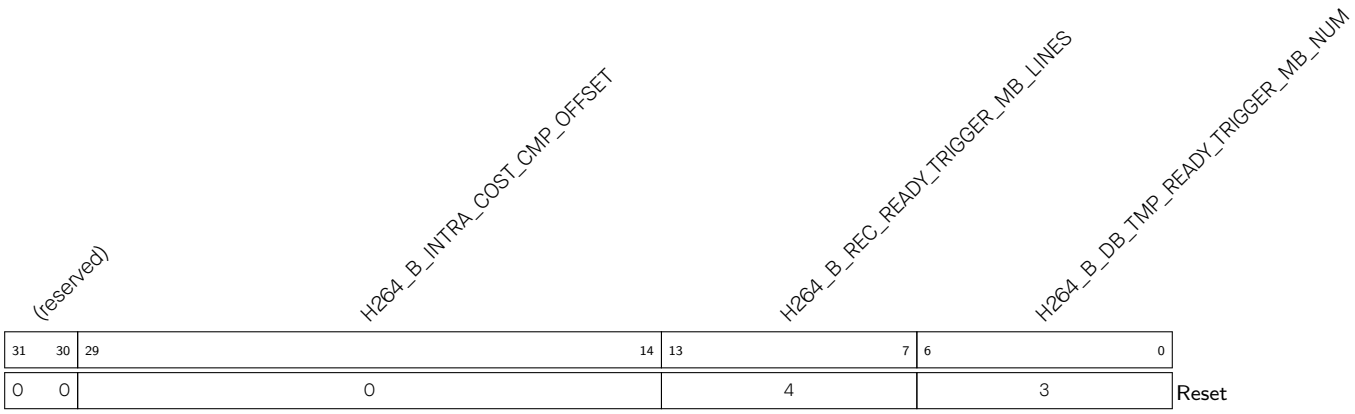


H264_A_ROI_MODE Configures the mode of ROI in video sequence A.

0: Fixed QP

1: Delta QP

(R/W)

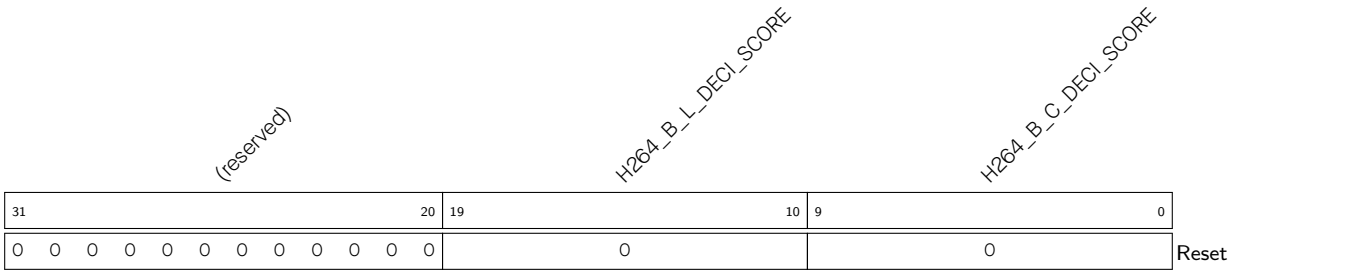


Register 41.22. H264_B_SYS_MB_RES_REG (0x0054)

H264_B_SYS_TOTAL_MB_Y Configures video sequence B vertical MB resolution. (R/W)

H264_B_SYS_TOTAL_MB_X Configures video sequence B horizontal MB resolution. (R/W)

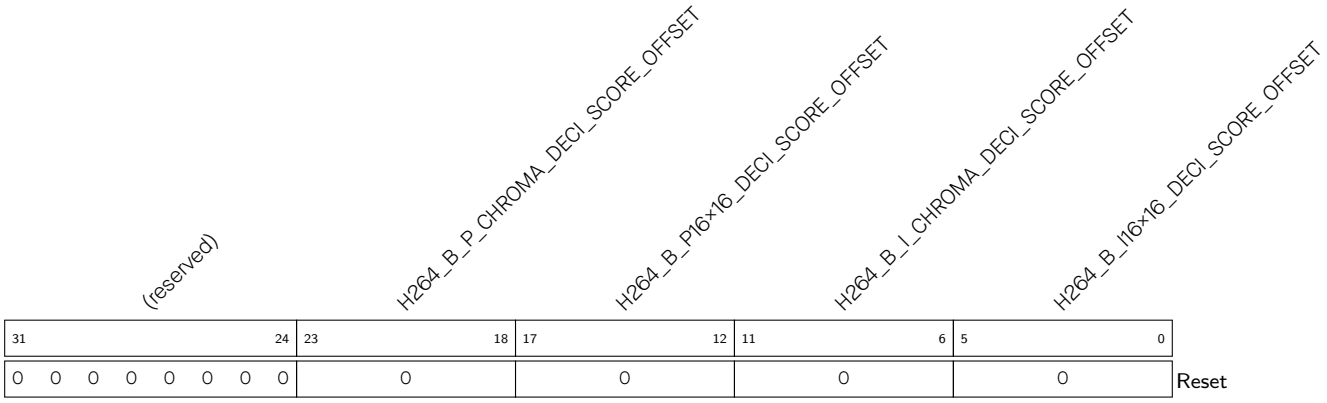
Register 41.23. H264_B_SYS_CONF_REG (0x0058)



H264_B_DB_TMP_READY_TRIGGER_MB_NUM Configures when to trigger video sequence B H264_DB_TMP_READY_INT. When the (MB number of written db temp+1) is greater than this field in first MB line, trigger H264_DB_TMP_READY_INT. Min is 3. (R/W)

H264_B_REC_READY_TRIGGER_MB_LINES Configures when to trigger video sequence B H264_REC_READY_INT. When the MB line number of generated reconstruct pixel is greater than this field, trigger H264_REC_READY_INT. Min is 4. (R/W)

H264_B_INTRA_COST_CMP_OFFSET Configures video sequence B intra cost offset when I MB compared with P MB. (R/W)

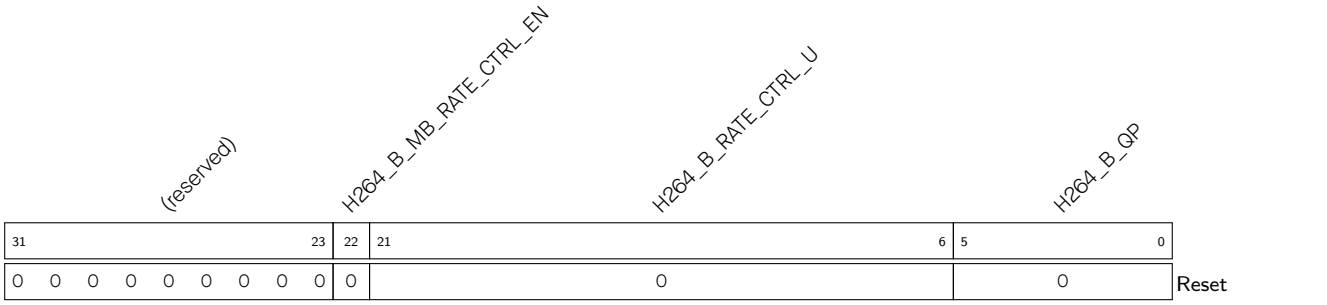


Register 41.24. H264_B_DECI_SCORE_REG (0x005C)

H264_B_C_DECI_SCORE Configures video sequence B chroma MB decimate score. When chroma score is smaller than it, chroma decimate will be enabled. (R/W)

H264_B_L_DECI_SCORE Configures video sequence B luma MB decimate score. When luma score is smaller than it, luma decimate will be enabled. (R/W)

Register 41.25. H264_B_DECI_SCORE_OFFSET_REG (0x0060)



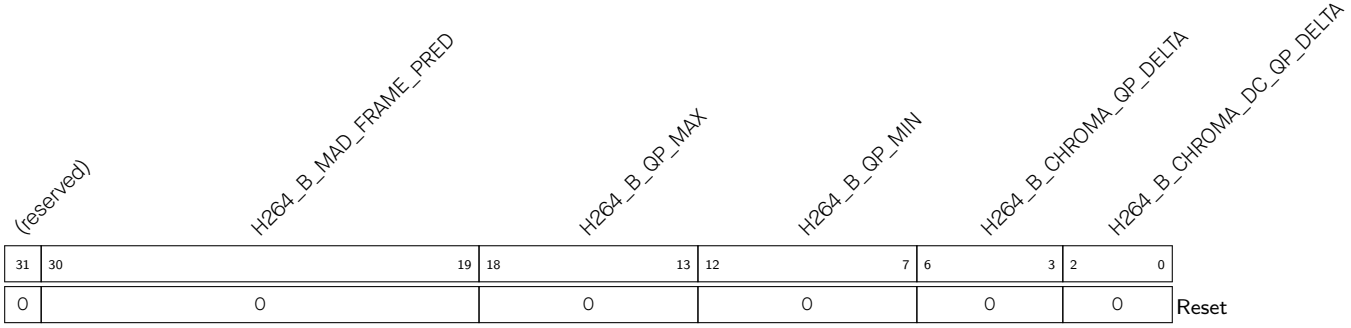
H264_B_I16×16_DECI_SCORE_OFFSET Configures video sequence B i16 × 16 MB decimate score offset. This offset will be added to i16 × 16 MB score. (R/W)

H264_B_I_CHROMA_DECI_SCORE_OFFSET Configures video sequence B I chroma MB decimate score offset. This offset will be added to I chroma MB score. (R/W)

H264_B_P16×16_DECI_SCORE_OFFSET Configures video sequence B p16 × 16 MB decimate score offset. This offset will be added to p16 × 16 MB score. (R/W)

H264_B_P_CHROMA_DECI_SCORE_OFFSET Configures video sequence B p chroma MB decimate score offset. This offset will be added to p chroma MB score. (R/W)

Register 41.26. H264_B_RC_CONF0_REG (0x0064)



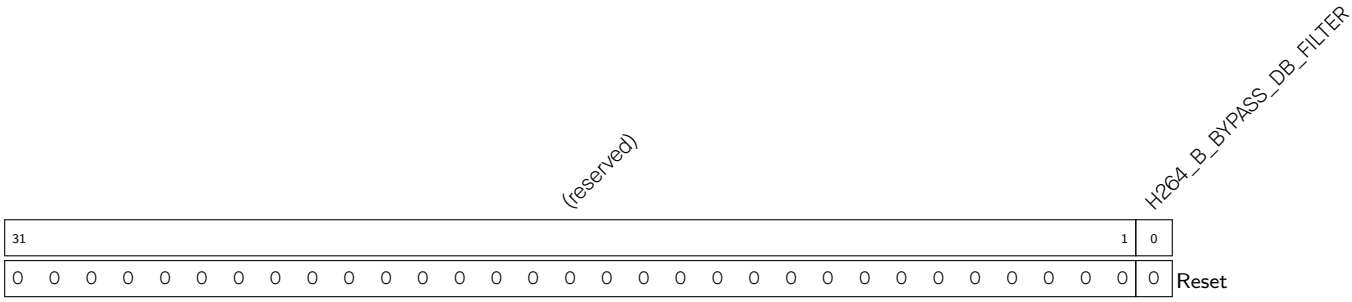
H264_B_QP Configures video sequence B frame level initial luma QP value. (R/W)

H264_B_RATE_CTRL_U Configures video sequence B parameter U value. U = int((float) u « 8). (R/W)

H264_B_MB_RATE_CTRL_EN Configures video sequence B whether to enable MB level rate ctrl.
0: Disable the MB level rate ctrl
1: Enable the MB level rate ctrl
(R/W)

Register 41.27. H264_B_RC_CONF1_REG (0x0068)

H264_B_CHROMA_DC_QP_DELTA Configures video sequence B chroma DC QP offset based on Chroma QP. Chroma DC QP = Chroma QP (after mapping) + reg_chroma_dc_QP_delta. (R/W)



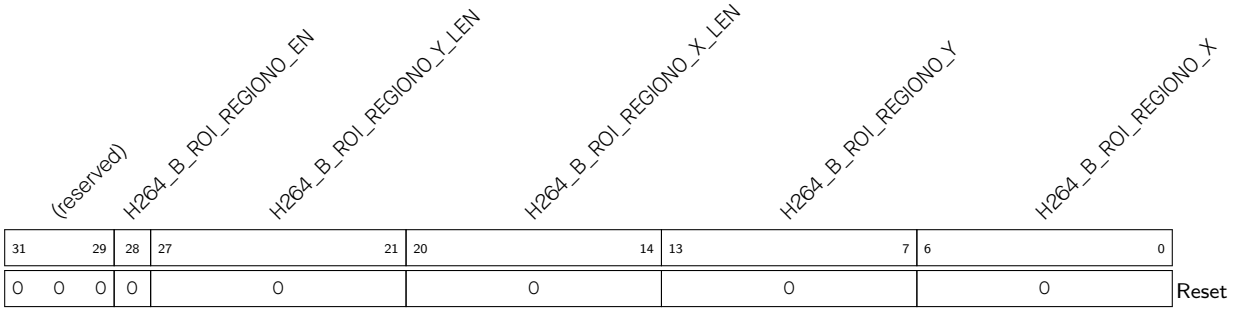
H264_B_CHROMA_QP_DELTA Configures video sequence B chroma QP offset based on luma QP. Chroma QP(before mapping) = Luma QP + reg_chroma_QP_delta. (R/W)

H264_B_QP_MIN Configures the minimum allowed luma QP value for video sequence B. (R/W)

H264_B_QP_MAX Configures the maximum allowed luma QP value for video sequence B. (R/W)

H264_B_MAD_FRAME_PRED Configures the MAD value for frame-level predicted MB in video sequence B. (R/W)

Register 41.28. H264_B_DB_BYPASS_REG (0x006C)



H264_B_BYPASS_DB_FILTER Configures whether to bypass video sequence B deblocking filter.

0: Do not bypass the deblocking filter

1: Bypass the deblocking filter

(R/W)

Register 41.29. H264_B_ROI_REGION0_REG (0x0070)

H264_B_ROI_REGION0_X Configures the horizontal start MBs of ROI 0 in video sequence B. (R/W)

H264_B_ROI_REGION0_Y Configures the vertical start MBs of ROI 0 in video sequence B. (R/W)

H264_B_ROI_REGION0_X_LEN Configures the number of MBs in horizontal direction of ROI 0 in video sequence B. (R/W)

H264_B_ROI_REGION0_Y_LEN Configures the number of MBs in vertical direction of ROI 0 in video sequence B. (R/W)

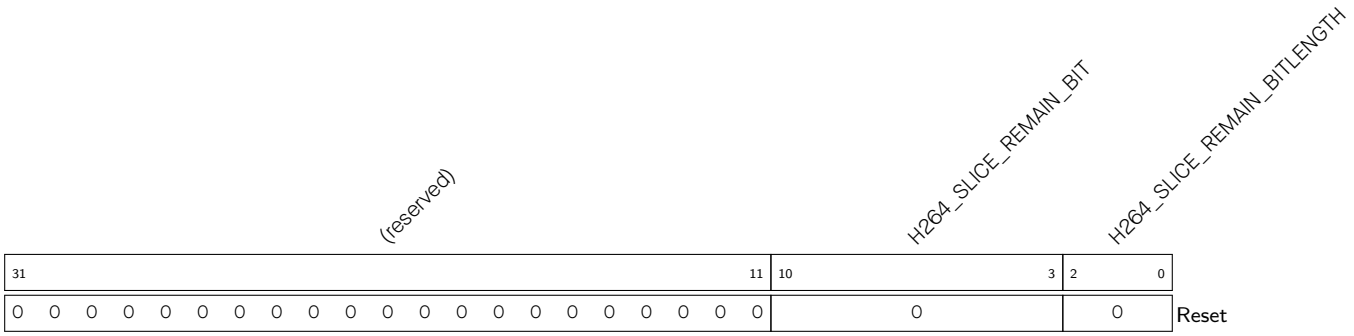
Register 41.40. H264_B_ROI_CONFIG_REG (0x009C)

H264_B_ROI_EN Configures whether to enable ROI in video sequence B.

0: Disable ROI

1: Enable ROI

(R/W)

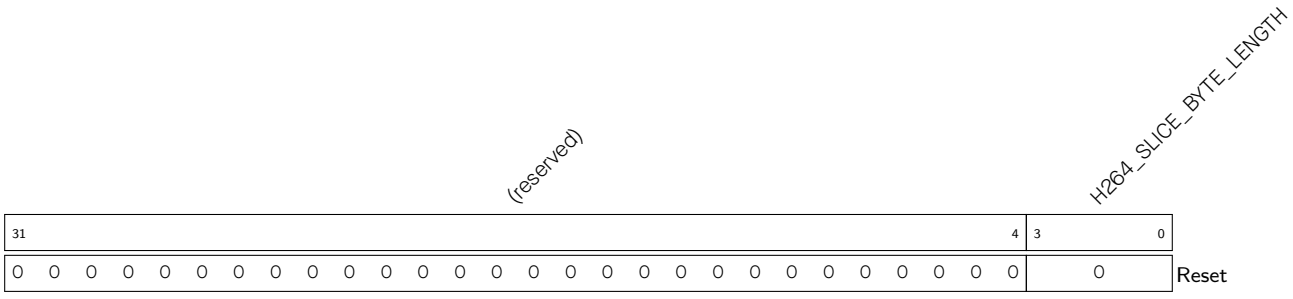


H264_B_ROI_MODE Configures the mode of ROI in video sequence B.

0: Fixed QP

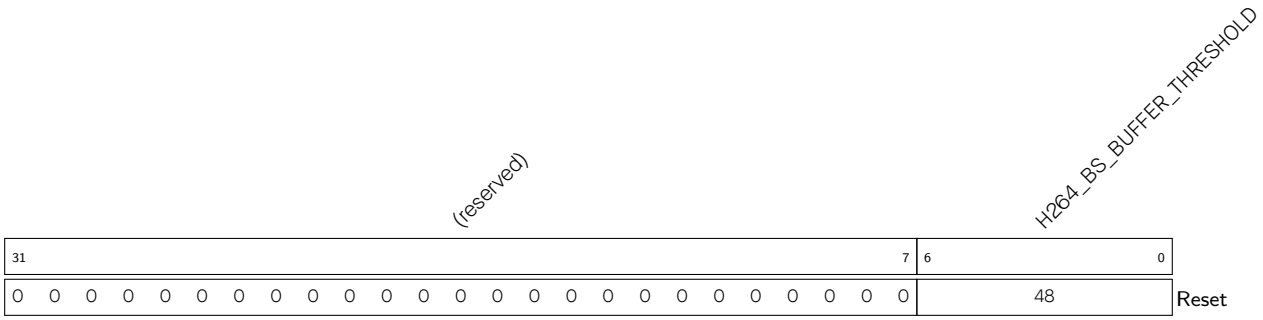
1: Delta QP

(R/W)



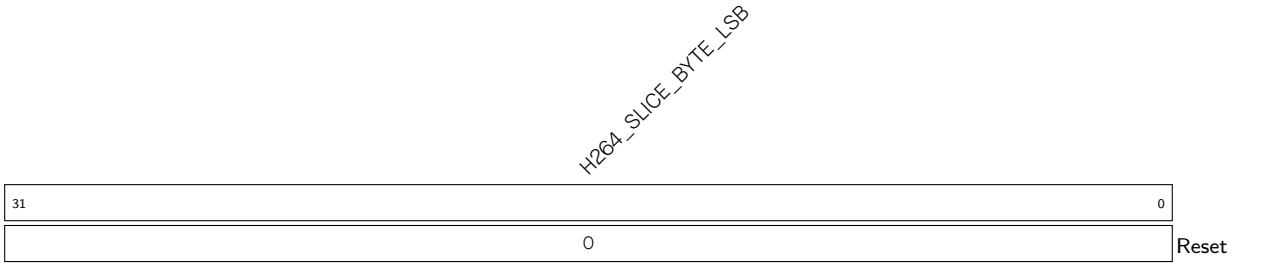
Register 41.41. H264_SLICE_HEADER_REMAIN_REG (0x00AC)

H264_SLICE_REMAIN_BITLENGTH Configures slice header remain bit number. (R/W)



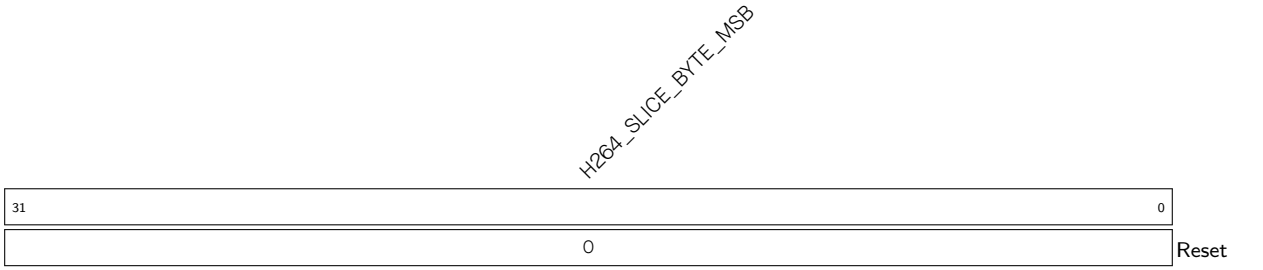
H264_SLICE_REMAIN_BIT Configures slice header remain bit. (R/W)

Register 41.42. H264_SLICE_HEADER_BYTE_LENGTH_REG (0x00B0)



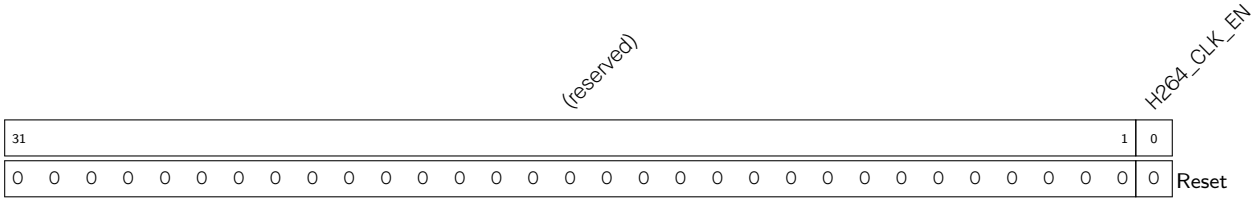
H264_SLICE_BYTE_LENGTH Configures slice header byte number. (R/W)

Register 41.43. H264_BS_THRESHOLD_REG (0x00B4)



H264_BS_BUFFER_THRESHOLD Configures bitstream buffer overflow threshold. This value should be bigger than the encoded bytes of one 4 × 4 sub MB. (R/W)

Register 41.44. H264_SLICE_HEADER_BYTE0_REG (0x00B8)

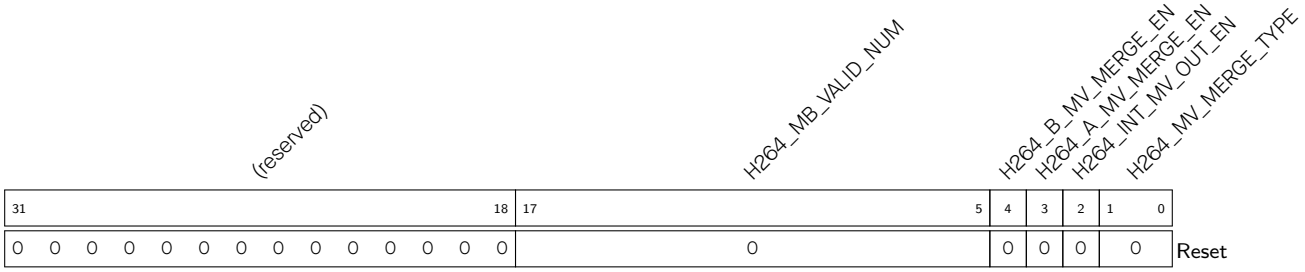


H264_SLICE_BYTE_LSB Configures slice header low 32 bit. (R/W)

Register 41.45. H264_SLICE_HEADER_BYTE1_REG (0x00BC)

H264_SLICE_BYTE_MSB Configures slice header high 32 bit. (R/W)

Register 41.46. H264_CONF_REG (0x00D0)



H264_CLK_EN Configures whether to enable the register clock gate.

0: Enable the clock gate only when application writes registers

1: Force enable the clock gate for register

(R/W)

Register 41.47. H264_MV_MERGE_CONFIG_REG (0x00D4)

H264_MV_MERGE_TYPE Configures MV merge type.

0: Merge p16 × 16 mv

1: Merge min mv

2: Merge max mv

3: Invalid. No effect

(R/W)

H264_INT_MV_OUT_EN Configures the output type of the merged MV.

0: Output the merged MV where any part (integer and fractional) is not zero

1: Output the merged MV where the integer part is not zero

(R/W)

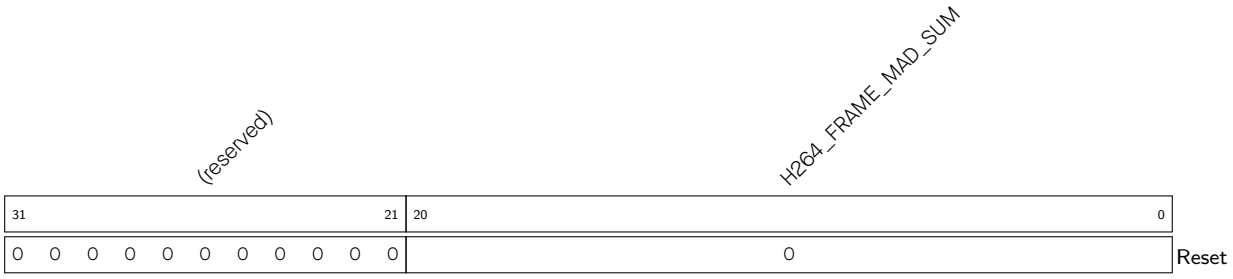
H264_A_MV_MERGE_EN Configures whether to enable MV merge for video sequence A.

0: Disable

1: Enable

(R/W)

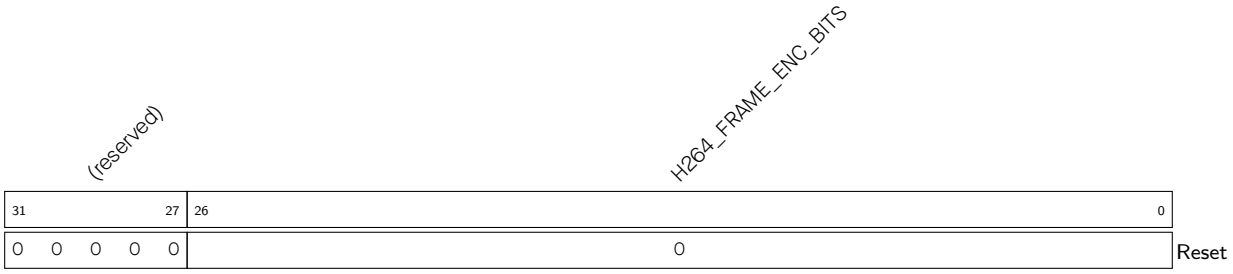
H264_B_MV_MERGE_EN Configures whether to enable MV merge for video sequence B.



0: Disable

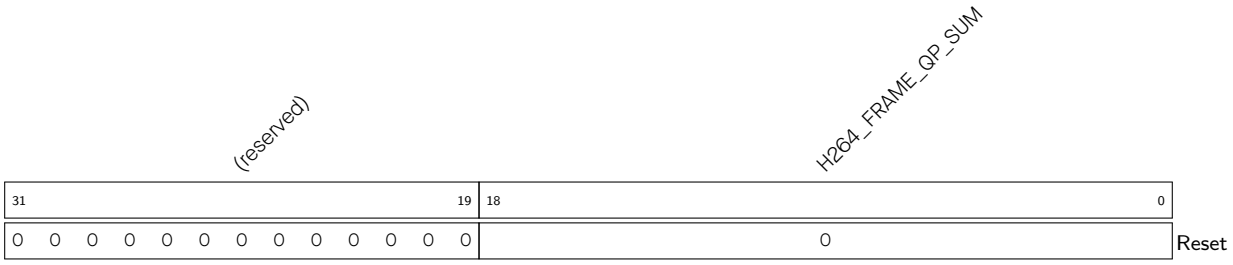
1: Enable

(R/W)



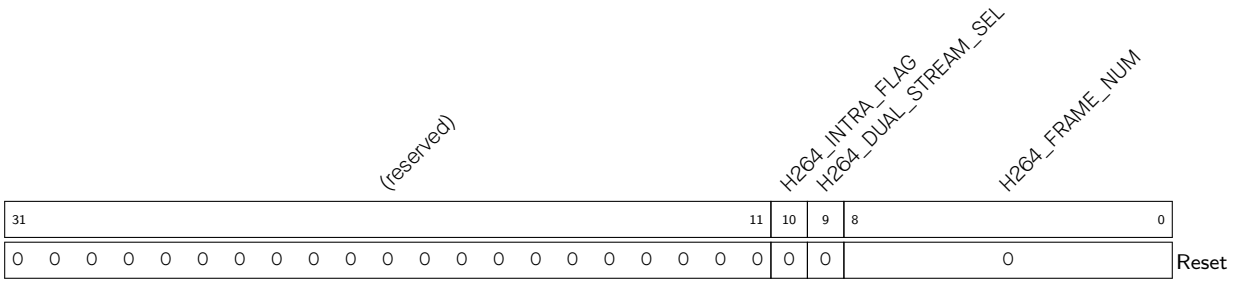
H264_MB_VALID_NUM Represents the number of MBs in the output that contains valid merged MVs. (RO)

Register 41.48. H264_RC_STATUS0_REG (0x00A0)



H264_FRAME_MAD_SUM Represents the sum of all MB actual MAD for one frame. (RO)

Register 41.49. H264_RC_STATUS1_REG (0x00A4)



H264_FRAME_ENC_BITS Represents the sum of all MB actual encoding bits for one frame. (RO)

Register 41.50. H264_RC_STATUS2_REG (0x00A8)

H264_FRAME_QP_SUM Represents all MB actual luma QP sum value of one frame. (RO)

Register 41.51. H264_SYS_STATUS_REG (0x00DC)

H264_FRAME_NUM Represents the current frame number. (RO)

H264_DUAL_STREAM_SEL Represents which register group is used for the current frame.

0: Register group A is used

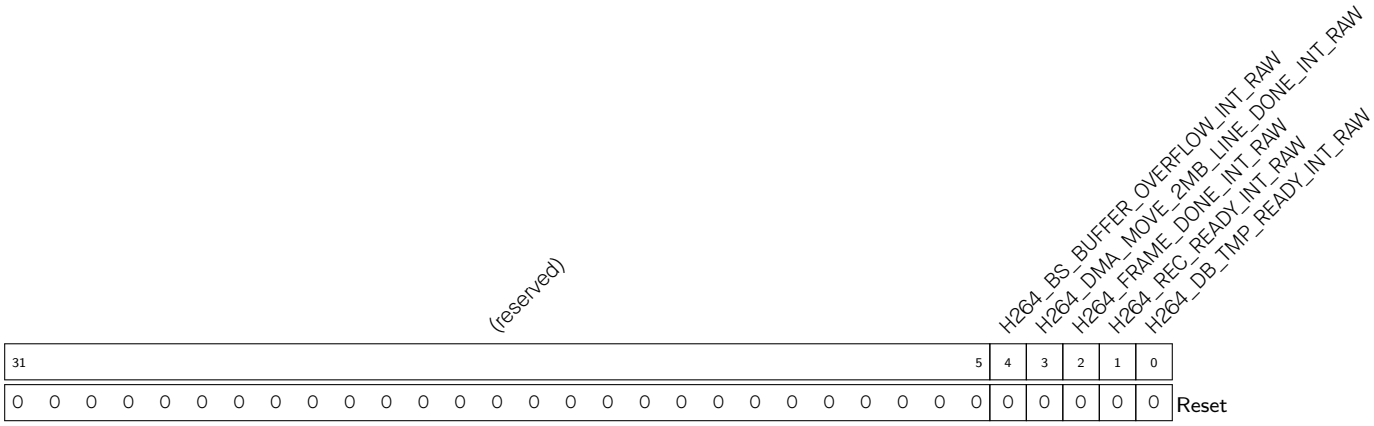
1: Register group B is used

(RO)

H264_INTRA_FLAG Represents the type of the current encoding frame.

0: P frame

1: I frame



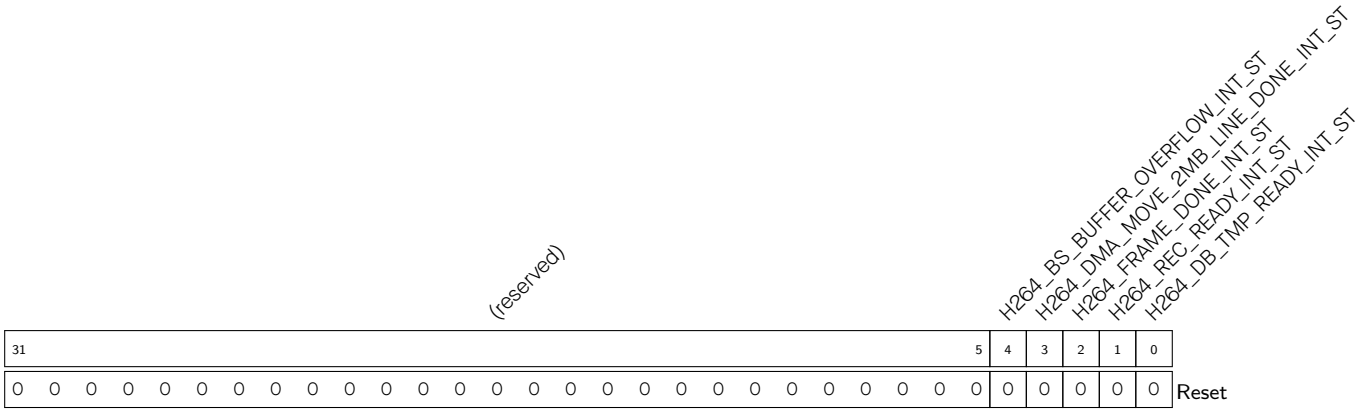
(RO)

Register 41.52. H264_FRAME_CODE_LENGTH_REG (0x00E0)

H264_FRAME_CODE_LENGTH Represents the byte length of the current frame code. (RO)

Register 41.53. H264_INT_RAW_REG (0x00C0)

H264_DB_TMP_READY_INT_RAW The raw interrupt status of H264_DB_TMP_READY_INT. (R/WTC/SS)



H264_REC_READY_INT_RAW The raw interrupt status of H264_REC_READY_INT. (R/WTC/SS)

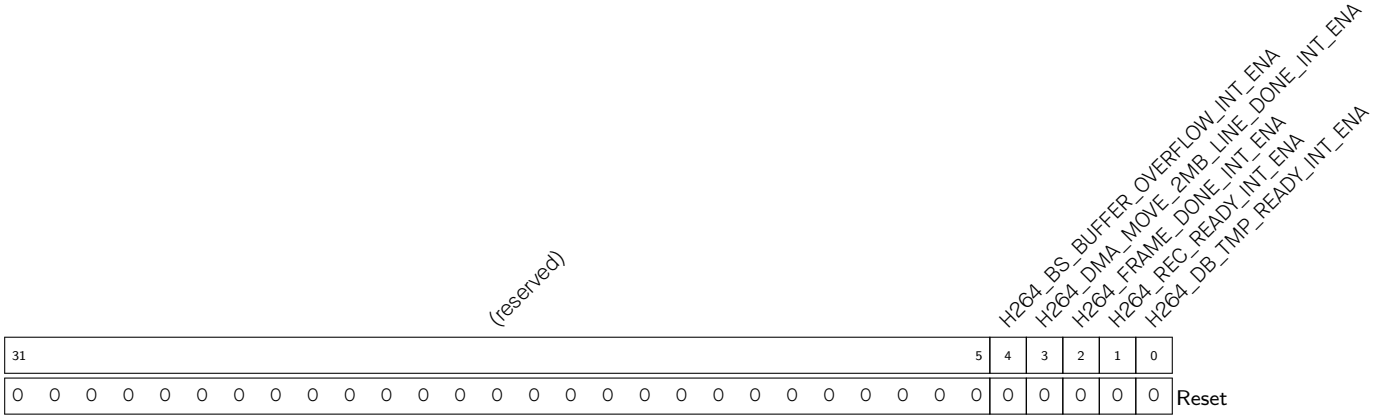
H264_FRAME_DONE_INT_RAW The raw interrupt status of H264_FRAME_DONE_INT. (R/WTC/SS)

H264_DMA_MOVE_2MB_LINE_DONE_INT_RAW The raw interrupt status of H264_DMA_MOVE_2MB_LINE_DONE_INT. (R/WTC/SS)

H264_BS_BUFFER_OVERFLOW_INT_RAW The raw interrupt status of H264_BS_BUFFER_OVERFLOW_INT. (R/WTC/SS)

Register 41.54. H264_INT_ST_REG (0x00C4)

H264_DB_TMP_READY_INT_ST The masked interrupt status of H264_DB_TMP_READY_INT. (RO)



H264_REC_READY_INT_ST The masked interrupt status of H264_REC_READY_INT. (RO)

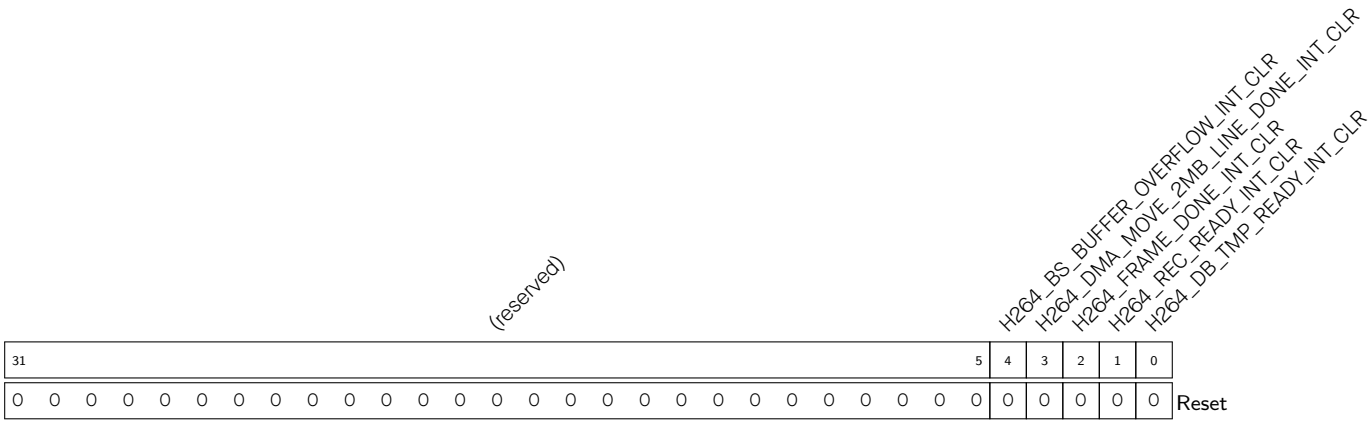
H264_FRAME_DONE_INT_ST The masked interrupt status of H264_FRAME_DONE_INT. (RO)

H264_DMA_MOVE_2MB_LINE_DONE_INT_ST The masked interrupt status of H264_DMA_MOVE_2MB_LINE_DONE_INT. (RO)

H264_BS_BUFFER_OVERFLOW_INT_ST The masked interrupt status of H264_BS_BUFFER_OVERFLOW_INT. (RO)

Register 41.55. H264_INT_ENA_REG (0x00C8)

H264_DB_TMP_READY_INT_ENA Write 1 to enable H264_DB_TMP_READY_INT. (R/W)



H264_REC_READY_INT_ENA Write 1 to enable H264_REC_READY_INT. (R/W)

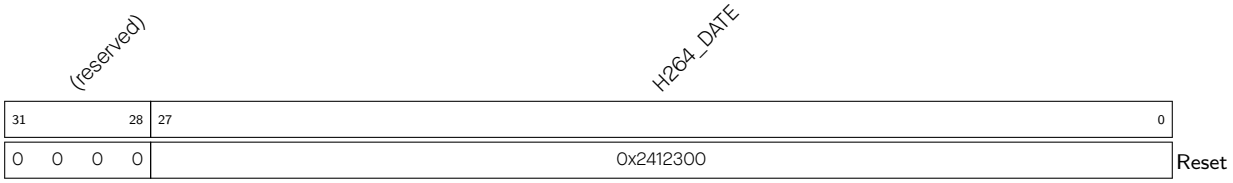
H264_FRAME_DONE_INT_ENA Write 1 to enable H264_FRAME_DONE_INT. (R/W)

H264_DMA_MOVE_2MB_LINE_DONE_INT_ENA Write 1 to enable H264_DMA_MOVE_2MB_-LINE_DONE_INT. (R/W)

H264_BS_BUFFER_OVERFLOW_INT_ENA Write 1 to enable H264_BS_BUFFER_OVERFLOW_INT. (R/W)

Register 41.56. H264_INT_CLR_REG (0x00CC)

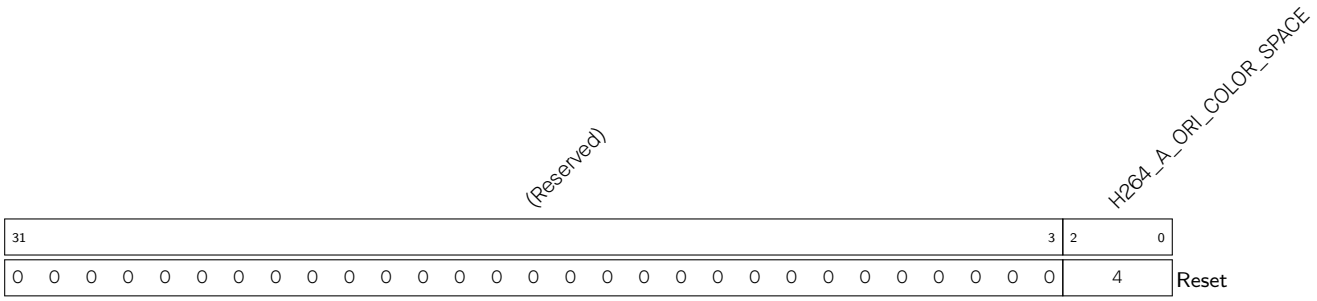
H264_DB_TMP_READY_INT_CLR Write 1 to clear H264_DB_TMP_READY_INT. (WT)



H264_REC_READY_INT_CLR Write 1 to clear H264_REC_READY_INT. (WT)

H264_FRAME_DONE_INT_CLR Write 1 to clear H264_FRAME_DONE_INT. (WT)

H264_DMA_MOVE_2MB_LINE_DONE_INT_CLR Write 1 to clear H264_DMA_MOVE_2MB_LINE_-DONE_INT. (WT)



H264_BS_BUFFER_OVERFLOW_INT_CLR Write 1 to clear H264_BS_BUFFER_OVERFLOW_INT. (WT)

Register 41.57. H264_DATE_REG (0x00F0)

H264_DATE Version control register. (R/W)

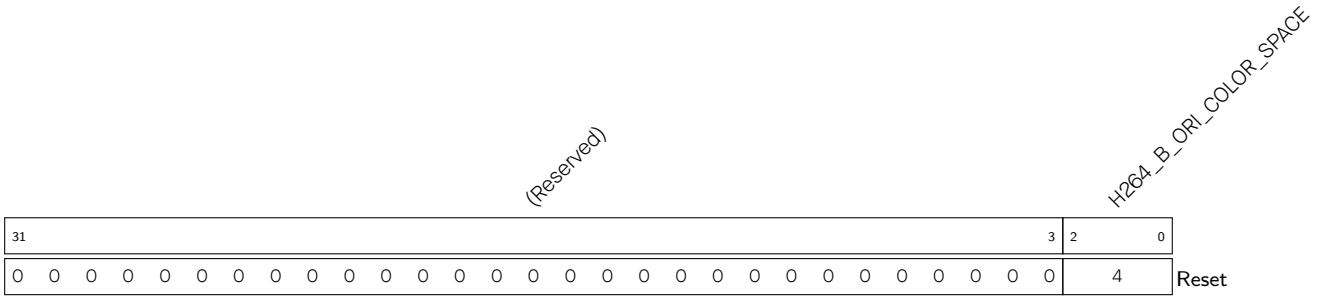
Register 41.58. H264_A_ORI_CONF_REG (0x00F4)

H264_A_ORI_COLOR_SPACE Configures the original picture color space of video sequence A.

0: RGB888

1: RGB565

2: YUV444



3: YUV422

4: YUV420

Others: Invalid. No effect

(R/W)

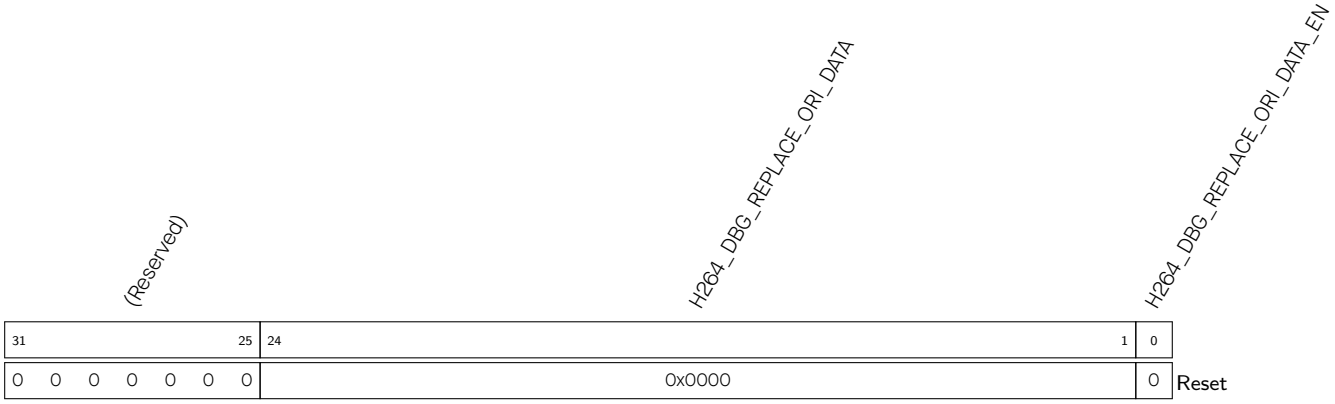
Register 41.59. H264_B_ORI_CONF_REG (0x00F8)

H264_B_ORI_COLOR_SPACE Configures the original picture color space of video sequence B.

0: RGB888

1: RGB565

2: YUV444

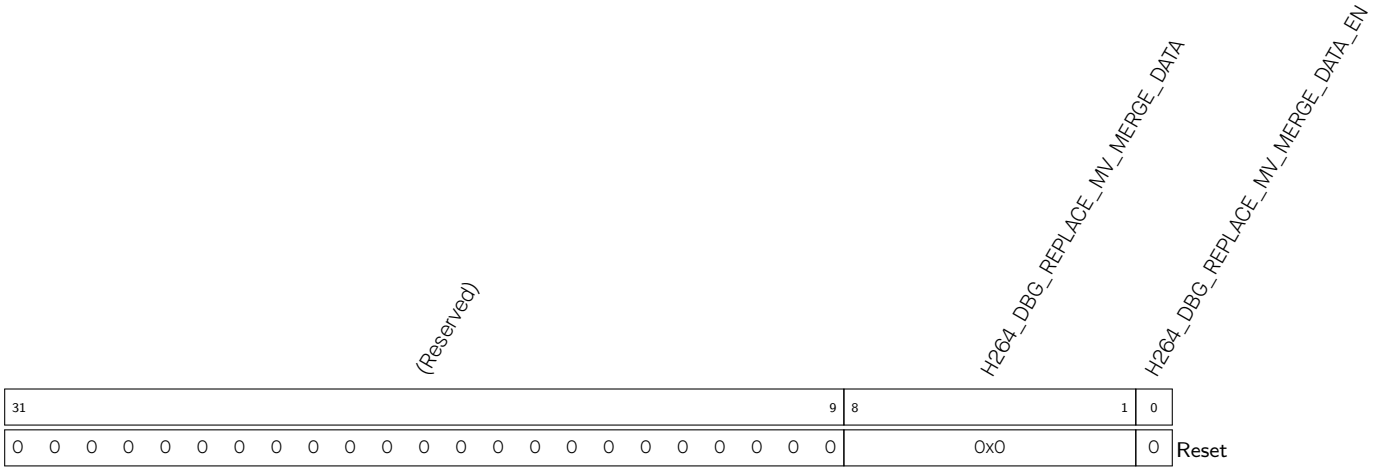


3: YUV422

4: YUV420

Others: Invalid. No effect

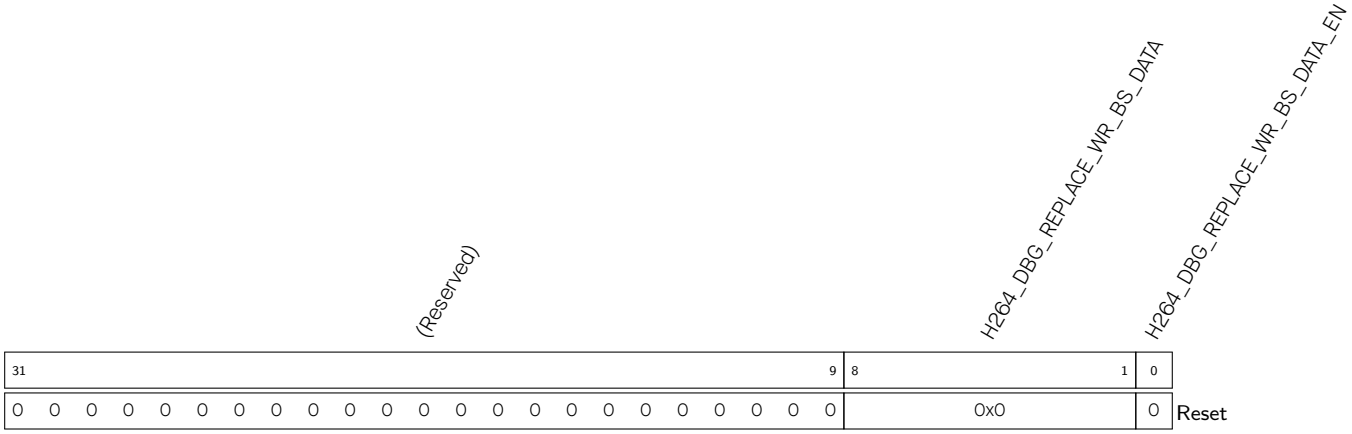
(R/W)



Register 41.60. H264_ORI_DEBUG_CONF_REG (0x00FC)

H264_DBG_REPLACE_ORI_DATA_EN Configures whether to replace the original video pixel data. 0: do not replace, 1: replace. (R/W)

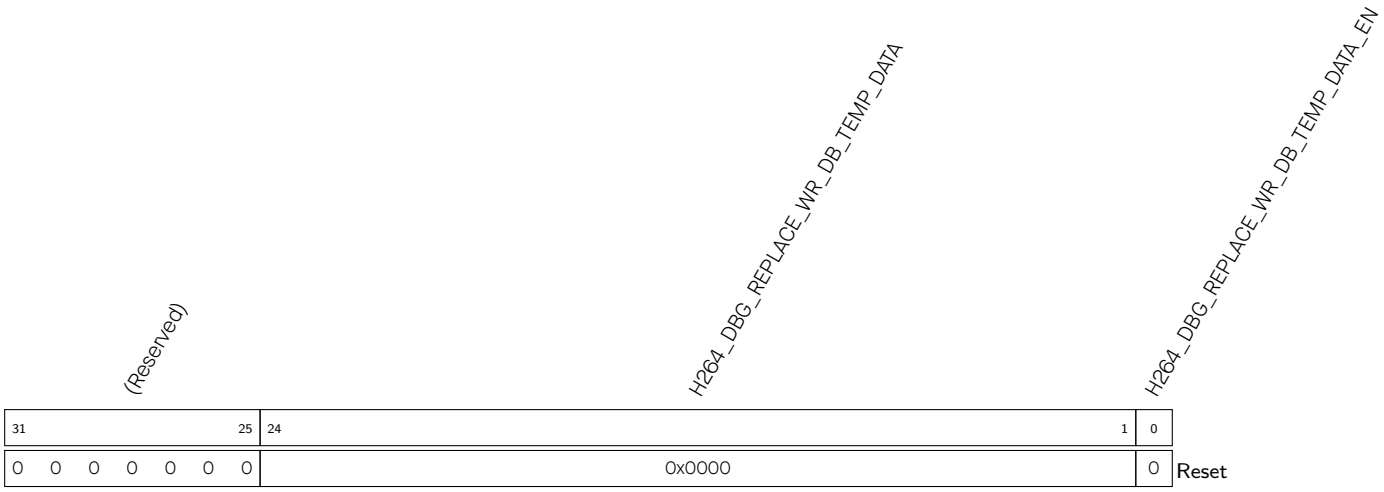
H264_DBG_REPLACE_ORI_DATA Configures the original video pixel data to replace. When the original video color space is RGB, byte0∼2 is BGR. When the color space is YUV, byte0∼2 is VUY. (R/W)



Register 41.61. H264_MV_MERGE_DEBUG_CONF_REG (0x0100)

H264_DBG_REPLACE_MV_MERGE_DATA_EN Configures whether to replace the MV merge data. 0: do not replace, 1: replace. (R/W)

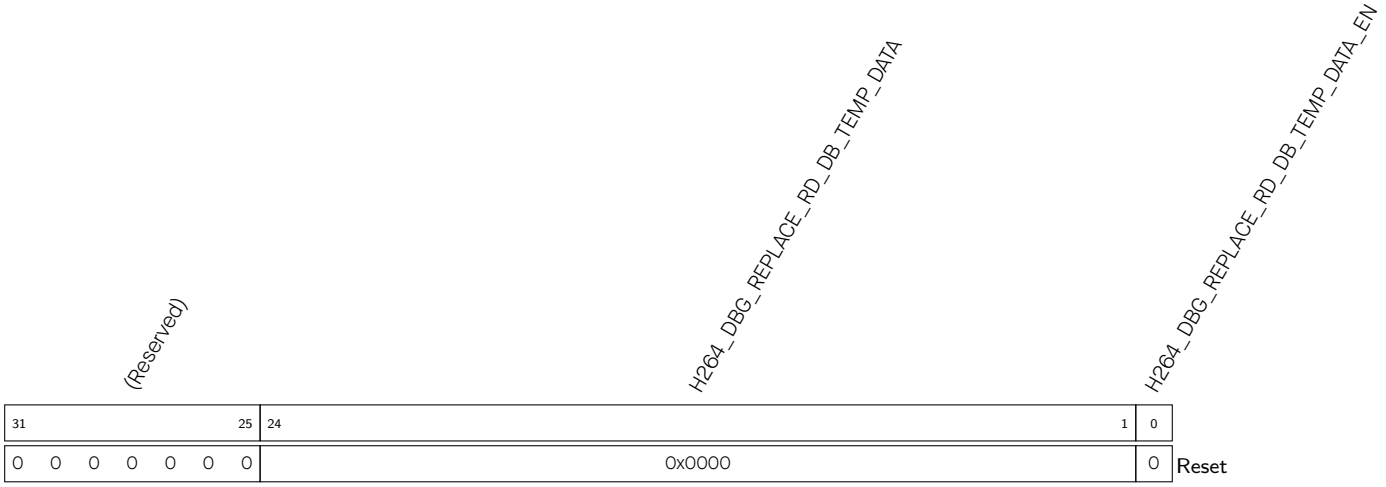
H264_DBG_REPLACE_MV_MERGE_DATA Configures the MV merge data to replace. (R/W)



Register 41.62. H264_BS_DEBUG_CONG_REG (0x0104)

H264_DBG_REPLACE_WR_BS_DATA_EN Configures whether to replace the bitstream data. 0: do not replace, 1: replace. (R/W)

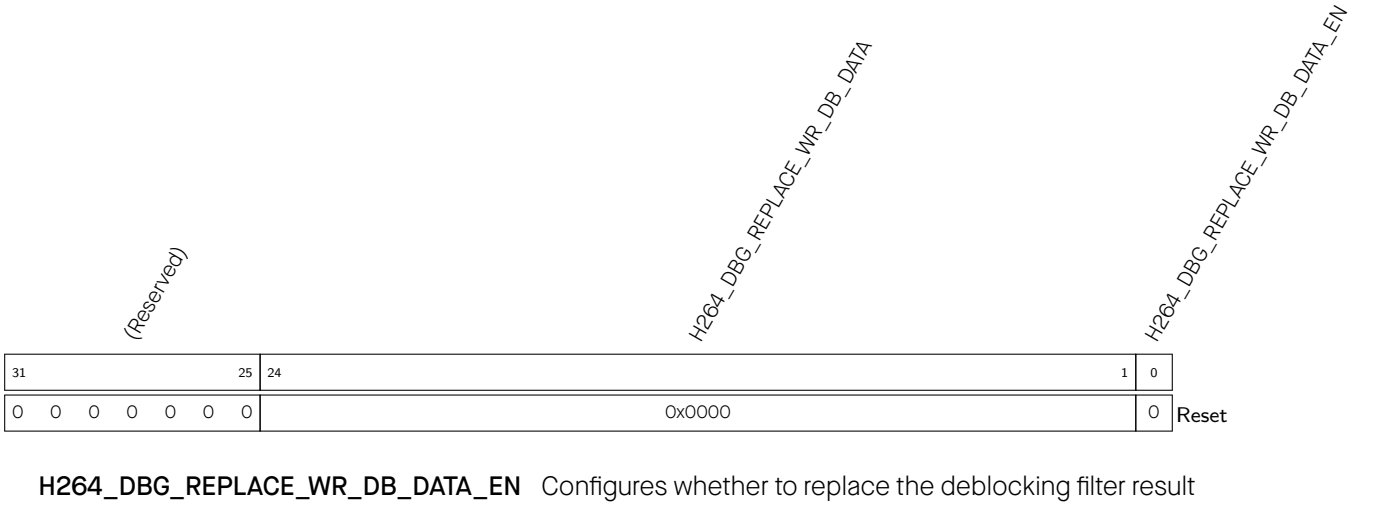
H264_DBG_REPLACE_WR_BS_DATA Configures the bitstream data to replace. (R/W)



Register 41.63. H264_DB_WR_TEMP_DEBUG_CONG_REG (0x0108)

H264_DBG_REPLACE_WR_DB_TEMP_DATA_EN Configures whether to replace the deblocking filter intermediate data written to H264_DMA. 0: do not replace, 1: replace. (R/W)

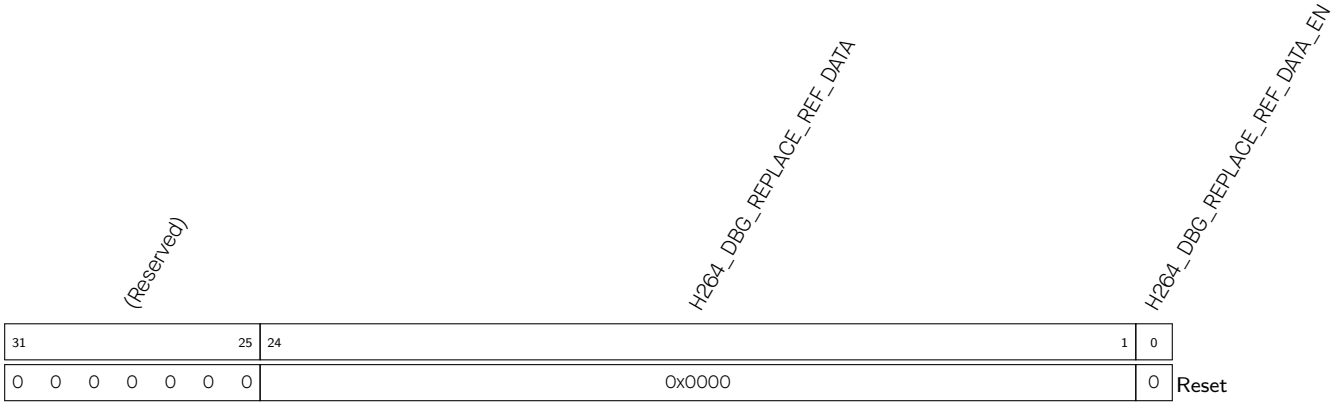
H264_DBG_REPLACE_WR_DB_TEMP_DATA Configures the deblocking filter intermediate data to replace when writing. byte0~2 is VUY. (R/W)



Register 41.64. H264_DB_RD_TEMP_DEBUG_CONG_REG (0x010C)

H264_DBG_REPLACE_RD_DB_TEMP_DATA_EN Configures whether to replace the deblocking filter intermediate data read from H264_DMA. 0: do not replace, 1: replace. (R/W)

H264_DBG_REPLACE_RD_DB_TEMP_DATA Configures the deblocking filter intermediate data to replace when reading. byte0~2 is VUY. (R/W)

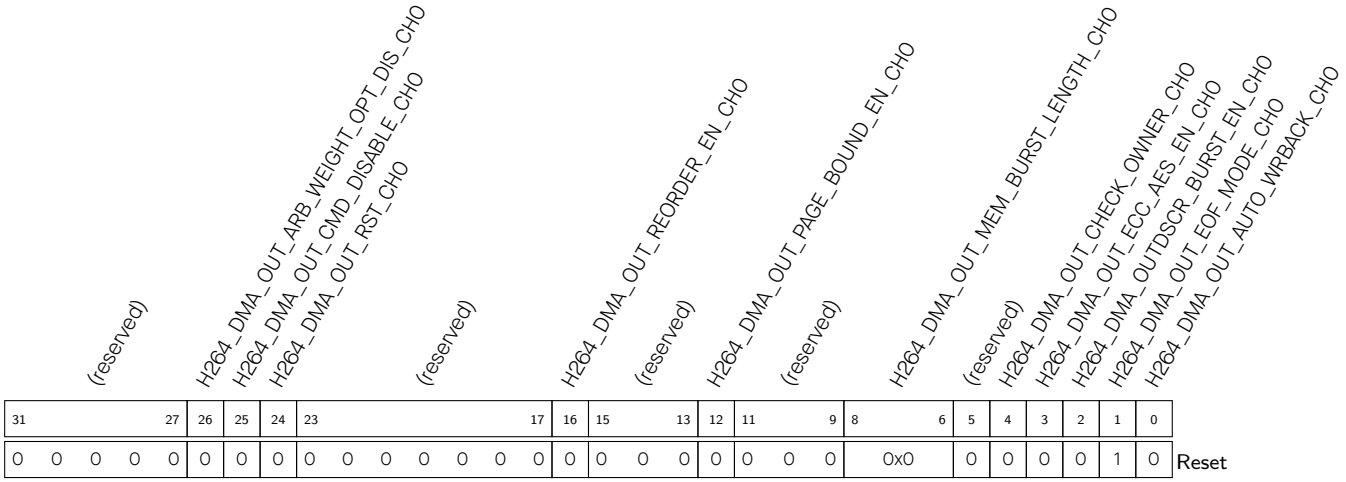


Register 41.65. H264_DB_WR_DEBUG_CONG_REG (0x0110)

H264_DBG_REPLACE_WR_DB_DATA_EN Configures whether to replace the deblocking filter result data. 0: do not replace, 1: replace. (R/W)

H264_DBG_REPLACE_WR_DB_DATA Configures the deblocking filter result data to replace. byte0~2 is VUY. (R/W)

Register 41.66. H264_REF_DEBUG_CONG_REG (0x0114)



H264_DBG_REPLACE_REF_DATA_EN Configures whether to replace the reference picture pixel data. 0: do not replace, 1: replace. (R/W)

H264_DBG_REPLACE_REF_DATA Configures the reference picture pixel data to replace. byte0∼2 is VUY. (R/W)

41.9.2 H264 DMA Registers

Register 41.67. H264_DMA_OUT_CONF0_CH0_REG (0x0000)

H264_DMA_OUT_AUTO_WRBACK_CH0 Configures whether to enable automatic outlink-writeback when all the data pointed by outlink descriptor has been received.

0: Disable

1: Enable

(R/W)

H264_DMA_OUT_EOF_MODE_CH0 Configures EOF flag generation mode for TX channel 0.

0: EOF flag is generated when last data has been pushed into FIFO in DMA

1: EOF flag is generated when last data has been popped from FIFO in DMA

(R/W)

H264_DMA_OUTDSCR_BURST_EN_CH0 Configures whether to enable INCR burst transfer for TX channel 0 to read descriptors.

0: Disable

1: Enable

(R/W)

H264_DMA_OUT_ECC_AES_EN_CH0 Configures whether DMA can access external memory space for ECC and AES via TX channel 0.

0: Not access

1: Access ECC/AES area. In this case, the start address of the memory region should be 16-byte aligned. The product of the width and the bytes per pixel must also be 16-byte aligned.

(R/W)

H264_DMA_OUT_CHECK_OWNER_CH0 Configures whether to enable owner bit check for TX channel 0.

0: Disable

1: Enable

(R/W)

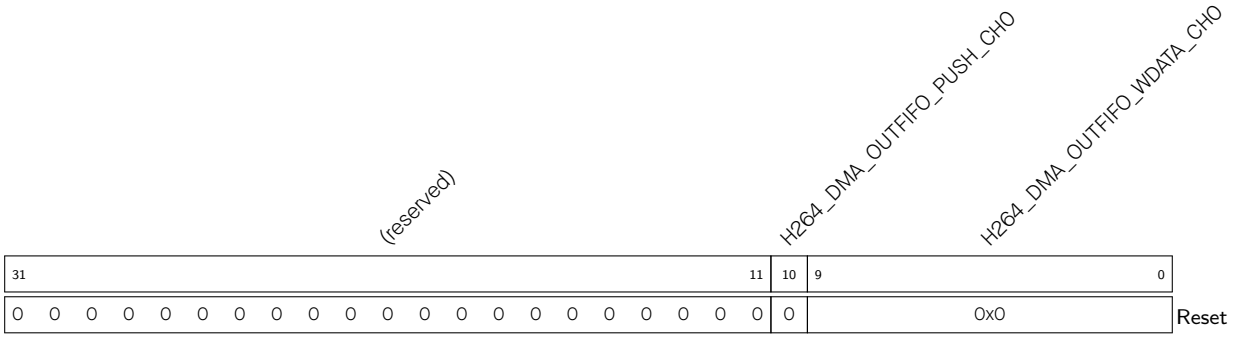
Continued on the next page...

Register 41.67. H264_DMA_OUT_CONF0_CH0_REG (0x0000)

Continued from the previous page...

H264_DMA_OUT_MEM_BURST_LENGTH_CH0 Configures the burst length for TX channel 0.
0: 8 bytes
1: 16 bytes
2: 32 bytes
3: 64 bytes
4: 128 bytes
5 ~ 7: Invalid. No effect
(R/W)

H264_DMA_OUT_PAGE_BOUND_EN_CH0 Configures whether to make sure AXI read data doesn't cross the address boundary which define by mem_burst_length.
0: AXI read data can cross the address boundary
1: AXI read data doesn't cross the address boundary
(R/W)



H264_DMA_OUT_REORDER_EN_CH0 Configures whether to enable TX channel 0 macro block reorder.
0: Disable
1: Enable
(R/W)

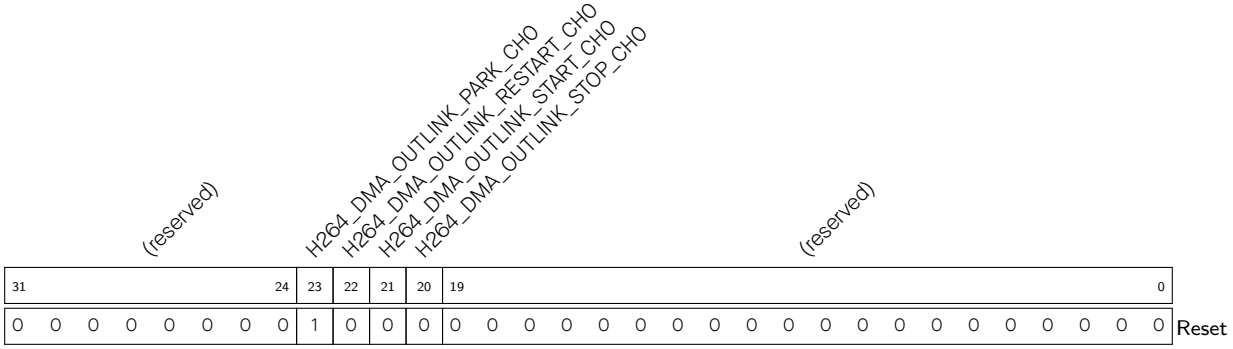
H264_DMA_OUT_RST_CH0 Write 1 then write 0 to reset TX channel 0. (R/W)

H264_DMA_OUT_CMD_DISABLE_CH0 Configures whether to disable command on TX channel 0.
0: Disable
1: Enable
(R/W)

H264_DMA_OUT_ARB_WEIGHT_OPT_DIS_CH0 Configures whether to disable weight arbitration for TX channel 0.
0: Enable
1: Disable
(R/W)

Register 41.68. H264_DMA_OUT_PUSH_CH0_REG (0x0018)

H264_DMA_OUTFIFO_WDATA_CH0 Represents the data that needs to be pushed into DMA TX FIFO. (R/W)



H264_DMA_OUTFIFO_PUSH_CH0 Configures whether to push data into DMA TX FIFO.

0: No effect

1: Push

(R/W/SC)

Register 41.69. H264_DMA_OUT_LINK_CONF_CH0_REG (0x001C)

H264_DMA_OUTLINK_STOP_CH0 Configures whether to stop processing the outlink descriptors.

0: No effect

1: Stop

(R/W/SC)

H264_DMA_OUTLINK_START_CH0 Configures whether to start processing the outlink descriptors.

0: No effect

1: Start

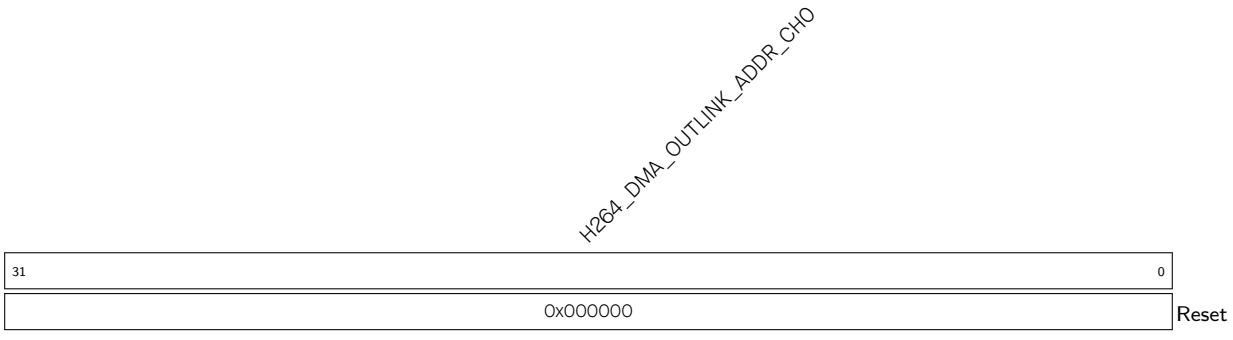
(R/W/SC)

H264_DMA_OUTLINK_RESTART_CH0 Configures whether to restart a new outlink from the last address.

0: No effect

1: Restart

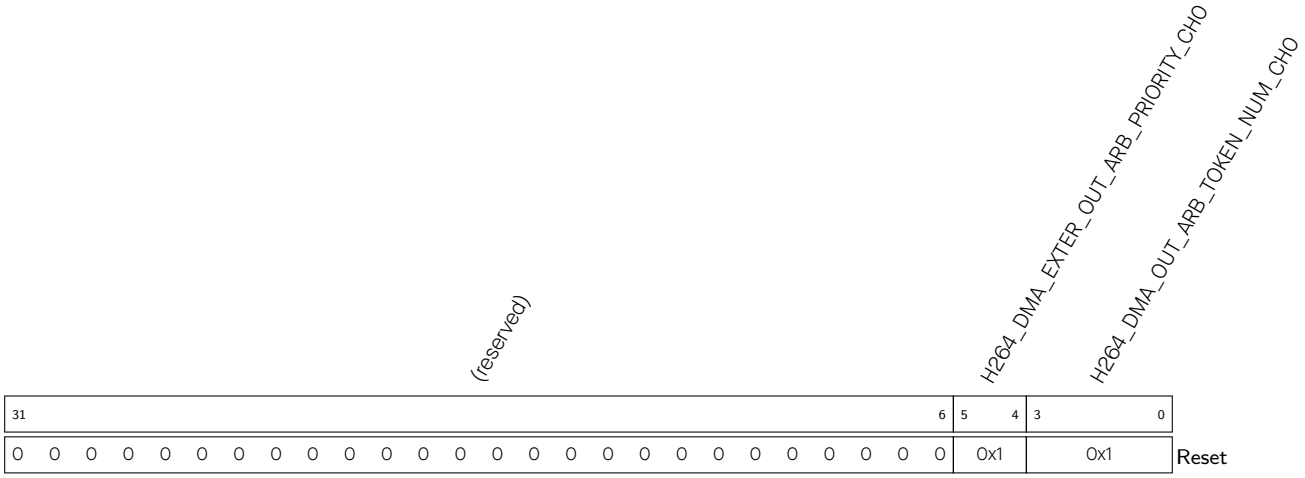
(R/W/SC)



H264_DMA_OUTLINK_PARK_CH0 Represents the status of the transmit descriptor's FSM.

0: The outlink descriptor's FSM is working

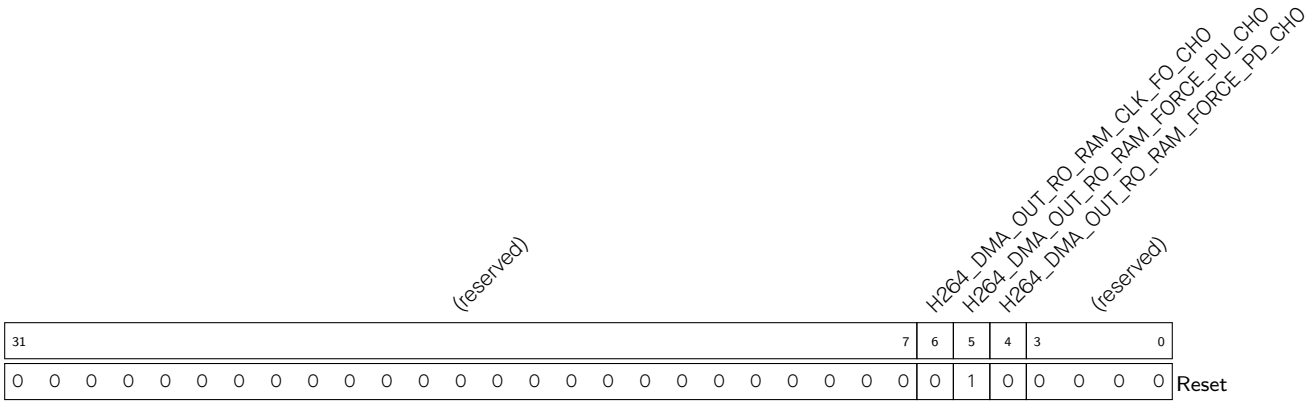
1: The outlink descriptor's FSM is in idle state



(RO)

Register 41.70. H264_DMA_OUT_LINK_ADDR_CH0_REG (0x0020)

H264_DMA_OUTLINK_ADDR_CH0 Configures the first outlink descriptor's address. (R/W)



Register 41.71. H264_DMA_OUT_ARB_CH0_REG (0x003C)

H264_DMA_OUT_ARB_TOKEN_NUM_CH0 Configures the maximum token count for the arbiter configuration. (R/W)

H264_DMA_EXTER_OUT_ARB_PRIORITY_CH0 Configures the priority of external memory access for TX channel 0. (R/W)

Register 41.72. H264_DMA_OUT_RO_PD_CONF_CH0_REG (0x0044)

H264_DMA_OUT_RO_RAM_FORCE_PD_CH0 Configures whether to force power down for DMA reorder RAM.

0: Not force power down

1: Force power down

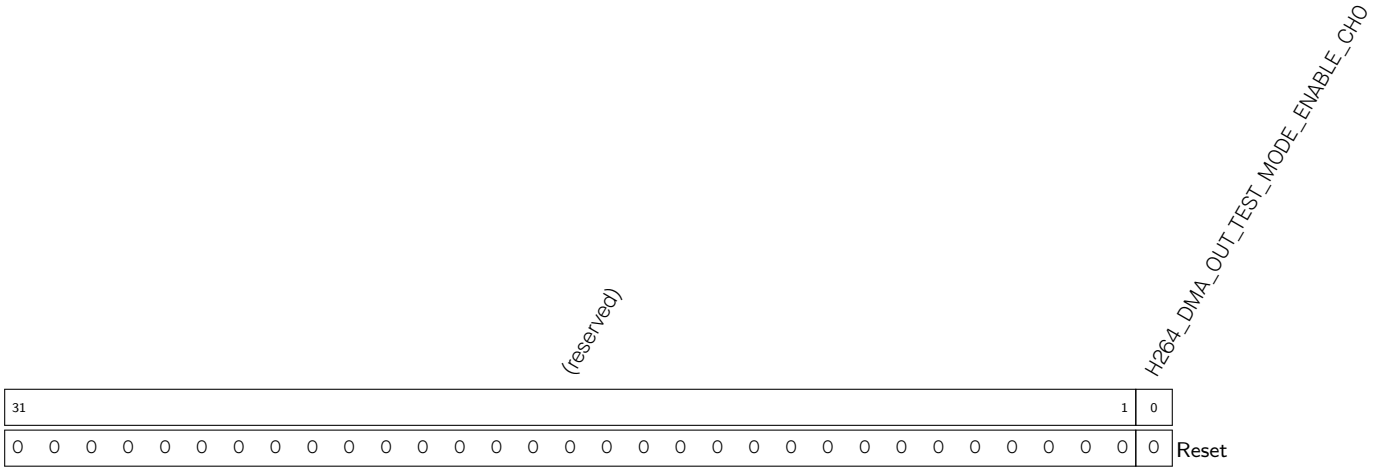
(R/W)

H264_DMA_OUT_RO_RAM_FORCE_PU_CH0 Configures whether to force power up for DMA reorder RAM.

0: Not force power up

1: Force power up

(R/W)



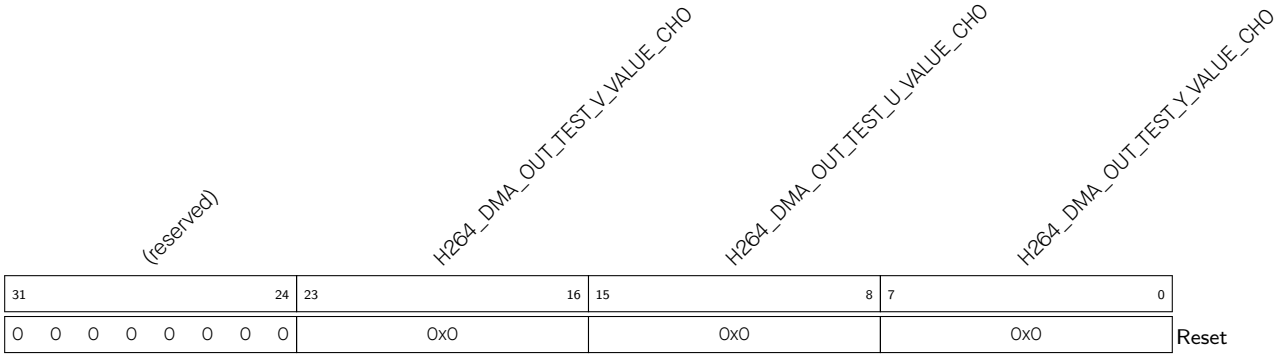
H264_DMA_OUT_RO_RAM_CLK_FO_CH0 Configures whether to force enable clock gating for DMA TX reorder RAM.

0: A clock gating will be used when accessing the RAM in DMA

1: Force to open the clock and bypass the clock gating when accessing the RAM in DMA

(R/W)

Register 41.73. H264_DMA_OUT_MODE_ENABLE_CH0_REG (0x0050)



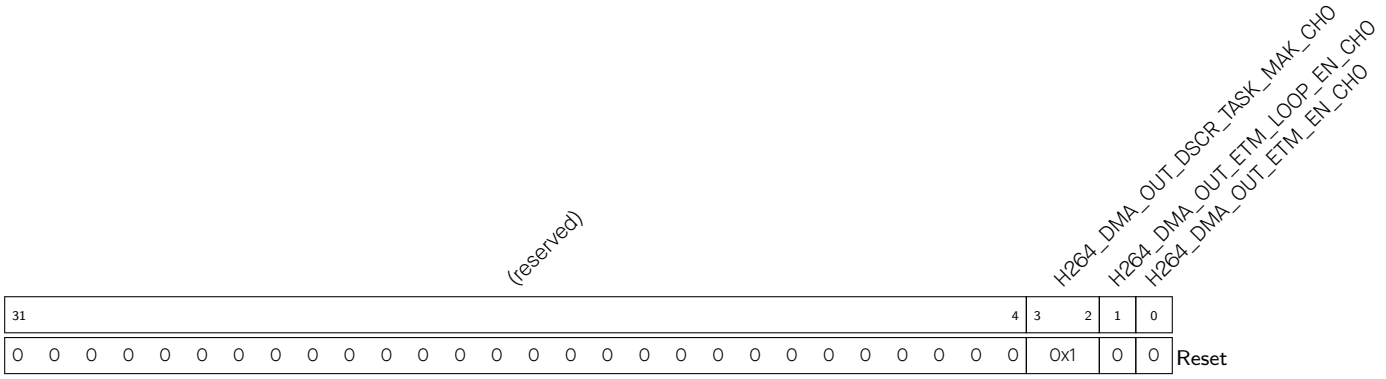
H264_DMA_OUT_TEST_MODE_ENABLE_CH0 Configures whether to enable test mode of TX channel 0.

0: TX channel 0 work in normal mode

1: TX channel 0 work in test mode

(R/W)

Register 41.74. H264_DMA_OUT_MODE_YUV_CH0_REG (0x0054)

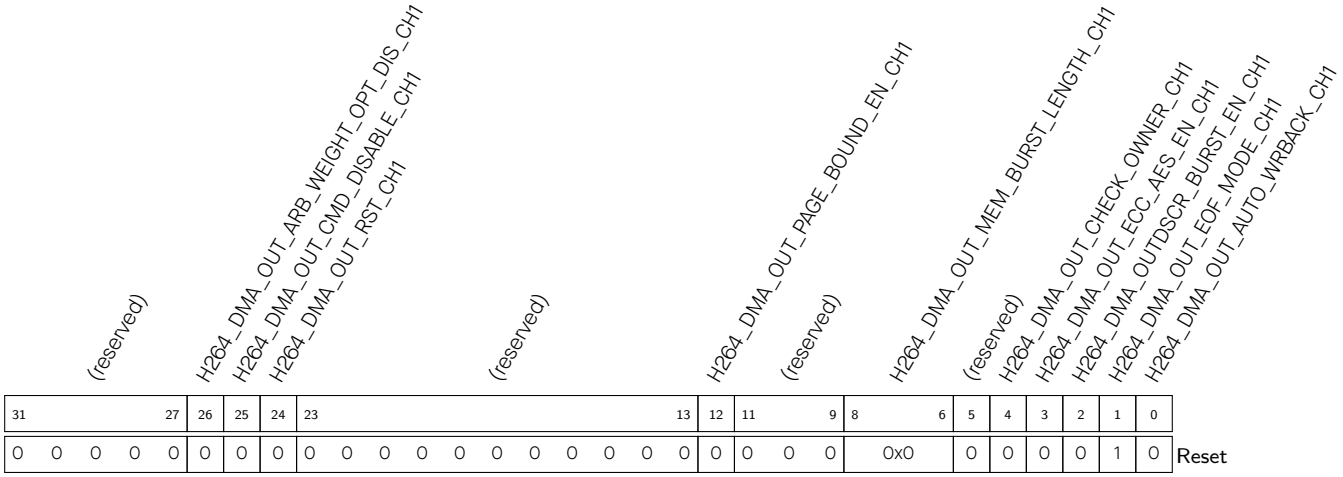


H264_DMA_OUT_TEST_Y_VALUE_CH0 Configures y value in test mode. (R/W)

H264_DMA_OUT_TEST_U_VALUE_CH0 Configures u value in test mode. (R/W)

H264_DMA_OUT_TEST_V_VALUE_CH0 Configures v value in test mode. (R/W)

Register 41.75. H264_DMA_OUT_ETM_CONF_CH0_REG (0x0068)



H264_DMA_OUT_ETM_EN_CH0 Set this bit to 1 to enable ETM task function (R/W)

H264_DMA_OUT_ETM_LOOP_EN_CH0 when this bit is 1, dscr can be processed after receiving a task (R/W)

H264_DMA_OUT_DSCR_TASK_MAK_CH0 ETM dscr_ready maximum cache numbers (R/W)

Register 41.76. H264_DMA_OUT_CONF0_CH1_REG (0x0100)

(reserved)
H264_DMA_OUT_ARB_WEIGHT_OPT_DIS_CH1
H264_DMA_OUT_CMD_DISABLE_CH1

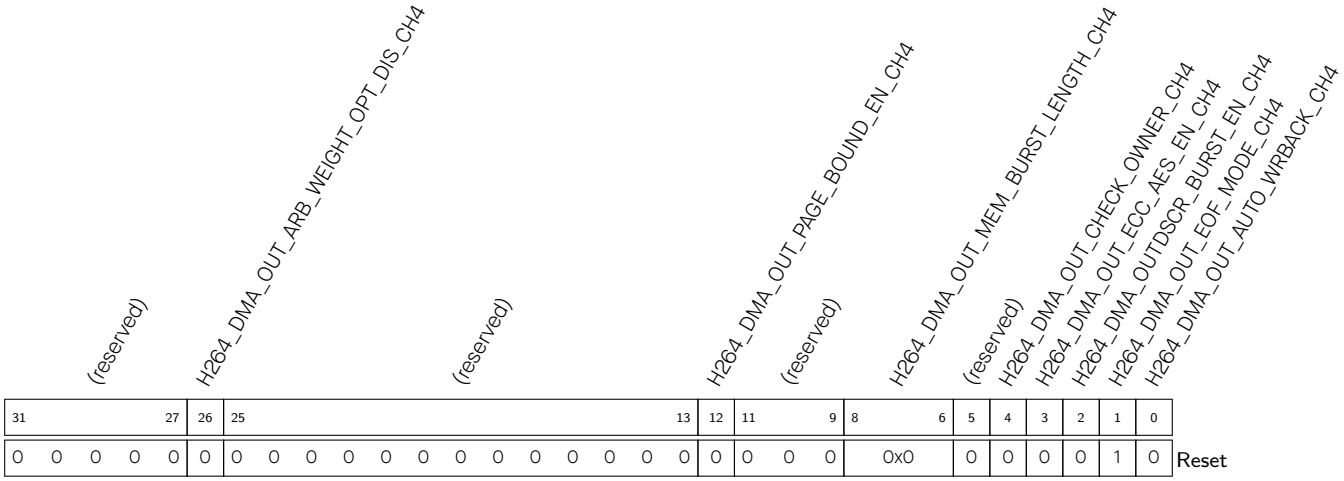
Register 41.93. H264_DMA_OUT_ETM_CONF_CH3_REG (0x0368)



H264_DMA_OUT_ETM_EN_CH3 Set this bit to 1 to enable ETM task function (R/W)

H264_DMA_OUT_ETM_LOOP_EN_CH3 when this bit is 1, dscr can be processed after receiving a task (R/W)

H264_DMA_OUT_DSCR_TASK_MAK_CH3 ETM dscr_ready maximum cache numbers (R/W)

Register 41.94. H264_DMA_OUT_CONF0_CH4_REG (0x0400)

H264_DMA_OUT_AUTO_WRBACK_CH4 Configures whether to enable automatic outlink-writeback when all the data pointed by outlink descriptor has been received.

0: Disable

1: Enable

(R/W)

H264_DMA_OUT_EOF_MODE_CH4 Configures EOF flag generation mode for TX channel 4.

0: EOF flag is generated when last data has been pushed into FIFO in DMA

1: EOF flag is generated when last data has been popped from FIFO in DMA

(R/W)

H264_DMA_OUTDSCR_BURST_EN_CH4 Configures whether to enable INCR burst transfer for TX channel 4 to read descriptors.

0: Disable

1: Enable

(R/W)

H264_DMA_OUT_ECC_AES_EN_CH4 Configures whether DMA can access external memory space for ECC and AES via TX channel 4.

0: Not access

1: Access ECC/AES area. In this case, the start address of the memory region should be 16-byte aligned. The product of the width and the bytes per pixel must also be 16-byte aligned.

(R/W)

H264_DMA_OUT_CHECK_OWNER_CH4 Configures whether to enable owner bit check for TX channel 4.

0: Disable

1: Enable

(R/W)

Continued on the next page...

Register 41.94. H264_DMA_OUT_CONF0_CH4_REG (0x0400)

Continued from the previous page...

H264_DMA_OUT_MEM_BURST_LENGTH_CH4 Configures the burst length for TX channel 4.

0: 8 bytes

1: 16 bytes

2: 32 bytes

3: 64 bytes

4: 128 bytes

5 ~ 7: Invalid. No effect

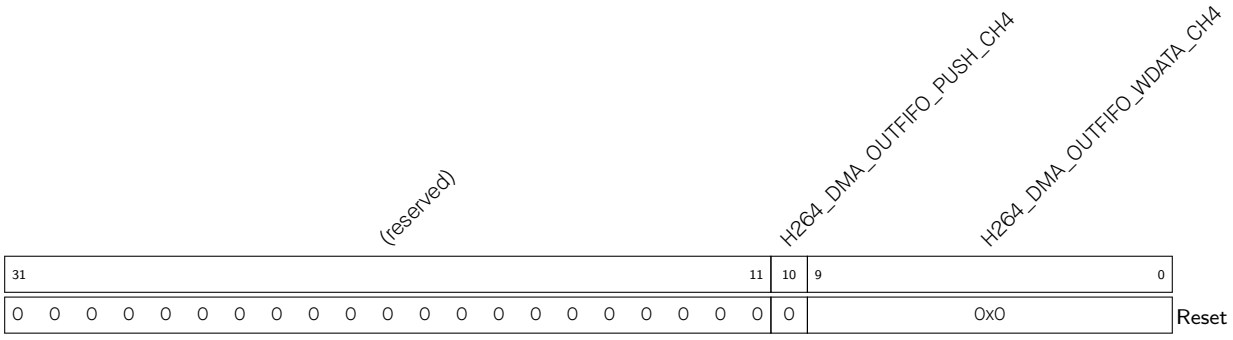
(R/W)

H264_DMA_OUT_PAGE_BOUND_EN_CH4 Configures whether to make sure AXI read data doesn't cross the address boundary which define by mem_burst_length.

0: AXI read data can cross the address boundary

1: AXI read data doesn't cross the address boundary

(R/W)



H264_DMA_OUT_ARB_WEIGHT_OPT_DIS_CH4 Configures whether to disable weight arbitration for TX channel 4.

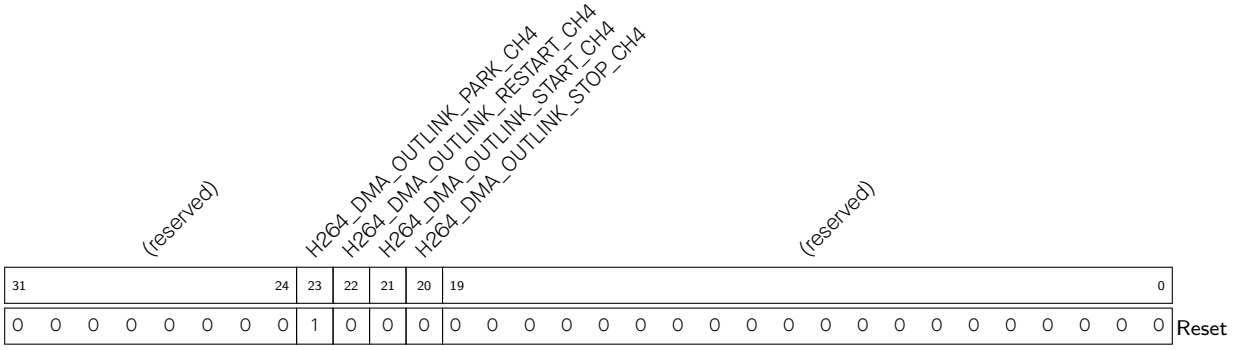
0: Enable

1: Disable

(R/W)

Register 41.95. H264_DMA_OUT_PUSH_CH4_REG (0x0418)

H264_DMA_OUTFIFO_WDATA_CH4 Represents the data that needs to be pushed into DMA TX FIFO. (R/W)



H264_DMA_OUTFIFO_PUSH_CH4 Configures whether to push data into DMA TX FIFO.

0: No effect

1: Push

(R/W/SC)

Register 41.96. H264_DMA_OUT_LINK_CONF_CH4_REG (0x041C)

H264_DMA_OUTLINK_STOP_CH4 Configures whether to stop processing the outlink descriptors.

0: No effect

1: Stop

(R/W/SC)

H264_DMA_OUTLINK_START_CH4 Configures whether to start processing the outlink descriptors.

0: No effect

1: Start

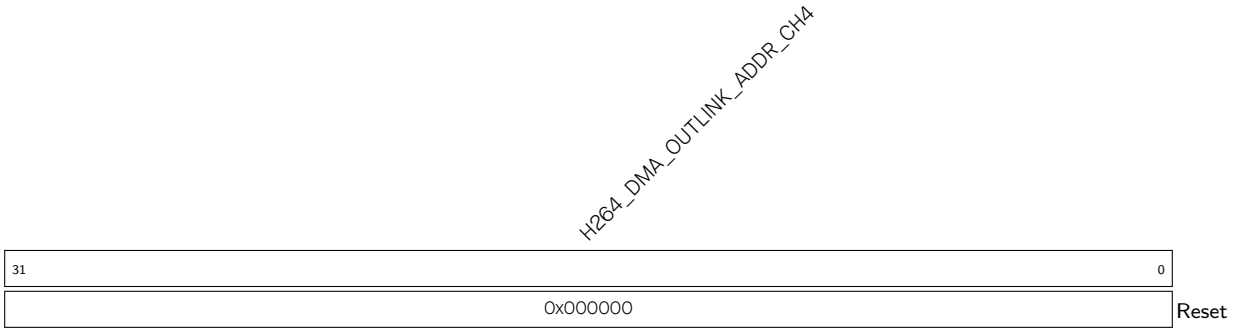
(R/W/SC)

H264_DMA_OUTLINK_RESTART_CH4 Configures whether to restart a new outlink from the last address.

0: No effect

1: Restart

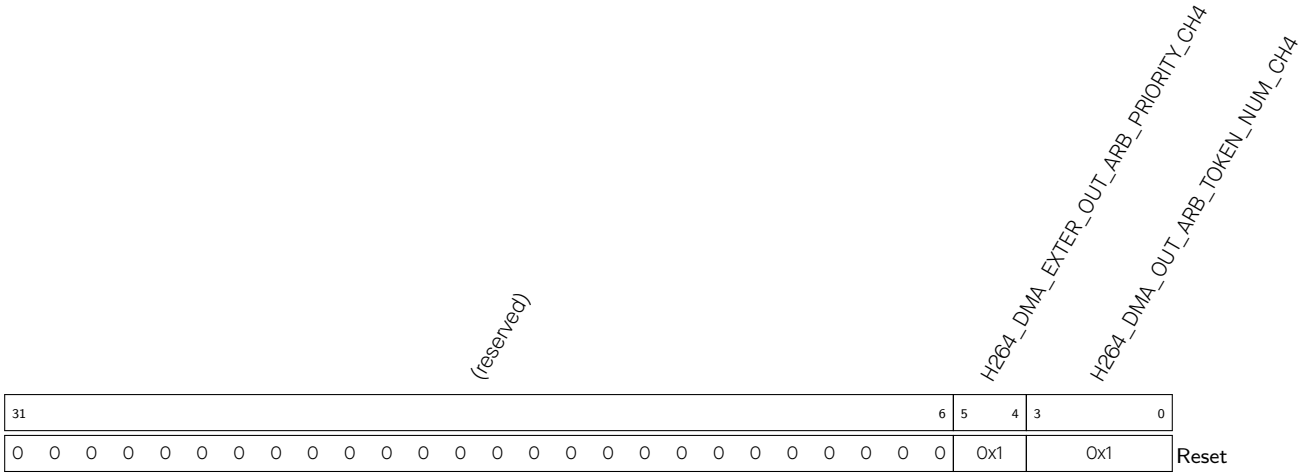
(R/W/SC)



H264_DMA_OUTLINK_PARK_CH4 Represents the status of the transmit descriptor's FSM.

0: The outlink descriptor's FSM is working

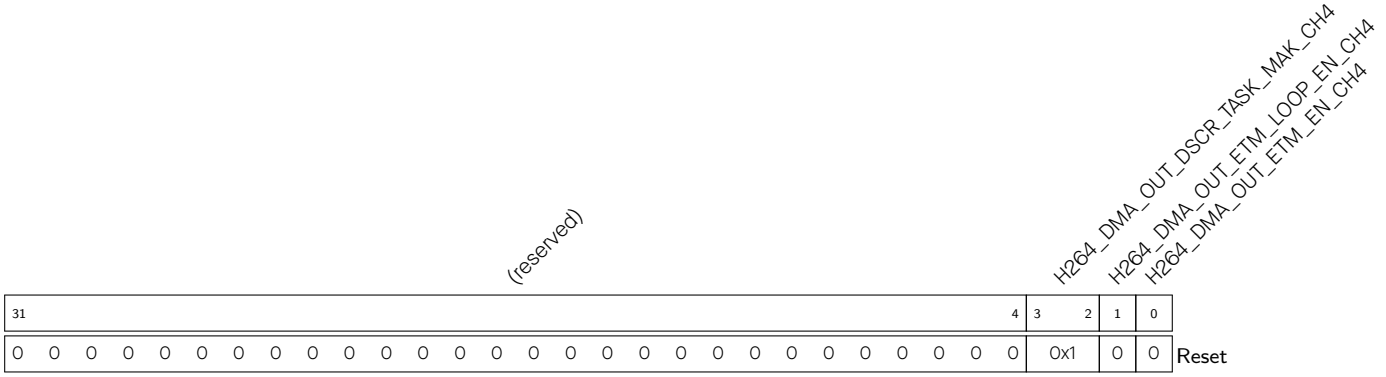
1: The outlink descriptor's FSM is in idle state



(RO)

Register 41.97. H264_DMA_OUT_LINK_ADDR_CH4_REG (0x0420)

H264_DMA_OUTLINK_ADDR_CH4 Configures the first outlink descriptor's address. (R/W)

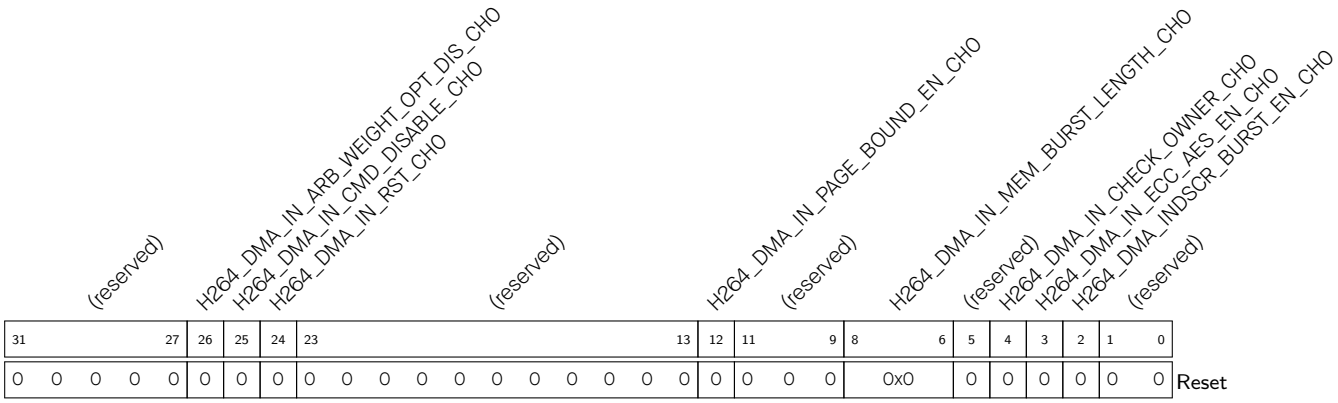


Register 41.98. H264_DMA_OUT_ARB_CH4_REG (0x043C)

H264_DMA_OUT_ARB_TOKEN_NUM_CH4 Configures the maximum token count for the arbiter configuration. (R/W)

H264_DMA_EXTER_OUT_ARB_PRIORITY_CH4 Configures the priority of external memory access for TX channel 4. (R/W)

Register 41.99. H264_DMA_OUT_ETM_CONF_CH4_REG (0x0468)



H264_DMA_OUT_ETM_EN_CH4 Set this bit to 1 to enable ETM task function (R/W)

H264_DMA_OUT_ETM_LOOP_EN_CH4 when this bit is 1, dscr can be processed after receiving a task (R/W)

H264_DMA_OUT_DSCR_TASK_MAK_CH4 ETM dscr_ready maximum cache numbers (R/W)

H264_DMA_IN_ARB_TOKEN_NUM_CH5 Configures the maximum token count for the arbiter configuration. (R/W)

H264_DMA_INTER_IN_ARB_PRIORITY_CH5 Configures the priority of internal memory access for RX channel 5. (R/W)

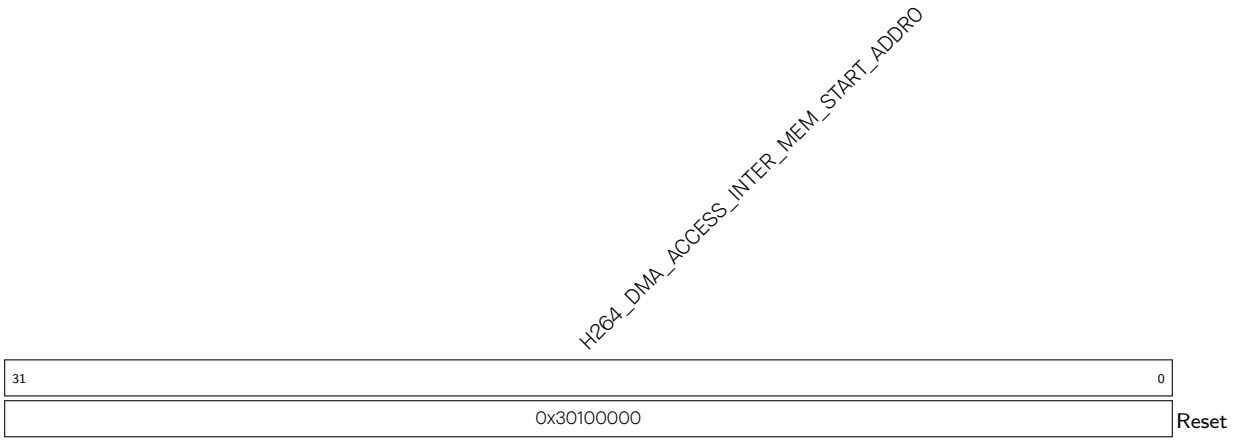
Register 41.137. H264_DMA_RST_CONF_REG (0x0B08)

H264_DMA_INTER_AXIM_RD_RST Write 1 and then 0 to reset the inter AXI read FSM. (R/W)

H264_DMA_INTER_AXIM_WR_RST Write 1 and then 0 to reset the inter AXI write FSM. (R/W)

H264_DMA_EXTER_AXIM_RD_RST Write 1 and then 0 to reset the exter AXI read FSM. (R/W)

H264_DMA_EXTER_AXIM_WR_RST Write 1 and then 0 to reset the exter AXI write FSM. (R/W)



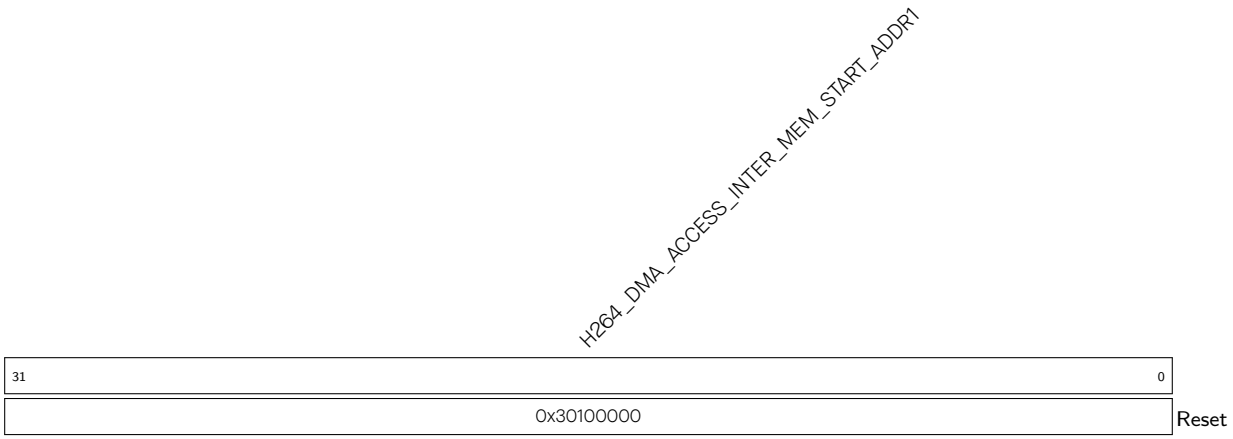
H264_DMA_CLK_EN Configures DMA clock gating.

0: Enable the clock only when the application writes registers

1: Always enable the clock for registers

(R/W)

Register 41.138. H264_DMA_INTER_MEM_START_ADDR0_REG (0x0B0C)



H264_DMA_ACCESS_INTER_MEM_START_ADDR0 Configures the start address of the accessible internal memory address0 space. (R/W)

Register 41.139. H264_DMA_INTER_MEM_END_ADDR0_REG (0x0B10)

H264_DMA_ACCESS_INTER_MEM_END_ADDR0 Configures the end address of the accessible internal memory address0 space. (R/W)

Register 41.140. H264_DMA_INTER_MEM_START_ADDR1_REG (0x0B14)

H264_DMA_ACCESS_INTER_MEM_START_ADDR1 Configures the start address of the accessible internal memory address1 space. (R/W)

Register 41.141. H264_DMA_INTER_MEM_END_ADDR1_REG (0x0B18)

H264_DMA_ACCESS_INTER_MEM_END_ADDR1 Configures the end address of the accessible internal memory address1 space. (R/W)

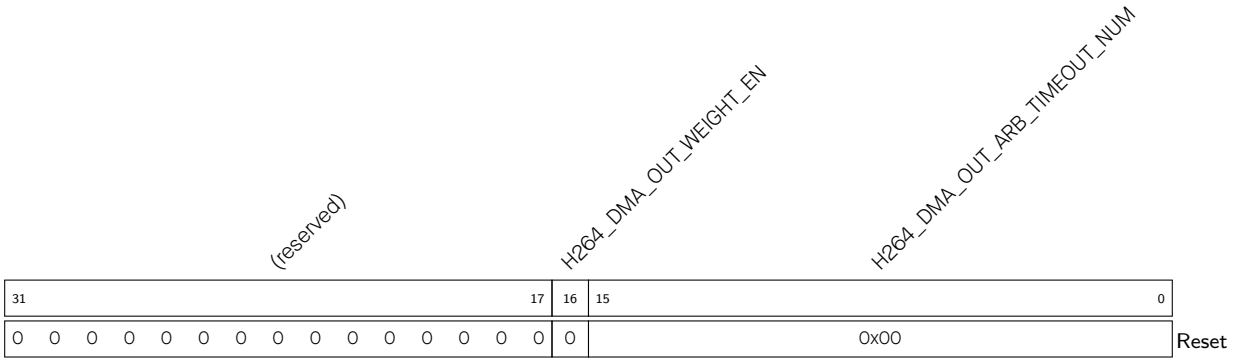
Register 41.142. H264_DMA_EXTER_MEM_START_ADDR0_REG (0x0B20)

H264_DMA_ACCESS_EXTER_MEM_START_ADDR0 Configures the start address of the accessible external memory address0 space. (R/W)

Register 41.143. H264_DMA_EXTER_MEM_END_ADDR0_REG (0x0B24)

H264_DMA_ACCESS_EXTER_MEM_END_ADDR0 Configures the end address of the accessible external memory address0 space. (R/W)

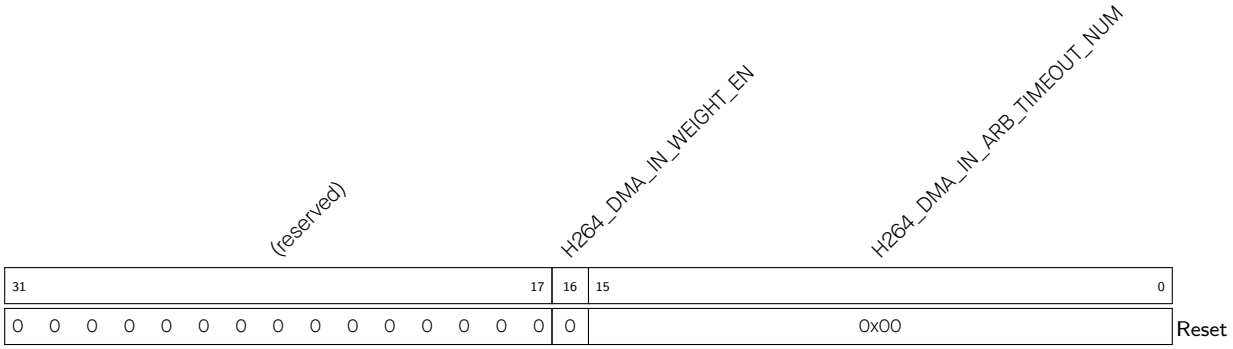
Register 41.144. H264_DMA_EXTER_MEM_START_ADDR1_REG (0x0B28)



H264_DMA_ACCESS_EXTER_MEM_START_ADDR1 Configures the start address of the accessible external memory address1 space. (R/W)

Register 41.145. H264_DMA_EXTER_MEM_END_ADDR1_REG (0x0B2C)

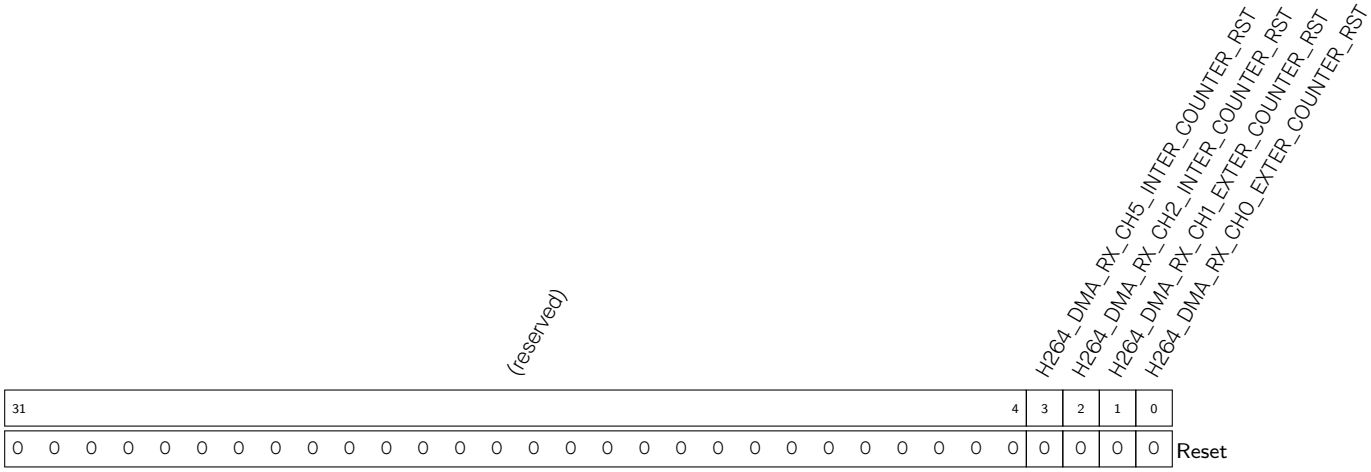
H264_DMA_ACCESS_EXTER_MEM_END_ADDR1 Configures the end address of the accessible external memory address1 space. (R/W)



Register 41.146. H264_DMA_OUT_ARB_CONFIG_REG (0x0B30)

H264_DMA_OUT_ARB_TIMEOUT_NUM Configures the max number of timeout count of arbiter. (R/W)

H264_DMA_OUT_WEIGHT_EN Configures whether to enable weight arbitration for TX. (R/W)

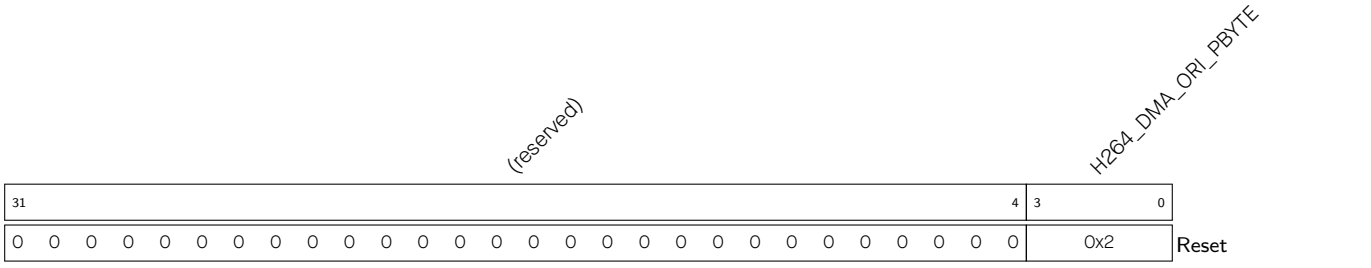


Register 41.147. H264_DMA_IN_ARB_CONFIG_REG (0x0B34)

H264_DMA_IN_ARB_TIMEOUT_NUM Configures the max number of timeout count of arbiter. (R/W)

H264_DMA_IN_WEIGHT_EN Configures whether to enable weight arbitration for RX. (R/W)

Register 41.148. H264_DMA_COUNTER_RST_REG (0x0B50)



H264_DMA_RX_CH0_EXTER_COUNTER_RST Write 1 then write 0 to reset RX ch0 counter. (R/W)

H264_DMA_RX_CH1_EXTER_COUNTER_RST Write 1 then write 0 to reset RX ch1 counter. (R/W)

H264_DMA_RX_CH2_INTER_COUNTER_RST Write 1 then write 0 to reset RX ch2 counter. (R/W)

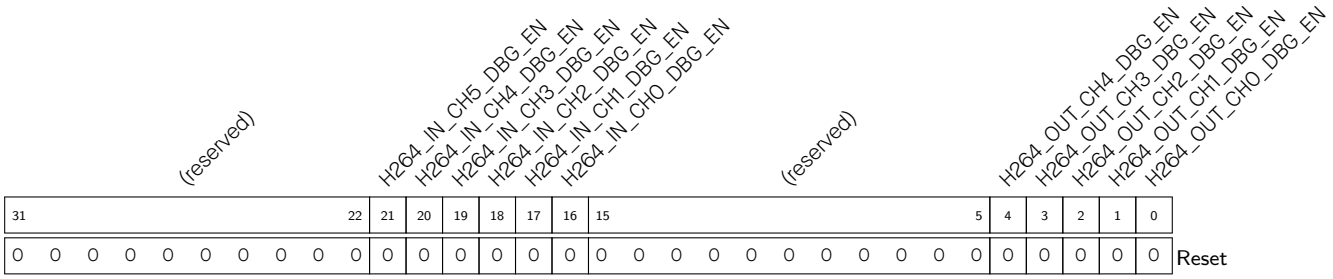
H264_DMA_RX_CH5_INTER_COUNTER_RST Write 1 then write 0 to reset RX ch5 counter. (R/W)

Register 41.149. H264_DMA_PBYTE_REG (0x0B64)

H264_DMA_ORI_PBYTE Configures bytes per pixel for the original picture.

0: 0.5 byte/pixel

1: 1 byte/pixel



2: 1.5 bytes/pixel

3: 2 bytes/pixel

4: 3 bytes/pixel

(R/W)

Register 41.150. H264_DMA_CH_DBG_EN_REG (0x0B68)

H264_OUT_CH0_DBG_EN Configures whether to enable out channel 0 debug.

0: Disable

1: Enable

(R/W)

H264_OUT_CH1_DBG_EN Configures whether to enable out channel 1 debug.

0: Disable

1: Enable

(R/W)

H264_OUT_CH2_DBG_EN Configures whether to enable out channel 2 debug.

0: Disable

1: Enable

(R/W)

H264_OUT_CH3_DBG_EN Configures whether to enable out channel 3 debug.

0: Disable

1: Enable

(R/W)

H264_OUT_CH4_DBG_EN Configures whether to enable out channel 4 debug.

0: Disable

1: Enable

(R/W)

H264_IN_CH0_DBG_EN Configures whether to enable in channel 0 debug.

0: Disable

1: Enable

(R/W)

H264_IN_CH1_DBG_EN Configures whether to enable in channel 1 debug.

0: Disable

1: Enable

(R/W)

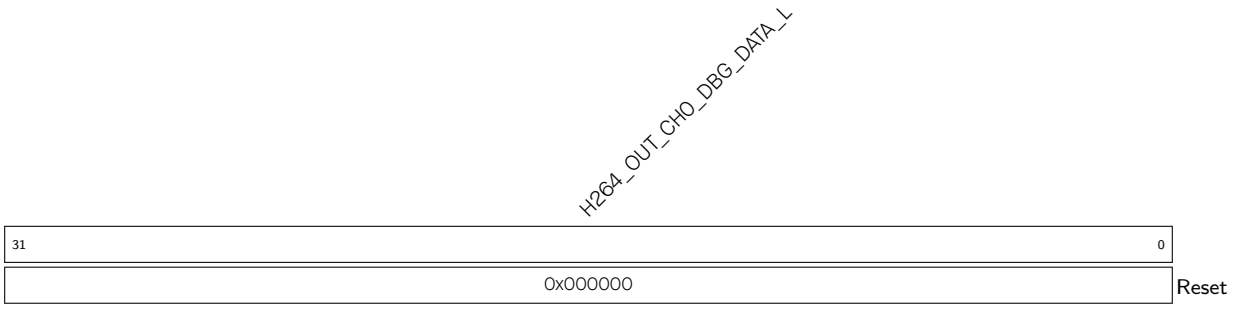
H264_IN_CH2_DBG_EN Configures whether to enable in channel 2 debug.

0: Disable

1: Enable

(R/W)

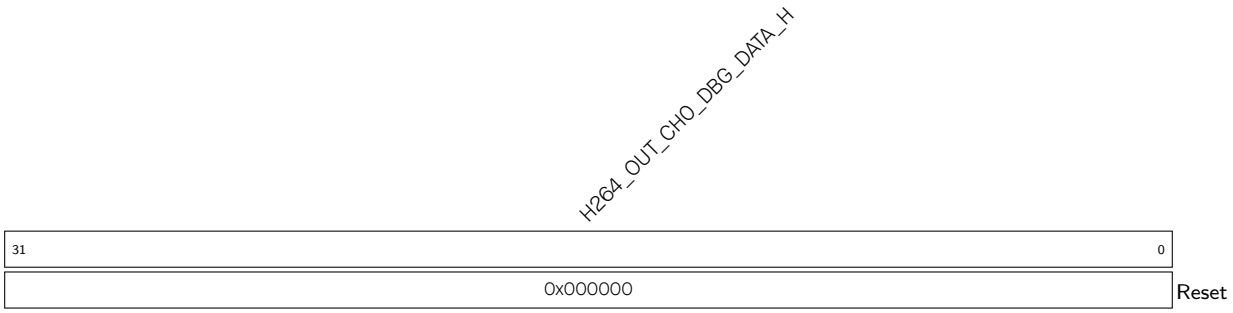
H264_IN_CH3_DBG_EN Configures whether to enable in channel 3 debug.



0: Disable

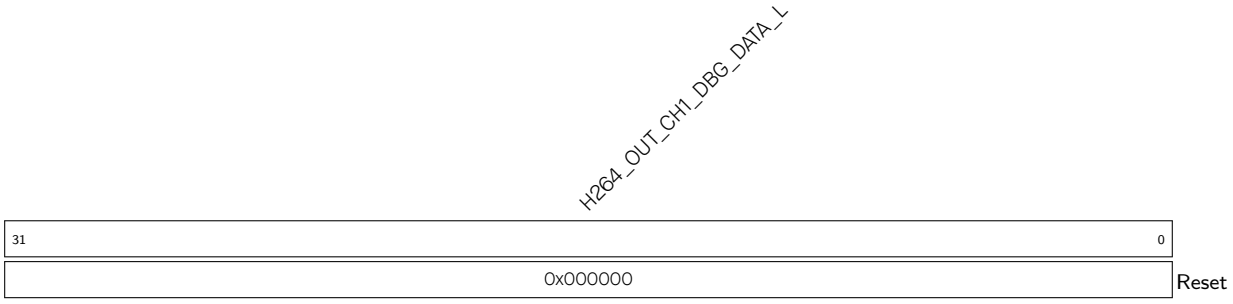
1: Enable

(R/W)



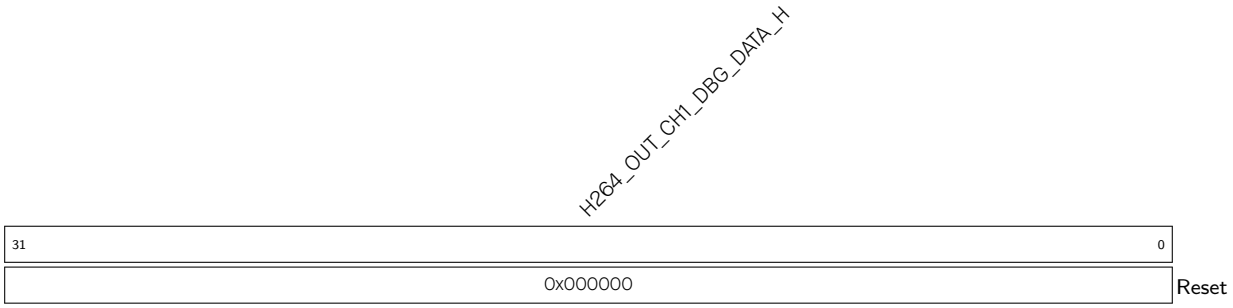
H264_IN_CH4_DBG_EN Configures whether to enable in channel 4 debug.

Register 41.151. H264_DMA_OUT_CH0_DBG_DATA_L_REG (0x0B6C)



H264_OUT_CH0_DBG_DATA_L Configures out channel 0 debug data bit 31-0 (R/W)

Register 41.152. H264_DMA_OUT_CH0_DBG_DATA_H_REG (0x0B70)

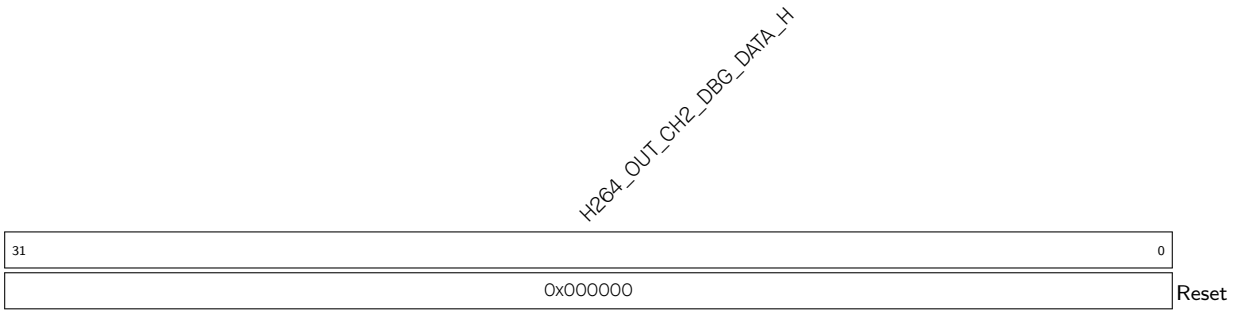


H264_OUT_CH0_DBG_DATA_H Configures out channel 0 debug data bit 63-32 (R/W)

Register 41.153. H264_DMA_OUT_CH1_DBG_DATA_L_REG (0x0B74)

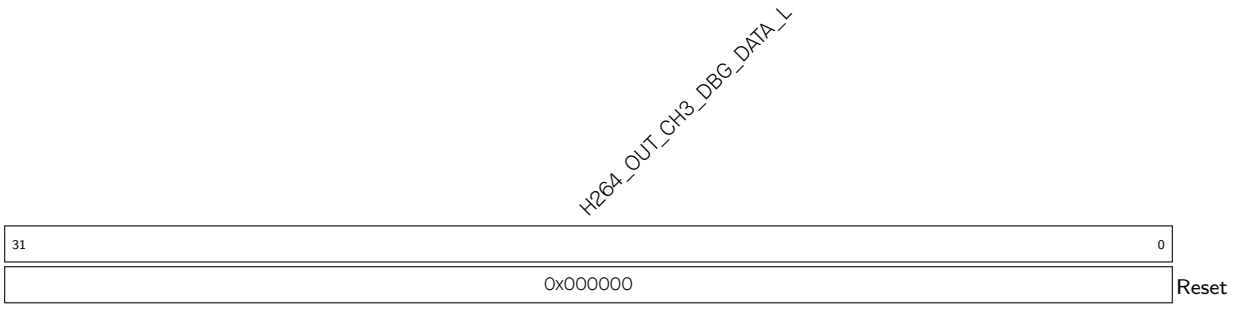
H264_OUT_CH1_DBG_DATA_L Configures out channel 1 debug data bit 31-0 (R/W)

Register 41.154. H264_DMA_OUT_CH1_DBG_DATA_H_REG (0x0B78)



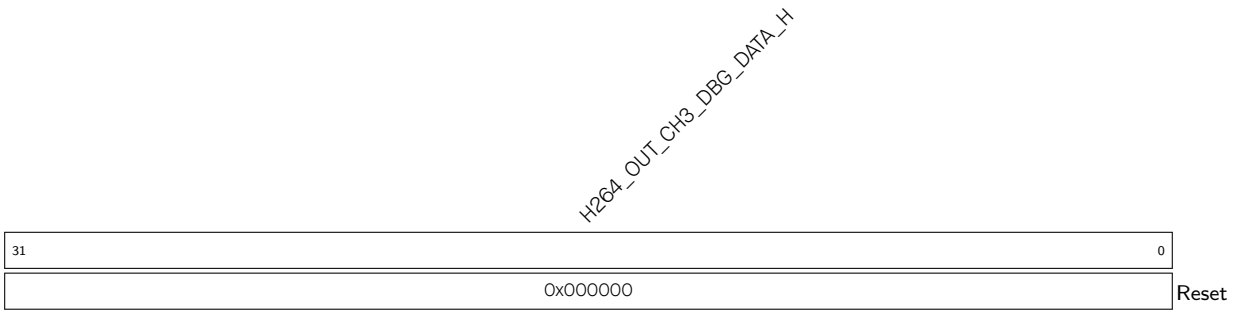
H264_OUT_CH1_DBG_DATA_H Configures out channel 1 debug data bit 63-32 (R/W)

Register 41.155. H264_DMA_OUT_CH2_DBG_DATA_L_REG (0x0B7C)



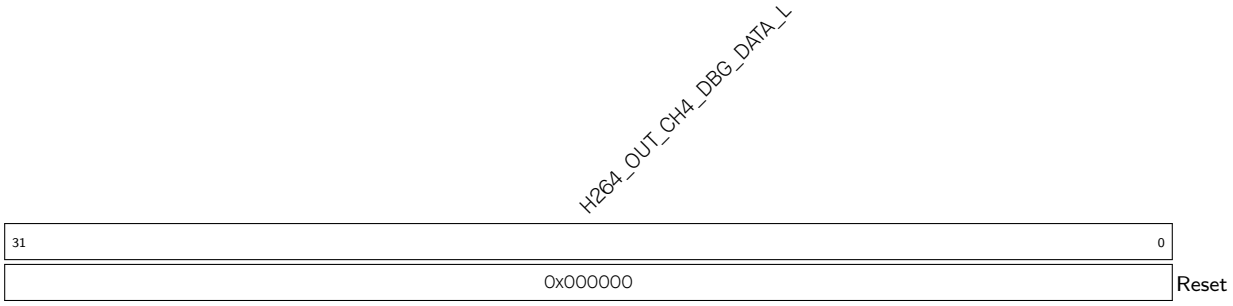
H264_OUT_CH2_DBG_DATA_L Configures out channel 2 debug data bit 31-0 (R/W)

Register 41.156. H264_DMA_OUT_CH2_DBG_DATA_H_REG (0x0B80)



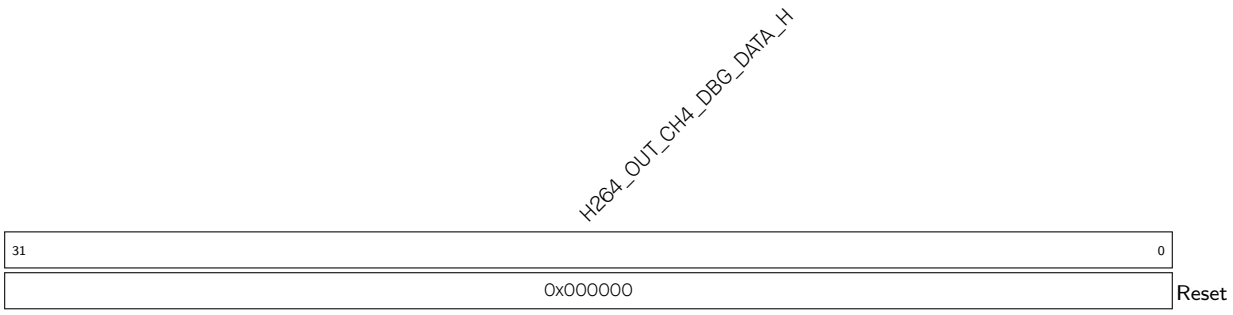
H264_OUT_CH2_DBG_DATA_H Configures out channel 2 debug data bit 63-32 (R/W)

Register 41.157. H264_DMA_OUT_CH3_DBG_DATA_L_REG (0x0B84)



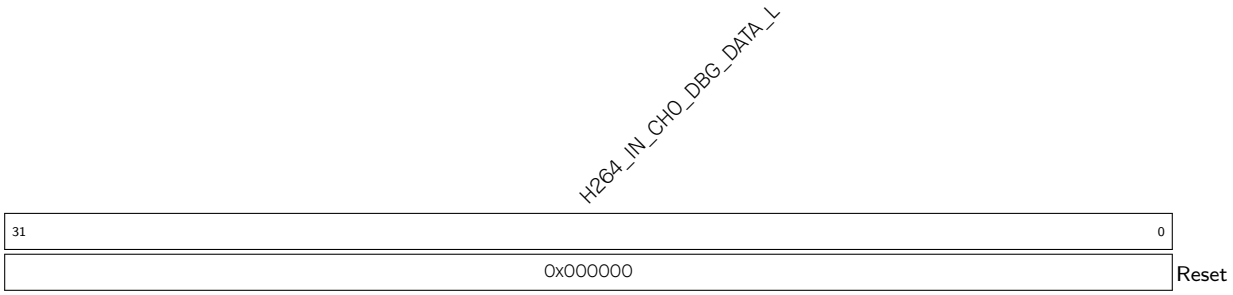
H264_OUT_CH3_DBG_DATA_L Configures out channel 3 debug data bit 31-0 (R/W)

Register 41.158. H264_DMA_OUT_CH3_DBG_DATA_H_REG (0x0B88)



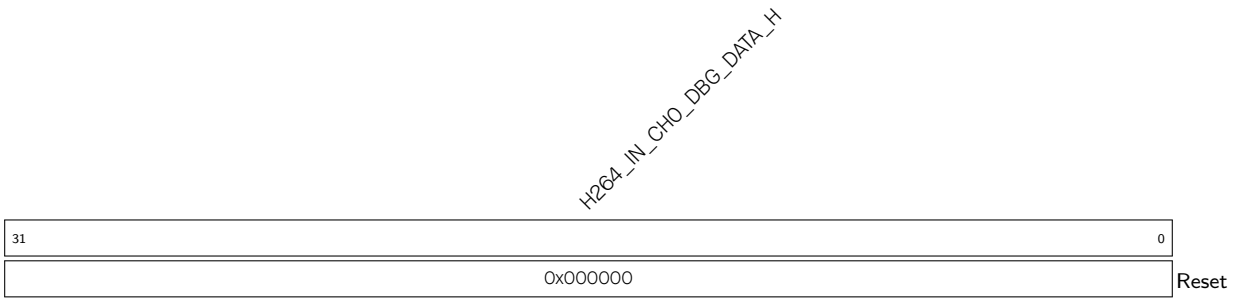
H264_OUT_CH3_DBG_DATA_H Configures out channel 3 debug data bit 63-32 (R/W)

Register 41.159. H264_DMA_OUT_CH4_DBG_DATA_L_REG (0x0B8C)



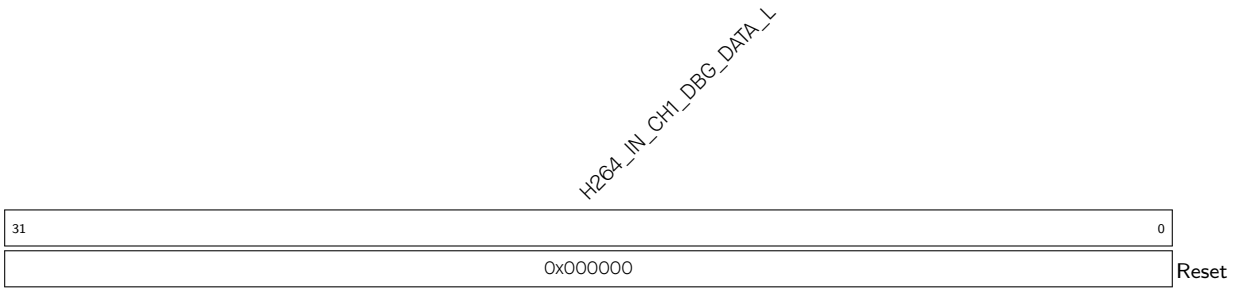
H264_OUT_CH4_DBG_DATA_L Configures out channel 4 debug data bit 31-0 (R/W)

Register 41.160. H264_DMA_OUT_CH4_DBG_DATA_H_REG (0x0B90)



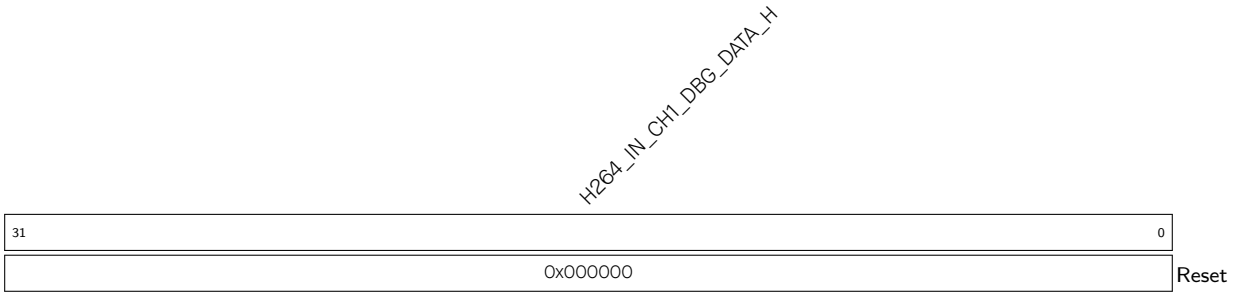
H264_OUT_CH4_DBG_DATA_H Configures out channel 4 debug data bit 63-32 (R/W)

Register 41.161. H264_DMA_IN_CH0_DBG_DATA_L_REG (0x0B94)



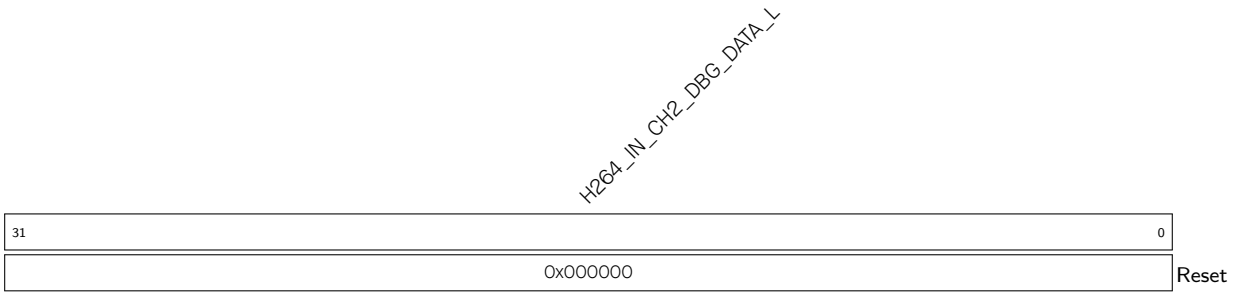
H264_IN_CH0_DBG_DATA_L Configures in channel 0 debug data bit 31-0 (R/W)

Register 41.162. H264_DMA_IN_CH0_DBG_DATA_H_REG (0x0B98)



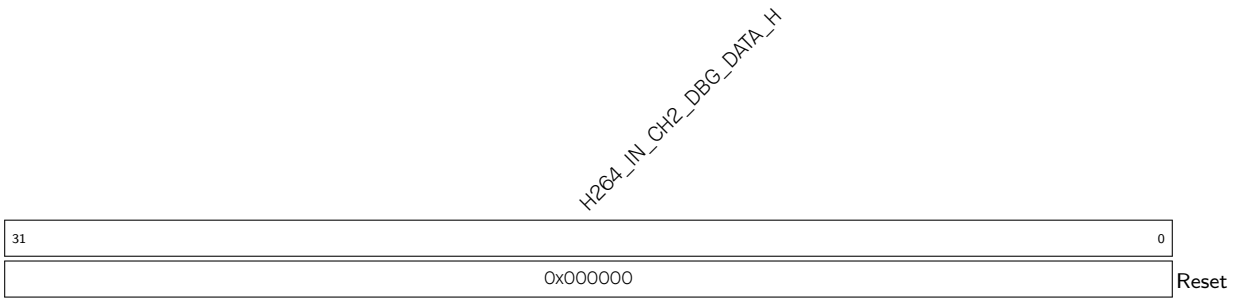
H264_IN_CH0_DBG_DATA_H Configures in channel 0 debug data bit 63-32 (R/W)

Register 41.163. H264_DMA_IN_CH1_DBG_DATA_L_REG (0x0B9C)



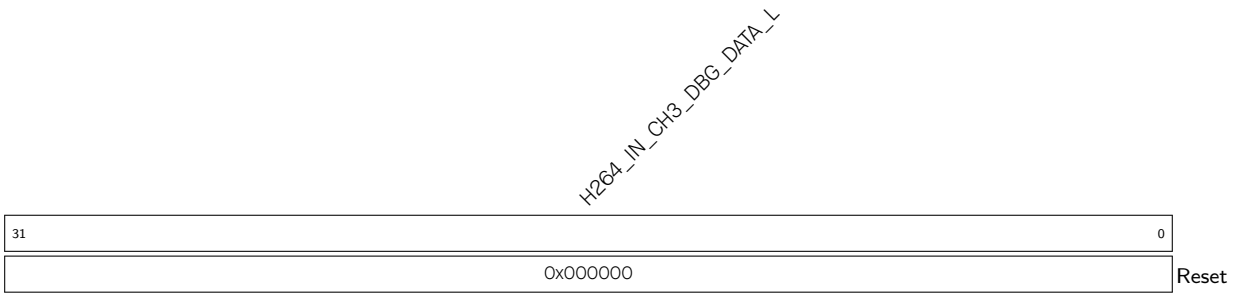
H264_IN_CH1_DBG_DATA_L Configures in channel 1 debug data bit 31-0 (R/W)

Register 41.164. H264_DMA_IN_CH1_DBG_DATA_H_REG (0x0BA0)



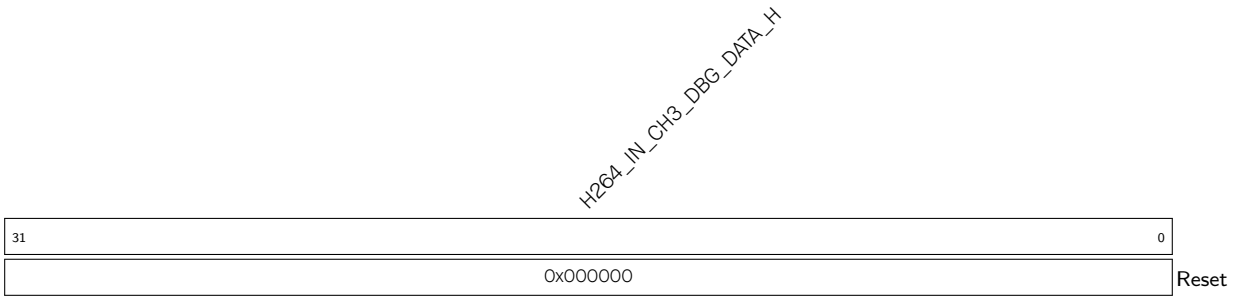
H264_IN_CH1_DBG_DATA_H Configures in channel 1 debug data bit 63-32 (R/W)

Register 41.165. H264_DMA_IN_CH2_DBG_DATA_L_REG (0x0BA4)



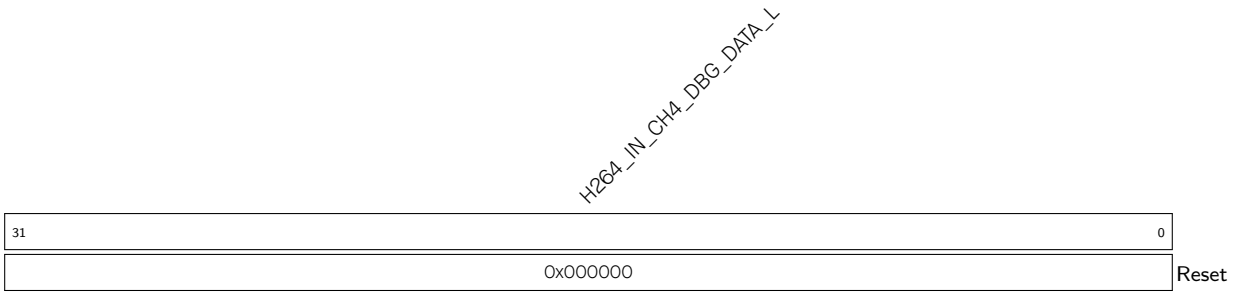
H264_IN_CH2_DBG_DATA_L Configures in channel 2 debug data bit 31-0 (R/W)

Register 41.166. H264_DMA_IN_CH2_DBG_DATA_H_REG (0x0BA8)



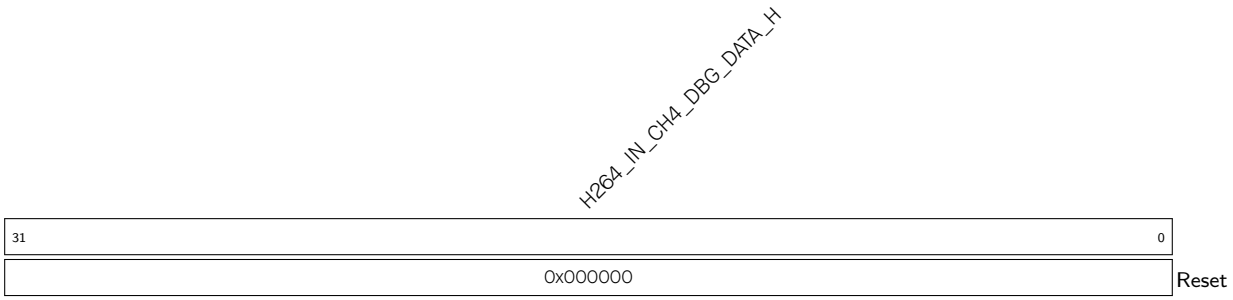
H264_IN_CH2_DBG_DATA_H Configures in channel 2 debug data bit 63-32 (R/W)

Register 41.167. H264_DMA_IN_CH3_DBG_DATA_L_REG (0x0BAC)



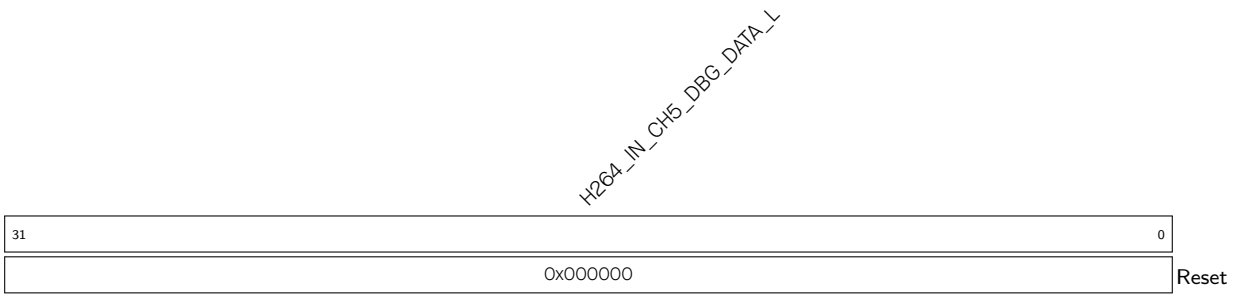
H264_IN_CH3_DBG_DATA_L Configures in channel 3 debug data bit 31-0 (R/W)

Register 41.168. H264_DMA_IN_CH3_DBG_DATA_H_REG (0x0BB0)



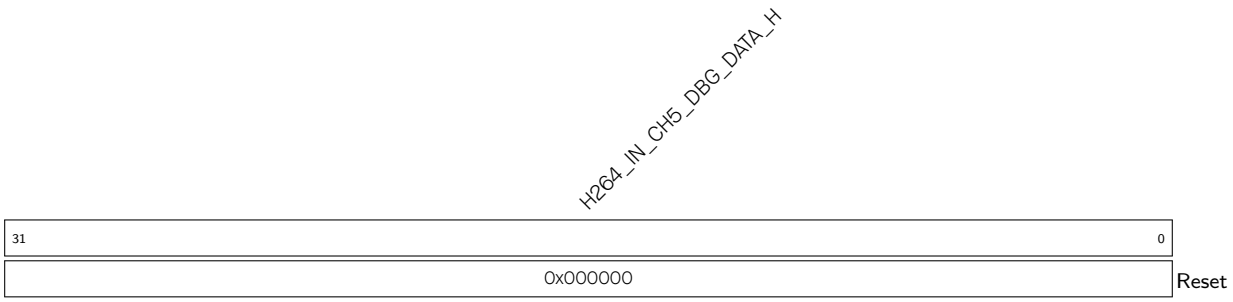
H264_IN_CH3_DBG_DATA_H Configures in channel 3 debug data bit 63-32 (R/W)

Register 41.169. H264_DMA_IN_CH4_DBG_DATA_L_REG (0x0BB4)



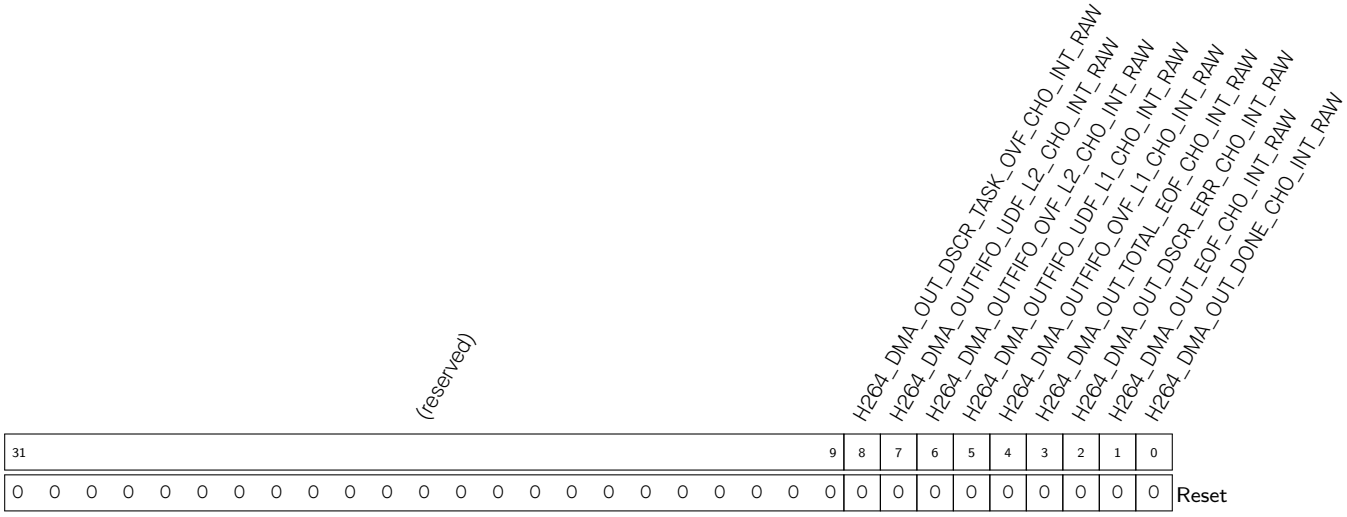
H264_IN_CH4_DBG_DATA_L Configures in channel 4 debug data bit 31-0 (R/W)

Register 41.170. H264_DMA_IN_CH4_DBG_DATA_H_REG (0x0BB8)



H264_IN_CH4_DBG_DATA_H Configures in channel 4 debug data bit 63-32 (R/W)

Register 41.171. H264_DMA_IN_CH5_DBG_DATA_L_REG (0x0BBC)



H264_IN_CH5_DBG_DATA_L Configures in channel 5 debug data bit 31-0 (R/W)

Register 41.172. H264_DMA_IN_CH5_DBG_DATA_H_REG (0x0BC0)

H264_IN_CH5_DBG_DATA_H Configures in channel 5 debug data bit 63-32 (R/W)

Register 41.173. H264_DMA_OUT_INT_RAW_CH0_REG (0x0004)

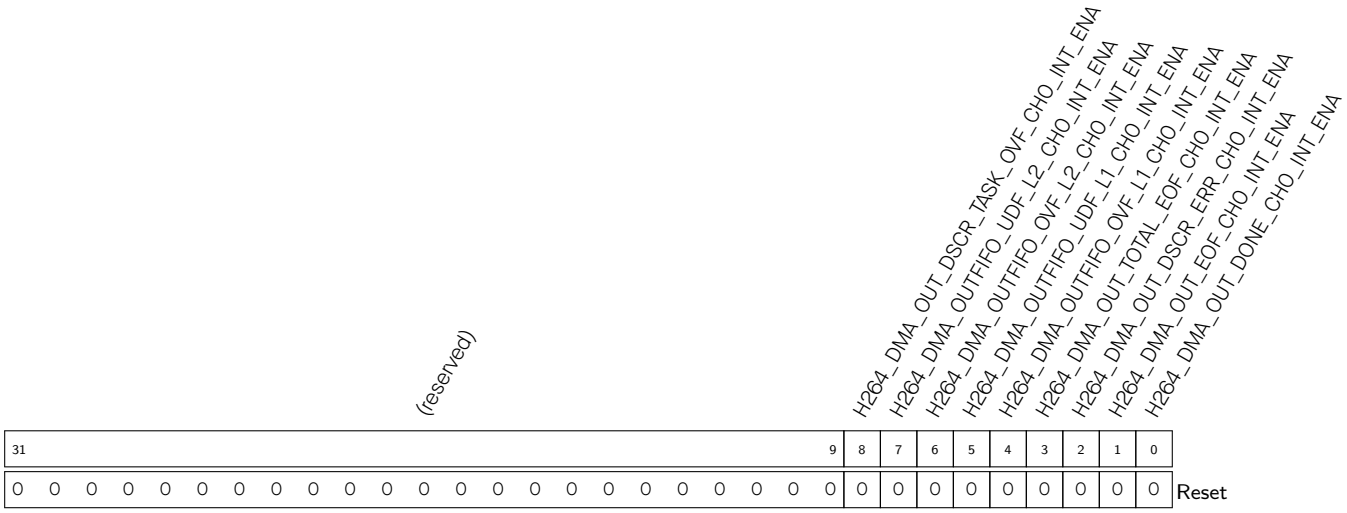
H264_DMA_OUT_DONE_CH0_INT_RAW The raw interrupt status of H264_DMA_OUT_DONE_CH0_INT. (R/WTC/SS)

H264_DMA_OUT_EOF_CH0_INT_RAW The raw interrupt status of H264_DMA_OUT_EOF_CH0_INT. (R/WTC/SS)

H264_DMA_OUT_DSCR_ERR_CH0_INT_RAW The raw interrupt status of H264_DMA_OUT_DSCR_ERR_CH0_INT. (R/WTC/SS)

H264_DMA_OUT_TOTAL_EOF_CH0_INT_RAW The raw interrupt status of H264_DMA_OUT_TOTAL_EOF_CH0_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_OVF_L1_CH0_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_OVF_L1_CH0_INT. (R/WTC/SS)



H264_DMA_OUTFIFO_UDF_L1_CH0_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_UDF_L1_CH0_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_OVF_L2_CH0_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_OVF_L2_CH0_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_UDF_L2_CH0_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_UDF_L2_CH0_INT. (R/WTC/SS)

H264_DMA_OUT_DSCR_TASK_OVF_CH0_INT_RAW The raw interrupt status of H264_DMA_OUT_DSCR_TASK_OVF_CH0_INT. (R/WTC/SS)

Register 41.174. H264_DMA_OUT_INT_ENA_CH0_REG (0x0008)

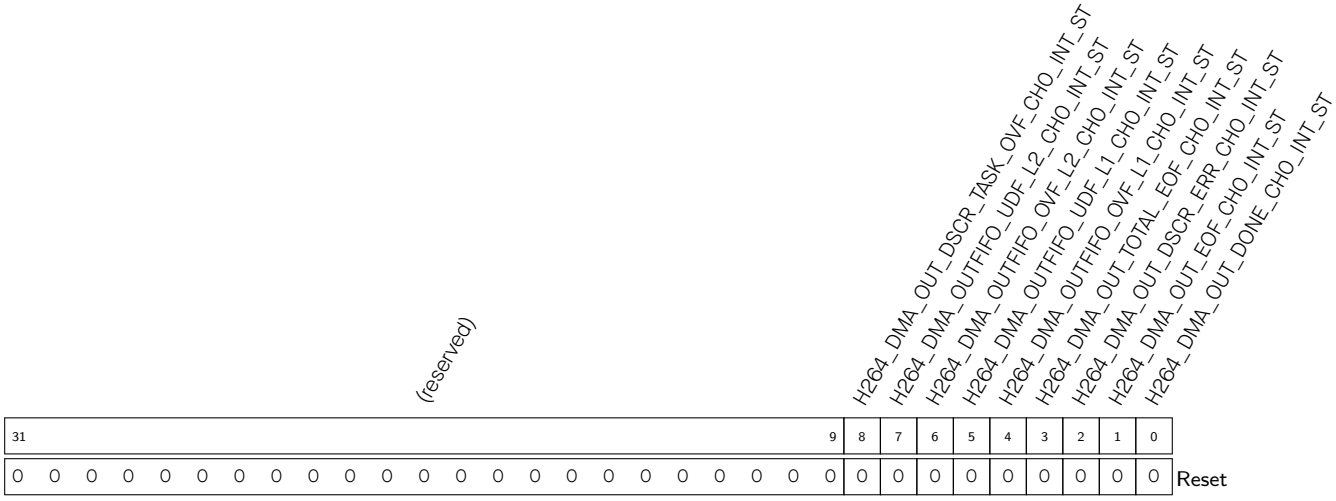
H264_DMA_OUT_DONE_CH0_INT_ENA Write 1 to enable H264_DMA_OUT_DONE_CH0_INT. (R/W)

H264_DMA_OUT_EOF_CH0_INT_ENA Write 1 to enable H264_DMA_OUT_EOF_CH0_INT. (R/W)

H264_DMA_OUT_DSCR_ERR_CH0_INT_ENA Write 1 to enable H264_DMA_OUT_DSCR_ERR_-CH0_INT. (R/W)

H264_DMA_OUT_TOTAL_EOF_CH0_INT_ENA Write 1 to enable H264_DMA_OUT_TOTAL_EOF_-CH0_INT. (R/W)

H264_DMA_OUTFIFO_OVF_L1_CH0_INT_ENA Write 1 to enable H264_DMA_OUTFIFO_OVF_L1_-CH0_INT. (R/W)



H264_DMA_OUTFIFO_UDF_L1_CH0_INT_ENA Write 1 to enable H264_DMA_OUTFIFO_UDF_L1_-CH0_INT. (R/W)

H264_DMA_OUTFIFO_OVF_L2_CH0_INT_ENA Write 1 to enable H264_DMA_OUTFIFO_OVF_L2_-CH0_INT. (R/W)

H264_DMA_OUTFIFO_UDF_L2_CH0_INT_ENA Write 1 to enable H264_DMA_OUTFIFO_UDF_L2_-CH0_INT. (R/W)

H264_DMA_OUT_DSCR_TASK_OVF_CH0_INT_ENA Write 1 to enable H264_DMA_OUT_DSCR_-TASK_OVF_CH0_INT. (R/W)

Register 41.175. H264_DMA_OUT_INT_ST_CH0_REG (0x000C)

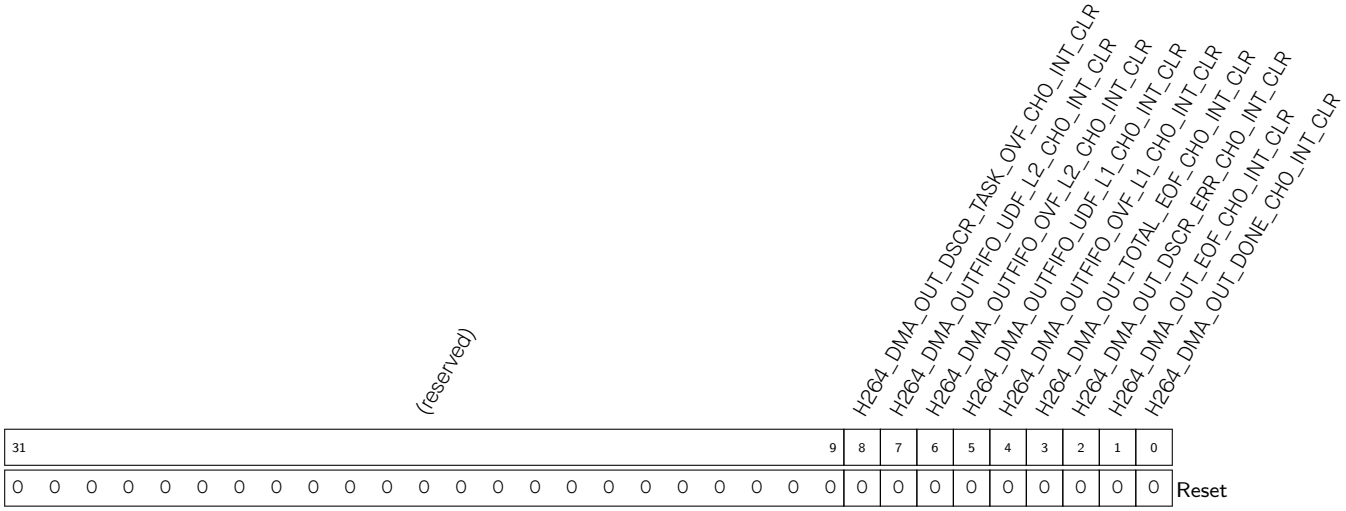
H264_DMA_OUT_DONE_CH0_INT_ST The masked interrupt status of H264_DMA_OUT_DONE_CH0_INT. (RO)

H264_DMA_OUT_EOF_CH0_INT_ST The masked interrupt status of H264_DMA_OUT_EOF_CH0_INT. (RO)

H264_DMA_OUT_DSCR_ERR_CH0_INT_ST The masked interrupt status of H264_DMA_OUT_DSCR_ERR_CH0_INT. (RO)

H264_DMA_OUT_TOTAL_EOF_CH0_INT_ST The masked interrupt status of H264_DMA_OUT_TOTAL_EOF_CH0_INT. (RO)

H264_DMA_OUTFIFO_OVF_L1_CH0_INT_ST The masked interrupt status of H264_DMA_OUTFIFO_OVF_L1_CH0_INT. (RO)



H264_DMA_OUTFIFO_UDF_L1_CH0_INT_ST The masked interrupt status of H264_DMA_OUTFIFO_UDF_L1_CH0_INT. (RO)

H264_DMA_OUTFIFO_OVF_L2_CH0_INT_ST The masked interrupt status of H264_DMA_OUTFIFO_OVF_L2_CH0_INT. (RO)

H264_DMA_OUTFIFO_UDF_L2_CH0_INT_ST The masked interrupt status of H264_DMA_OUTFIFO_UDF_L2_CH0_INT. (RO)

H264_DMA_OUT_DSCR_TASK_OVF_CH0_INT_ST The masked interrupt status of H264_DMA_OUT_DSCR_TASK_OVF_CH0_INT. (RO)

Register 41.176. H264_DMA_OUT_INT_CLR_CH0_REG (0x0010)

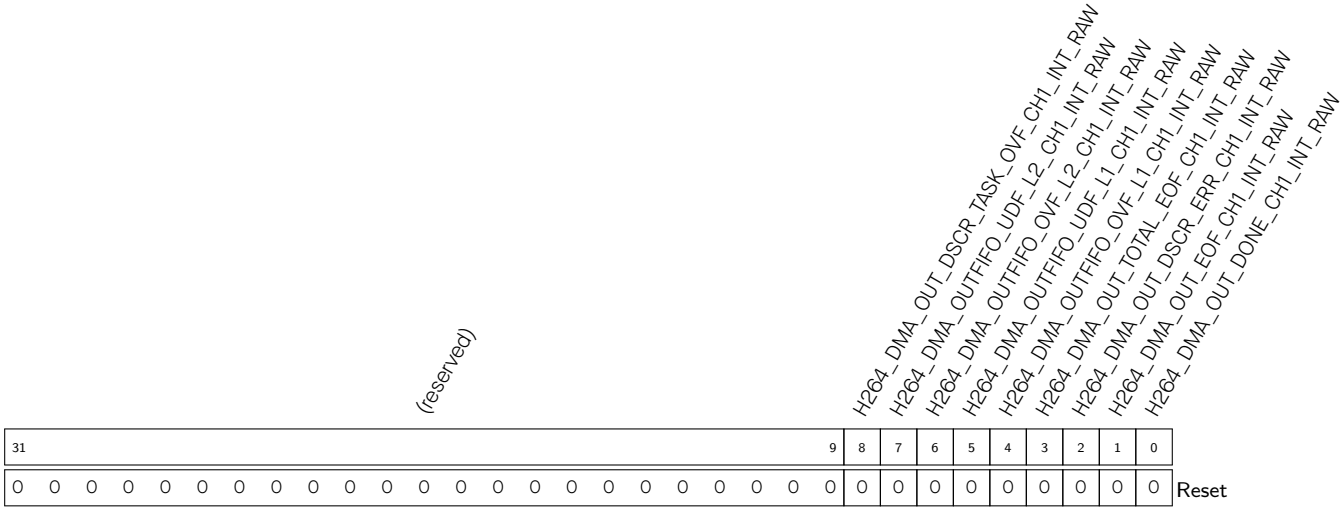
H264_DMA_OUT_DONE_CH0_INT_CLR Write 1 to clear H264_DMA_OUT_DONE_CH0_INT. (WT)

H264_DMA_OUT_EOF_CH0_INT_CLR Write 1 to clear H264_DMA_OUT_EOF_CH0_INT. (WT)

H264_DMA_OUT_DSCR_ERR_CH0_INT_CLR Write 1 to clear H264_DMA_OUT_DSCR_ERR_CH0_-INT. (WT)

H264_DMA_OUT_TOTAL_EOF_CH0_INT_CLR Write 1 to clear H264_DMA_OUT_TOTAL_EOF_-CH0_INT. (WT)

H264_DMA_OUTFIFO_OVF_L1_CH0_INT_CLR Write 1 to clear H264_DMA_OUTFIFO_OVF_L1_-CH0_INT. (WT)



H264_DMA_OUTFIFO_UDF_L1_CH0_INT_CLR Write 1 to clear H264_DMA_OUTFIFO_UDF_L1_-CH0_INT. (WT)

H264_DMA_OUTFIFO_OVF_L2_CH0_INT_CLR Write 1 to clear H264_DMA_OUTFIFO_OVF_L2_-CH0_INT. (WT)

H264_DMA_OUTFIFO_UDF_L2_CH0_INT_CLR Write 1 to clear H264_DMA_OUTFIFO_UDF_L2_-CH0_INT. (WT)

H264_DMA_OUT_DSCR_TASK_OVF_CH0_INT_CLR Write 1 to clear H264_DMA_OUT_DSCR_-TASK_OVF_CH0_INT. (WT)

Register 41.177. H264_DMA_OUT_INT_RAW_CH1_REG (0x0104)

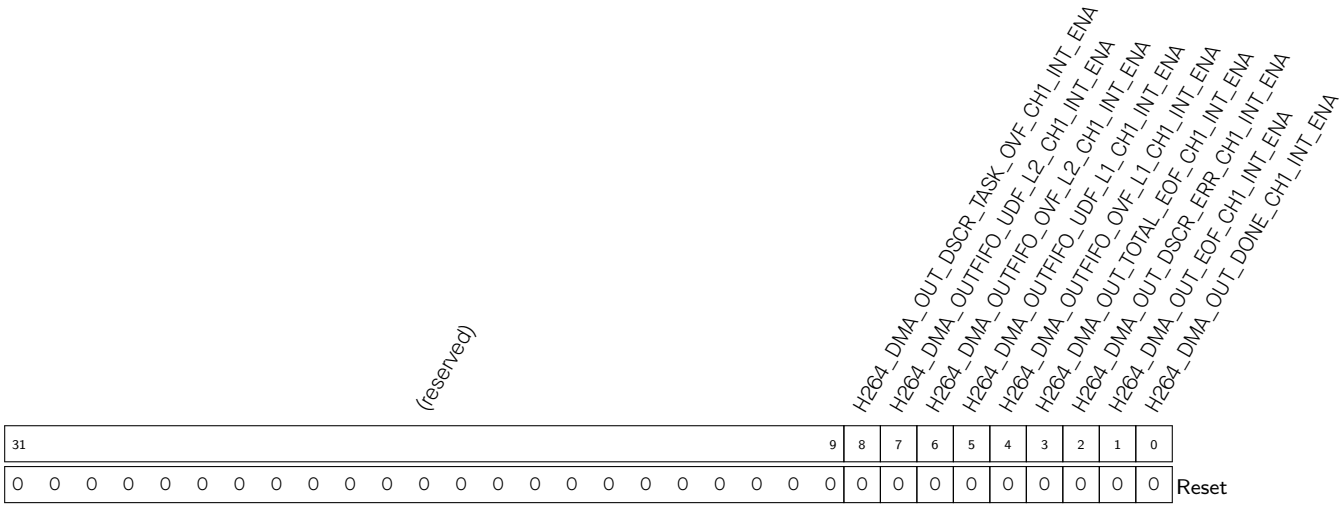
H264_DMA_OUT_DONE_CH1_INT_RAW The raw interrupt status of H264_DMA_OUT_DONE_CH1_INT. (R/WTC/SS)

H264_DMA_OUT_EOF_CH1_INT_RAW The raw interrupt status of H264_DMA_OUT_EOF_CH1_INT. (R/WTC/SS)

H264_DMA_OUT_DSCR_ERR_CH1_INT_RAW The raw interrupt status of H264_DMA_OUT_DSCR_ERR_CH1_INT. (R/WTC/SS)

H264_DMA_OUT_TOTAL_EOF_CH1_INT_RAW The raw interrupt status of H264_DMA_OUT_TOTAL_EOF_CH1_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_OVF_L1_CH1_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_OVF_L1_CH1_INT. (R/WTC/SS)



H264_DMA_OUTFIFO_UDF_L1_CH1_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_UDF_L1_CH1_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_OVF_L2_CH1_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_OVF_L2_CH1_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_UDF_L2_CH1_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_UDF_L2_CH1_INT. (R/WTC/SS)

H264_DMA_OUT_DSCR_TASK_OVF_CH1_INT_RAW The raw interrupt status of H264_DMA_OUT_DSCR_TASK_OVF_CH1_INT. (R/WTC/SS)

Register 41.178. H264_DMA_OUT_INT_ENA_CH1_REG (0x0108)

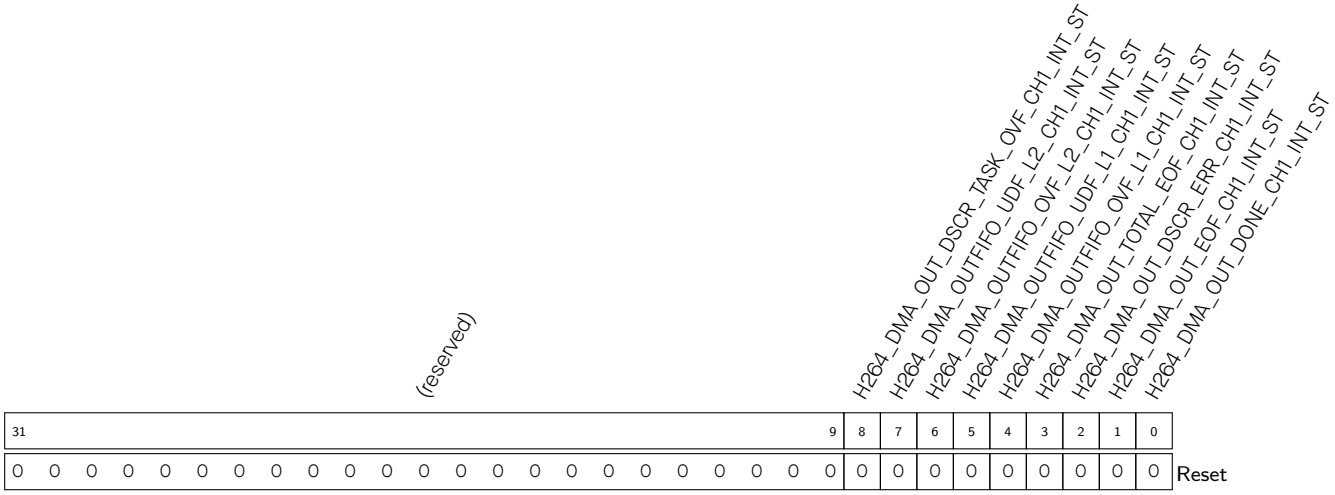
H264_DMA_OUT_DONE_CH1_INT_ENA Write 1 to enable H264_DMA_OUT_DONE_CH1_INT. (R/W)

H264_DMA_OUT_EOF_CH1_INT_ENA Write 1 to enable H264_DMA_OUT_EOF_CH1_INT. (R/W)

H264_DMA_OUT_DSCR_ERR_CH1_INT_ENA Write 1 to enable H264_DMA_OUT_DSCR_ERR_CH1_INT. (R/W)

H264_DMA_OUT_TOTAL_EOF_CH1_INT_ENA Write 1 to enable H264_DMA_OUT_TOTAL_EOF_CH1_INT. (R/W)

H264_DMA_OUTFIFO_OVF_L1_CH1_INT_ENA Write 1 to enable H264_DMA_OUTFIFO_OVF_L1_CH1_INT. (R/W)



H264_DMA_OUTFIFO_UDF_L1_CH1_INT_ENA Write 1 to enable H264_DMA_OUTFIFO_UDF_L1_CH1_INT. (R/W)

H264_DMA_OUTFIFO_OVF_L2_CH1_INT_ENA Write 1 to enable H264_DMA_OUTFIFO_OVF_L2_CH1_INT. (R/W)

H264_DMA_OUTFIFO_UDF_L2_CH1_INT_ENA Write 1 to enable H264_DMA_OUTFIFO_UDF_L2_CH1_INT. (R/W)

H264_DMA_OUT_DSCR_TASK_OVF_CH1_INT_ENA Write 1 to enable H264_DMA_OUT_DSCR_TASK_OVF_CH1_INT. (R/W)

Register 41.179. H264_DMA_OUT_INT_ST_CH1_REG (0x010C)

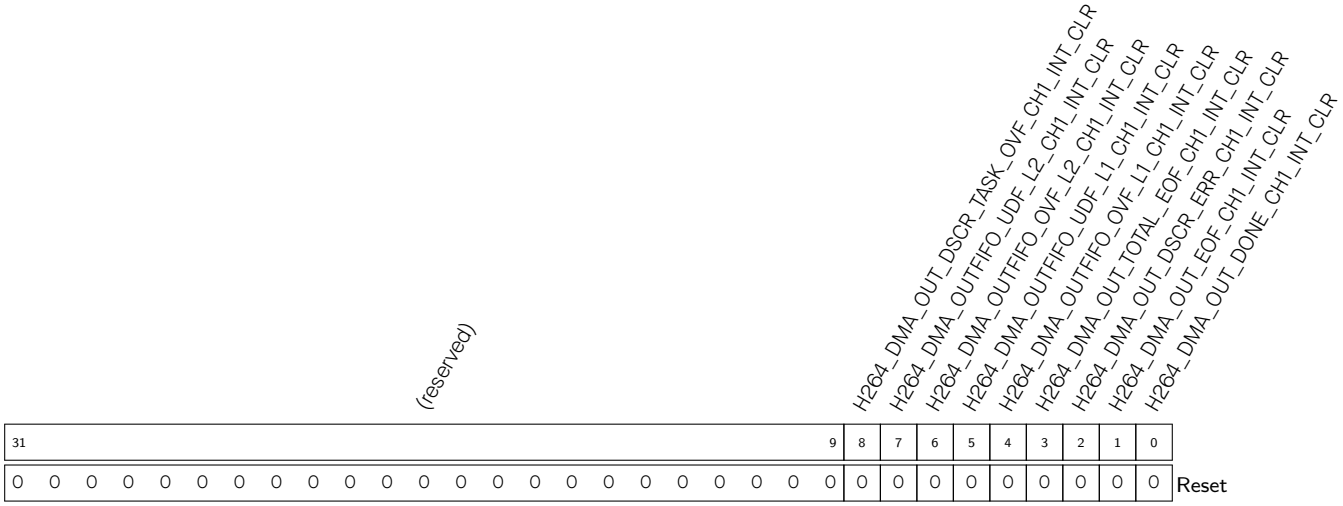
H264_DMA_OUT_DONE_CH1_INT_ST The masked interrupt status of H264_DMA_OUT_DONE_CH1_INT. (RO)

H264_DMA_OUT_EOF_CH1_INT_ST The masked interrupt status of H264_DMA_OUT_EOF_CH1_INT. (RO)

H264_DMA_OUT_DSCR_ERR_CH1_INT_ST The masked interrupt status of H264_DMA_OUT_DSCR_ERR_CH1_INT. (RO)

H264_DMA_OUT_TOTAL_EOF_CH1_INT_ST The masked interrupt status of H264_DMA_OUT_TOTAL_EOF_CH1_INT. (RO)

H264_DMA_OUTFIFO_OVF_L1_CH1_INT_ST The masked interrupt status of H264_DMA_OUTFIFO_OVF_L1_CH1_INT. (RO)



H264_DMA_OUTFIFO_UDF_L1_CH1_INT_ST The masked interrupt status of H264_DMA_OUTFIFO_UDF_L1_CH1_INT. (RO)

H264_DMA_OUTFIFO_OVF_L2_CH1_INT_ST The masked interrupt status of H264_DMA_OUTFIFO_OVF_L2_CH1_INT. (RO)

H264_DMA_OUTFIFO_UDF_L2_CH1_INT_ST The masked interrupt status of H264_DMA_OUTFIFO_UDF_L2_CH1_INT. (RO)

H264_DMA_OUT_DSCR_TASK_OVF_CH1_INT_ST The masked interrupt status of H264_DMA_OUT_DSCR_TASK_OVF_CH1_INT. (RO)

Register 41.180. H264_DMA_OUT_INT_CLR_CH1_REG (0x0110)

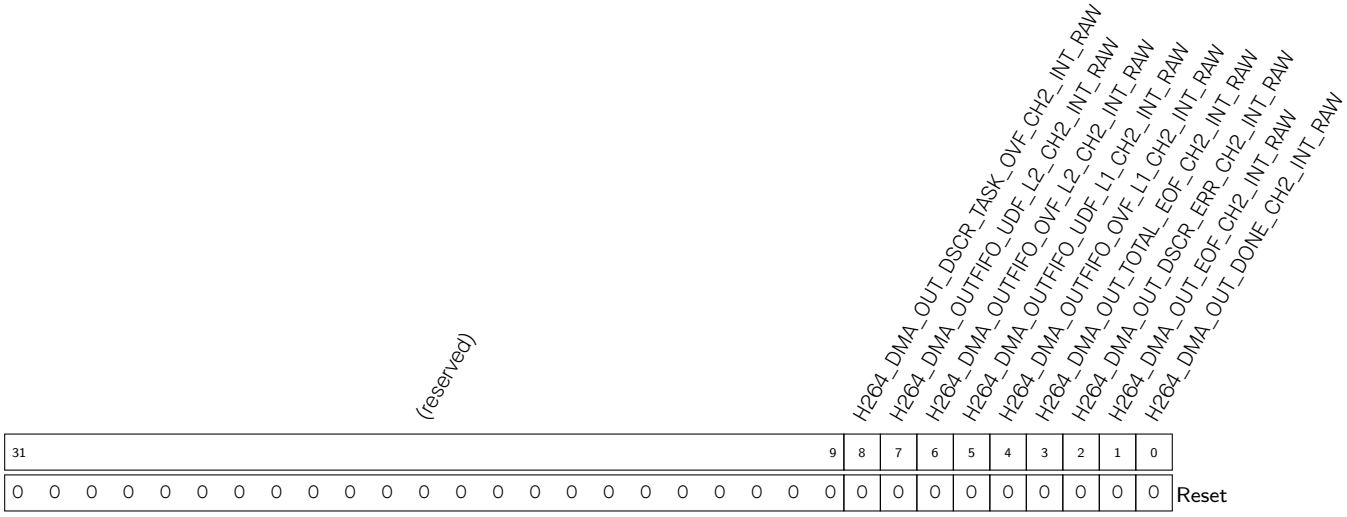
H264_DMA_OUT_DONE_CH1_INT_CLR Write 1 to clear H264_DMA_OUT_DONE_CH1_INT. (WT)

H264_DMA_OUT_EOF_CH1_INT_CLR Write 1 to clear H264_DMA_OUT_EOF_CH1_INT. (WT)

H264_DMA_OUT_DSCR_ERR_CH1_INT_CLR Write 1 to clear H264_DMA_OUT_DSCR_ERR_CH1_INT. (WT)

H264_DMA_OUT_TOTAL_EOF_CH1_INT_CLR Write 1 to clear H264_DMA_OUT_TOTAL_EOF_CH1_INT. (WT)

H264_DMA_OUTFIFO_OVF_L1_CH1_INT_CLR Write 1 to clear H264_DMA_OUTFIFO_OVF_L1_CH1_INT. (WT)



H264_DMA_OUTFIFO_UDF_L1_CH1_INT_CLR Write 1 to clear H264_DMA_OUTFIFO_UDF_L1_CH1_INT. (WT)

H264_DMA_OUTFIFO_OVF_L2_CH1_INT_CLR Write 1 to clear H264_DMA_OUTFIFO_OVF_L2_CH1_INT. (WT)

H264_DMA_OUTFIFO_UDF_L2_CH1_INT_CLR Write 1 to clear H264_DMA_OUTFIFO_UDF_L2_CH1_INT. (WT)

H264_DMA_OUT_DSCR_TASK_OVF_CH1_INT_CLR Write 1 to clear H264_DMA_OUT_DSCR_TASK_OVF_CH1_INT. (WT)

Register 41.181. H264_DMA_OUT_INT_RAW_CH2_REG (0x0204)

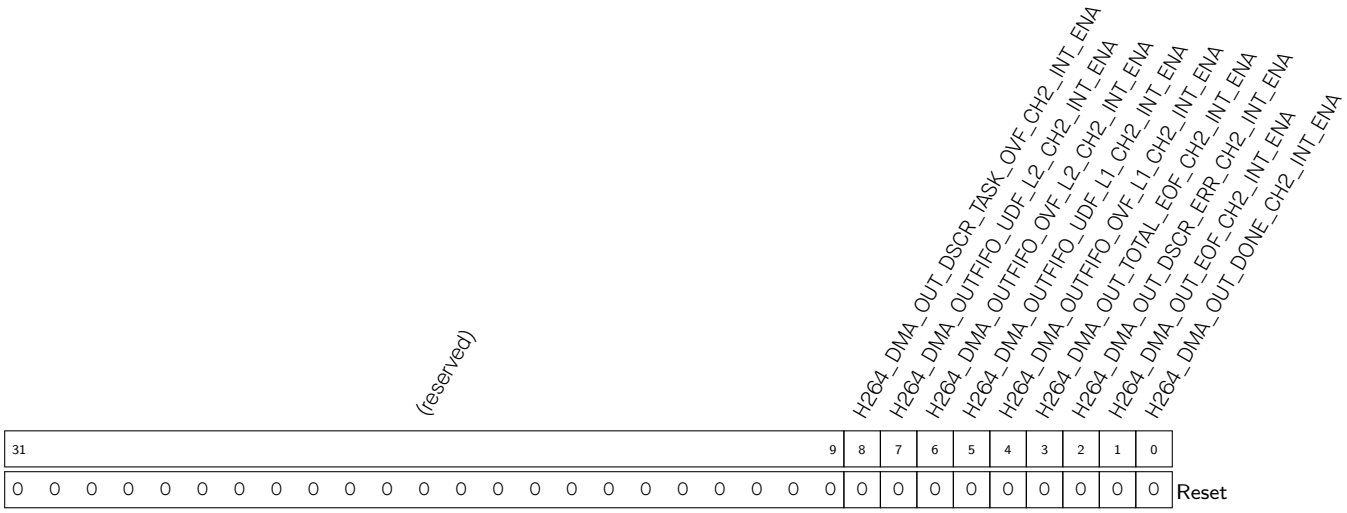
H264_DMA_OUT_DONE_CH2_INT_RAW The raw interrupt status of H264_DMA_OUT_DONE_CH2_INT. Triggered when all data corresponding to a transmit descriptor has been sent via TX channel 2. (R/WTC/SS)

H264_DMA_OUT_EOF_CH2_INT_RAW The raw interrupt status of H264_DMA_OUT_EOF_CH2_INT. (R/WTC/SS)

H264_DMA_OUT_DSCR_ERR_CH2_INT_RAW The raw interrupt status of H264_DMA_OUT_DSCR_ERR_CH2_INT. (R/WTC/SS)

H264_DMA_OUT_TOTAL_EOF_CH2_INT_RAW The raw interrupt status of H264_DMA_OUT_TOTAL_EOF_CH2_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_OVF_L1_CH2_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_OVF_L1_CH2_INT. (R/WTC/SS)



H264_DMA_OUTFIFO_UDF_L1_CH2_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_UDF_L1_CH2_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_OVF_L2_CH2_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_OVF_L2_CH2_INT. (R/WTC/SS)

H264_DMA_OUTFIFO_UDF_L2_CH2_INT_RAW The raw interrupt status of H264_DMA_OUTFIFO_UDF_L2_CH2_INT. (R/WTC/SS)

H264_DMA_OUT_DSCR_TASK_OVF_CH2_INT_RAW The raw interrupt status of H264_DMA_OUT_DSCR_TASK_OVF_CH2_INT. (R/WTC/SS)

Register 41.182. H264_DMA_OUT_INT_ENA_CH2_REG (0x0208)

H264_DMA_OUT_DONE_CH2_INT_ENA Write 1 to enable H264_DMA_OUT_DONE_CH2_INT. (R/W)

H264_DMA_OUT_EOF_CH2_INT_ENA Write 1 to enable H264_DMA_OUT_EOF_CH2_INT. (R/W)

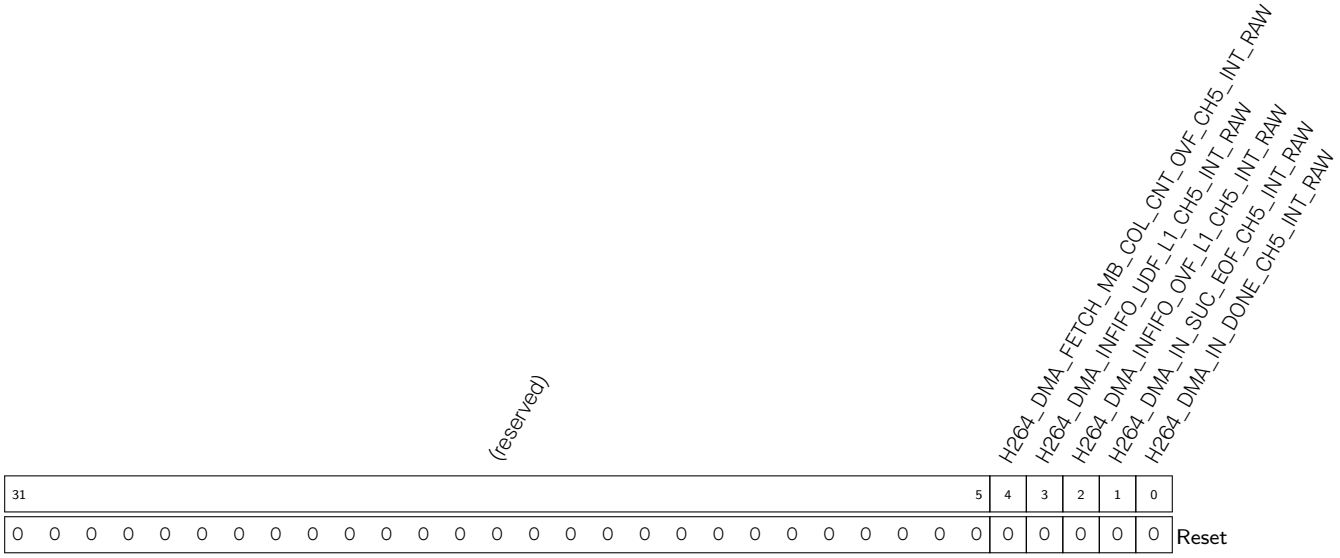
H264_DMA_IN_SUC_EOF_CH4_INT_CLR Write 1 to clear H264_DMA_IN_SUC_EOF_CH4_INT. (WT)

H264_DMA_IN_ERR_EOF_CH4_INT_CLR Write 1 to clear H264_DMA_IN_ERR_EOF_CH4_INT. (WT)

H264_DMA_IN_DSCR_ERR_CH4_INT_CLR Write 1 to clear H264_DMA_IN_DSCR_ERR_CH4_INT. (WT)

H264_DMA_INFIFO_OVF_L1_CH4_INT_CLR Write 1 to clear H264_DMA_INFIFO_OVF_L1_CH4_INT. (WT)

H264_DMA_INFIFO_UDF_L1_CH4_INT_CLR Write 1 to clear H264_DMA_INFIFO_UDF_L1_CH4_INT. (WT)



H264_DMA_INFIFO_OVF_L2_CH4_INT_CLR Write 1 to clear H264_DMA_INFIFO_OVF_L2_CH4_INT. (WT)

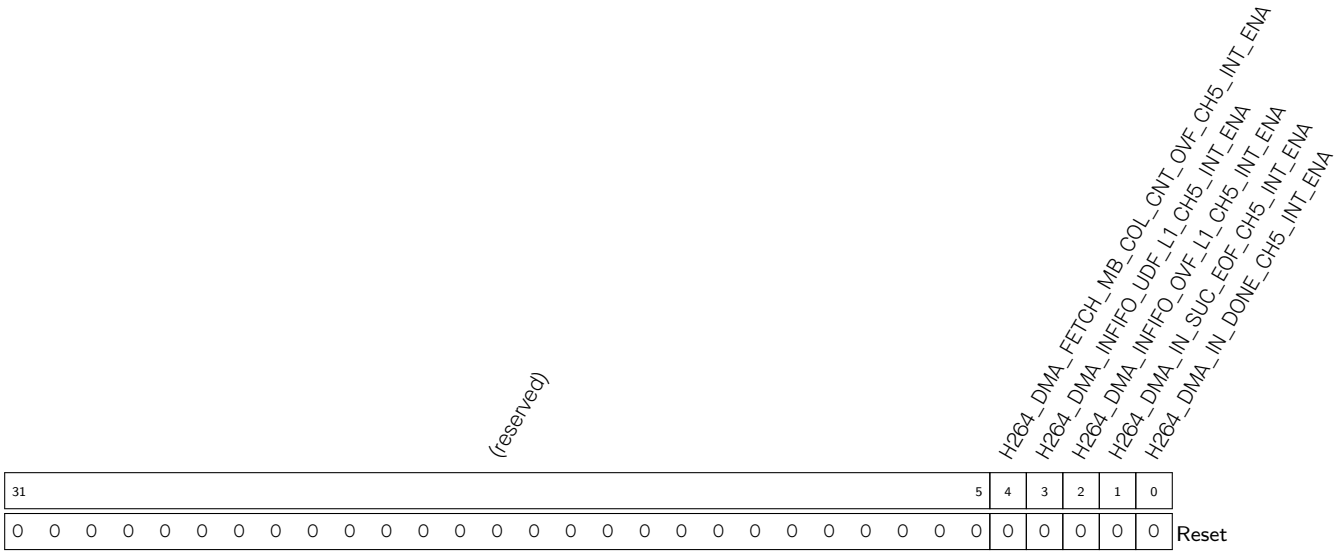
H264_DMA_INFIFO_UDF_L2_CH4_INT_CLR Write 1 to clear H264_DMA_INFIFO_UDF_L2_CH4_INT. (WT)

H264_DMA_IN_DSCR_EMPTY_CH4_INT_CLR Write 1 to clear H264_DMA_IN_DSCR_EMPTY_CH4_INT. (WT)

H264_DMA_IN_DSCR_TASK_OVF_CH4_INT_CLR Write 1 to clear H264_DMA_IN_DSCR_TASK_OVF_CH4_INT. (WT)

Register 41.213. H264_DMA_IN_INT_RAW_CH5_REG (0x0A10)

H264_DMA_IN_DONE_CH5_INT_RAW The raw interrupt status of H264_DMA_IN_DONE_CH5_INT. (R/WTC/SS)



H264_DMA_IN_SUC_EOF_CH5_INT_RAW The raw interrupt status of H264_DMA_IN_SUC_EOF_CH5_INT. (R/WTC/SS)

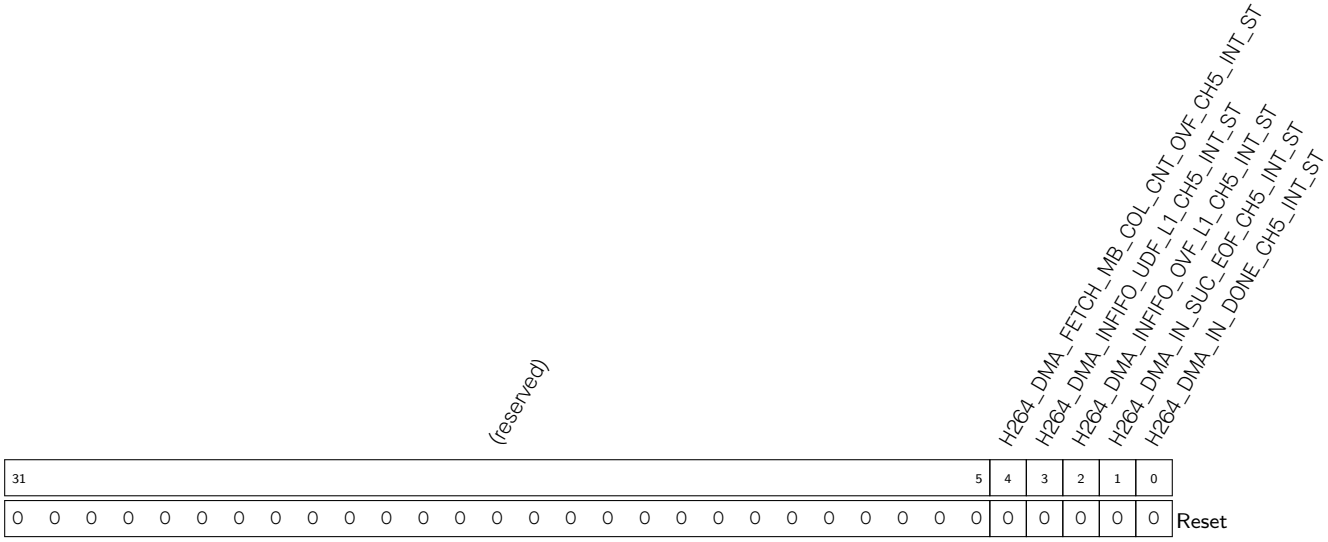
H264_DMA_INFIFO_OVF_L1_CH5_INT_RAW The raw interrupt status of H264_DMA_INFIFO_OVF_L1_CH5_INT. (R/WTC/SS)

H264_DMA_INFIFO_UDF_L1_CH5_INT_RAW The raw interrupt status of H264_DMA_INFIFO_UDF_L1_CH5_INT. (R/WTC/SS)

H264_DMA_FETCH_MB_COL_CNT_OVF_CH5_INT_RAW The raw interrupt status of H264_DMA_FETCH_MB_COL_CNT_OVF_CH5_INT. (R/WTC/SS)

Register 41.214. H264_DMA_IN_INT_ENA_CH5_REG (0x0A14)

H264_DMA_IN_DONE_CH5_INT_ENA Write 1 to enable H264_DMA_IN_DONE_CH5_INT. (R/W)



H264_DMA_IN_SUC_EOF_CH5_INT_ENA Write 1 to enable H264_DMA_IN_SUC_EOF_CH5_INT. (R/W)

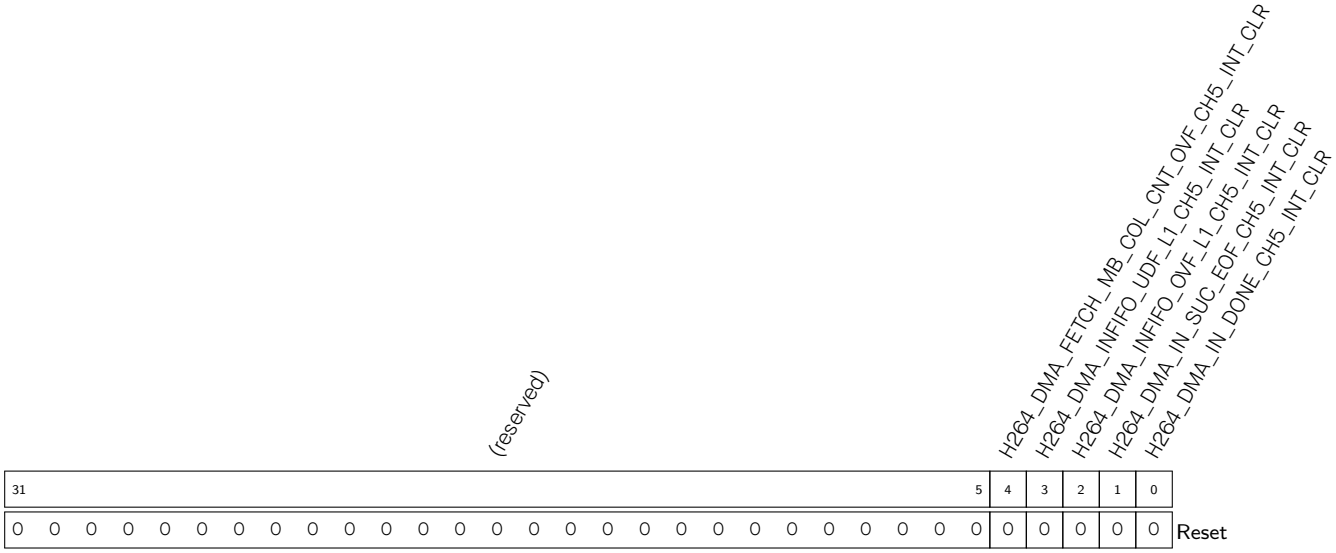
H264_DMA_INFIFO_OVF_L1_CH5_INT_ENA Write 1 to enable H264_DMA_INFIFO_OVF_L1_CH5_-INT. (R/W)

H264_DMA_INFIFO_UDF_L1_CH5_INT_ENA Write 1 to enable H264_DMA_INFIFO_UDF_L1_CH5_-INT. (R/W)

H264_DMA_FETCH_MB_COL_CNT_OVF_CH5_INT_ENA Write 1 to enable H264_DMA_FETCH_-MB_COL_CNT_OVF_CH5_INT. (R/W)

Register 41.215. H264_DMA_IN_INT_ST_CH5_REG (0x0A18)

H264_DMA_IN_DONE_CH5_INT_ST The masked interrupt status of H264_DMA_IN_DONE_CH5_INT. (RO)



H264_DMA_IN_SUC_EOF_CH5_INT_ST The masked interrupt status of H264_DMA_IN_SUC_EOF_CH5_INT. (RO)

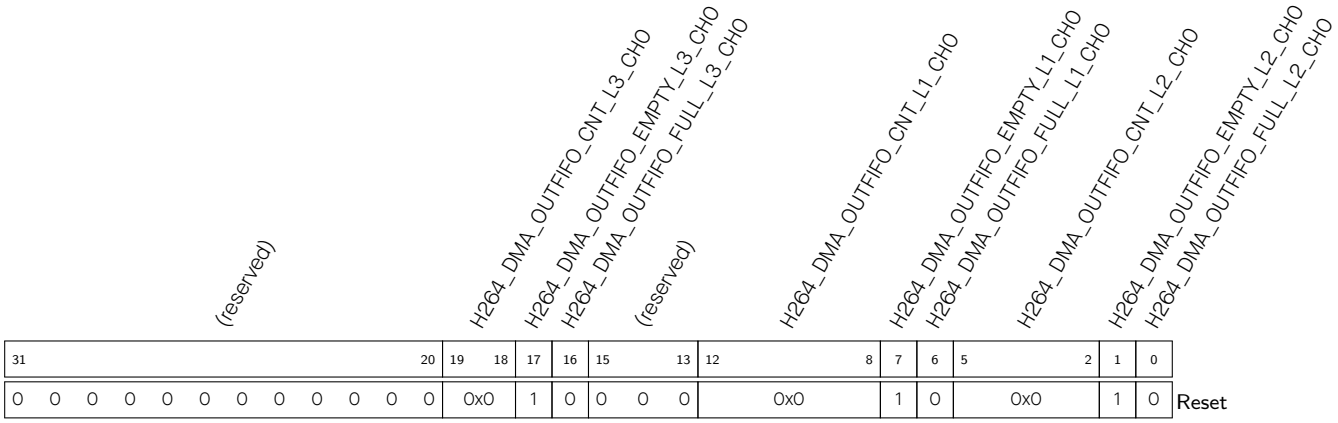
H264_DMA_INFIFO_OVF_L1_CH5_INT_ST The masked interrupt status of H264_DMA_INFIFO_OVF_L1_CH5_INT. (RO)

H264_DMA_INFIFO_UDF_L1_CH5_INT_ST The masked interrupt status of H264_DMA_INFIFO_UDF_L1_CH5_INT. (RO)

H264_DMA_FETCH_MB_COL_CNT_OVF_CH5_INT_ST The masked interrupt status of H264_DMA_FETCH_MB_COL_CNT_OVF_CH5_INT. (RO)

Register 41.216. H264_DMA_IN_INT_CLR_CH5_REG (0x0A1C)

H264_DMA_IN_DONE_CH5_INT_CLR Write 1 to clear H264_DMA_IN_DONE_CH5_INT. (WT)



H264_DMA_IN_SUC_EOF_CH5_INT_CLR Write 1 to clear H264_DMA_IN_SUC_EOF_CH5_INT. (WT)

H264_DMA_INFIFO_OVF_L1_CH5_INT_CLR Write 1 to clear H264_DMA_INFIFO_OVF_L1_CH5_-INT. (WT)

H264_DMA_INFIFO_UDF_L1_CH5_INT_CLR Write 1 to clear H264_DMA_INFIFO_UDF_L1_CH5_-INT. (WT)

H264_DMA_FETCH_MB_COL_CNT_OVF_CH5_INT_CLR Write 1 to clear H264_DMA_FETCH_MB_COL_CNT_OVF_CH5. (WT)

Register 41.217. H264_DMA_OUTFIFO_STATUS_CH0_REG (0x0014)

H264_DMA_OUTFIFO_FULL_L2_CH0 Represents whether l2 FIFO of TX channel 0 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L2_CH0 Represents whether l2 FIFO of TX channel 0 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L2_CH0 Represents the data quantity in l2 FIFO for TX channel 0. Measurement unit: 16 bytes. (RO)

H264_DMA_OUTFIFO_FULL_L1_CH0 Represents whether l1 FIFO of TX channel 0 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L1_CH0 Represents whether l1 FIFO of TX channel 0 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L1_CH0 Represents the data quantity in l1 FIFO for TX channel 0. Measurement unit: byte. (RO)

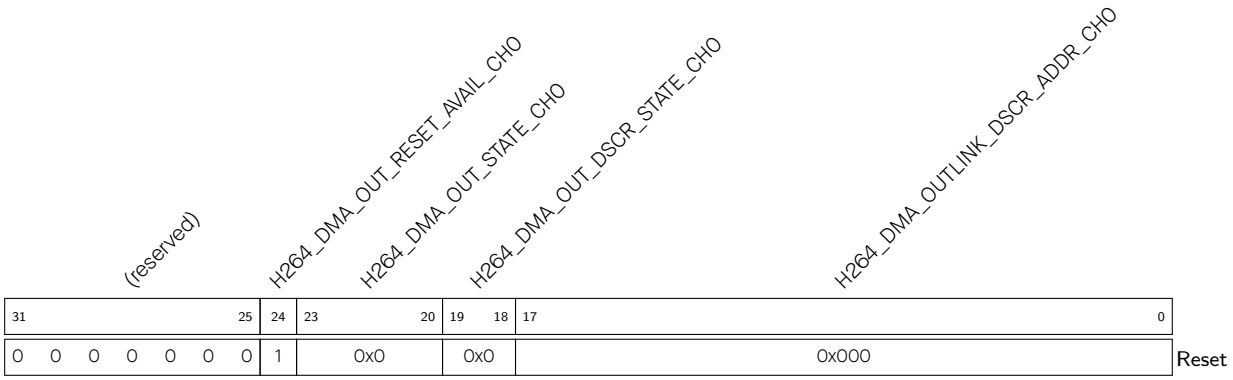
H264_DMA_OUTFIFO_FULL_L3_CH0 Represents whether l3 FIFO of TX channel 0 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L3_CH0 Represents whether l3 FIFO of TX channel 0 is empty.



0: Not empty

1: Empty

(RO)

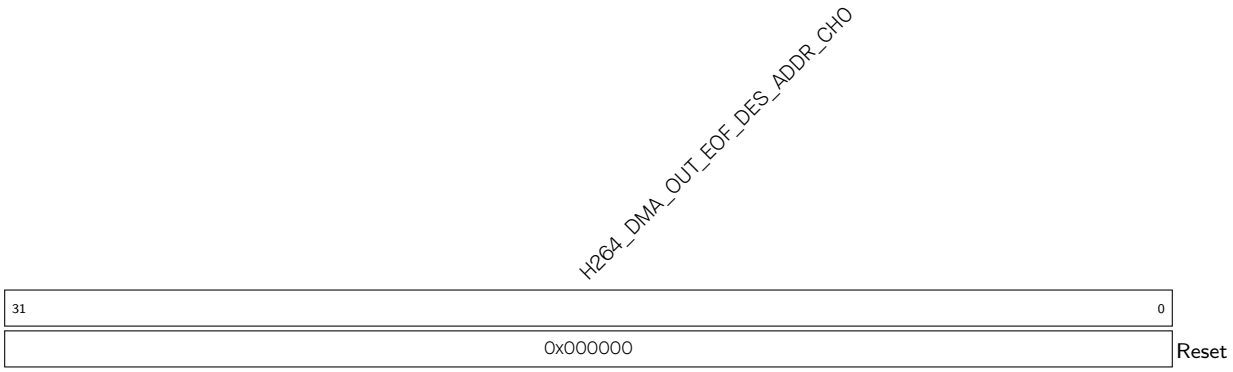
H264_DMA_OUTFIFO_CNT_L3_CH0 Represents the data quantity in l3 FIFO for TX channel 0. Measurement unit: 8 bytes. (RO)

Register 41.218. H264_DMA_OUT_STATE_CH0_REG (0x0024)

H264_DMA_OUTLINK_DSCR_ADDR_CH0 Represents the current outlink descriptor's address for TX channel 0. (RO)

H264_DMA_OUT_DSCR_STATE_CH0 Represents the current state of the descriptor state machine for TX channel 0. (RO)

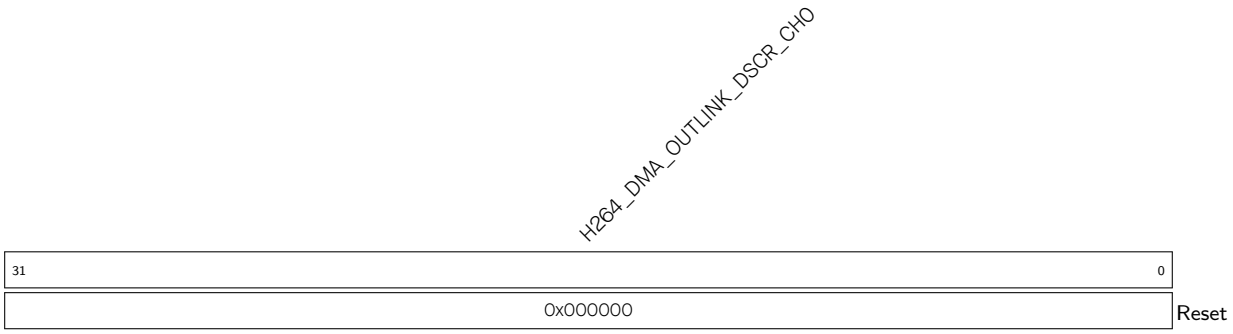
H264_DMA_OUT_STATE_CH0 Represents the current control module state machine state for TX channel 0. (RO)



H264_DMA_OUT_RESET_AVAIL_CH0 Represents whether it is safe to reset the channel.

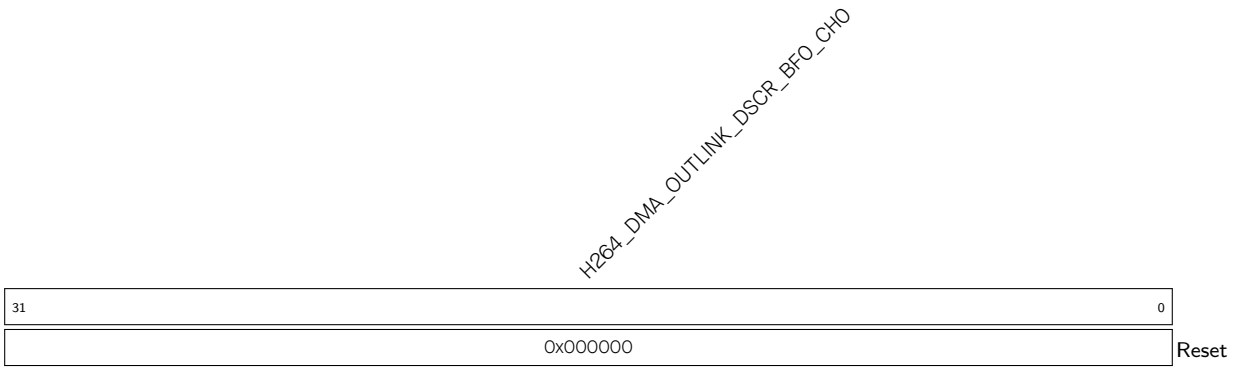
0: Unsafe

1: Safe



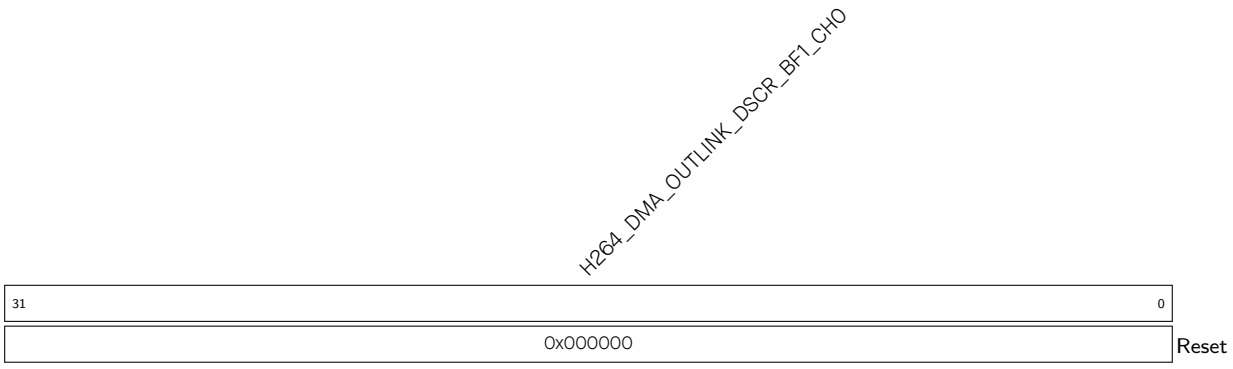
(RO)

Register 41.219. H264_DMA_OUT_EOF_DES_ADDR_CH0_REG (0x0028)



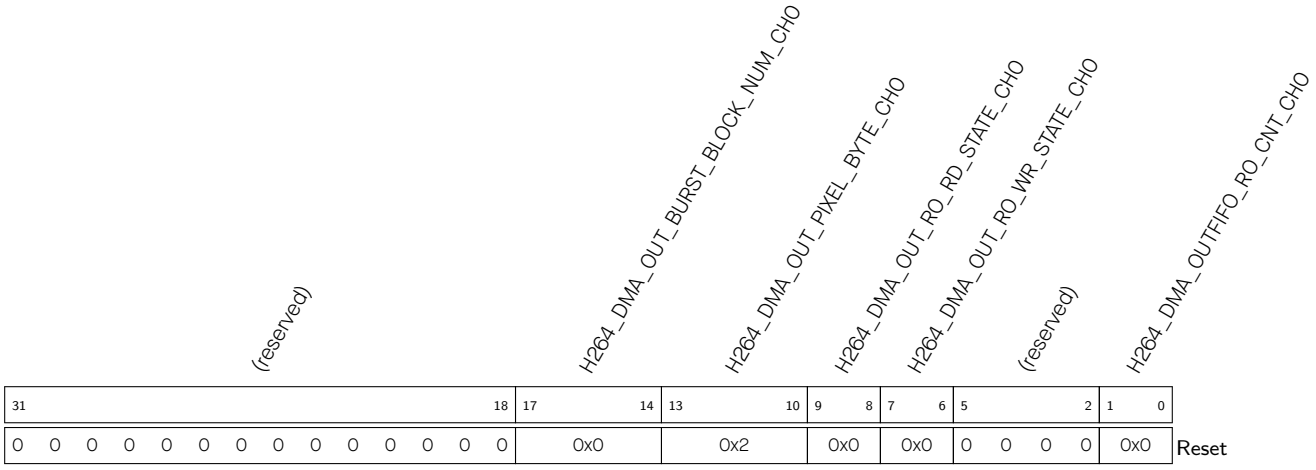
H264_DMA_OUT_EOF_DES_ADDR_CH0 Represents the address of the outlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.220. H264_DMA_OUT_DSCR_CH0_REG (0x002C)



H264_DMA_OUTLINK_DSCR_CH0 Represents the address of the next descriptor y+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.221. H264_DMA_OUT_DSCR_BF0_CH0_REG (0x0030)



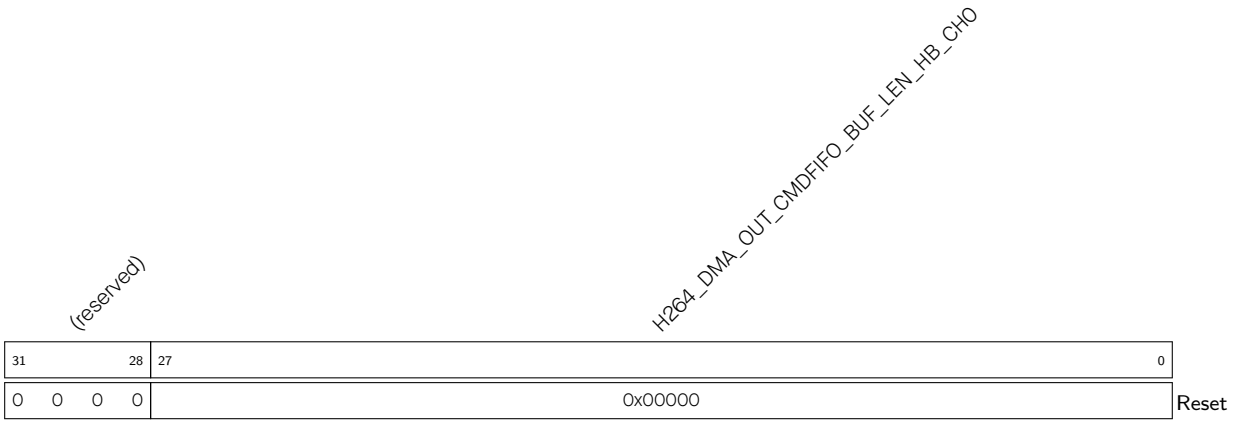
H264_DMA_OUTLINK_DSCR_BF0_CH0 Represents the address of the current descriptor y that is pre-read. (RO)

Register 41.222. H264_DMA_OUT_DSCR_BF1_CH0_REG (0x0034)

H264_DMA_OUTLINK_DSCR_BF1_CH0 Represents the address of the previous descriptor y-1 that is pre-read. (RO)

Register 41.223. H264_DMA_OUT_RO_STATUS_CH0_REG (0x0040)

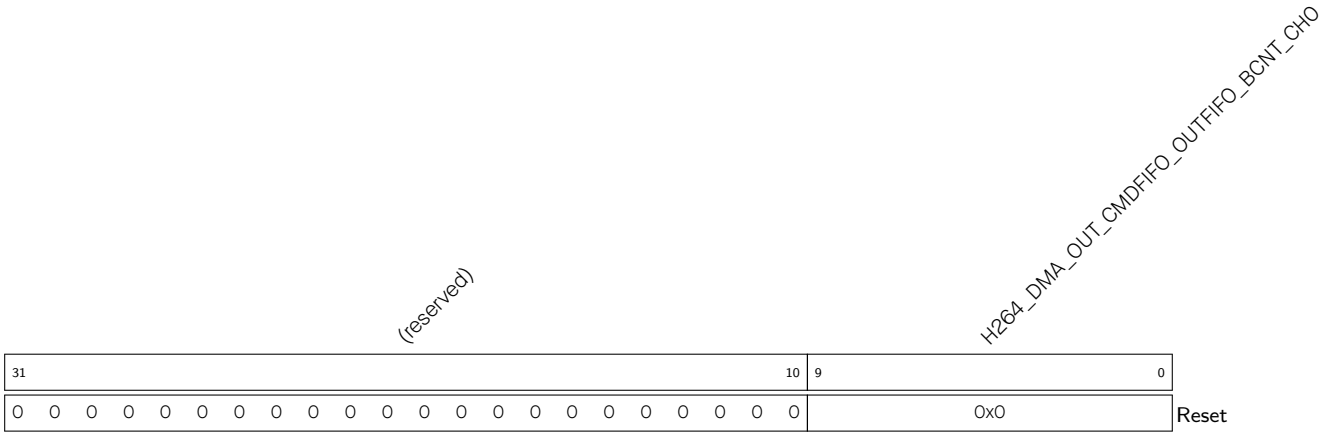
H264_DMA_OUTFIFO_RO_CNT_CH0 Represents the 8-byte number of the data in the reordered TX FIFO for channel 0. (RO)



H264_DMA_OUT_RO_WR_STATE_CH0 Represents the state of writing RAM for reorder. (RO)

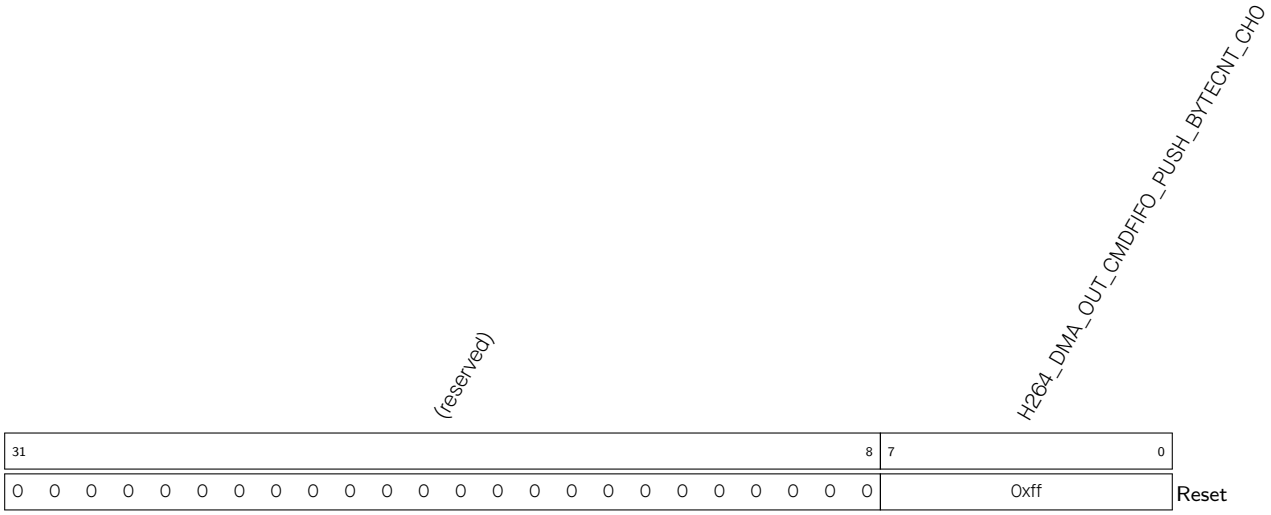
H264_DMA_OUT_RO_RD_STATE_CH0 Represents the state of reading RAM for reorder. (RO)

H264_DMA_OUT_PIXEL_BYTE_CH0 Represents the number of bytes contained in a pixel at TX channel 0.
0: 1 byte
1: 1.5 bytes
2: 2 bytes
3: 2.5 bytes
4: 3 bytes
5: 4 bytes
(RO)



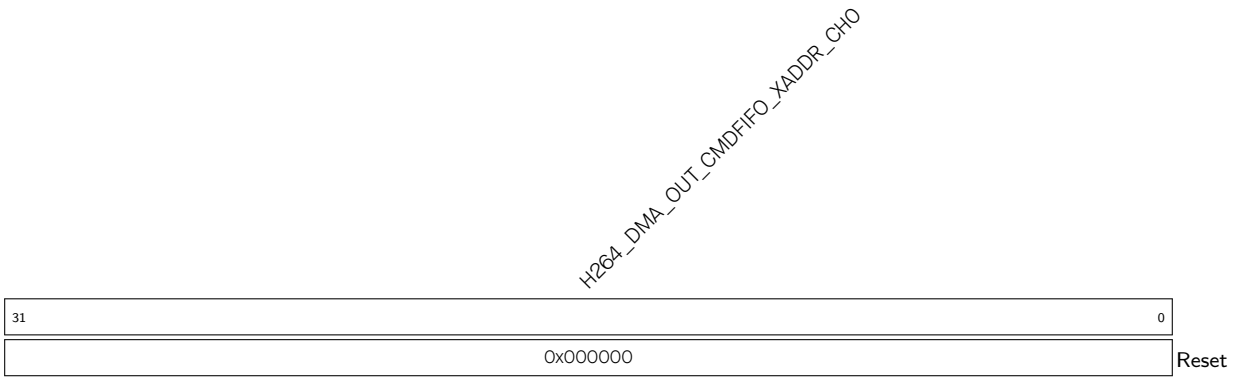
H264_DMA_OUT_BURST_BLOCK_NUM_CH0 Reserved. (RO)

Register 41.224. H264_DMA_OUT_BUF_LEN_CH0_REG (0x0070)



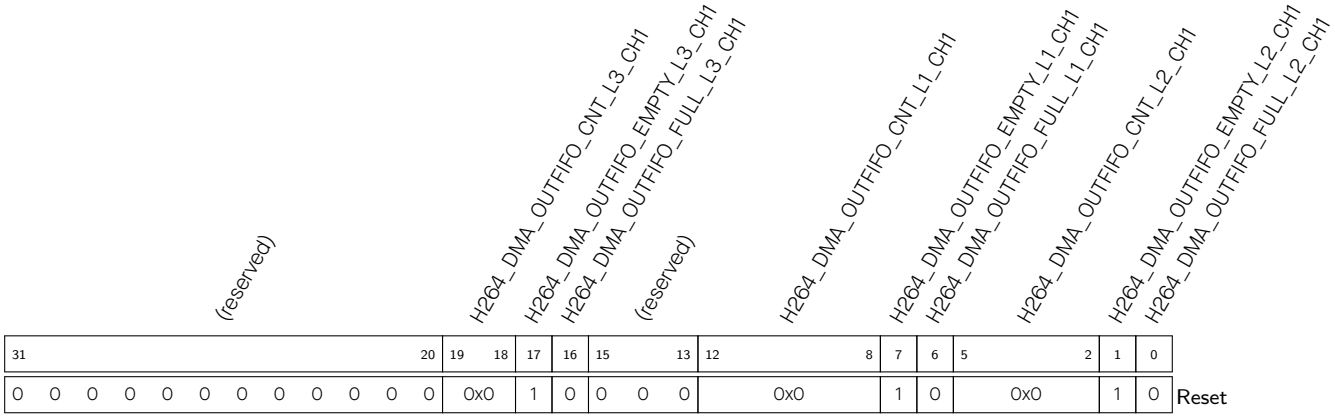
H264_DMA_OUT_CMDFIFO_BUF_LEN_HB_CH0 Represents the remaining request data. (RO)

Register 41.225. H264_DMA_OUT_FIFO_BCNT_CH0_REG (0x0074)



H264_DMA_OUT_CMDFIFO_OUTFIFO_BCNT_CH0 Represents that the data space has been used in FIFO. (RO)

Register 41.226. H264_DMA_OUT_PUSH_BYTECNT_CH0_REG (0x0078)



H264_DMA_OUT_CMDFIFO_PUSH_BYTECNT_CH0 Represents the data quantity in the current AXI request. (RO)

Register 41.227. H264_DMA_OUT_XADDR_CH0_REG (0x007C)

H264_DMA_OUT_CMDFIFO_XADDR_CH0 Represents the address of the current AXI request. (RO)

Register 41.228. H264_DMA_OUTFIFO_STATUS_CH1_REG (0x0114)

H264_DMA_OUTFIFO_FULL_L2_CH1 Represents whether l2 FIFO of TX channel 1 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L2_CH1 Represents whether l2 FIFO of TX channel 1 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L2_CH1 Represents the data quantity in l2 FIFO for TX channel 1. Measurement unit: 16 bytes. (RO)

H264_DMA_OUTFIFO_FULL_L1_CH1 Represents whether l1 FIFO of TX channel 1 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L1_CH1 Represents whether l1 FIFO of TX channel 1 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L1_CH1 Represents the data quantity in l1 FIFO for TX channel 1. Measurement unit: byte. (RO)

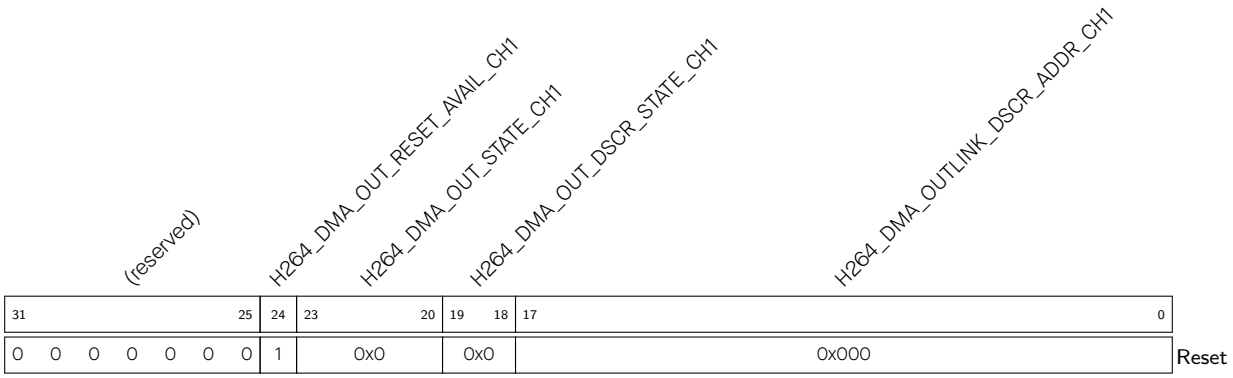
H264_DMA_OUTFIFO_FULL_L3_CH1 Represents whether l3 FIFO of TX channel 1 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L3_CH1 Represents whether l3 FIFO of TX channel 1 is empty.



0: Not empty

1: Empty

(RO)

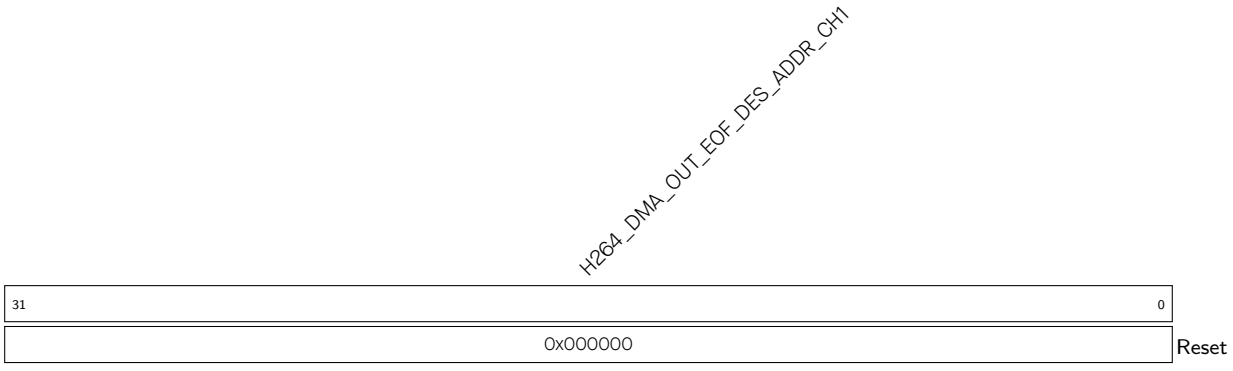
H264_DMA_OUTFIFO_CNT_L3_CH1 Represents the data quantity in l3 FIFO for TX channel 1. Measurement unit: 8 bytes. (RO)

Register 41.229. H264_DMA_OUT_STATE_CH1_REG (0x0124)

H264_DMA_OUTLINK_DSCR_ADDR_CH1 Represents the current outlink descriptor's address for TX channel 1. (RO)

H264_DMA_OUT_DSCR_STATE_CH1 Represents the current state of the descriptor state machine for TX channel 1. (RO)

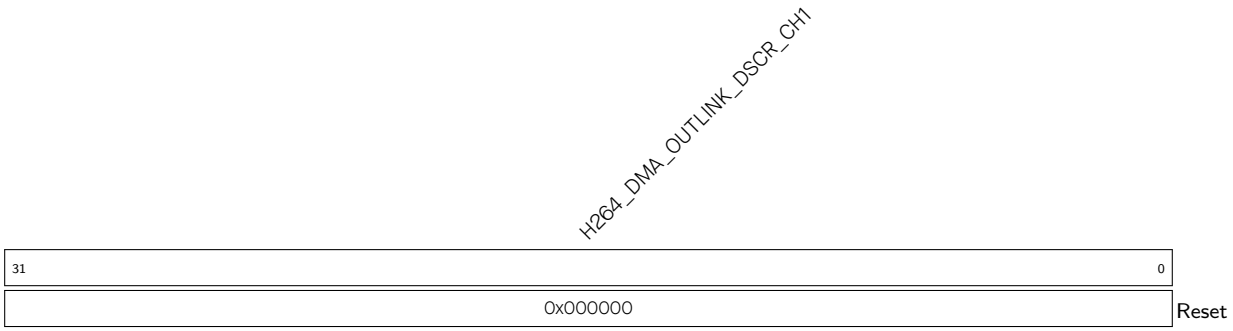
H264_DMA_OUT_STATE_CH1 Represents the current control module state machine state for TX channel 1. (RO)



H264_DMA_OUT_RESET_AVAIL_CH1 Represents whether it is safe to reset the channel.

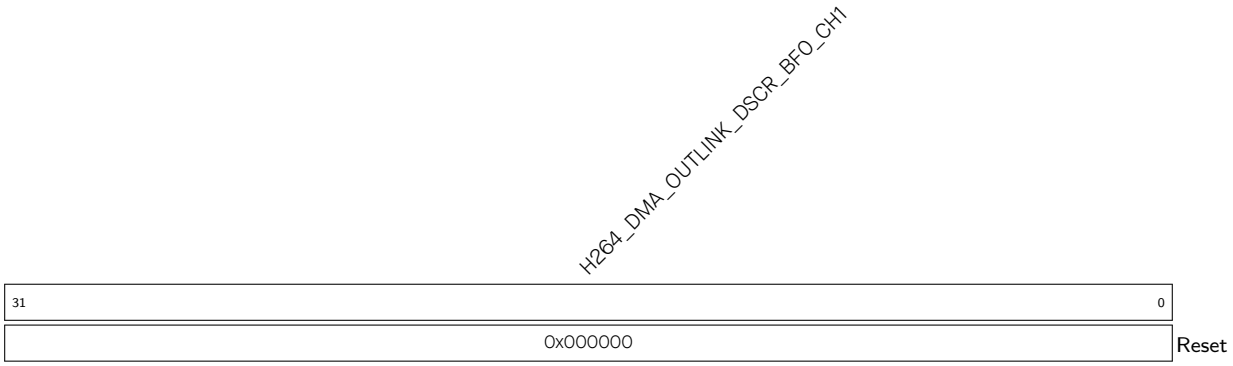
0: Unsafe

1: Safe



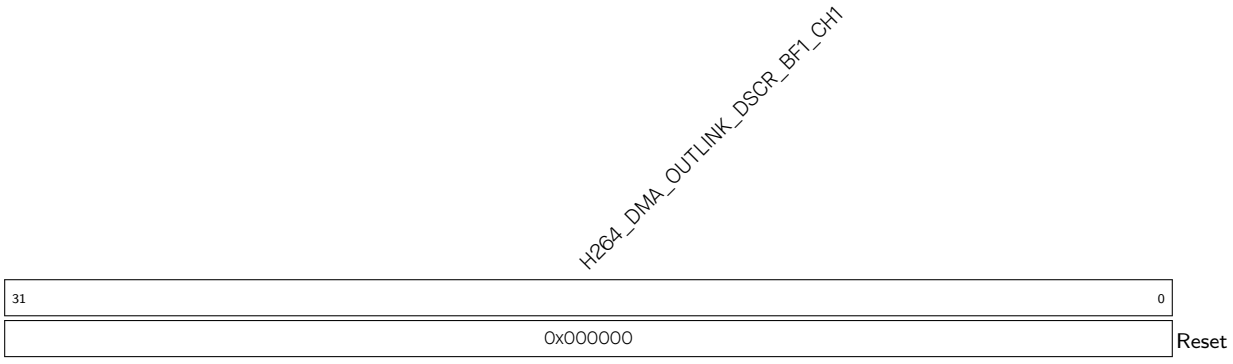
(RO)

Register 41.230. H264_DMA_OUT_EOF_DES_ADDR_CH1_REG (0x0128)



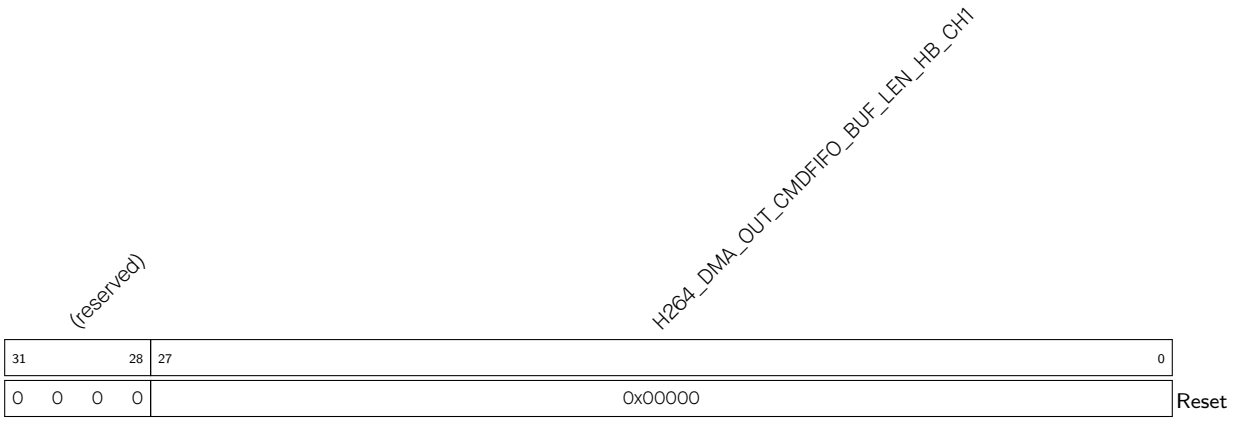
H264_DMA_OUT_EOF_DES_ADDR_CH1 Represents the address of the outlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.231. H264_DMA_OUT_DSCR_CH1_REG (0x012C)



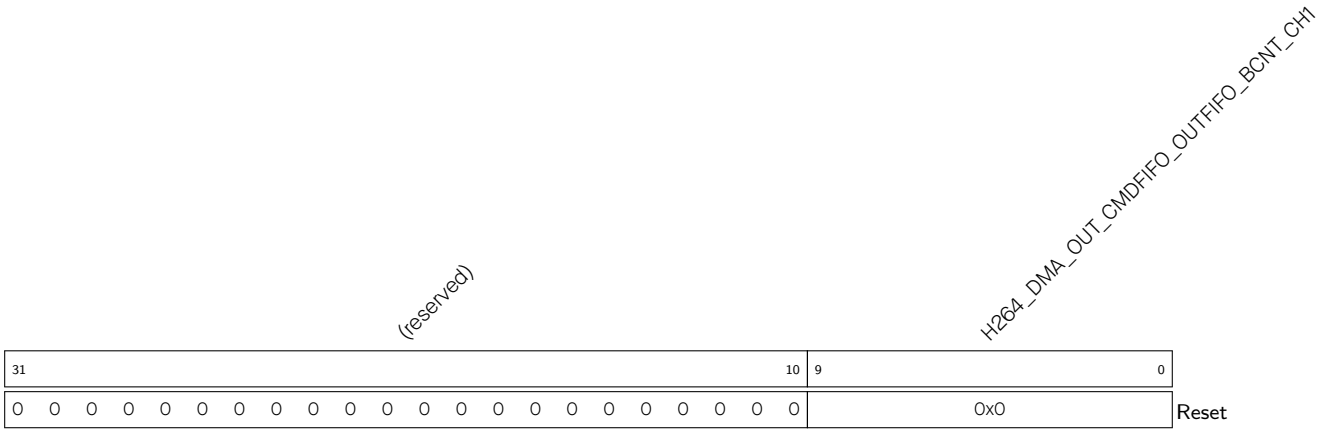
H264_DMA_OUTLINK_DSCR_CH1 Represents the address of the next descriptor y+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.232. H264_DMA_OUT_DSCR_BF0_CH1_REG (0x0130)



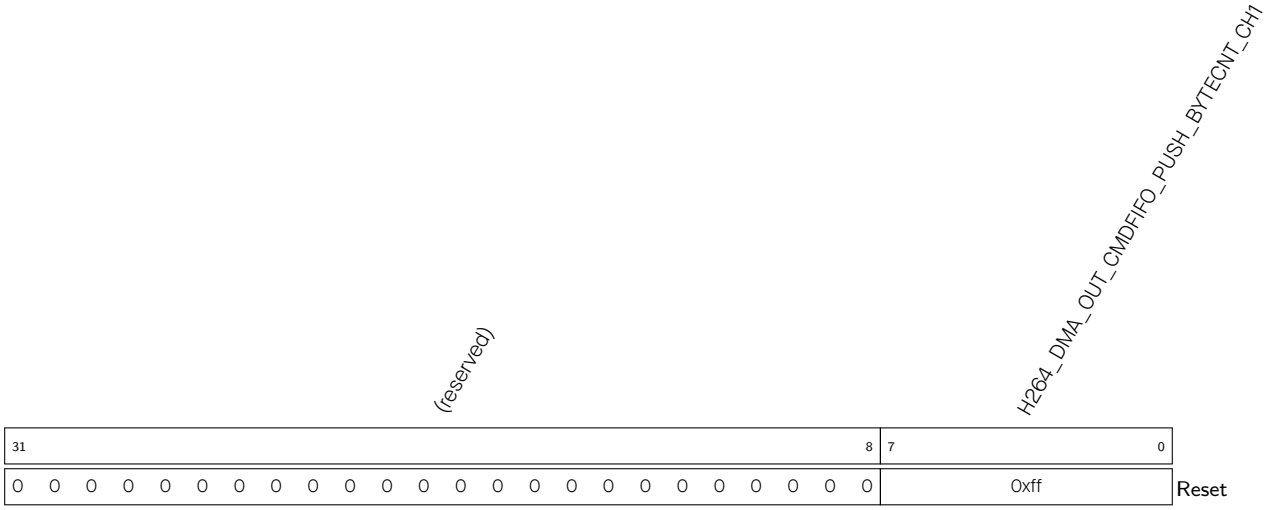
H264_DMA_OUTLINK_DSCR_BF0_CH1 Represents the address of the current descriptor y that is pre-read. (RO)

Register 41.233. H264_DMA_OUT_DSCR_BF1_CH1_REG (0x0134)



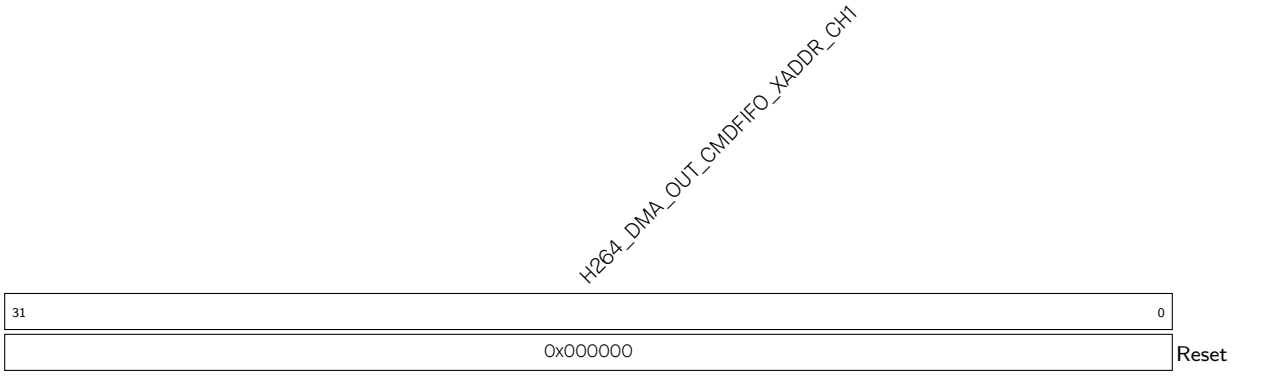
H264_DMA_OUTLINK_DSCR_BF1_CH1 Represents the address of the previous descriptor y-1 that is pre-read. (RO)

Register 41.234. H264_DMA_OUT_BUF_LEN_CH1_REG (0x0170)



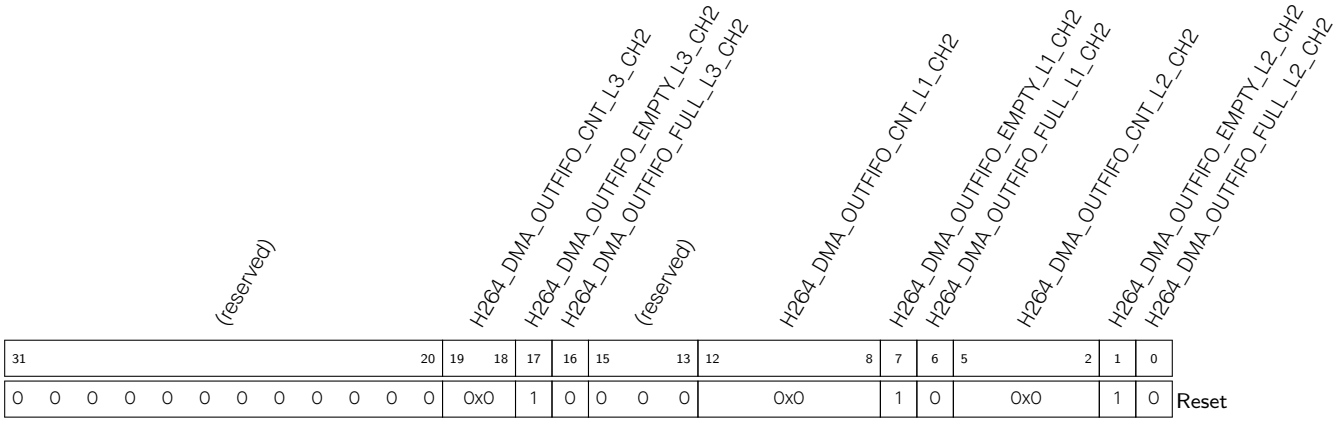
H264_DMA_OUT_CMDFIFO_BUF_LEN_HB_CH1 Represents the remaining request data. (RO)

Register 41.235. H264_DMA_OUT_FIFO_BCNT_CH1_REG (0x0174)



H264_DMA_OUT_CMDFIFO_OUTFIFO_BCNT_CH1 Represents that the data space has been used in FIFO. (RO)

Register 41.236. H264_DMA_OUT_PUSH_BYTECNT_CH1_REG (0x0178)



H264_DMA_OUT_CMDFIFO_PUSH_BYTECNT_CH1 Represents the data quantity in the current AXI request. (RO)

Register 41.237. H264_DMA_OUT_XADDR_CH1_REG (0x017C)

H264_DMA_OUT_CMDFIFO_XADDR_CH1 Represents the address of the current AXI request. (RO)

Register 41.238. H264_DMA_OUTFIFO_STATUS_CH2_REG (0x0214)

H264_DMA_OUTFIFO_FULL_L2_CH2 Represents whether l2 FIFO of TX channel 2 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L2_CH2 Represents whether l2 FIFO of TX channel 2 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L2_CH2 Represents the data quantity in l2 FIFO for TX channel 2. Measurement unit: 16 bytes. (RO)

H264_DMA_OUTFIFO_FULL_L1_CH2 Represents whether l1 FIFO of TX channel 2 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L1_CH2 Represents whether l1 FIFO of TX channel 2 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L1_CH2 Represents the data quantity in l1 FIFO for TX channel 2. Measurement unit: byte. (RO)

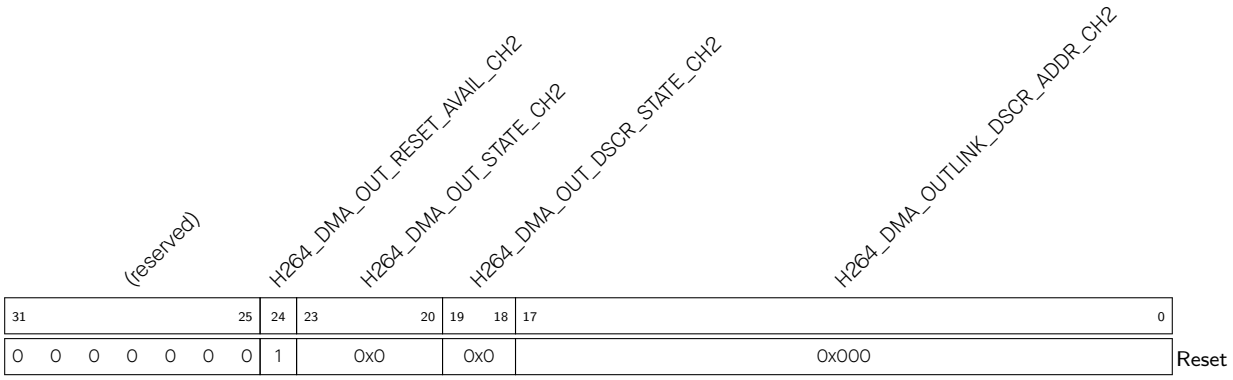
H264_DMA_OUTFIFO_FULL_L3_CH2 Represents whether l3 FIFO of TX channel 2 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L3_CH2 Represents whether l3 FIFO of TX channel 2 is empty.



0: Not empty

1: Empty

(RO)

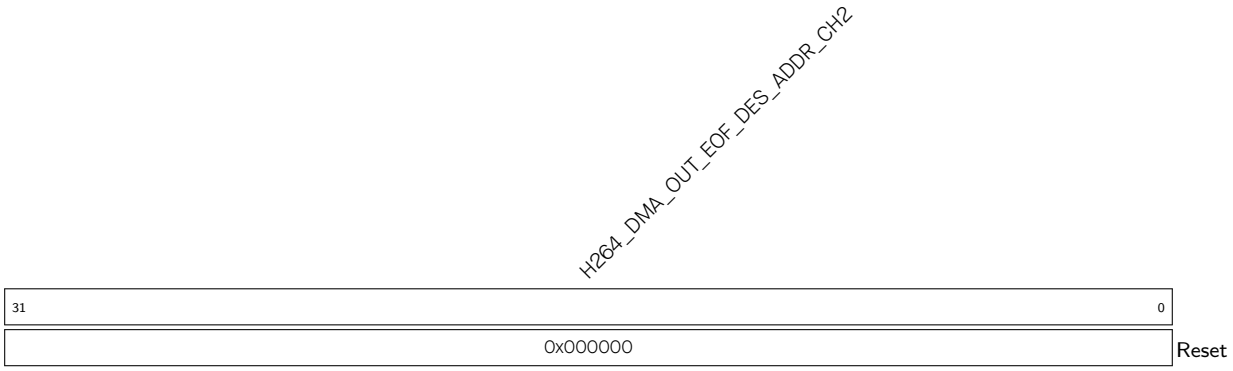
H264_DMA_OUTFIFO_CNT_L3_CH2 Represents the data quantity in l3 FIFO for TX channel 2. Measurement unit: 8 bytes. (RO)

Register 41.239. H264_DMA_OUT_STATE_CH2_REG (0x0224)

H264_DMA_OUTLINK_DSCR_ADDR_CH2 Represents the current outlink descriptor's address for TX channel 2. (RO)

H264_DMA_OUT_DSCR_STATE_CH2 Represents the current state of the descriptor state machine for TX channel 2. (RO)

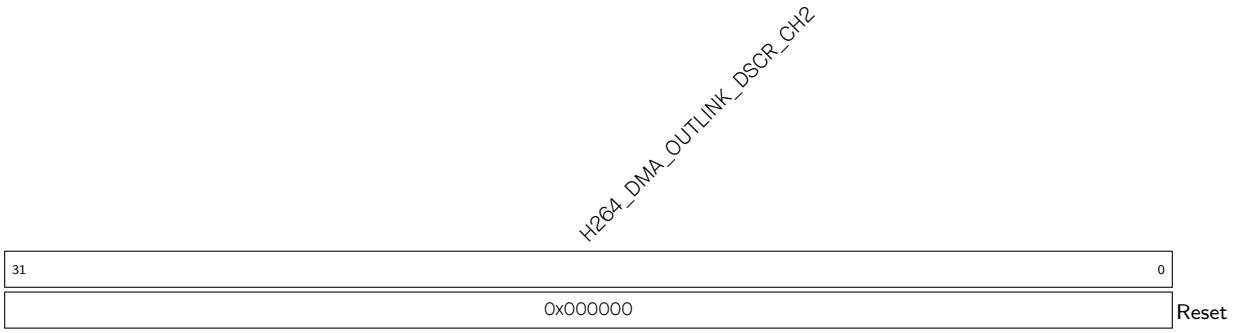
H264_DMA_OUT_STATE_CH2 Represents the current control module state machine state for TX channel 2. (RO)



H264_DMA_OUT_RESET_AVAIL_CH2 Represents whether it is safe to reset the channel.

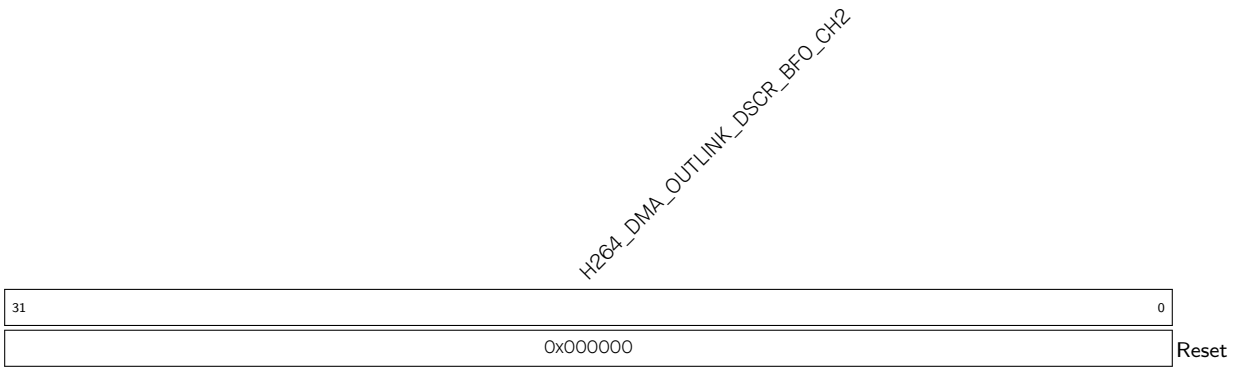
0: Unsafe

1: Safe



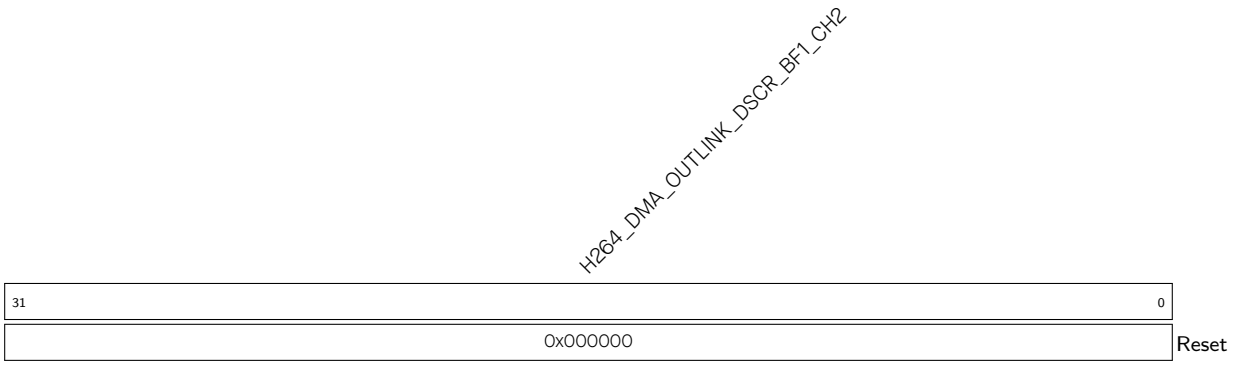
(RO)

Register 41.240. H264_DMA_OUT_EOF_DES_ADDR_CH2_REG (0x0228)



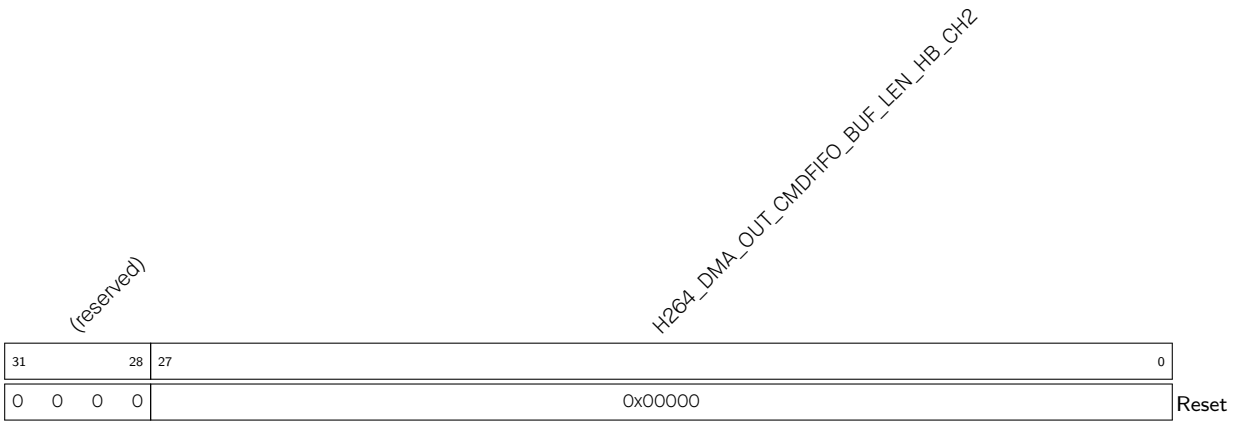
H264_DMA_OUT_EOF_DES_ADDR_CH2 Represents the address of the inlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.241. H264_DMA_OUT_DSCR_CH2_REG (0x022C)



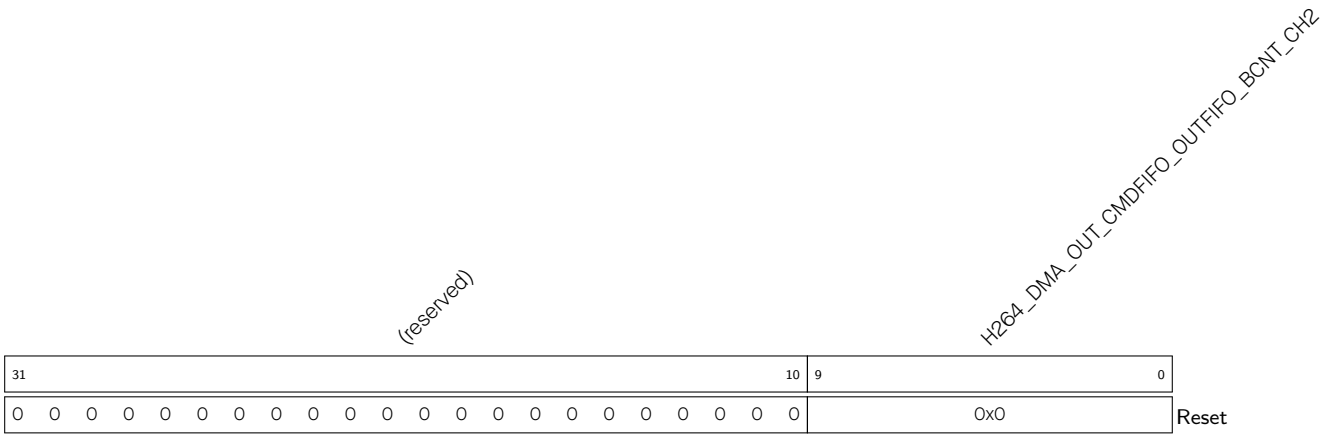
H264_DMA_OUTLINK_DSCR_CH2 Represents the address of the next descriptor y+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.242. H264_DMA_OUT_DSCR_BF0_CH2_REG (0x0230)



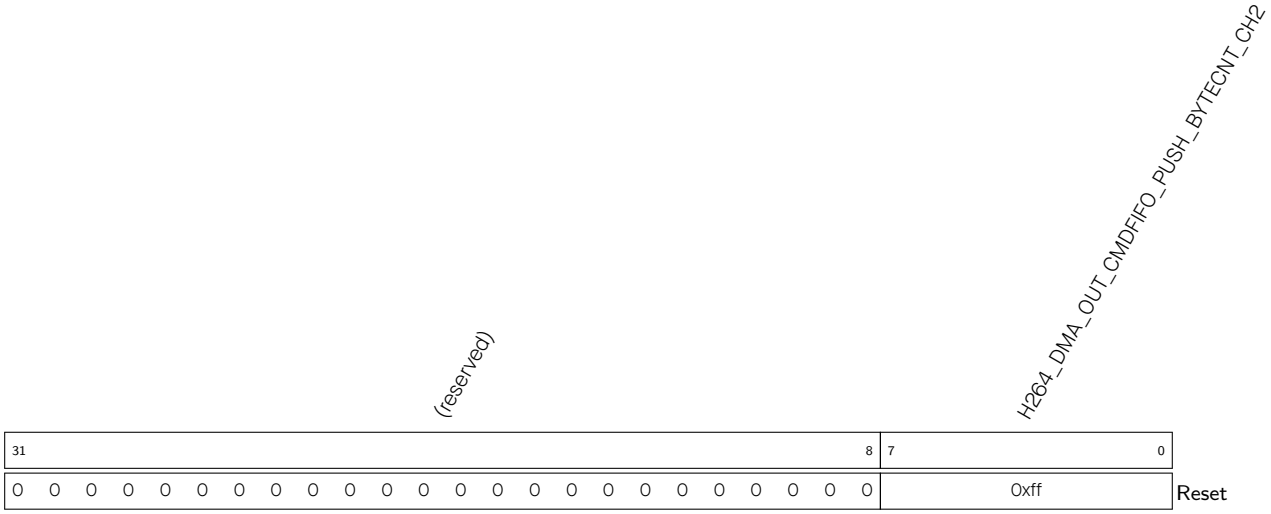
H264_DMA_OUTLINK_DSCR_BF0_CH2 Represents the address of the current descriptor y that is pre-read. (RO)

Register 41.243. H264_DMA_OUT_DSCR_BF1_CH2_REG (0x0234)



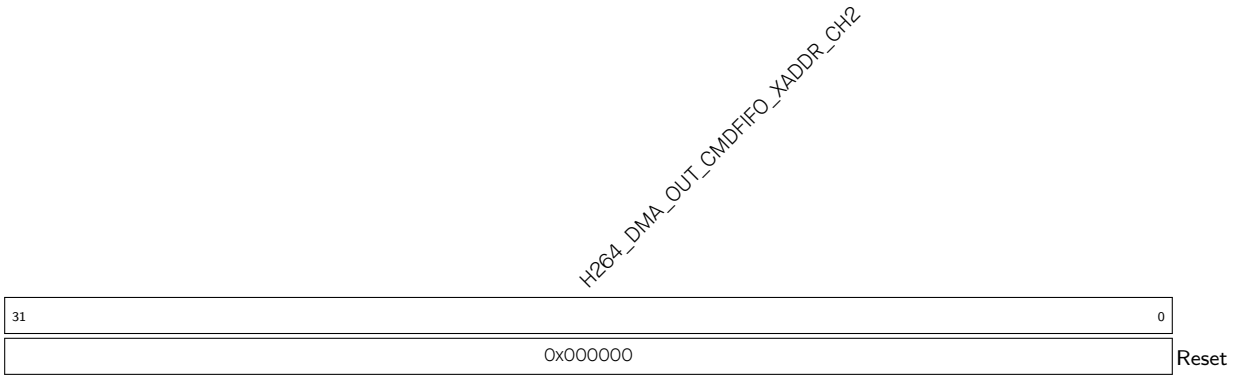
H264_DMA_OUTLINK_DSCR_BF1_CH2 Represents the address of the previous descriptor y-1 that is pre-read. (RO)

Register 41.244. H264_DMA_OUT_BUF_LEN_CH2_REG (0x0270)



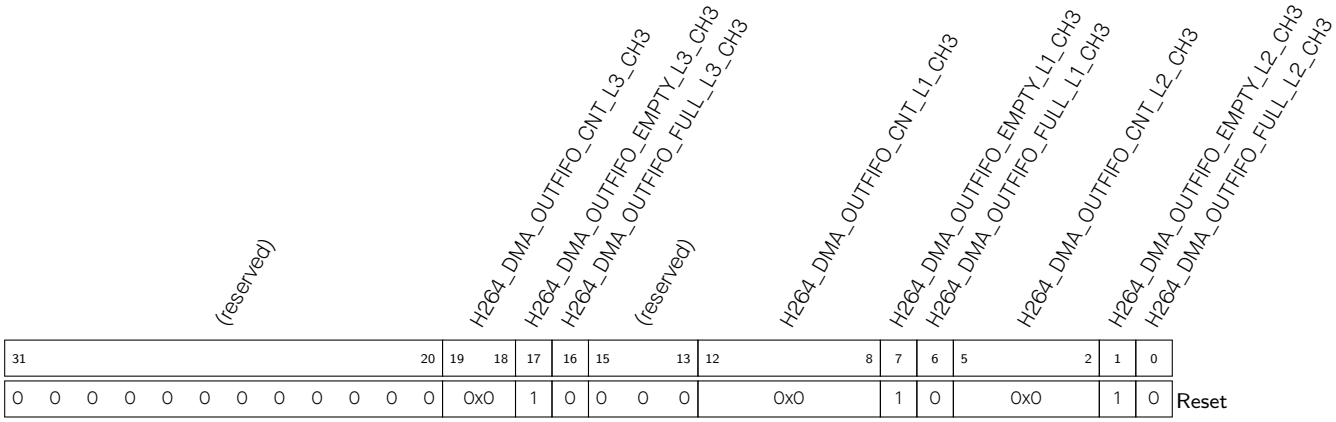
H264_DMA_OUT_CMDFIFO_BUF_LEN_HB_CH2 Represents the remaining request data. (RO)

Register 41.245. H264_DMA_OUT_FIFO_BCNT_CH2_REG (0x0274)



H264_DMA_OUT_CMDFIFO_OUTFIFO_BCNT_CH2 Represents that the data space has been used in FIFO. (RO)

Register 41.246. H264_DMA_OUT_PUSH_BYTECNT_CH2_REG (0x0278)



H264_DMA_OUT_CMDFIFO_PUSH_BYTECNT_CH2 Represents the data quantity in the current AXI request. (RO)

Register 41.247. H264_DMA_OUT_XADDR_CH2_REG (0x027C)

H264_DMA_OUT_CMDFIFO_XADDR_CH2 Represents the address of the current AXI request. (RO)

Register 41.248. H264_DMA_OUTFIFO_STATUS_CH3_REG (0x0314)

H264_DMA_OUTFIFO_FULL_L2_CH3 Represents whether l2 FIFO of TX channel 3 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L2_CH3 Represents whether l2 FIFO of TX channel 3 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L2_CH3 Represents the data quantity in l2 FIFO for TX channel 3. Measurement unit: 16 bytes. (RO)

H264_DMA_OUTFIFO_FULL_L1_CH3 Represents whether l1 FIFO of TX channel 3 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L1_CH3 Represents whether l1 FIFO of TX channel 3 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L1_CH3 Represents the data quantity in l1 FIFO for TX channel 3. Measurement unit: byte. (RO)

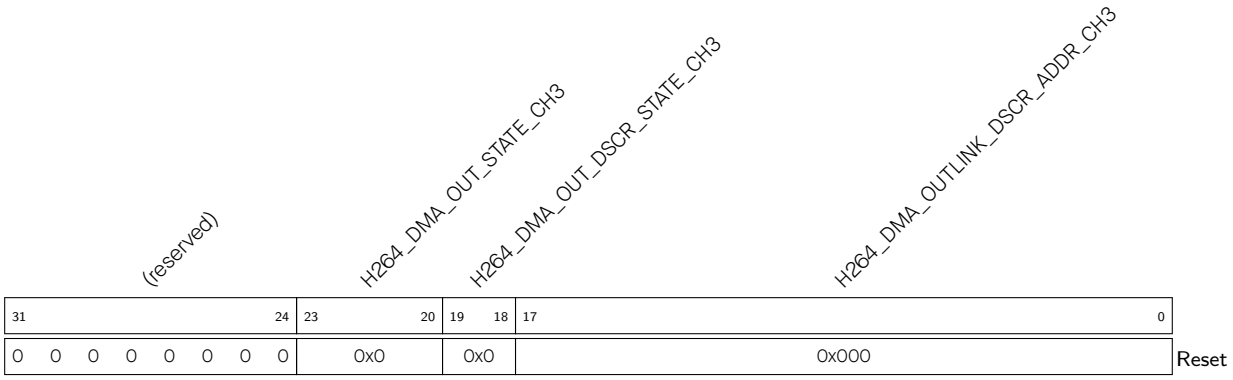
H264_DMA_OUTFIFO_FULL_L3_CH3 Represents whether l3 FIFO of TX channel 3 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L3_CH3 Represents whether l3 FIFO of TX channel 3 is empty.



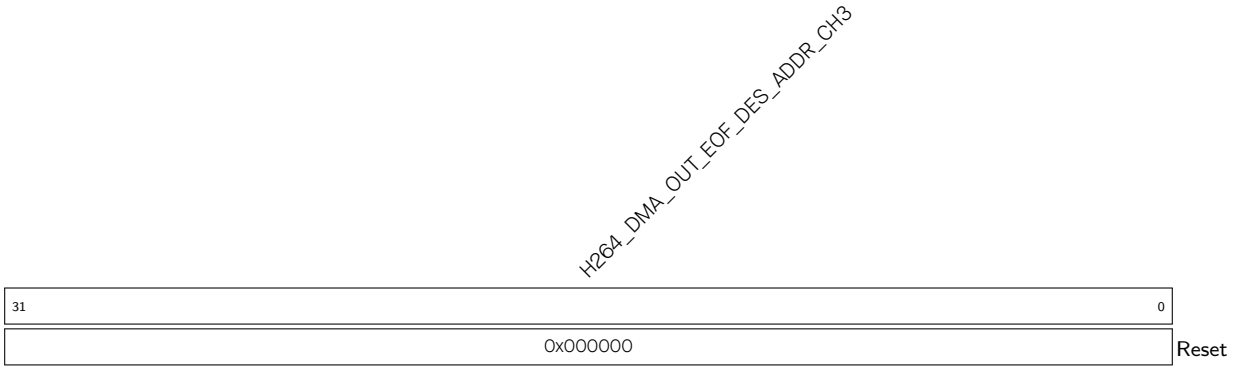
0: Not empty

1: Empty

(RO)

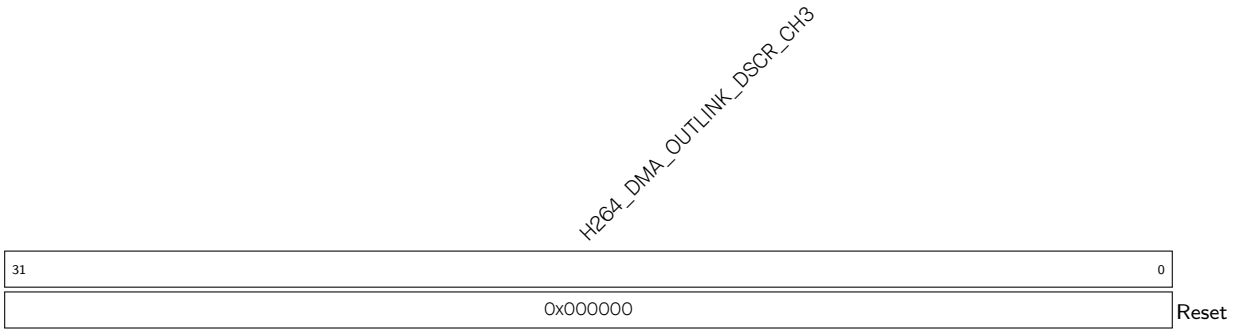
H264_DMA_OUTFIFO_CNT_L3_CH3 Represents the data quantity in l3 FIFO for TX channel 3. Measurement unit: 8 bytes. (RO)

Register 41.249. H264_DMA_OUT_STATE_CH3_REG (0x0324)



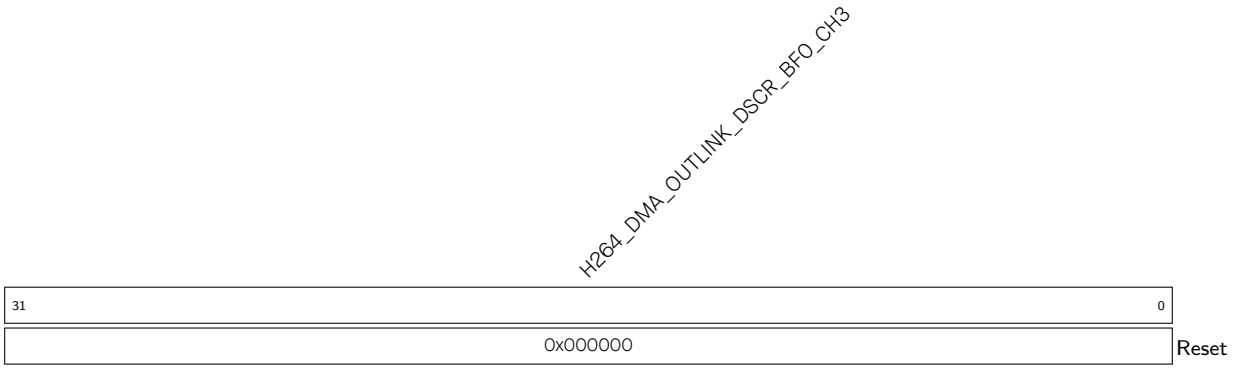
H264_DMA_OUTLINK_DSCR_ADDR_CH3 Represents the current outlink descriptor's address for TX channel 3. (RO)

H264_DMA_OUT_DSCR_STATE_CH3 Represents the current state of the descriptor state machine for TX channel 3. (RO)



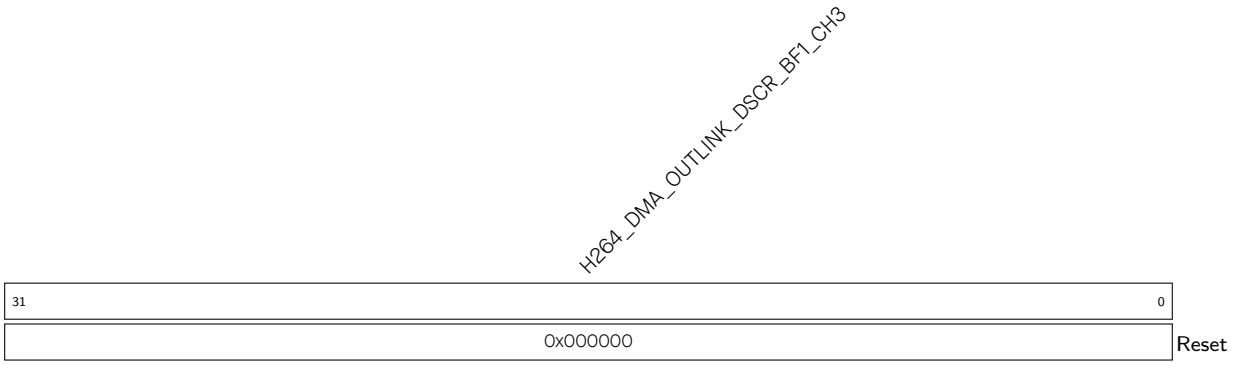
H264_DMA_OUT_STATE_CH3 Represents the current control module state machine state for TX channel 3. (RO)

Register 41.250. H264_DMA_OUT_EOF_DES_ADDR_CH3_REG (0x0328)



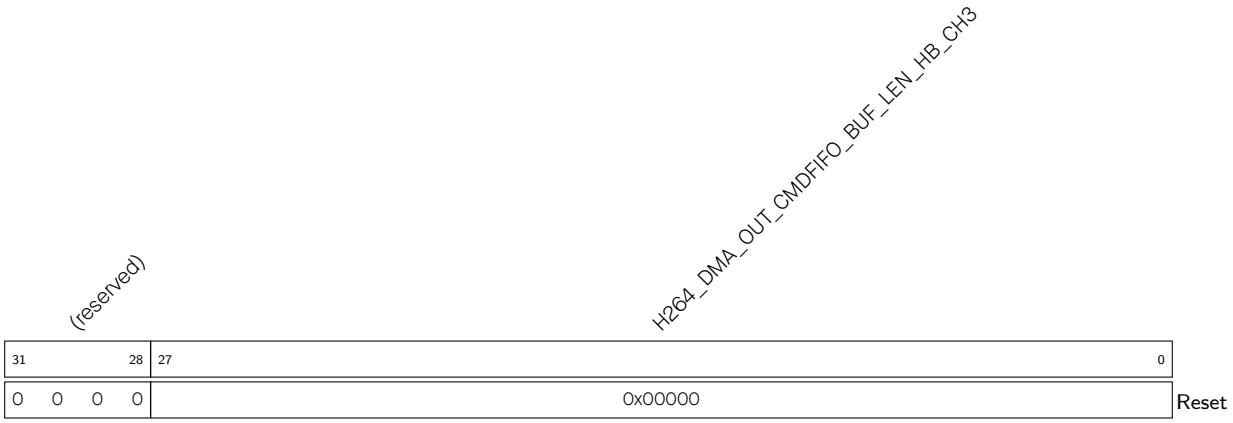
H264_DMA_OUT_EOF_DES_ADDR_CH3 Represents the address of the inlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.251. H264_DMA_OUT_DSCR_CH3_REG (0x032C)



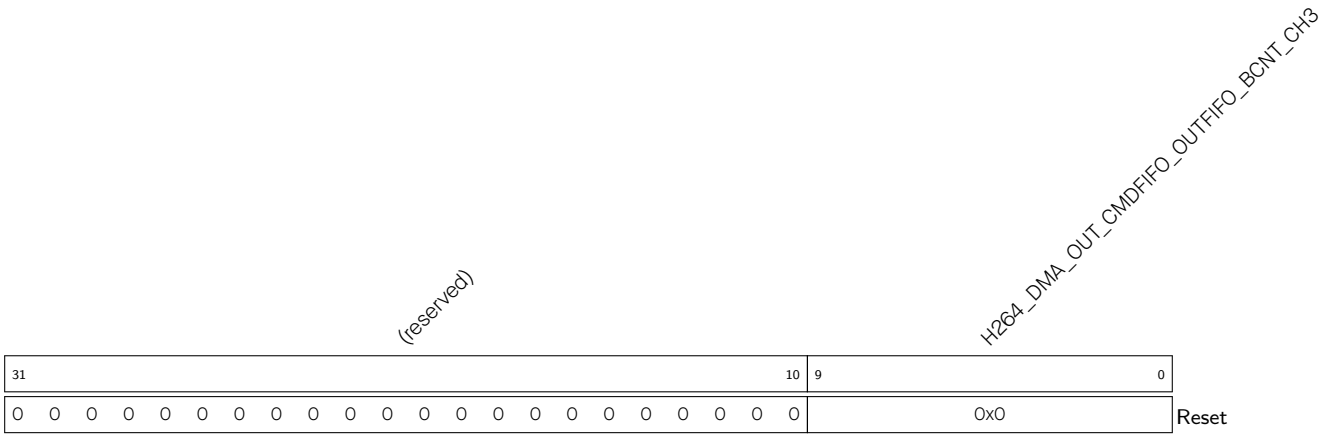
H264_DMA_OUTLINK_DSCR_CH3 Represents the address of the next descriptor y+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.252. H264_DMA_OUT_DSCR_BF0_CH3_REG (0x0330)



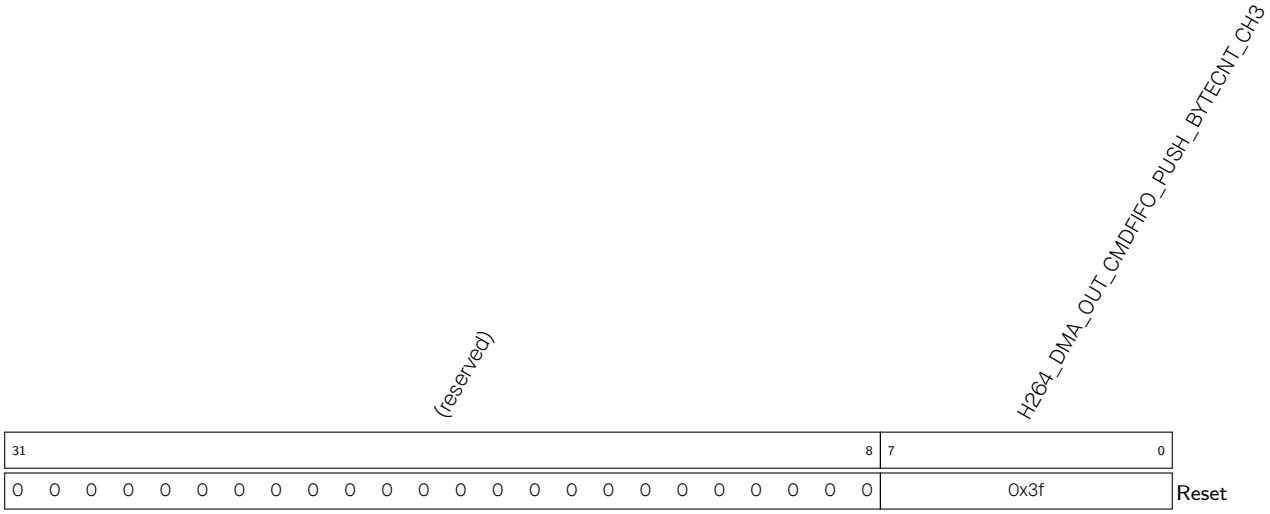
H264_DMA_OUTLINK_DSCR_BF0_CH3 Represents the address of the current descriptor y that is pre-read. (RO)

Register 41.253. H264_DMA_OUT_DSCR_BF1_CH3_REG (0x0334)



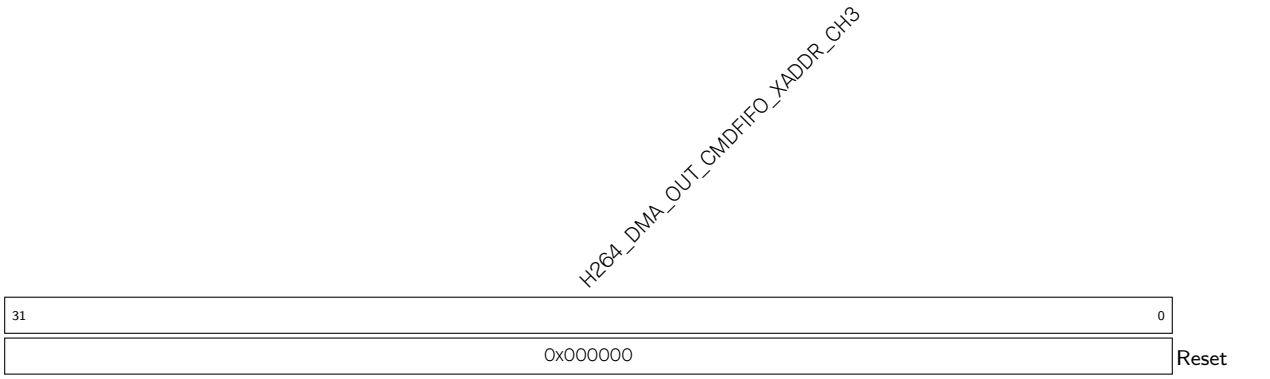
H264_DMA_OUTLINK_DSCR_BF1_CH3 Represents the address of the previous descriptor y-1 that is pre-read. (RO)

Register 41.254. H264_DMA_OUT_BUF_LEN_CH3_REG (0x0370)



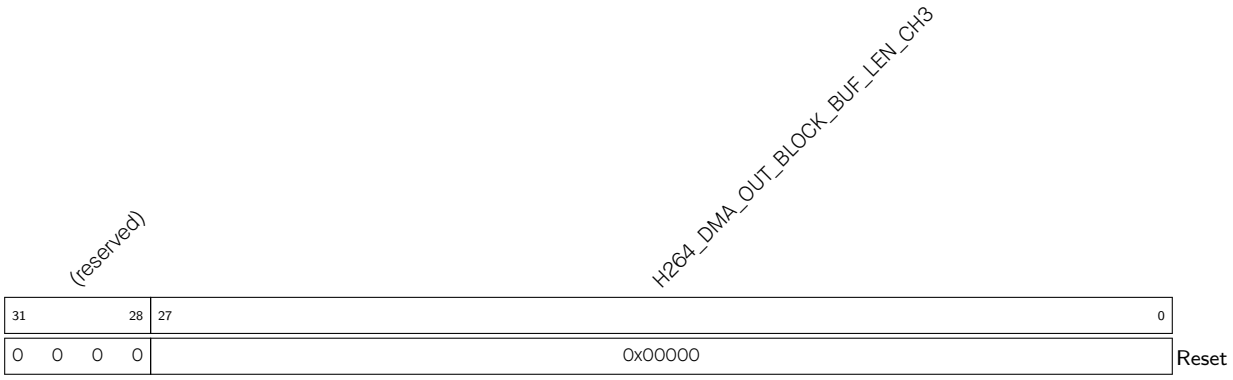
H264_DMA_OUT_CMDFIFO_BUF_LEN_HB_CH3 Represents the remaining request data. (RO)

Register 41.255. H264_DMA_OUT_FIFO_BCNT_CH3_REG (0x0374)



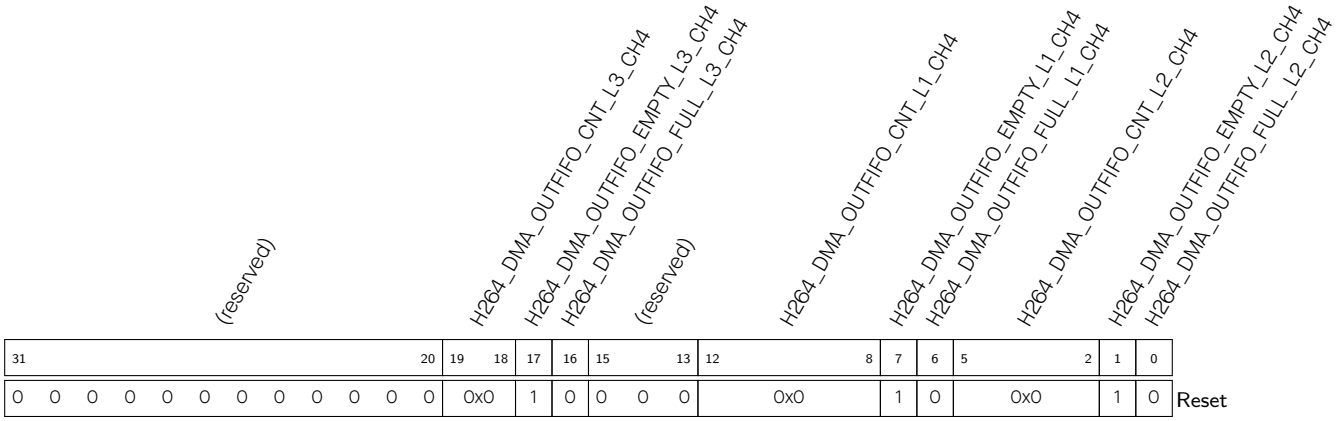
H264_DMA_OUT_CMDFIFO_OUTFIFO_BCNT_CH3 Represents that the data space has been used in FIFO. (RO)

Register 41.256. H264_DMA_OUT_PUSH_BYTECNT_CH3_REG (0x0378)



H264_DMA_OUT_CMDFIFO_PUSH_BYTECNT_CH3 Represents the data quantity in the current AXI request. (RO)

Register 41.257. H264_DMA_OUT_XADDR_CH3_REG (0x037C)



H264_DMA_OUT_CMDFIFO_XADDR_CH3 Represents the address of the current AXI request. (RO)

Register 41.258. H264_DMA_OUT_BLOCK_BUF_LEN_CH3_REG (0x0380)

H264_DMA_OUT_BLOCK_BUF_LEN_CH3 Represents the remaining block request data. (RO)

Register 41.259. H264_DMA_OUTFIFO_STATUS_CH4_REG (0x0414)

H264_DMA_OUTFIFO_FULL_L2_CH4 Represents whether l2 FIFO of TX channel 4 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L2_CH4 Represents whether l2 FIFO of TX channel 4 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_OUTFIFO_CNT_L1_CH4 Represents the data quantity in l1 FIFO for TX channel 4. Measurement unit: byte. (RO)

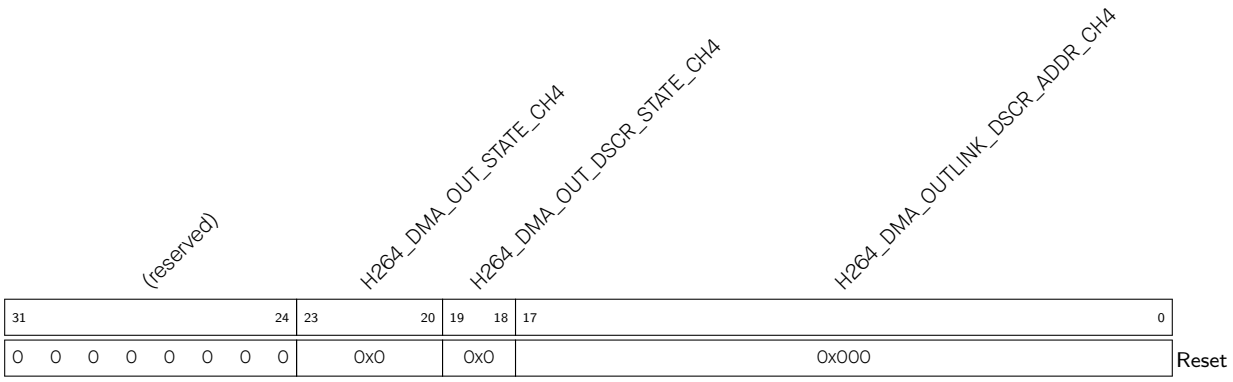
H264_DMA_OUTFIFO_FULL_L3_CH4 Represents whether l3 FIFO of TX channel 4 is full.

0: Not Full

1: Full

(RO)

H264_DMA_OUTFIFO_EMPTY_L3_CH4 Represents whether l3 FIFO of TX channel 4 is empty.



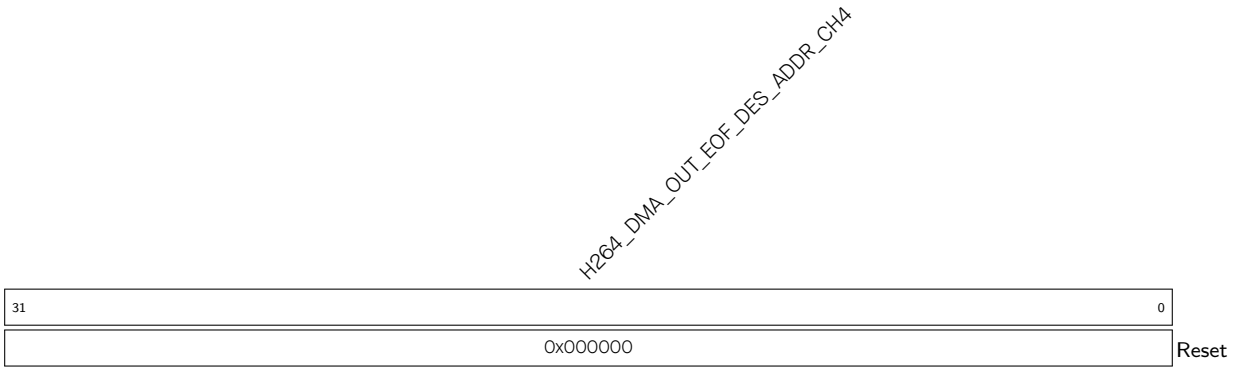
0: Not empty

1: Empty

(RO)

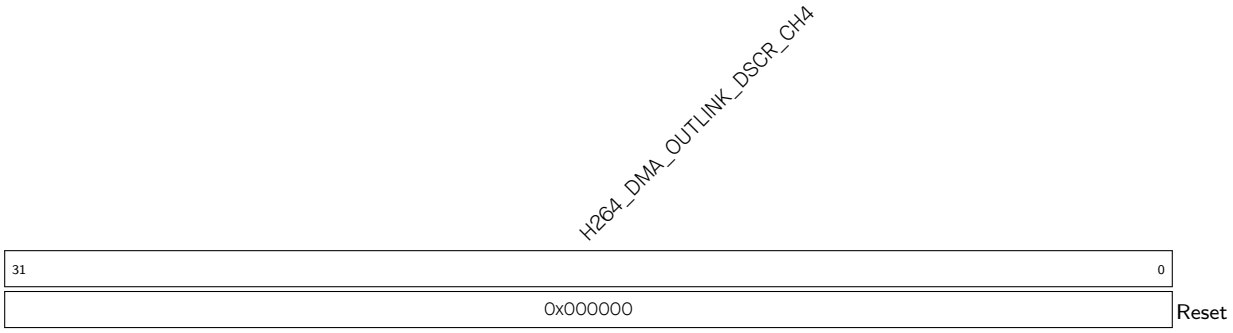
H264_DMA_OUTFIFO_CNT_L3_CH4 Represents the data quantity in l3 FIFO for TX channel 4. Measurement unit: 8 bytes. (RO)

Register 41.260. H264_DMA_OUT_STATE_CH4_REG (0x0424)



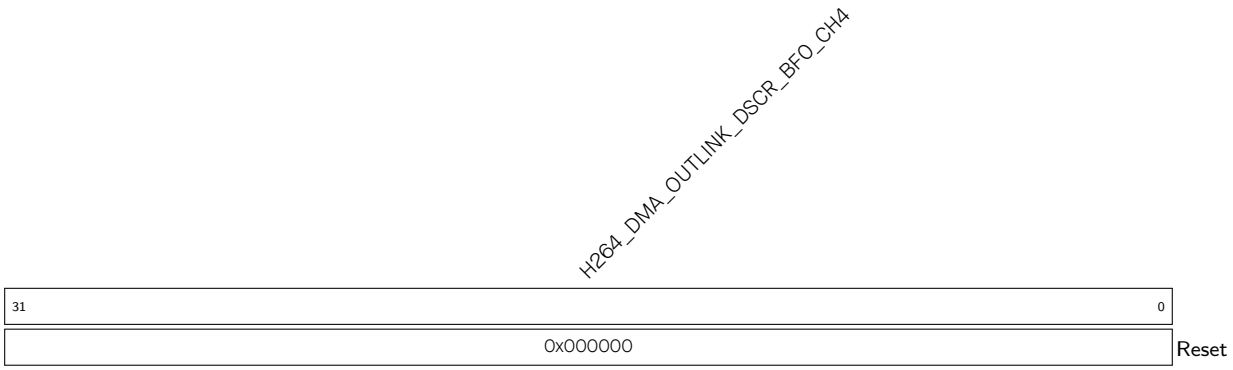
H264_DMA_OUTLINK_DSCR_ADDR_CH4 Represents the current outlink descriptor's address for TX channel 4. (RO)

H264_DMA_OUT_DSCR_STATE_CH4 Represents the current state of the descriptor state machine for TX channel 4. (RO)



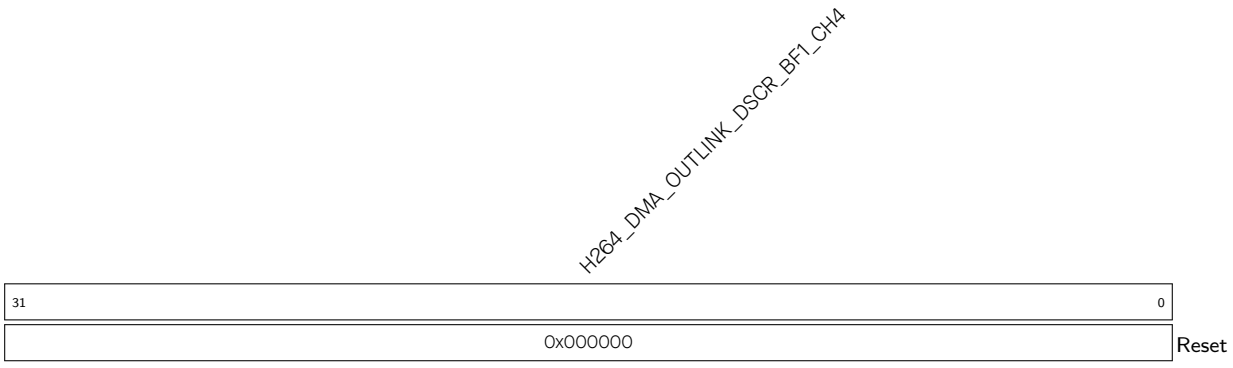
H264_DMA_OUT_STATE_CH4 Represents the current control module state machine state for TX channel 4. (RO)

Register 41.261. H264_DMA_OUT_EOF_DES_ADDR_CH4_REG (0x0428)



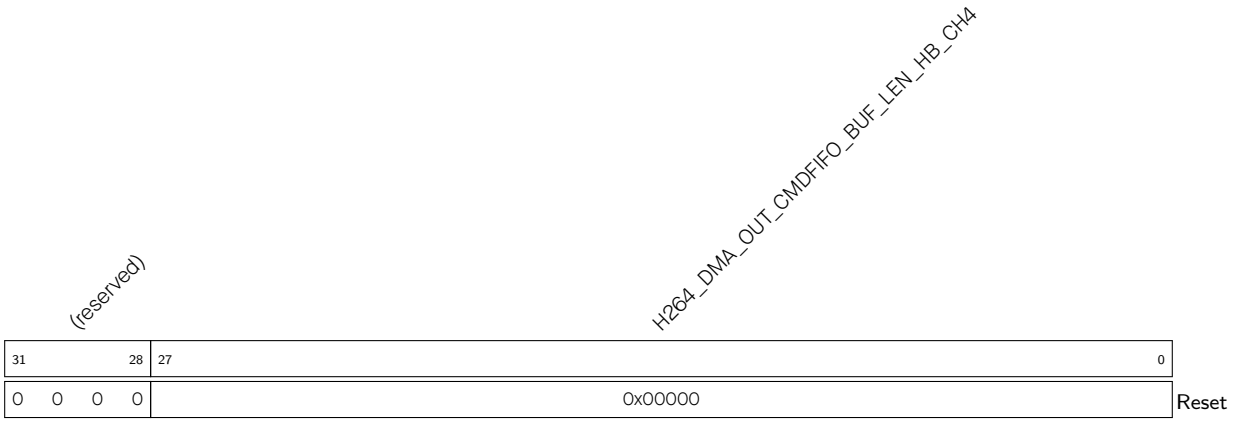
H264_DMA_OUT_EOF_DES_ADDR_CH4 Represents the address of the inlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.262. H264_DMA_OUT_DSCR_CH4_REG (0x042C)



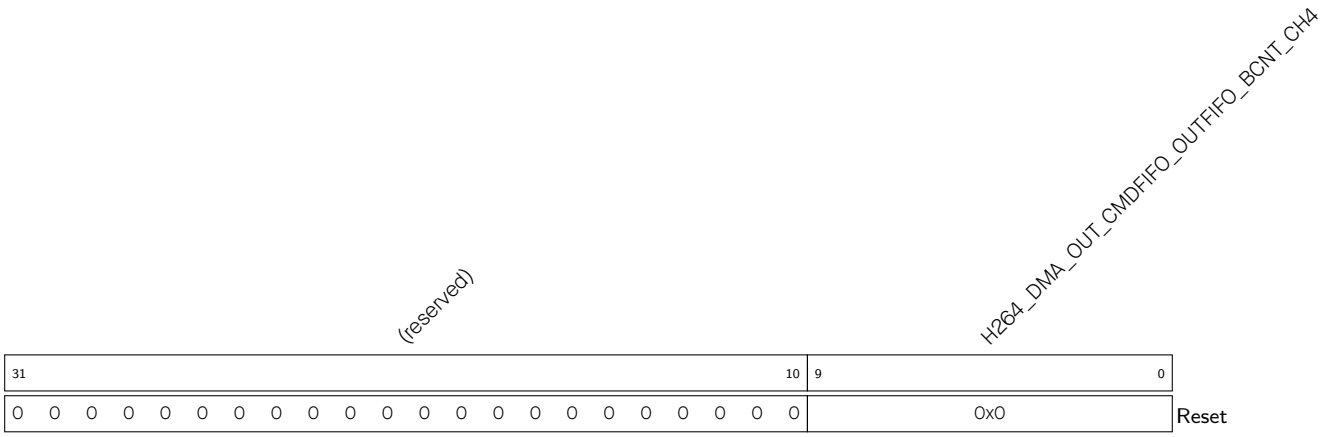
H264_DMA_OUTLINK_DSCR_CH4 Represents the address of the next descriptor y+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.263. H264_DMA_OUT_DSCR_BF0_CH4_REG (0x0430)



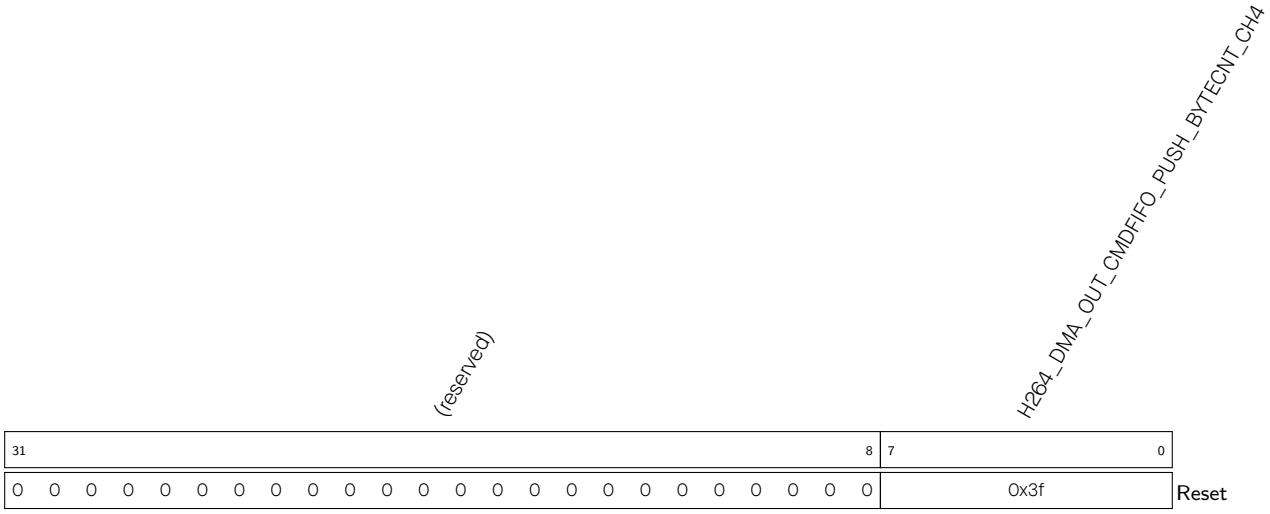
H264_DMA_OUTLINK_DSCR_BF0_CH4 Represents the address of the current descriptor y that is pre-read. (RO)

Register 41.264. H264_DMA_OUT_DSCR_BF1_CH4_REG (0x0434)



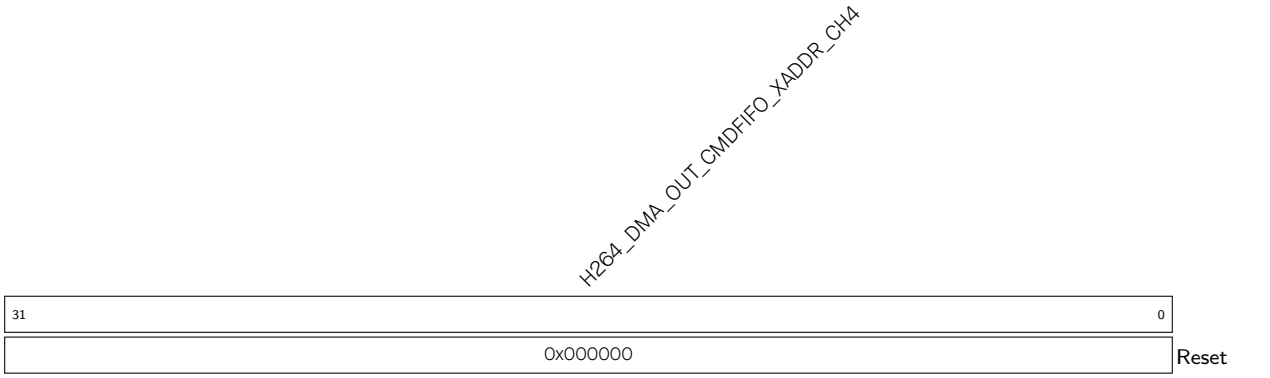
H264_DMA_OUTLINK_DSCR_BF1_CH4 Represents the address of the previous descriptor y-1 that is pre-read. (RO)

Register 41.265. H264_DMA_OUT_BUF_LEN_CH4_REG (0x0470)



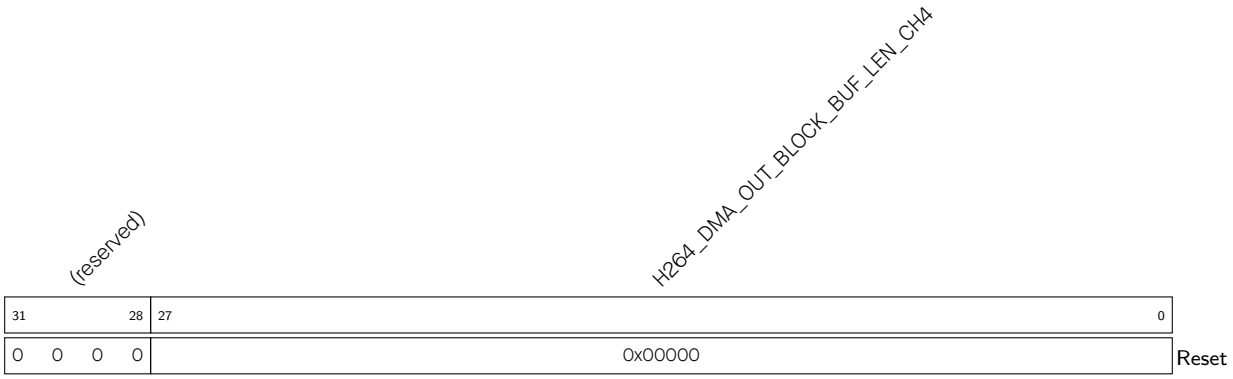
H264_DMA_OUT_CMDFIFO_BUF_LEN_HB_CH4 Represents the remaining request data. (RO)

Register 41.266. H264_DMA_OUT_FIFO_BCNT_CH4_REG (0x0474)



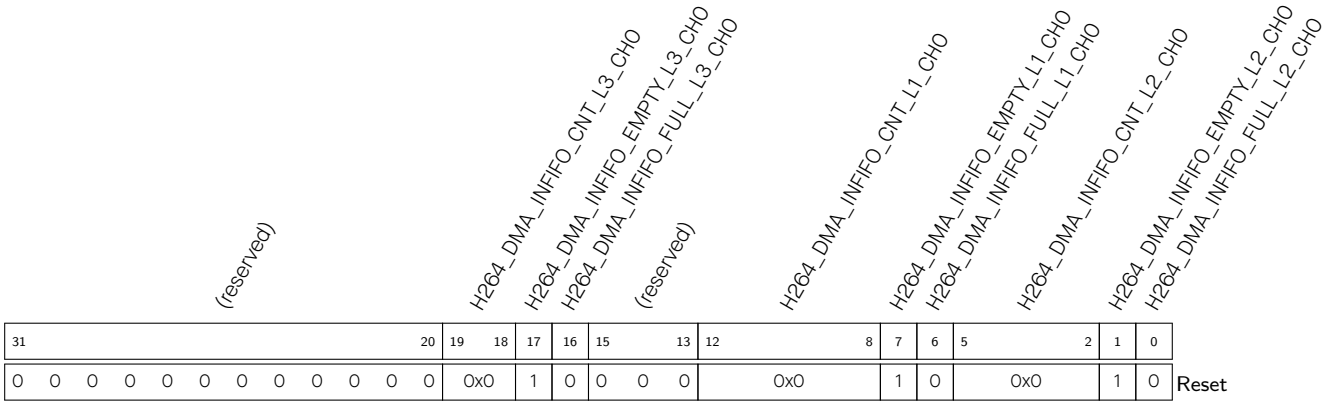
H264_DMA_OUT_CMDFIFO_OUTFIFO_BCNT_CH4 Represents that the data space has been used in FIFO. (RO)

Register 41.267. H264_DMA_OUT_PUSH_BYTECNT_CH4_REG (0x0478)



H264_DMA_OUT_CMDFIFO_PUSH_BYTECNT_CH4 Represents the data quantity in the current AXI request. (RO)

Register 41.268. H264_DMA_OUT_XADDR_CH4_REG (0x047C)



H264_DMA_OUT_CMDFIFO_XADDR_CH4 Represents the address of the current AXI request. (RO)

Register 41.269. H264_DMA_OUT_BLOCK_BUF_LEN_CH4_REG (0x0480)

H264_DMA_OUT_BLOCK_BUF_LEN_CH4 Represents the remaining block request data. (RO)

Register 41.270. H264_DMA_INFIFO_STATUS_CH0_REG (0x0514)

H264_DMA_INFIFO_FULL_L2_CH0 Represents whether l2 FIFO of RX channel 0 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L2_CH0 Represents whether l2 FIFO of RX channel 0 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_INFIFO_CNT_L2_CH0 Represents the data quantity in l2 FIFO for RX channel 0. Measurement unit: 16 bytes. (RO)

H264_DMA_INFIFO_FULL_L1_CH0 Represents whether l1 FIFO of RX channel 0 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L1_CH0 Represents whether l1 FIFO of RX channel 0 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_INFIFO_CNT_L1_CH0 Represents the data quantity in l1 FIFO for RX channel 0. Measurement unit: byte. (RO)

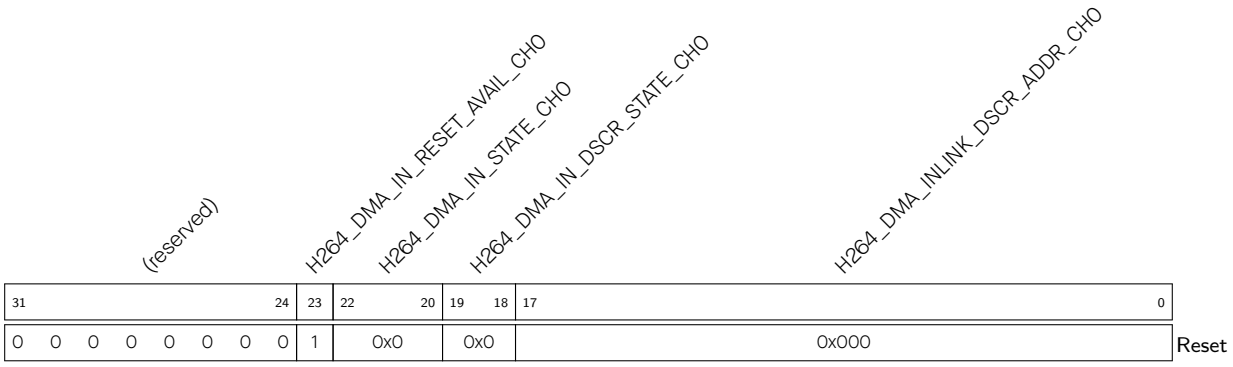
H264_DMA_INFIFO_FULL_L3_CH0 Represents whether l3 FIFO of RX channel 0 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L3_CH0 Represents whether l3 FIFO of RX channel 0 is empty.



0: Not empty

1: Empty

(RO)

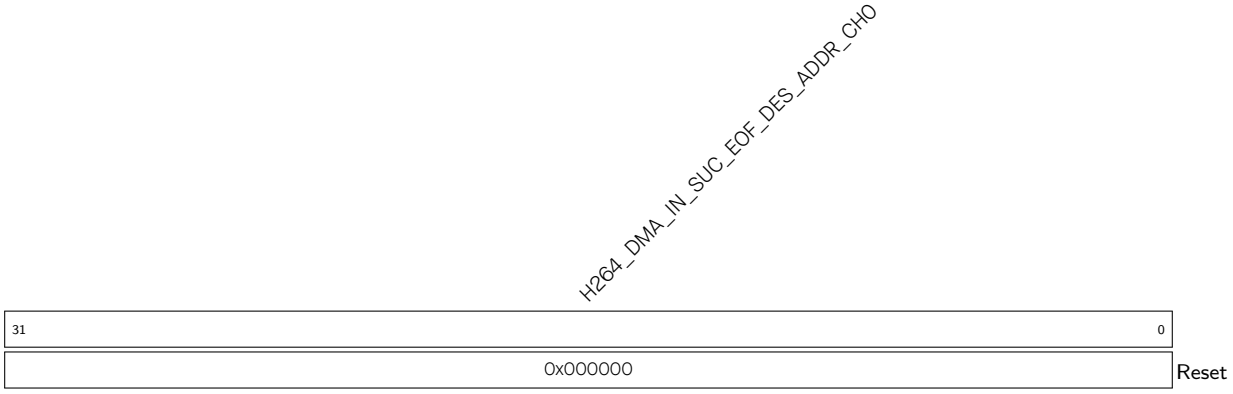
H264_DMA_INFIFO_CNT_L3_CH0 Represents the data quantity in l3 FIFO for RX channel 0. Measurement unit: 8 bytes. (RO)

Register 41.271. H264_DMA_IN_STATE_CH0_REG (0x0524)

H264_DMA_INLINK_DSCR_ADDR_CH0 Represents the current inlink descriptor's address for RX channel 0. (RO)

H264_DMA_IN_DSCR_STATE_CH0 Represents the current state of the descriptor state machine for RX channel 0. (RO)

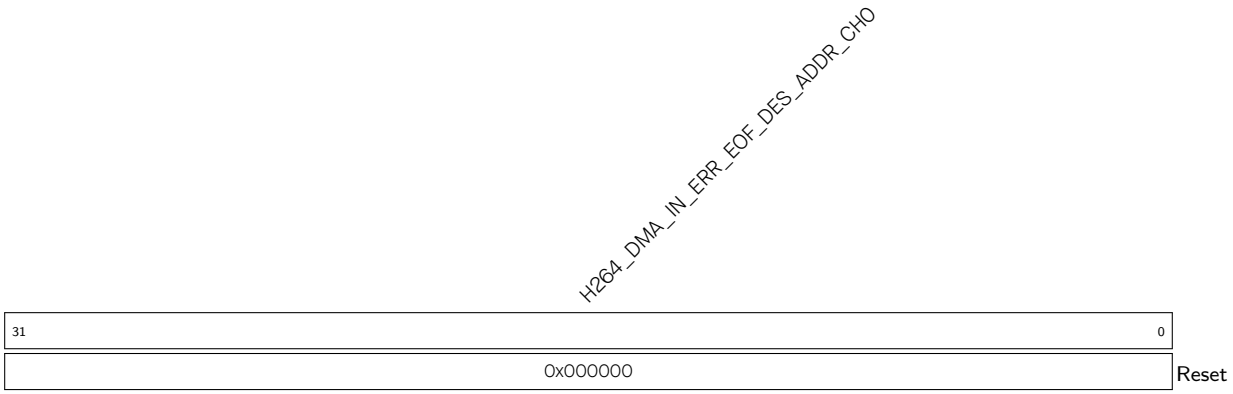
H264_DMA_IN_STATE_CH0 Represents the current control module state machine state for RX channel 0. (RO)



H264_DMA_IN_RESET_AVAIL_CH0 Represents whether it is safe to reset the channel.

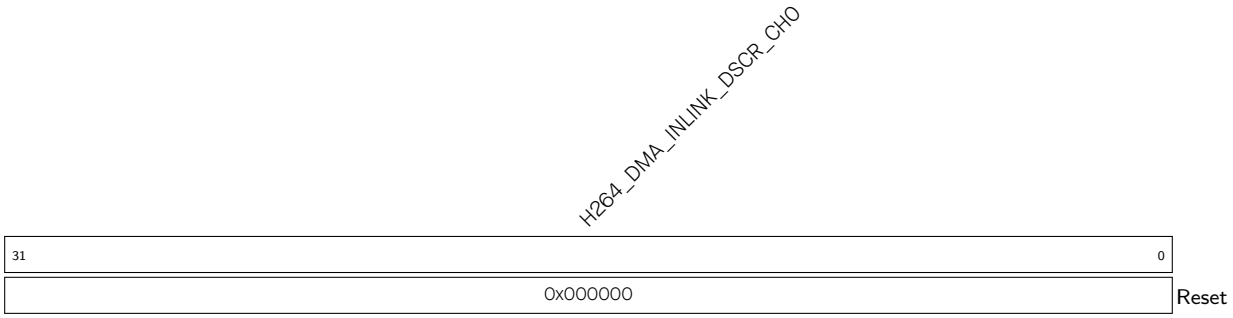
0: Unsafe

1: Safe



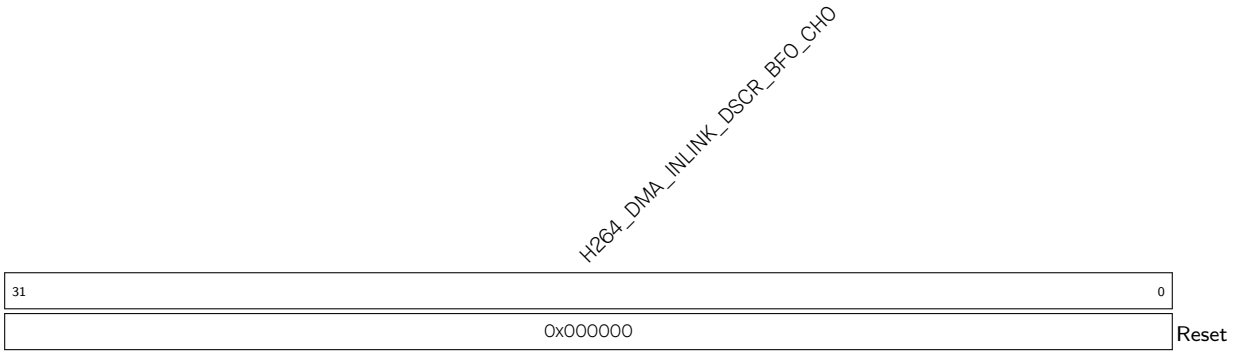
(RO)

Register 41.272. H264_DMA_IN_SUC_EOF_DES_ADDR_CH0_REG (0x0528)



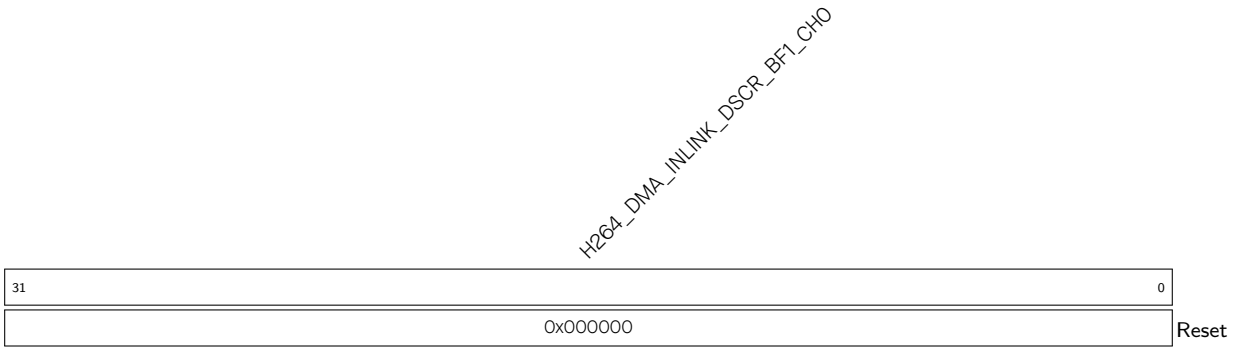
H264_DMA_IN_SUC_EOF_DES_ADDR_CH0 Represents the address of the inlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.273. H264_DMA_IN_ERR_EOF_DES_ADDR_CH0_REG (0x052C)



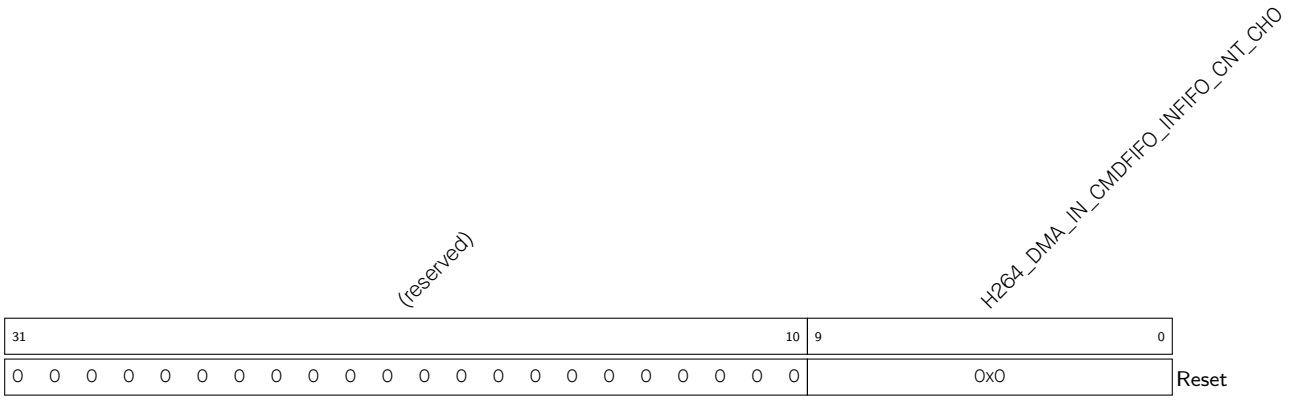
H264_DMA_IN_ERR_EOF_DES_ADDR_CH0 Represents the address of the inlink descriptor when there are errors during the current data reception. (RO)

Register 41.274. H264_DMA_IN_DSCR_CH0_REG (0x0530)



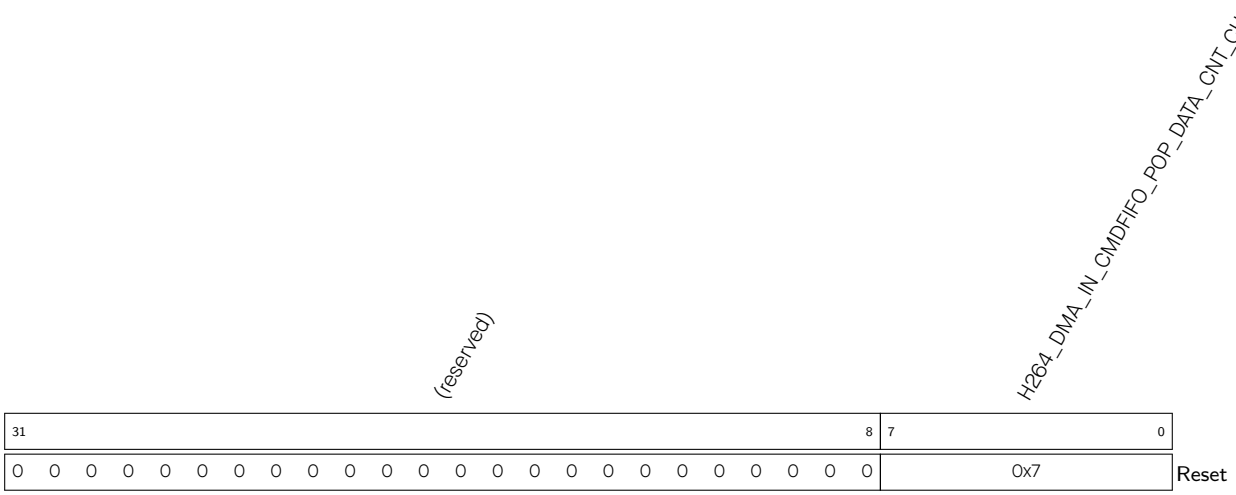
H264_DMA_INLINK_DSCR_CH0 Represents the address of the next descriptor x+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.275. H264_DMA_IN_DSCR_BF0_CH0_REG (0x0534)



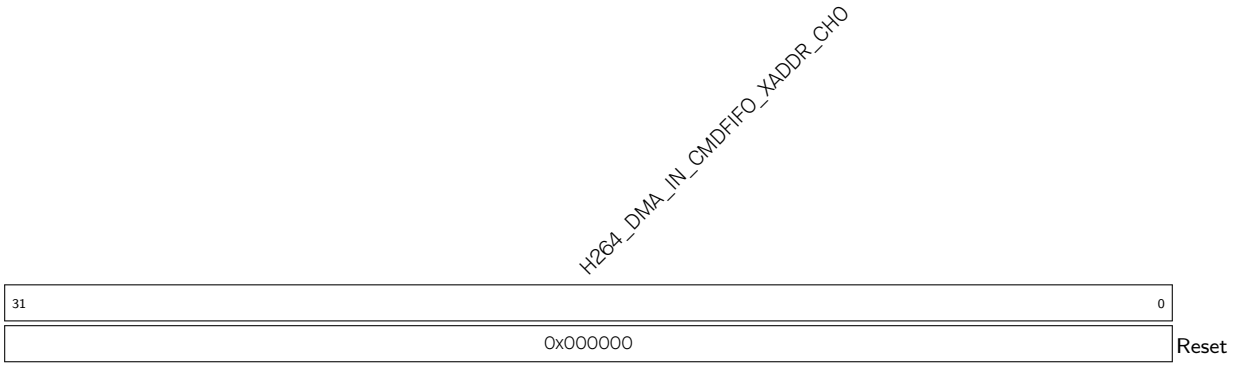
H264_DMA_INLINK_DSCR_BF0_CH0 Represents the address of the current descriptor x that is pre-read. (RO)

Register 41.276. H264_DMA_IN_DSCR_BF1_CH0_REG (0x0538)



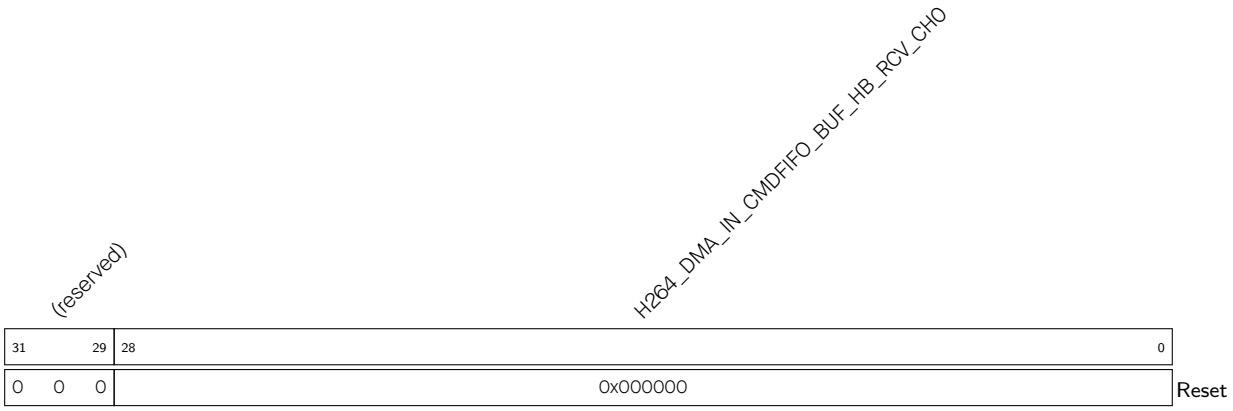
H264_DMA_INLINK_DSCR_BF1_CH0 Represents the address of the previous descriptor x-1 that is pre-read. (RO)

Register 41.277. H264_DMA_IN_FIFO_CNT_CH0_REG (0x0580)



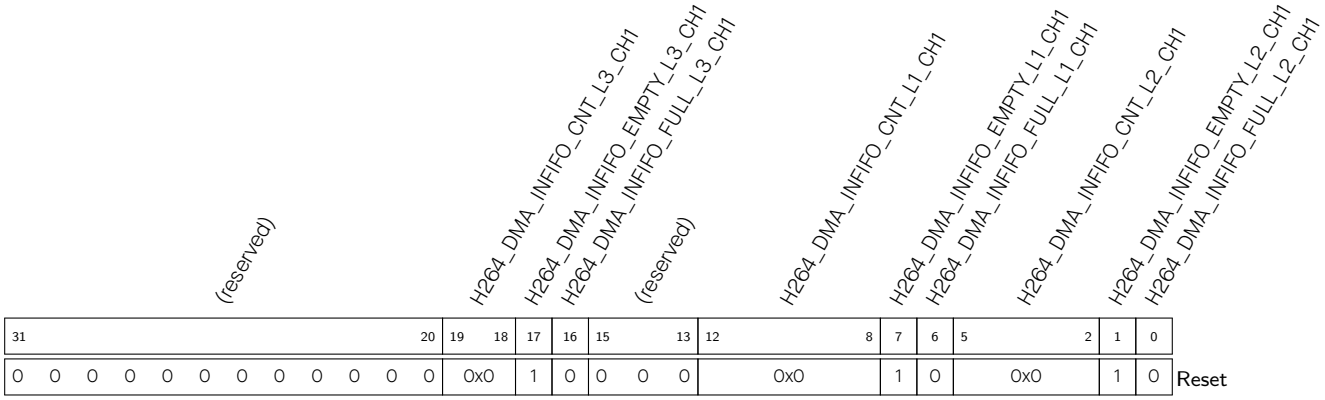
H264_DMA_IN_CMDFIFO_INFIFO_CNT_CH0 Represents the remaining request data in FIFO. (RO)

Register 41.278. H264_DMA_IN_POP_DATA_CNT_CH0_REG (0x0584)



H264_DMA_IN_CMDFIFO_POP_DATA_CNT_CH0 Represents the data quantity in the current AXI request. (RO)

Register 41.279. H264_DMA_IN_XADDR_CH0_REG (0x0588)



H264_DMA_IN_CMDFIFO_XADDR_CH0 Represents the address of the current AXI request. (RO)

Register 41.280. H264_DMA_IN_BUF_HB_RCV_CH0_REG (0x058C)

H264_DMA_IN_CMDFIFO_BUF_HB_RCV_CH0 Represents the data quantity that has been requested. (RO)

Register 41.281. H264_DMA_INFIFO_STATUS_CH1_REG (0x0614)

H264_DMA_INFIFO_FULL_L2_CH1 Represents whether l2 FIFO of RX channel 1 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L2_CH1 Represents whether l2 FIFO of RX channel 1 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_INFIFO_CNT_L2_CH1 Represents the data quantity in l2 FIFO for RX channel 1. Measurement unit: 16 bytes. (RO)

H264_DMA_INFIFO_FULL_L1_CH1 Represents whether l1 FIFO of RX channel 1 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L1_CH1 Represents whether l1 FIFO of RX channel 1 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_INFIFO_CNT_L1_CH1 Represents the data quantity in l1 FIFO for RX channel 1. Measurement unit: byte. (RO)

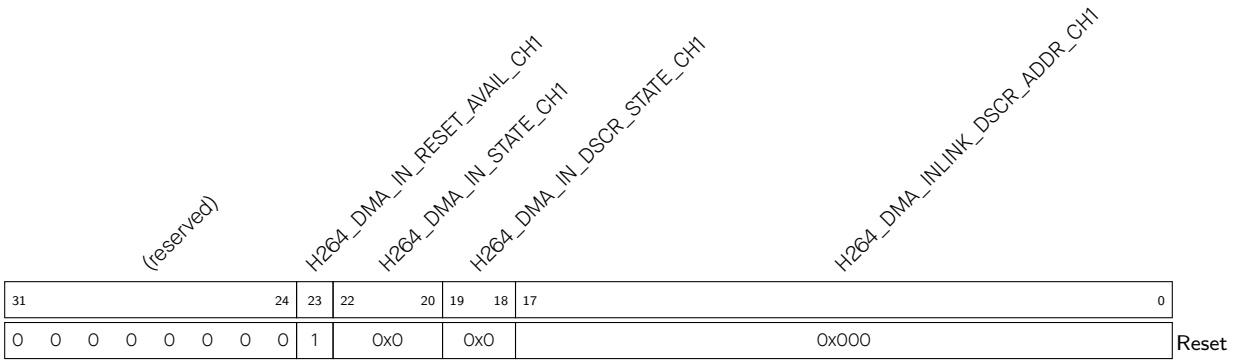
H264_DMA_INFIFO_FULL_L3_CH1 Represents whether l3 FIFO of RX channel 1 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L3_CH1 Represents whether l3 FIFO of RX channel 1 is empty.



0: Not empty

1: Empty

(RO)

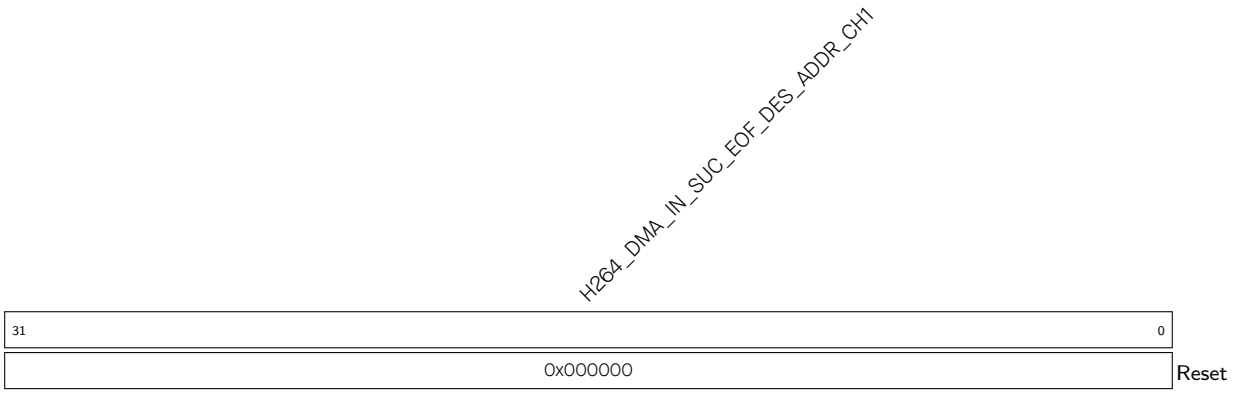
H264_DMA_INFIFO_CNT_L3_CH1 Represents the data quantity in l3 FIFO for RX channel 1. Measurement unit: 8 bytes. (RO)

Register 41.282. H264_DMA_IN_STATE_CH1_REG (0x0624)

H264_DMA_INLINK_DSCR_ADDR_CH1 Represents the current inlink descriptor's address for RX channel 1. (RO)

H264_DMA_IN_DSCR_STATE_CH1 Represents the current state of the descriptor state machine for RX channel 1. (RO)

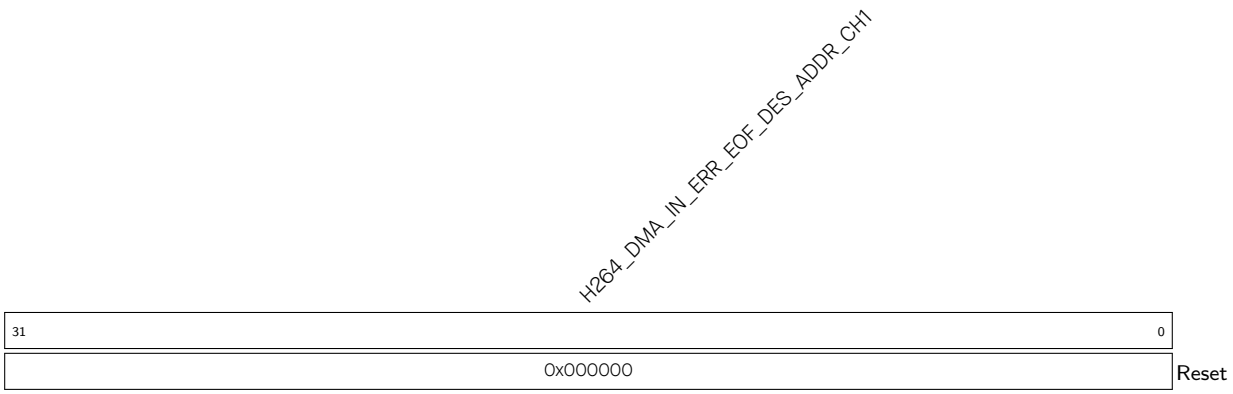
H264_DMA_IN_STATE_CH1 Represents the current control module state machine state for RX channel 1. (RO)



H264_DMA_IN_RESET_AVAIL_CH1 Represents whether it is safe to reset the channel.

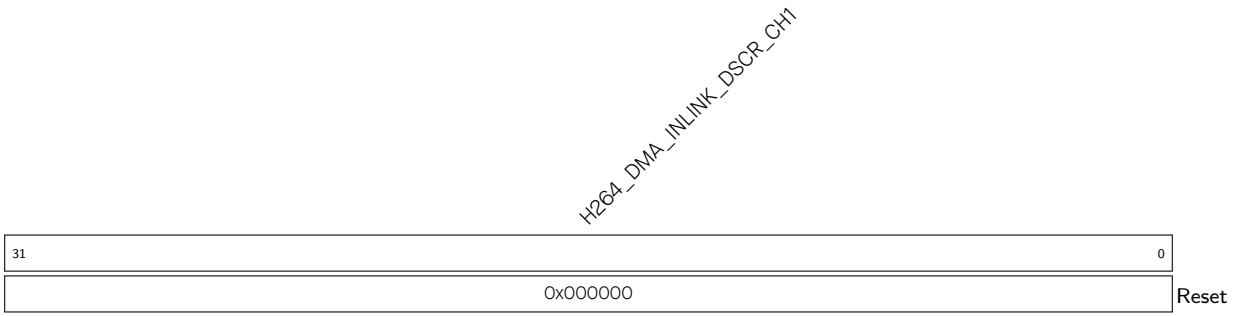
0: Unsafe

1: Safe



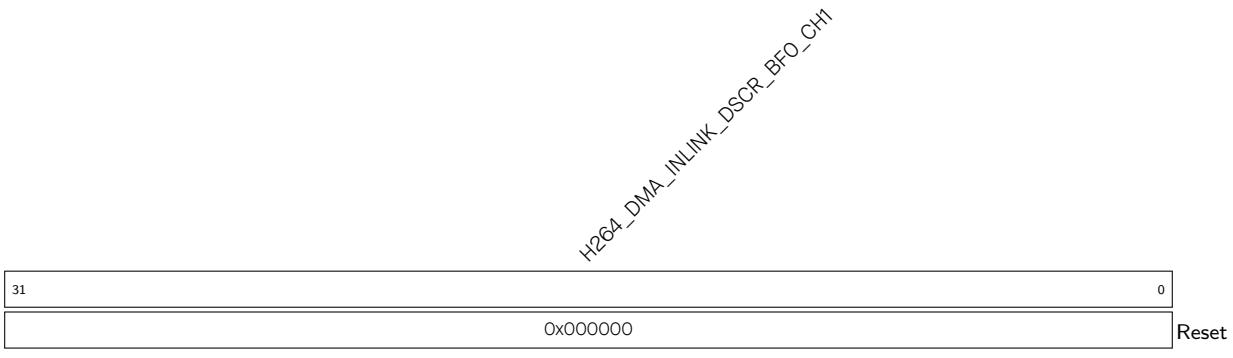
(RO)

Register 41.283. H264_DMA_IN_SUC_EOF_DES_ADDR_CH1_REG (0x0628)



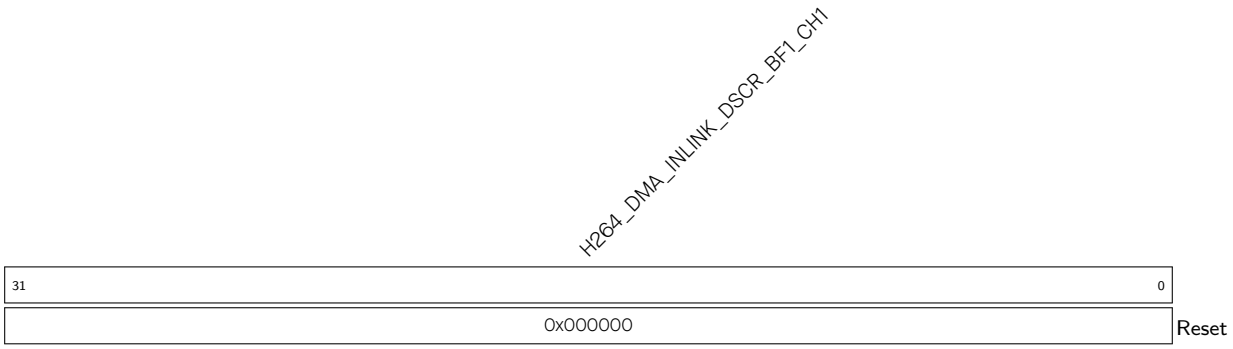
H264_DMA_IN_SUC_EOF_DES_ADDR_CH1 Represents the address of the inlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.284. H264_DMA_IN_ERR_EOF_DES_ADDR_CH1_REG (0x062C)



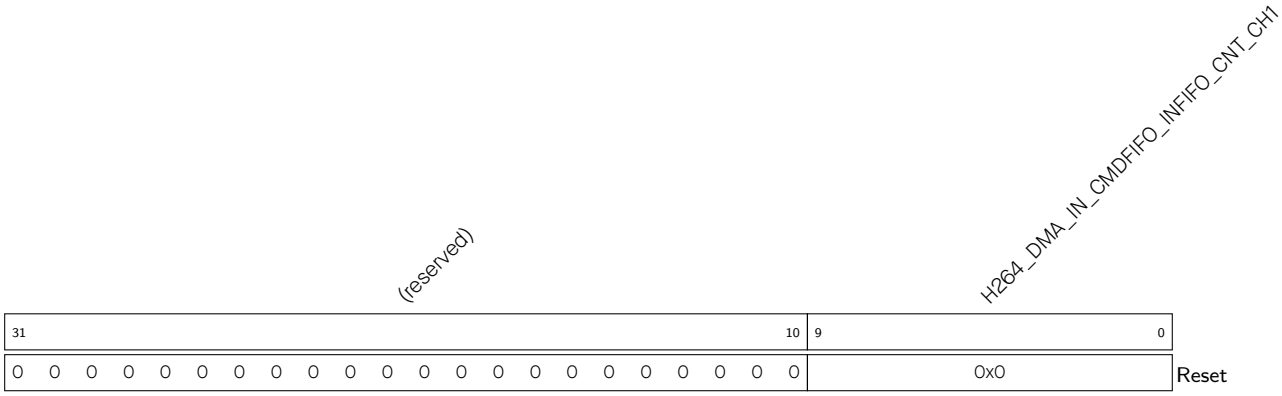
H264_DMA_IN_ERR_EOF_DES_ADDR_CH1 Represents the address of the inlink descriptor when there are errors during the current data reception. (RO)

Register 41.285. H264_DMA_IN_DSCR_CH1_REG (0x0630)



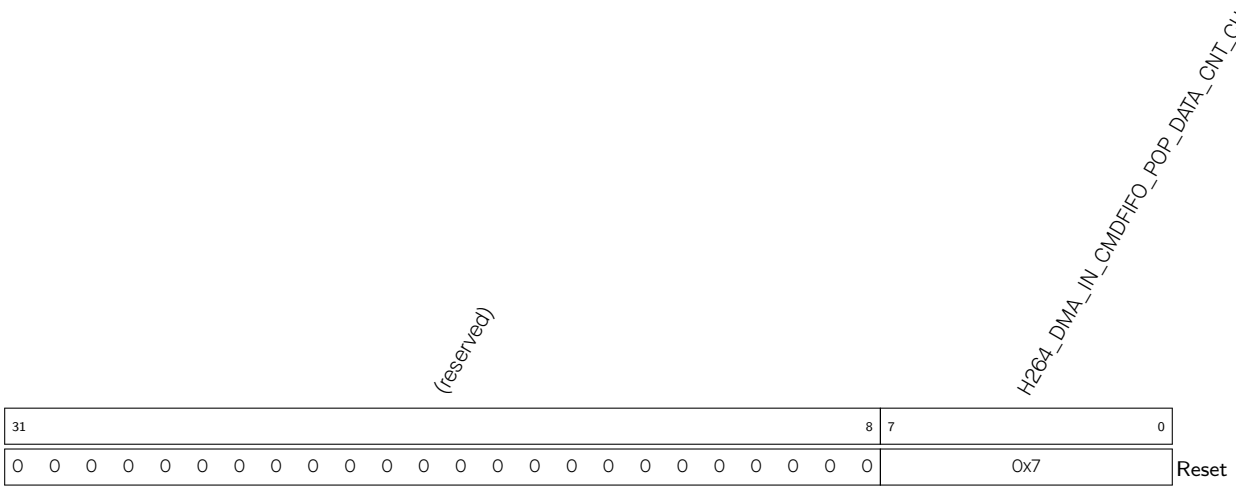
H264_DMA_INLINK_DSCR_CH1 Represents the address of the next descriptor x+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.286. H264_DMA_IN_DSCR_BF0_CH1_REG (0x0634)



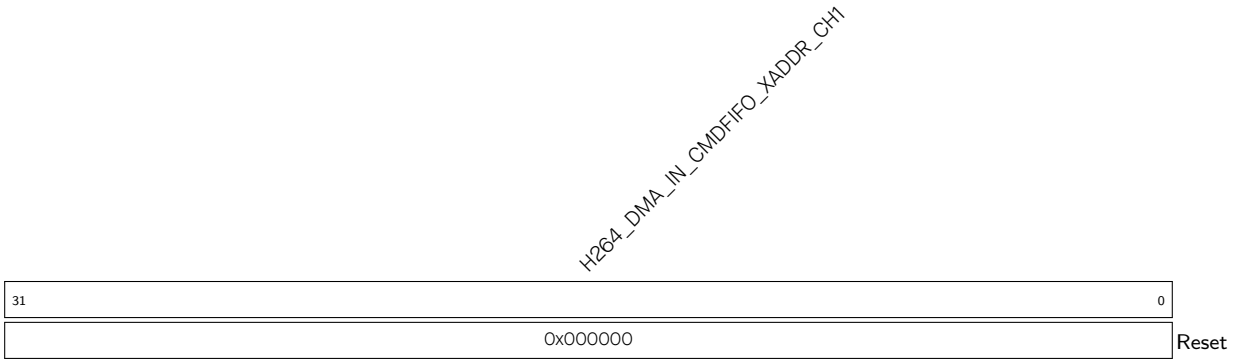
H264_DMA_INLINK_DSCR_BF0_CH1 Represents the address of the current descriptor x that is pre-read. (RO)

Register 41.287. H264_DMA_IN_DSCR_BF1_CH1_REG (0x0638)



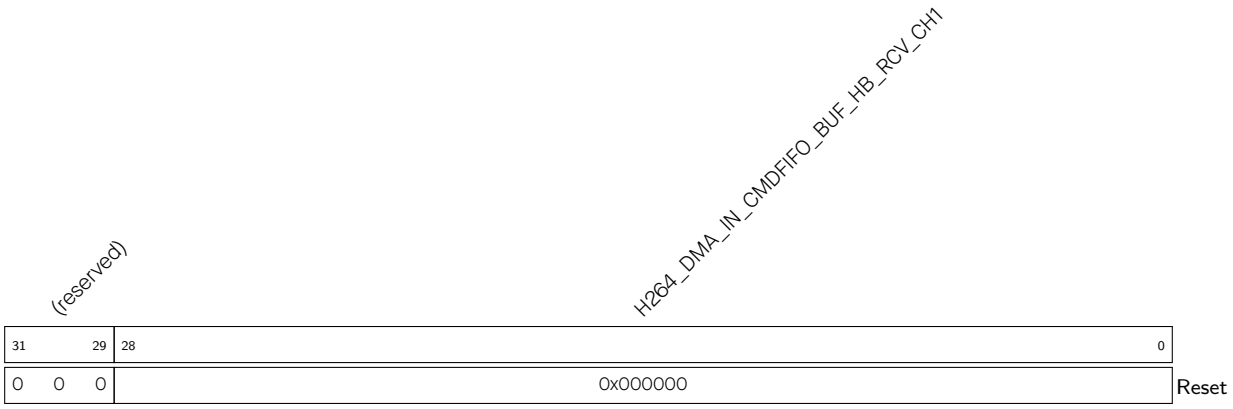
H264_DMA_INLINK_DSCR_BF1_CH1 Represents the address of the previous descriptor x-1 that is pre-read. (RO)

Register 41.288. H264_DMA_IN_FIFO_CNT_CH1_REG (0x0680)



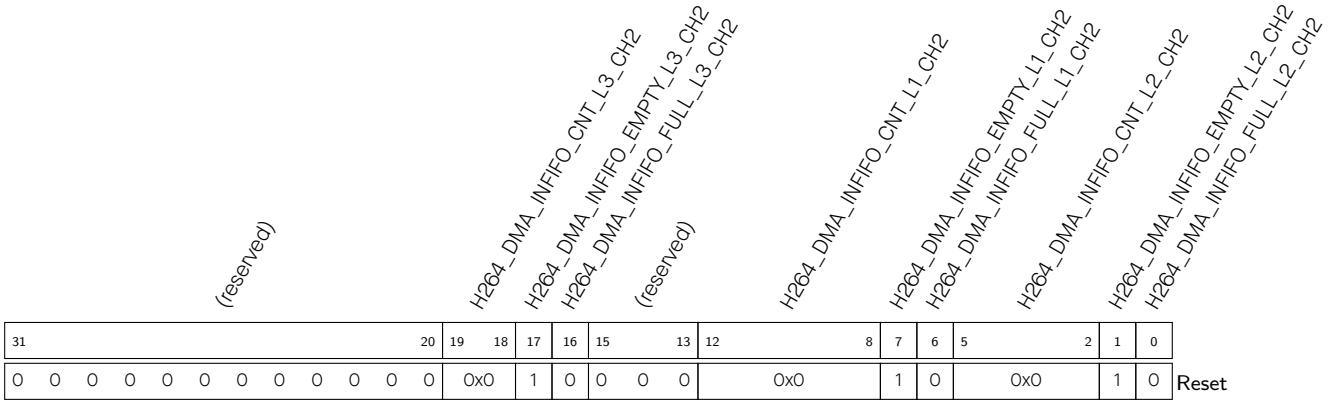
H264_DMA_IN_CMDFIFO_INFIFO_CNT_CH1 Represents the remaining request data in FIFO. (RO)

Register 41.289. H264_DMA_IN_POP_DATA_CNT_CH1_REG (0x0684)



H264_DMA_IN_CMDFIFO_POP_DATA_CNT_CH1 Represents the data quantity in the current AXI request. (RO)

Register 41.290. H264_DMA_IN_XADDR_CH1_REG (0x0688)



H264_DMA_IN_CMDFIFO_XADDR_CH1 Represents the address of the current AXI request. (RO)

Register 41.291. H264_DMA_IN_BUF_HB_RCV_CH1_REG (0x068C)

H264_DMA_IN_CMDFIFO_BUF_HB_RCV_CH1 Represents the data quantity that has been requested. (RO)

Register 41.292. H264_DMA_INFIFO_STATUS_CH2_REG (0x0714)

H264_DMA_INFIFO_FULL_L2_CH2 Represents whether l2 FIFO of RX channel 2 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L2_CH2 Represents whether l2 FIFO of RX channel 2 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_INFIFO_CNT_L2_CH2 Represents the data quantity in l2 FIFO for RX channel 2. Measurement unit: 16 bytes. (RO)

H264_DMA_INFIFO_FULL_L1_CH2 Represents whether l1 FIFO of RX channel 2 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L1_CH2 Represents whether l1 FIFO of RX channel 2 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_INFIFO_CNT_L1_CH2 Represents the data quantity in l1 FIFO for RX channel 2. Measurement unit: byte. (RO)

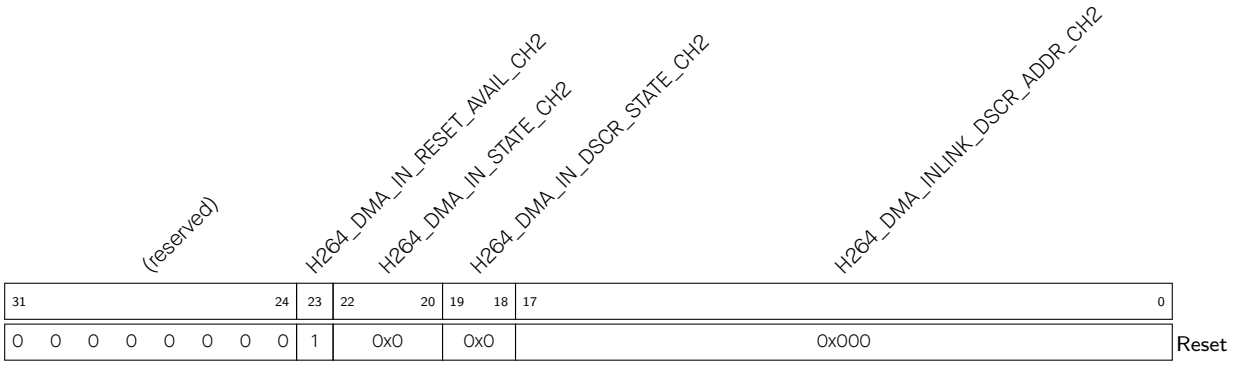
H264_DMA_INFIFO_FULL_L3_CH2 Represents whether l3 FIFO of RX channel 2 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L3_CH2 Represents whether l3 FIFO of RX channel 2 is empty.



0: Not empty

1: Empty

(RO)

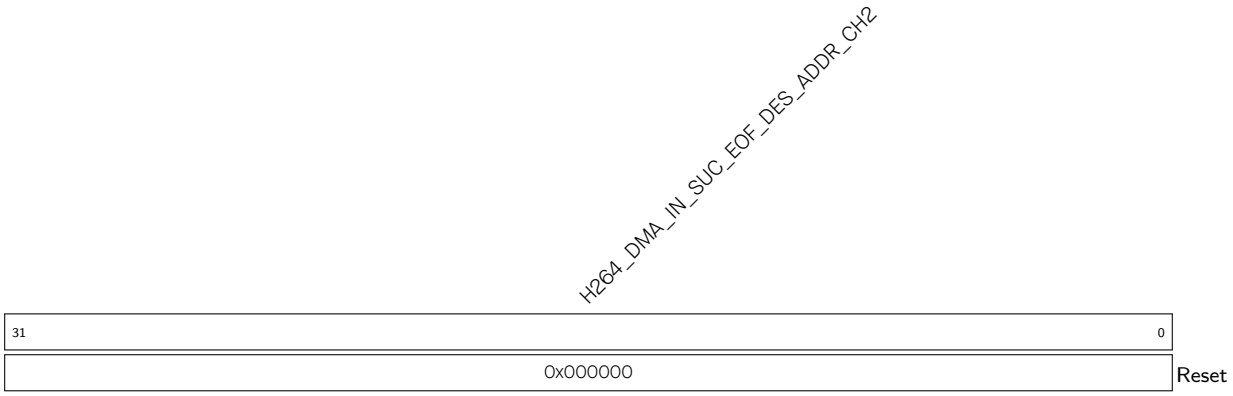
H264_DMA_INFIFO_CNT_L3_CH2 Represents the data quantity in l3 FIFO for RX channel 2. Measurement unit: 8 bytes. (RO)

Register 41.293. H264_DMA_IN_STATE_CH2_REG (0x0724)

H264_DMA_INLINK_DSCR_ADDR_CH2 Represents the current inlink descriptor's address for RX channel 2. (RO)

H264_DMA_IN_DSCR_STATE_CH2 Represents the current state of the descriptor state machine for RX channel 2. (RO)

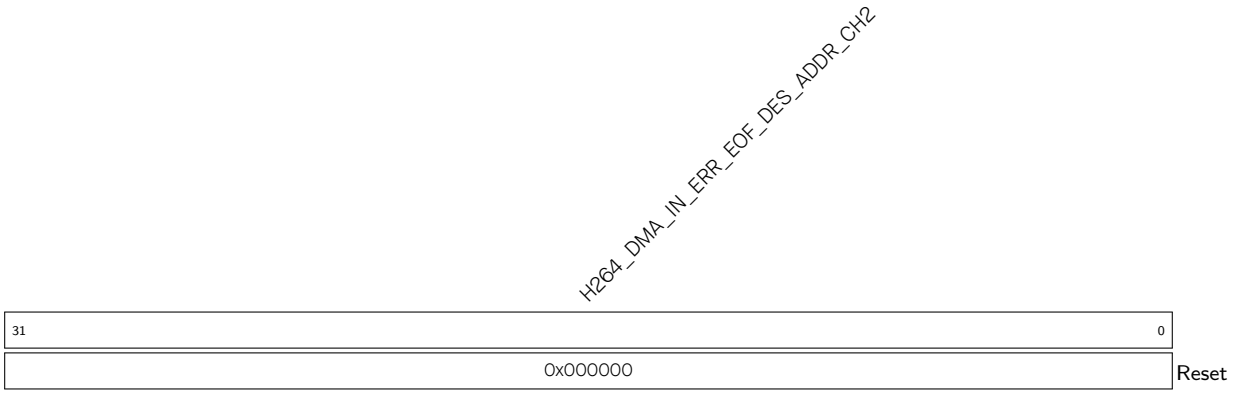
H264_DMA_IN_STATE_CH2 Represents the current control module state machine state for RX channel 2. (RO)



H264_DMA_IN_RESET_AVAIL_CH2 Represents whether it is safe to reset the channel.

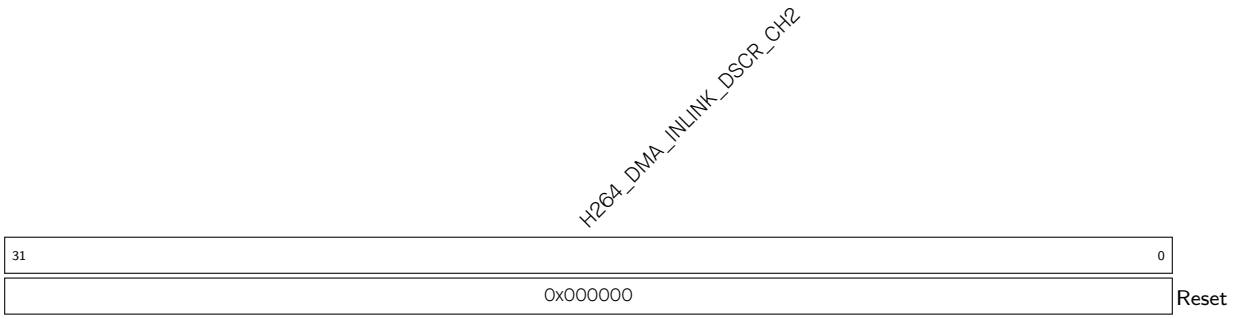
0: Unsafe

1: Safe



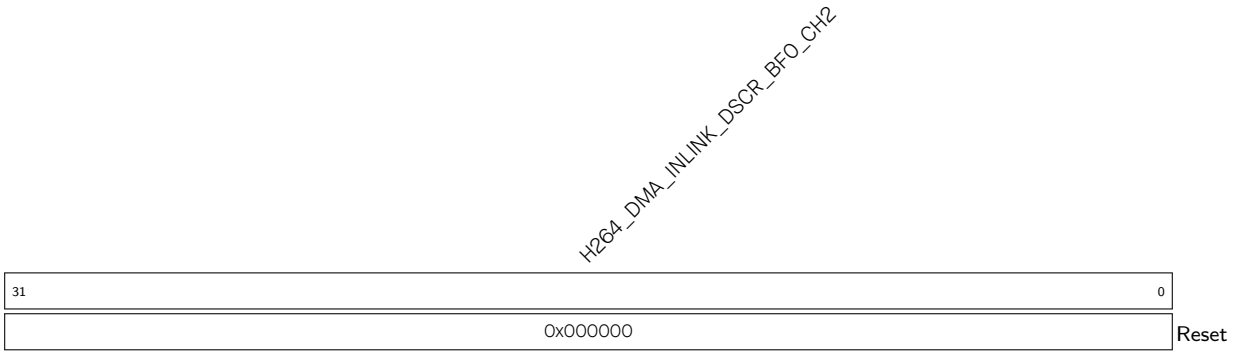
(RO)

Register 41.294. H264_DMA_IN_SUC_EOF_DES_ADDR_CH2_REG (0x0728)



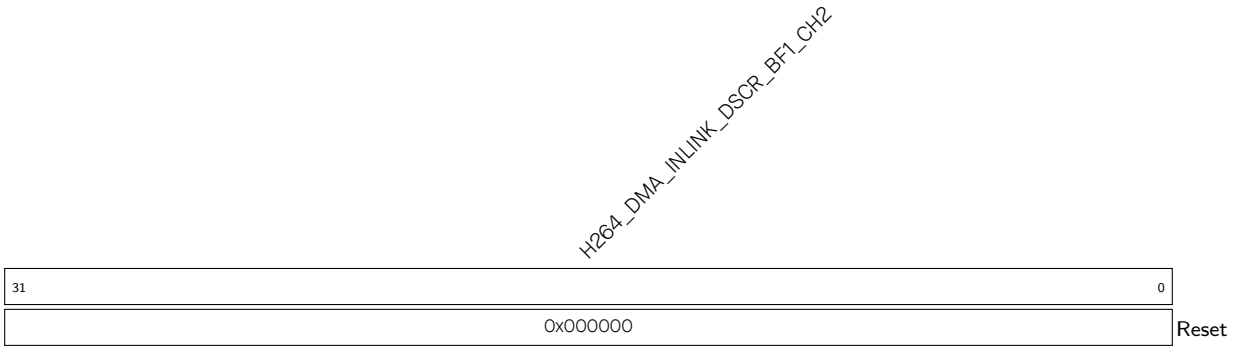
H264_DMA_IN_SUC_EOF_DES_ADDR_CH2 Represents the address of the inlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.295. H264_DMA_IN_ERR_EOF_DES_ADDR_CH2_REG (0x072C)



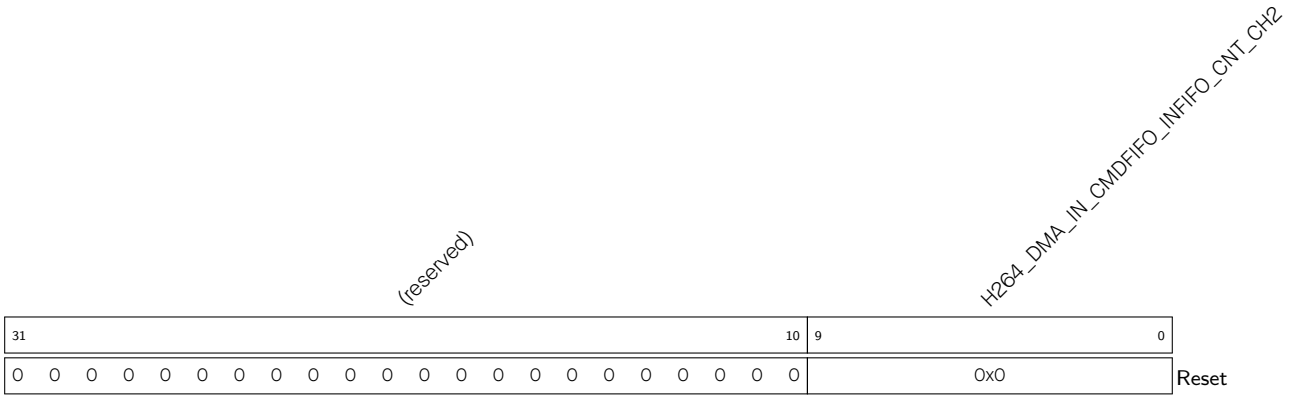
H264_DMA_IN_ERR_EOF_DES_ADDR_CH2 Represents the address of the inlink descriptor when there are errors during the current data reception. (RO)

Register 41.296. H264_DMA_IN_DSCR_CH2_REG (0x0730)



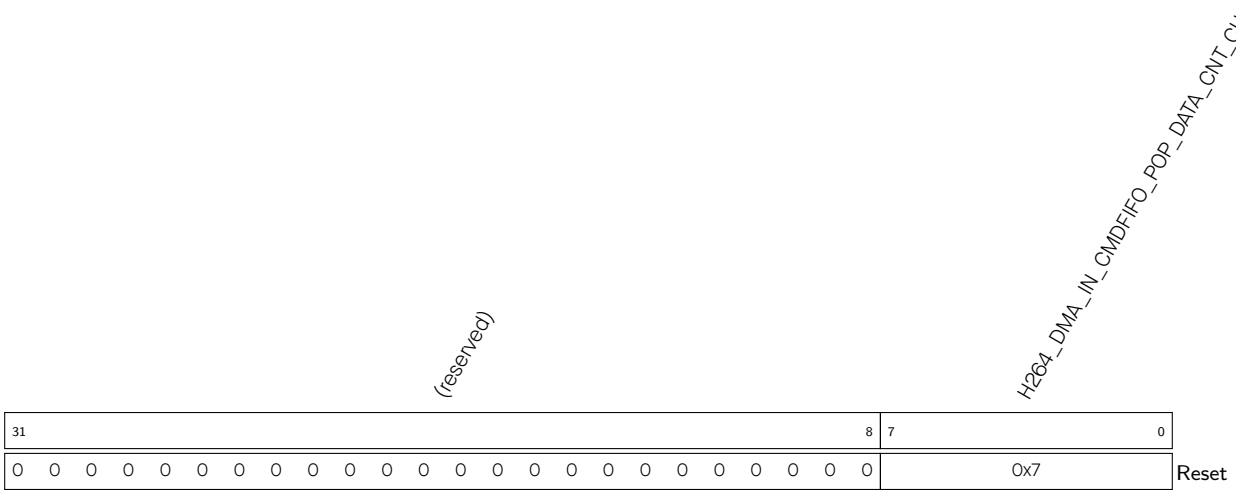
H264_DMA_INLINK_DSCR_CH2 Represents the address of the next descriptor x+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.297. H264_DMA_IN_DSCR_BF0_CH2_REG (0x0734)



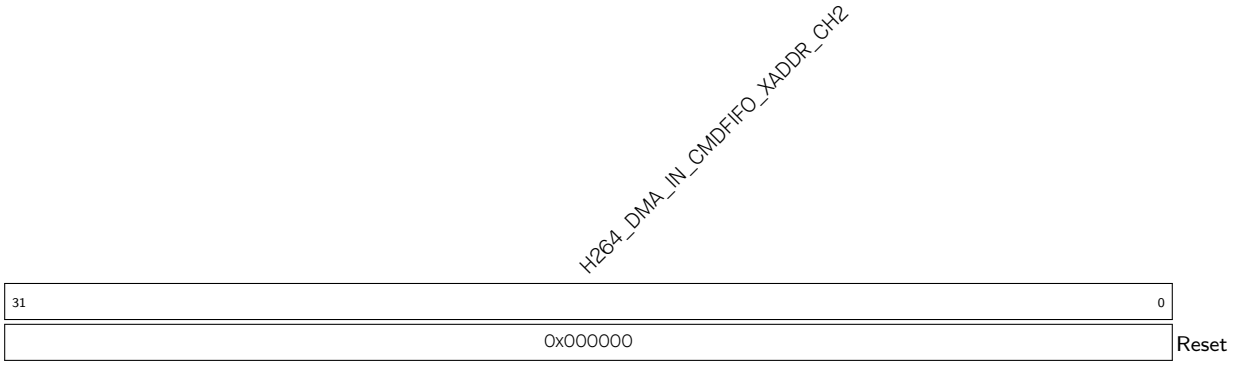
H264_DMA_INLINK_DSCR_BF0_CH2 Represents the address of the current descriptor x that is pre-read. (RO)

Register 41.298. H264_DMA_IN_DSCR_BF1_CH2_REG (0x0738)



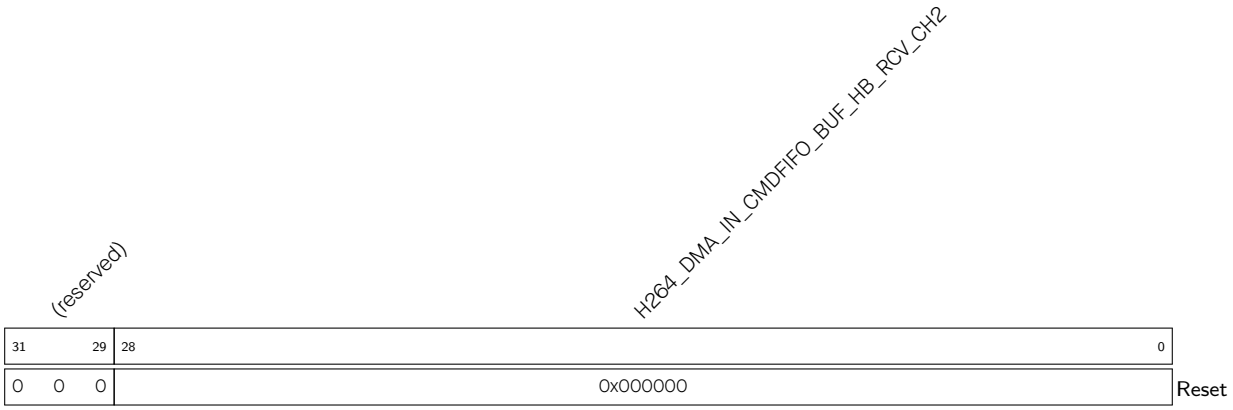
H264_DMA_INLINK_DSCR_BF1_CH2 Represents the address of the previous descriptor x-1 that is pre-read. (RO)

Register 41.299. H264_DMA_IN_FIFO_CNT_CH2_REG (0x0780)



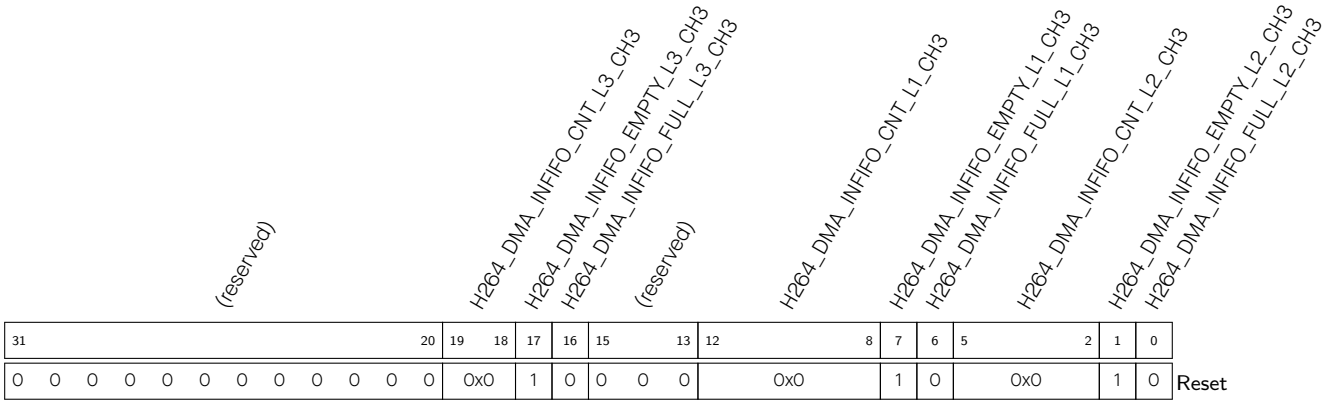
H264_DMA_IN_CMDFIFO_INFIFO_CNT_CH2 Represents the remaining request data in FIFO. (RO)

Register 41.300. H264_DMA_IN_POP_DATA_CNT_CH2_REG (0x0784)



H264_DMA_IN_CMDFIFO_POP_DATA_CNT_CH2 Represents the data quantity in the current AXI request. (RO)

Register 41.301. H264_DMA_IN_XADDR_CH2_REG (0x0788)



H264_DMA_IN_CMDFIFO_XADDR_CH2 Represents the address of the current AXI request. (RO)

Register 41.302. H264_DMA_IN_BUF_HB_RCV_CH2_REG (0x078C)

H264_DMA_IN_CMDFIFO_BUF_HB_RCV_CH2 Represents the data quantity that has been requested. (RO)

Register 41.303. H264_DMA_INFIFO_STATUS_CH3_REG (0x0814)

H264_DMA_INFIFO_FULL_L2_CH3 Represents whether l2 FIFO of RX channel 3 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L2_CH3 Represents whether l2 FIFO of RX channel 3 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_INFIFO_CNT_L2_CH3 Represents the data quantity in l2 FIFO for RX channel 3. Measurement unit: 16 bytes. (RO)

H264_DMA_INFIFO_FULL_L1_CH3 Represents whether l1 FIFO of RX channel 3 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L1_CH3 Represents whether l1 FIFO of RX channel 3 is empty.

0: Not empty

1: Empty

(RO)

H264_DMA_INFIFO_CNT_L1_CH3 Represents the data quantity in l1 FIFO for RX channel 3. Measurement unit: byte. (RO)

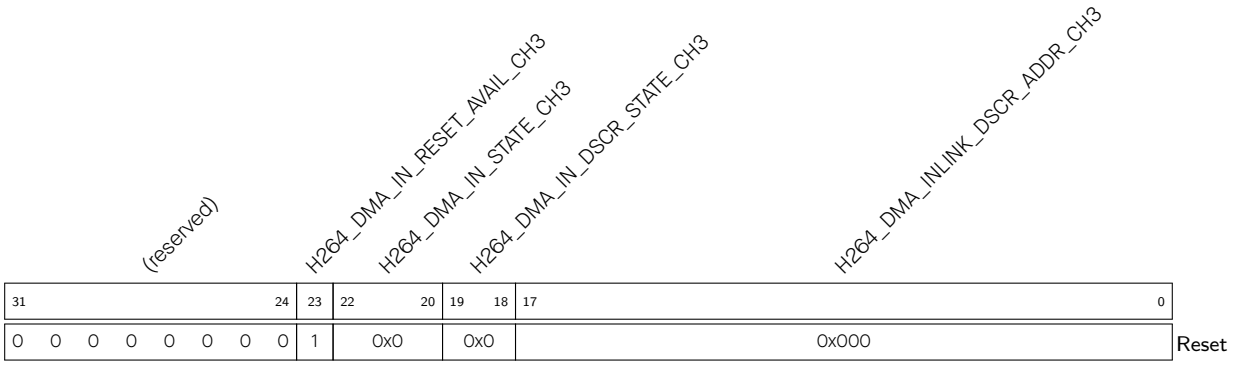
H264_DMA_INFIFO_FULL_L3_CH3 Represents whether l3 FIFO of RX channel 3 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L3_CH3 Represents whether l3 FIFO of RX channel 3 is empty.



0: Not empty

1: Empty

(RO)

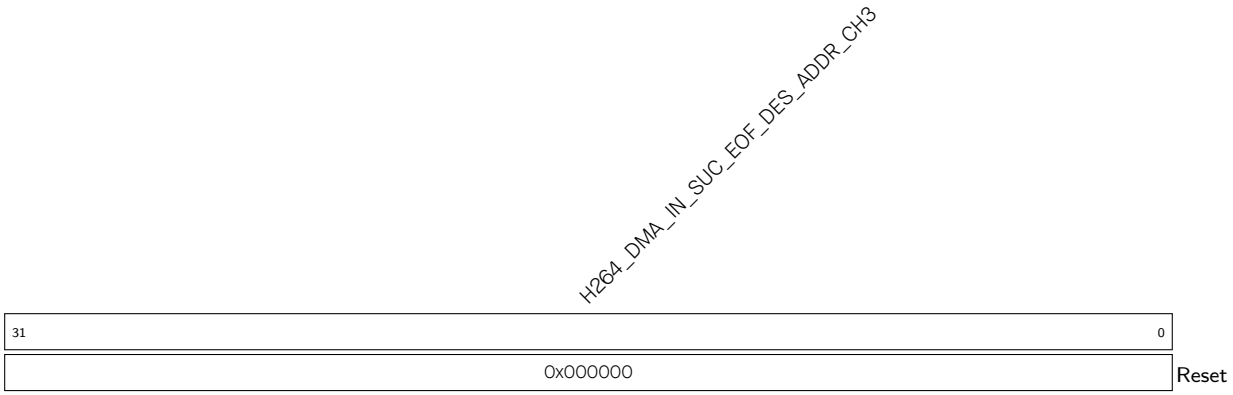
H264_DMA_INFIFO_CNT_L3_CH3 Represents the data quantity in l3 FIFO for RX channel 3. Measurement unit: 8 bytes. (RO)

Register 41.304. H264_DMA_IN_STATE_CH3_REG (0x0824)

H264_DMA_INLINK_DSCR_ADDR_CH3 Represents the current inlink descriptor's address for RX channel 3. (RO)

H264_DMA_IN_DSCR_STATE_CH3 Represents the current state of the descriptor state machine for RX channel 3. (RO)

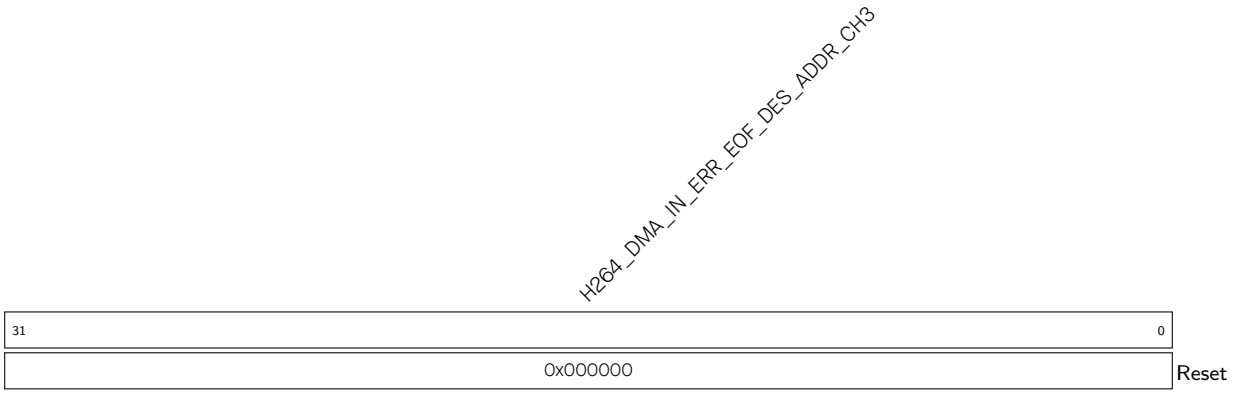
H264_DMA_IN_STATE_CH3 Represents the current control module state machine state for RX channel 3. (RO)



H264_DMA_IN_RESET_AVAIL_CH3 Represents whether it is safe to reset the channel.

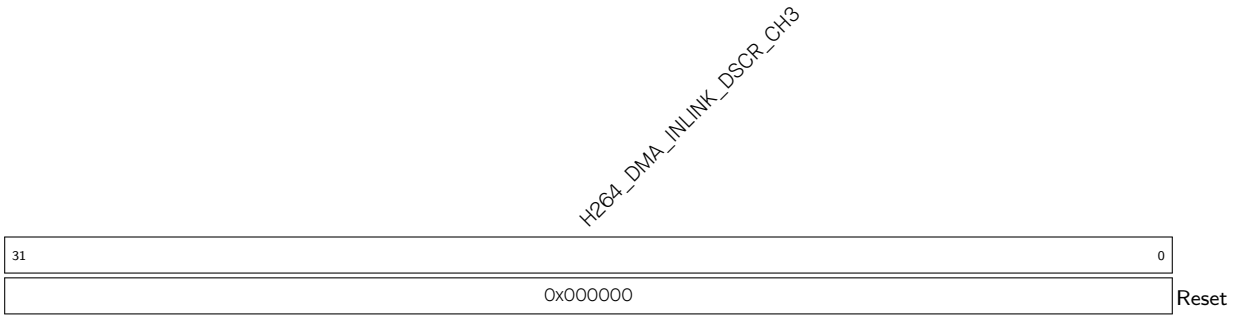
0: Unsafe

1: Safe



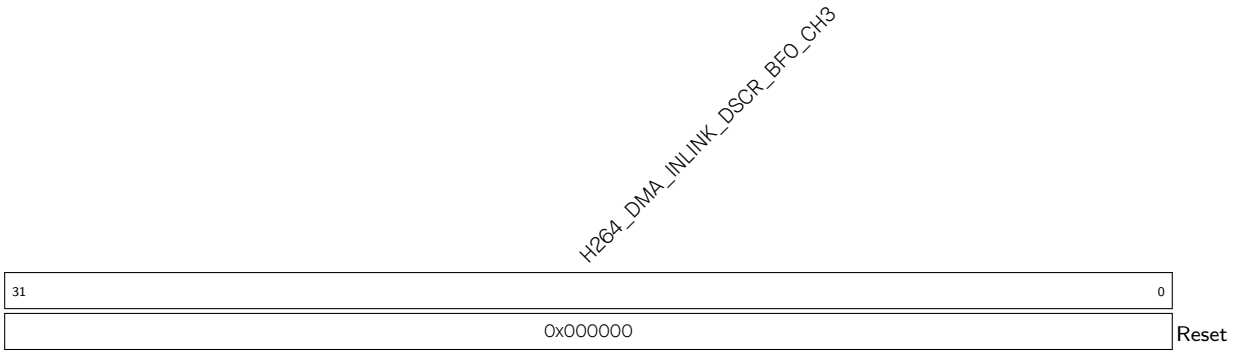
(RO)

Register 41.305. H264_DMA_IN_SUC_EOF_DES_ADDR_CH3_REG (0x0828)



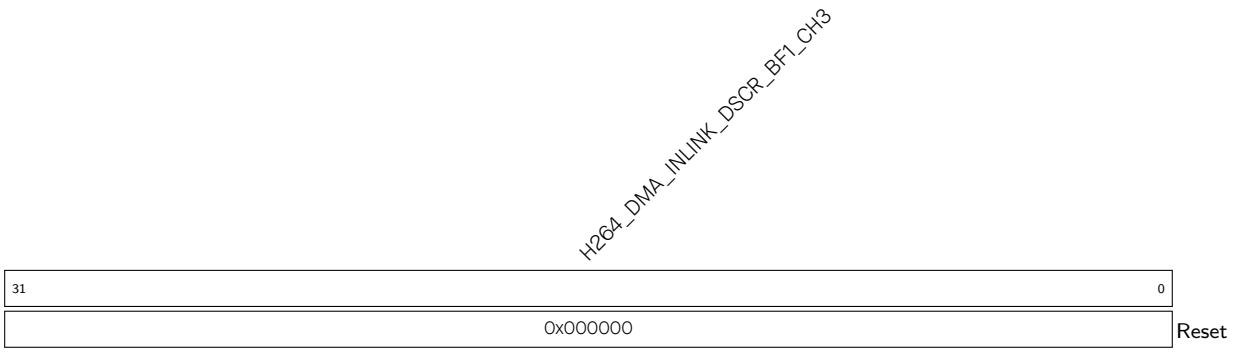
H264_DMA_IN_SUC_EOF_DES_ADDR_CH3 Represents the address of the inlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.306. H264_DMA_IN_ERR_EOF_DES_ADDR_CH3_REG (0x082C)



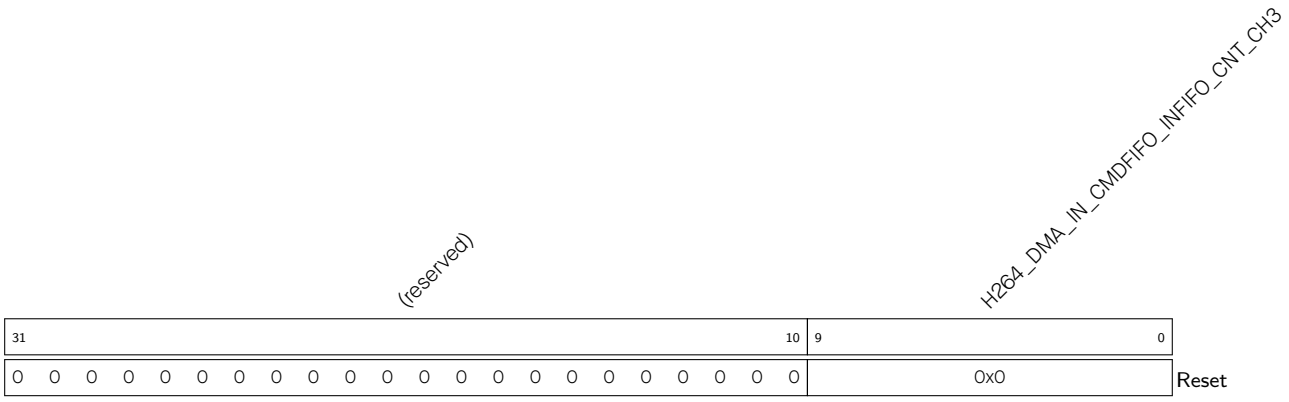
H264_DMA_IN_ERR_EOF_DES_ADDR_CH3 Represents the address of the inlink descriptor when there are errors during the current data reception. (RO)

Register 41.307. H264_DMA_IN_DSCR_CH3_REG (0x0830)



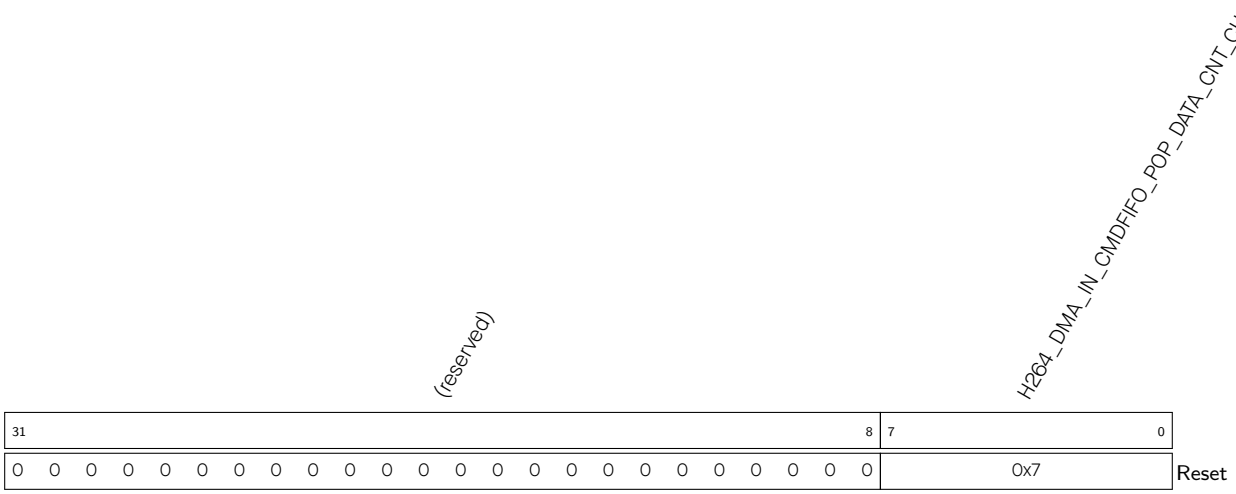
H264_DMA_INLINK_DSCR_CH3 Represents the address of the next descriptor x+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.308. H264_DMA_IN_DSCR_BF0_CH3_REG (0x0834)



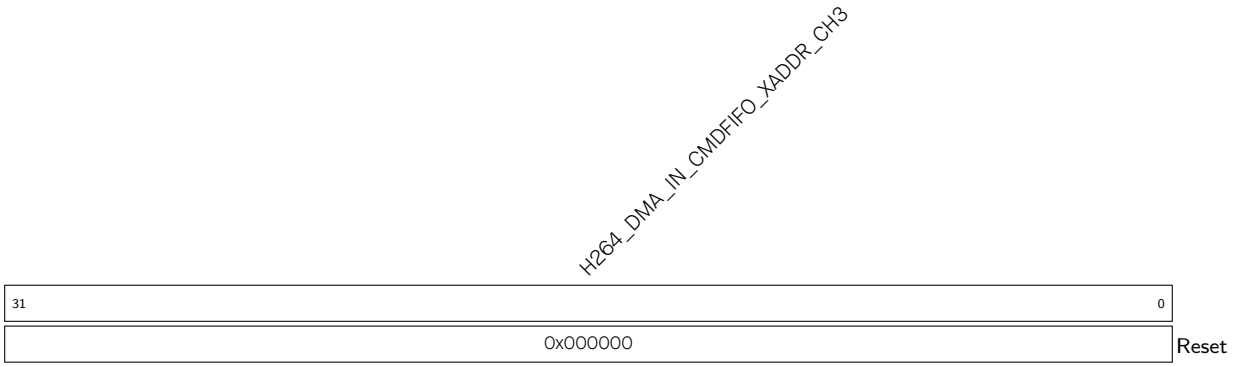
H264_DMA_INLINK_DSCR_BF0_CH3 Represents the address of the current descriptor x that is pre-read. (RO)

Register 41.309. H264_DMA_IN_DSCR_BF1_CH3_REG (0x0838)



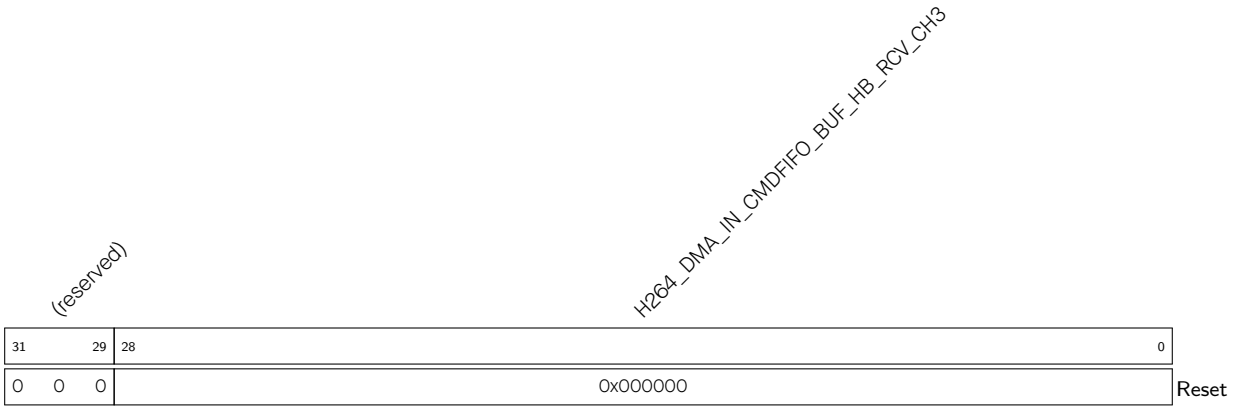
H264_DMA_INLINK_DSCR_BF1_CH3 Represents the address of the previous descriptor x-1 that is pre-read. (RO)

Register 41.310. H264_DMA_IN_FIFO_CNT_CH3_REG (0x0880)



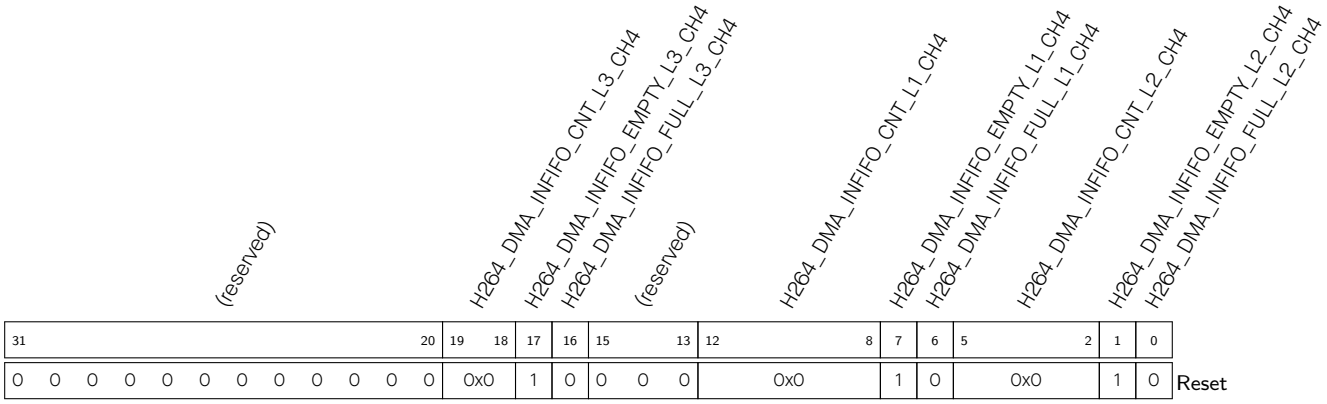
H264_DMA_IN_CMDFIFO_INFIFO_CNT_CH3 Represents the remaining request data in FIFO. (RO)

Register 41.311. H264_DMA_IN_POP_DATA_CNT_CH3_REG (0x0884)



H264_DMA_IN_CMDFIFO_POP_DATA_CNT_CH3 Represents the data quantity in the current AXI request. (RO)

Register 41.312. H264_DMA_IN_XADDR_CH3_REG (0x0888)



H264_DMA_IN_CMDFIFO_XADDR_CH3 Represents the address of the current AXI request. (RO)

Register 41.313. H264_DMA_IN_BUF_HB_RCV_CH3_REG (0x088C)

H264_DMA_IN_CMDFIFO_BUF_HB_RCV_CH3 Represents the data quantity that has been requested. (RO)

Register 41.314. H264_DMA_INFIFO_STATUS_CH4_REG (0x0914)

H264_DMA_INFIFO_FULL_L2_CH4 Represents whether l2 FIFO of RX channel 4 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L2_CH4 Represents whether l2 FIFO of RX channel 4 is empty.

0: Not empty

1: Empty

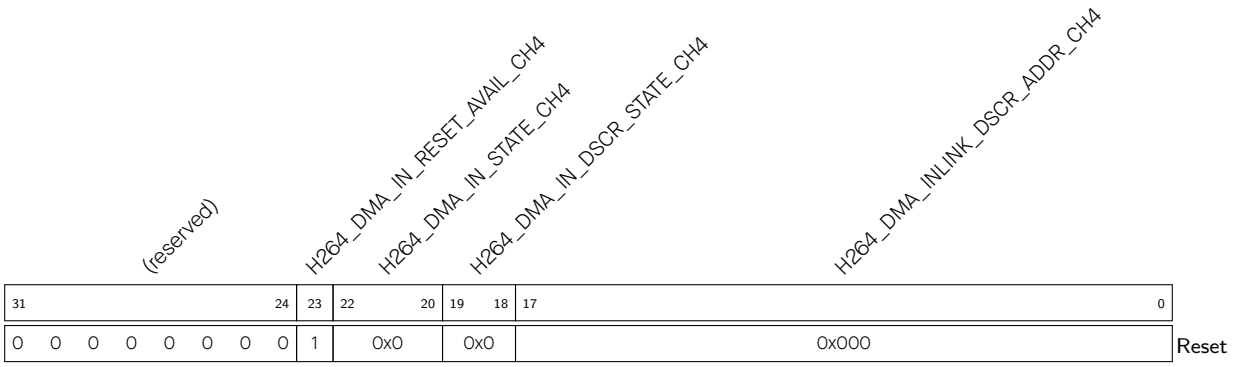
H264_DMA_INFIFO_FULL_L3_CH4 Represents whether l3 FIFO of RX channel 4 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L3_CH4 Represents whether l3 FIFO of RX channel 4 is empty.



0: Not empty

1: Empty

(RO)

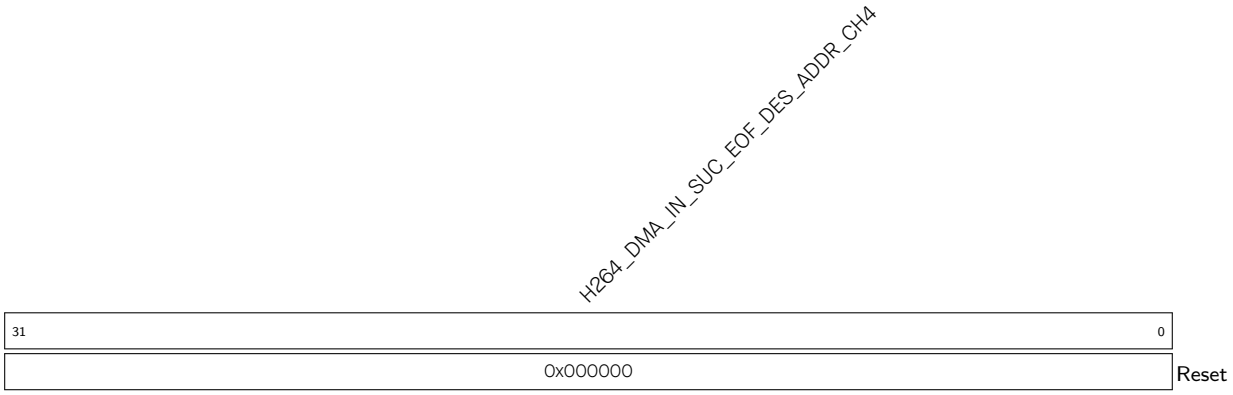
H264_DMA_INFIFO_CNT_L3_CH4 Represents the data quantity in l3 FIFO for RX channel 4. Measurement unit: 8 bytes. (RO)

Register 41.315. H264_DMA_IN_STATE_CH4_REG (0x0924)

H264_DMA_INLINK_DSCR_ADDR_CH4 Represents the current inlink descriptor's address for RX channel 4. (RO)

H264_DMA_IN_DSCR_STATE_CH4 Represents the current state of the descriptor state machine for RX channel 4. (RO)

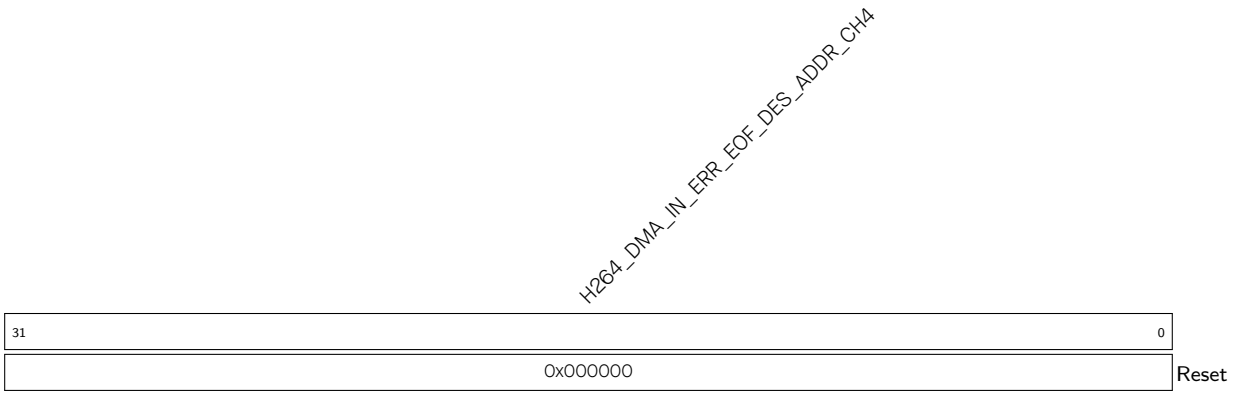
H264_DMA_IN_STATE_CH4 Represents the current control module state machine state for RX channel 4. (RO)



H264_DMA_IN_RESET_AVAIL_CH4 Represents whether it is safe to reset the channel.

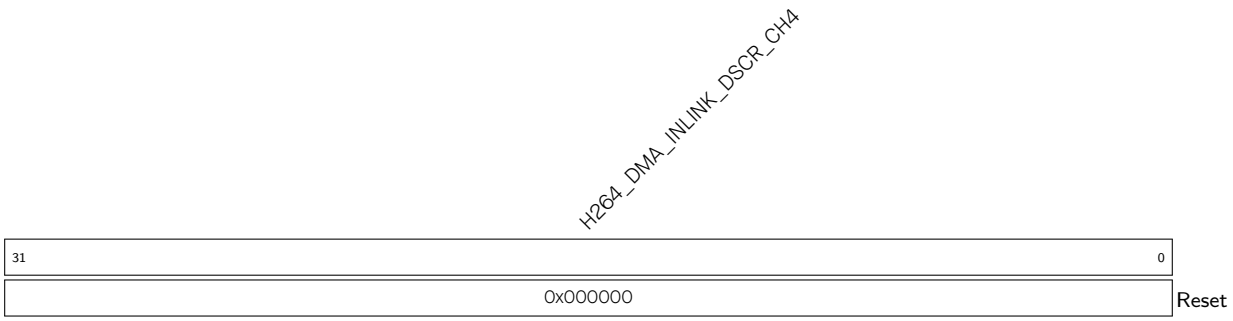
0: Unsafe

1: Safe



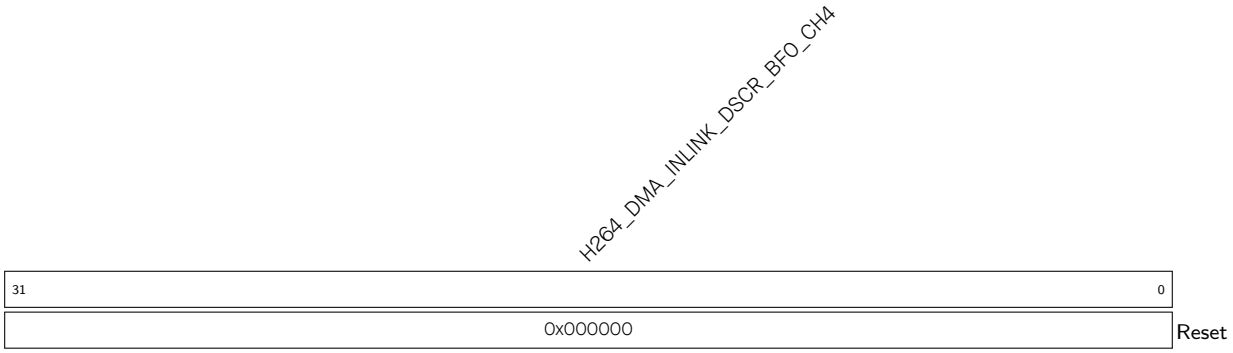
(RO)

Register 41.316. H264_DMA_IN_SUC_EOF_DES_ADDR_CH4_REG (0x0928)



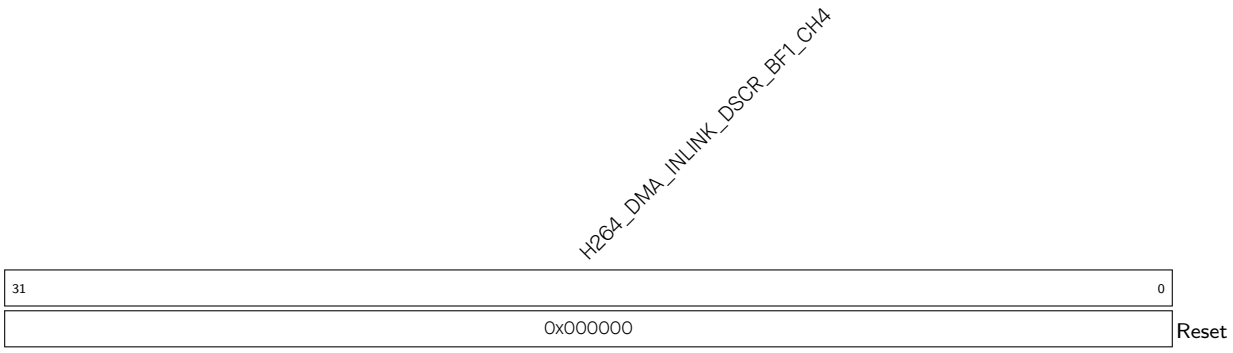
H264_DMA_IN_SUC_EOF_DES_ADDR_CH4 Represents the address of the inlink descriptor when the EOF bit in this descriptor is 1. (RO)

Register 41.317. H264_DMA_IN_ERR_EOF_DES_ADDR_CH4_REG (0x092C)



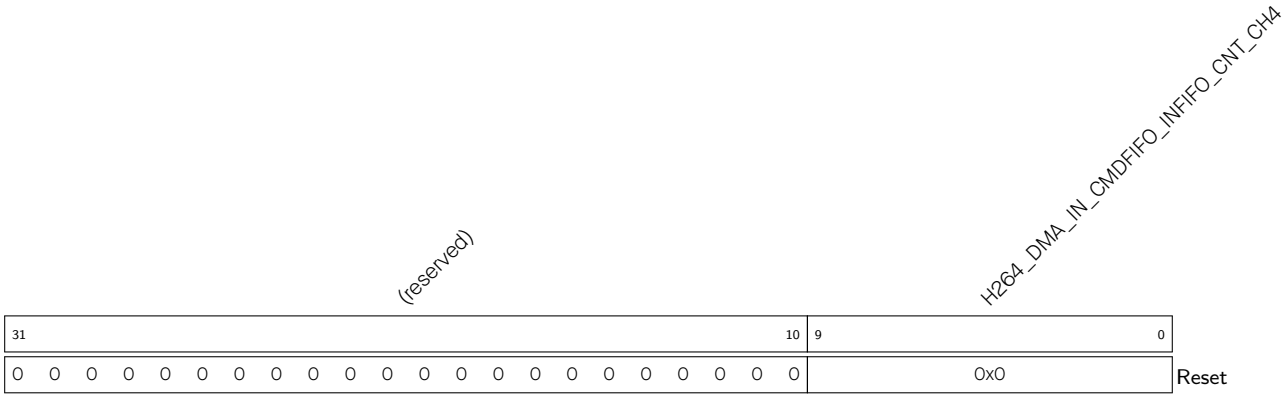
H264_DMA_IN_ERR_EOF_DES_ADDR_CH4 Represents the address of the inlink descriptor when there are errors during the current data reception. (RO)

Register 41.318. H264_DMA_IN_DSCR_CH4_REG (0x0930)



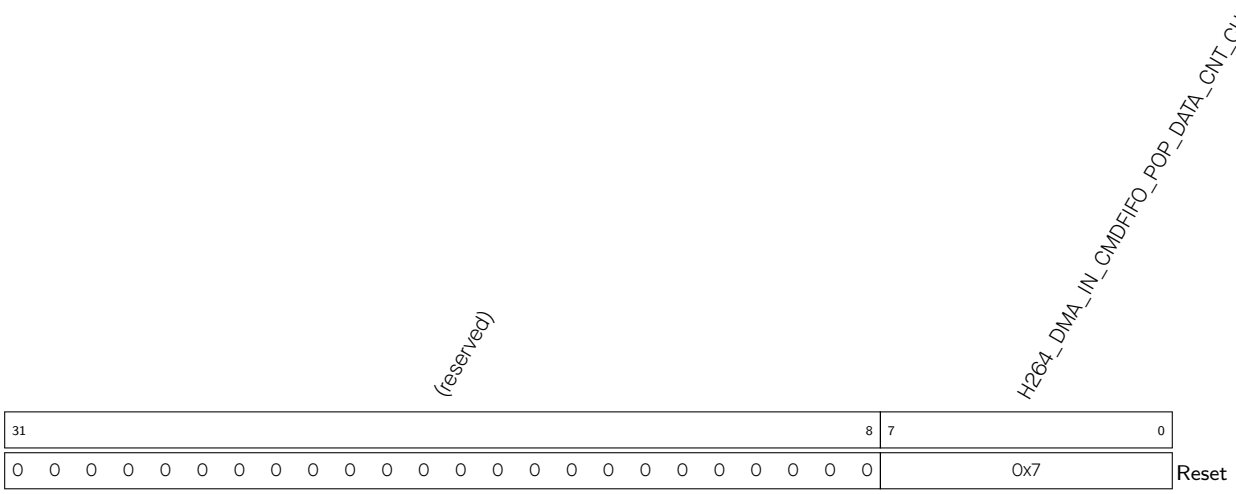
H264_DMA_INLINK_DSCR_CH4 Represents the address of the next descriptor x+1 pointed by the current descriptor that is pre-read. (RO)

Register 41.319. H264_DMA_IN_DSCR_BF0_CH4_REG (0x0934)



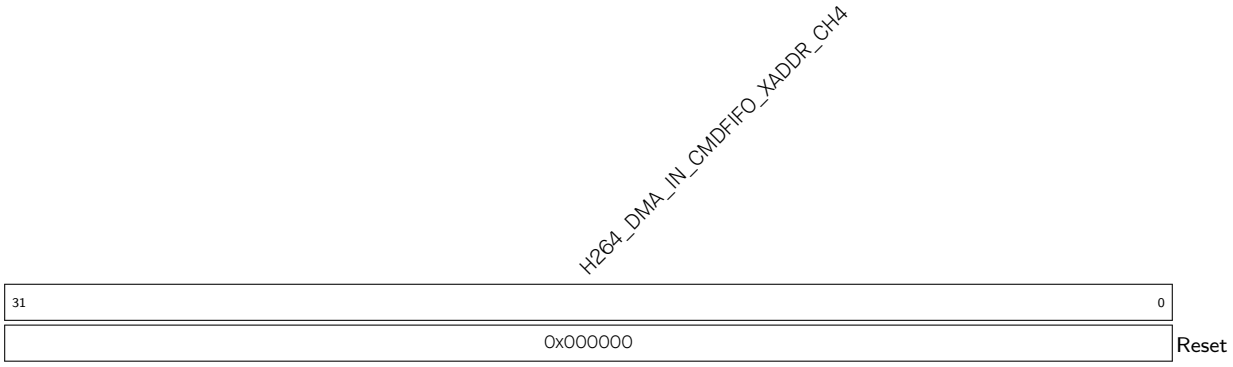
H264_DMA_INLINK_DSCR_BF0_CH4 Represents the address of the current descriptor x that is pre-read. (RO)

Register 41.320. H264_DMA_IN_DSCR_BF1_CH4_REG (0x0938)



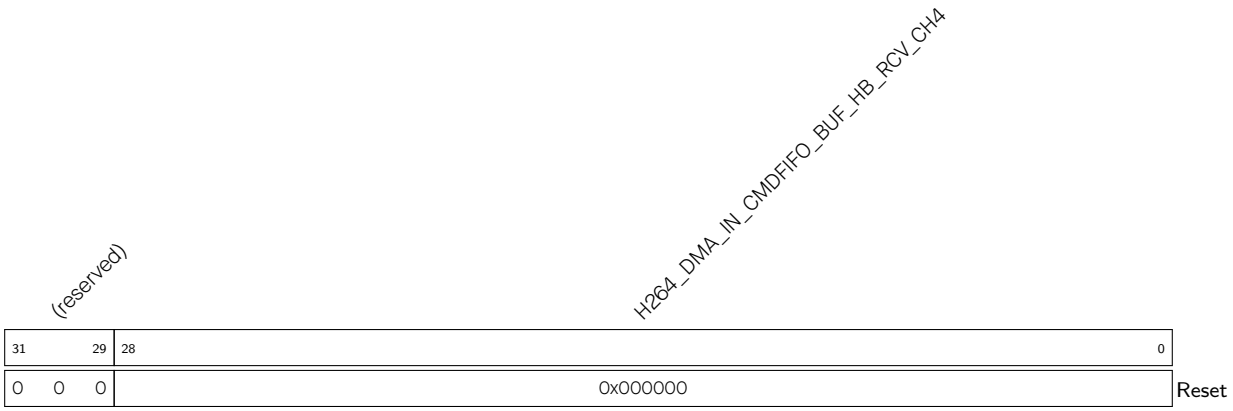
H264_DMA_INLINK_DSCR_BF1_CH4 Represents the address of the previous descriptor x-1 that is pre-read. (RO)

Register 41.321. H264_DMA_IN_FIFO_CNT_CH4_REG (0x0980)



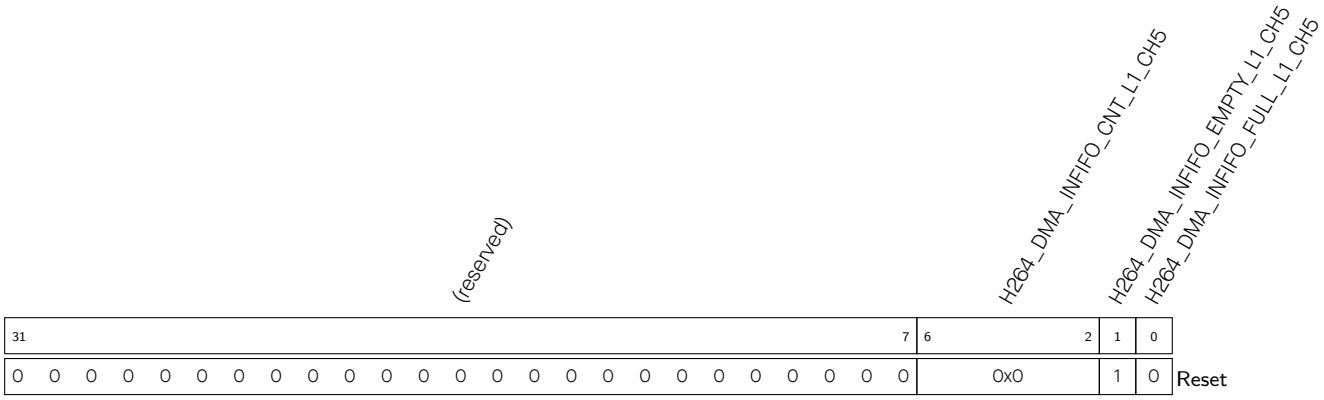
H264_DMA_IN_CMDFIFO_INFIFO_CNT_CH4 Represents the remaining request data in FIFO. (RO)

Register 41.322. H264_DMA_IN_POP_DATA_CNT_CH4_REG (0x0984)



H264_DMA_IN_CMDFIFO_POP_DATA_CNT_CH4 Represents the data quantity in the current AXI request. (RO)

Register 41.323. H264_DMA_IN_XADDR_CH4_REG (0x0988)



H264_DMA_IN_CMDFIFO_XADDR_CH4 Represents the address of the current AXI request. (RO)

Register 41.324. H264_DMA_IN_BUF_HB_RCV_CH4_REG (0x098C)

H264_DMA_IN_CMDFIFO_BUF_HB_RCV_CH4 Represents the data quantity that has been requested. (RO)

Register 41.325. H264_DMA_INFIFO_STATUS_CH5_REG (0x0A20)

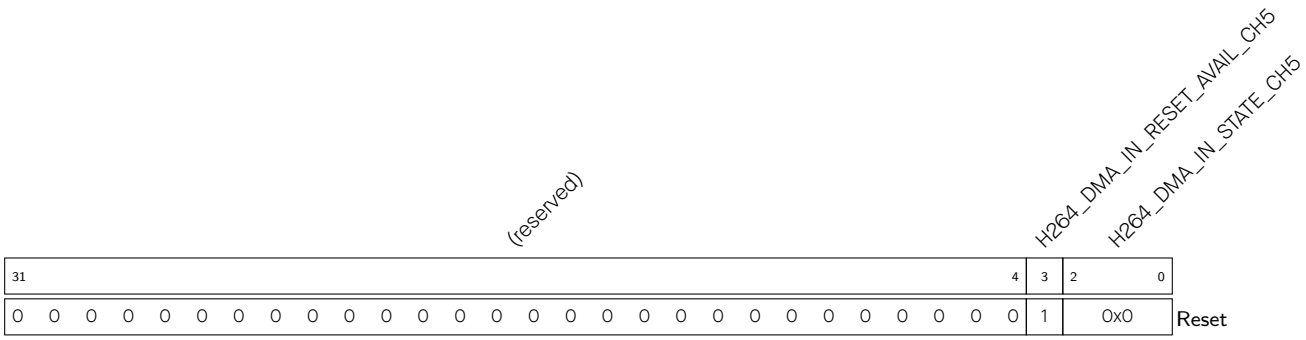
H264_DMA_INFIFO_FULL_L1_CH5 Represents whether l1 FIFO of RX channel 5 is full.

0: Not Full

1: Full

(RO)

H264_DMA_INFIFO_EMPTY_L1_CH5 Represents whether l1 FIFO of RX channel 5 is empty.



0: Not empty

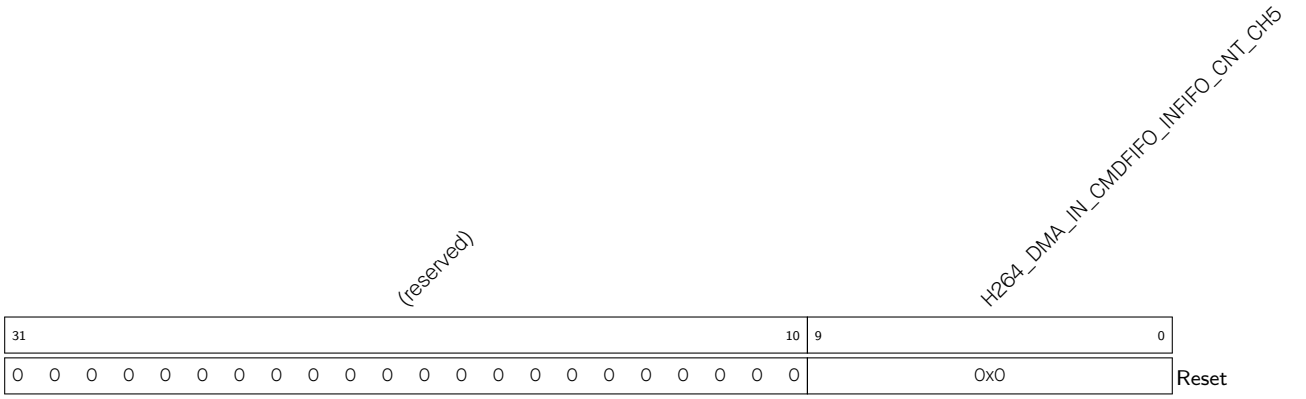
1: Empty

(RO)

H264_DMA_INFIFO_CNT_L1_CH5 Represents the data quantity in l1 FIFO for RX channel 5. Measurement unit: byte. (RO)

Register 41.326. H264_DMA_IN_STATE_CH5_REG (0x0A28)

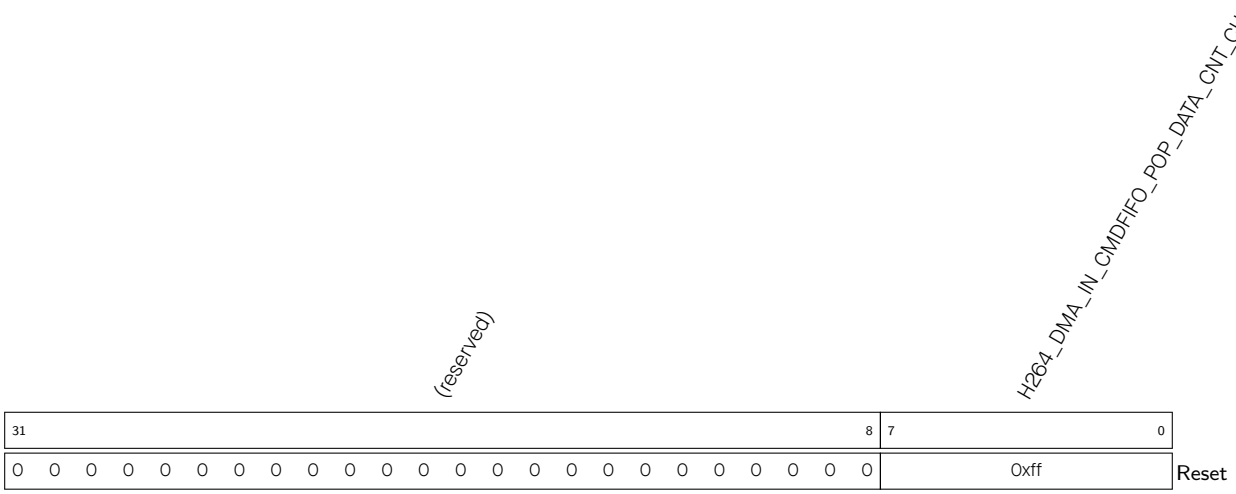
H264_DMA_IN_STATE_CH5 Represents the current control module state machine state for RX channel 5. (RO)



H264_DMA_IN_RESET_AVAIL_CH5 Represents whether it is safe to reset the channel.

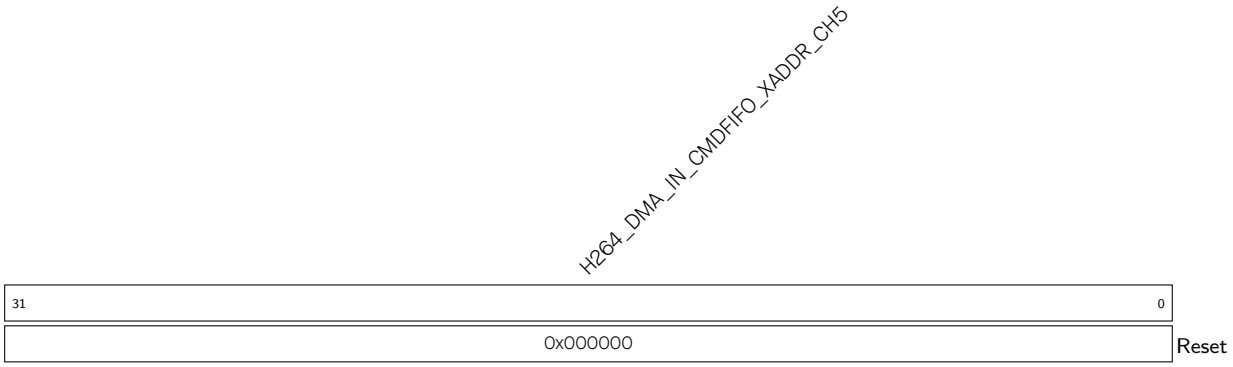
0: Unsafe

1: Safe



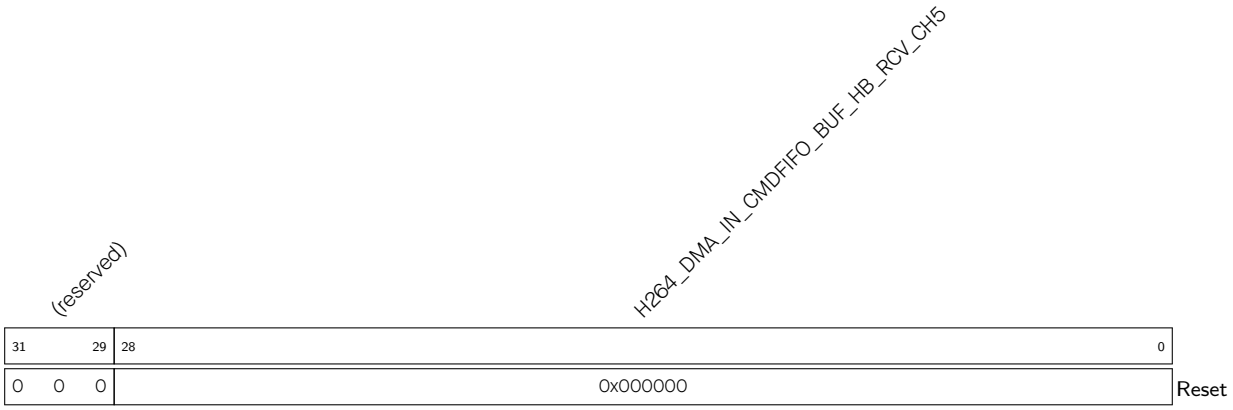
(RO)

Register 41.327. H264_DMA_IN_FIFO_CNT_CH5_REG (0x0A80)



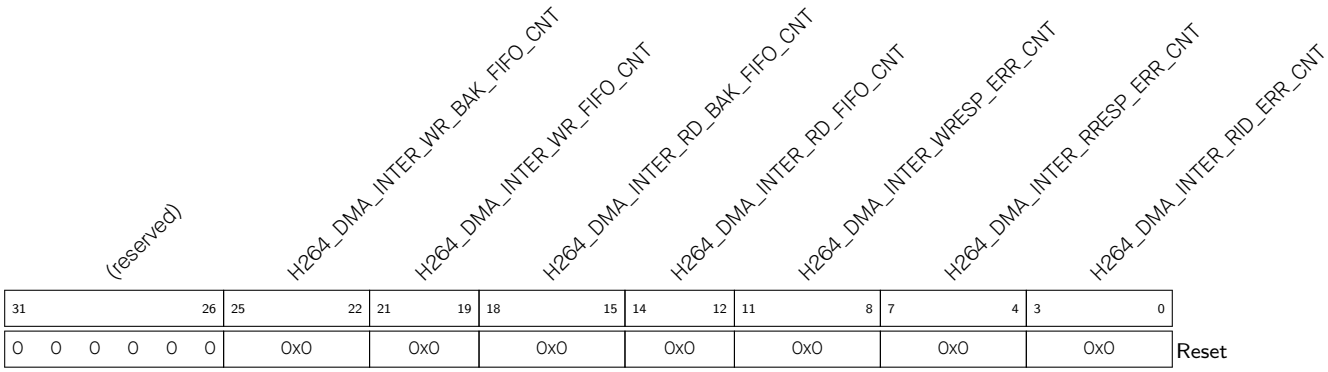
H264_DMA_IN_CMDFIFO_INFIFO_CNT_CH5 Represents the remaining request data in FIFO. (RO)

Register 41.328. H264_DMA_IN_POP_DATA_CNT_CH5_REG (0x0A84)



H264_DMA_IN_CMDFIFO_POP_DATA_CNT_CH5 Represents the data quantity in the current AXI request. (RO)

Register 41.329. H264_DMA_IN_XADDR_CH5_REG (0x0A88)



H264_DMA_IN_CMDFIFO_XADDR_CH5 Represents the address of the current AXI request. (RO)

Register 41.330. H264_DMA_IN_BUF_HB_RCV_CH5_REG (0x0A8C)

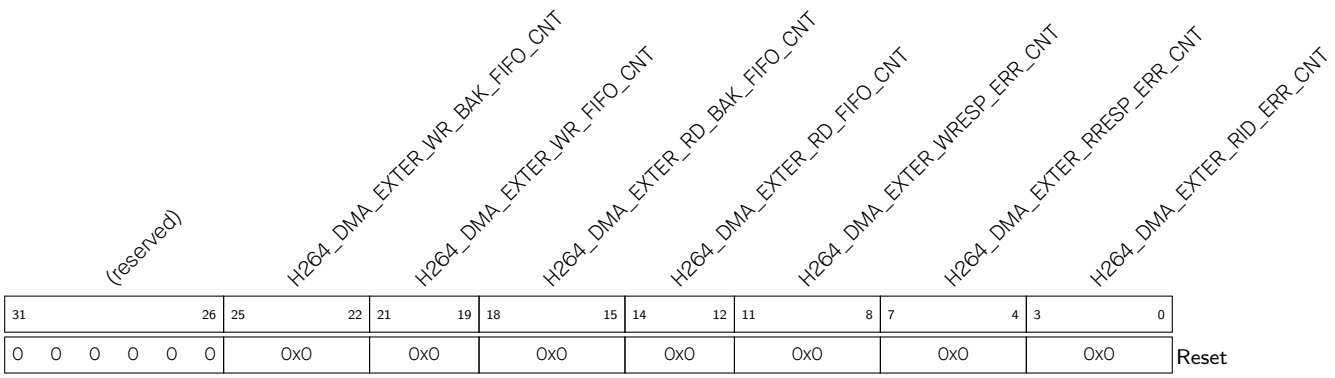
H264_DMA_IN_CMDFIFO_BUF_HB_RCV_CH5 Represents the data quantity that has been requested. (RO)

Register 41.331. H264_DMA_INTER_AXI_ERR_REG (0x0B00)

H264_DMA_INTER_RID_ERR_CNT Represents the count of errors in the internal memory ID for AXI read operations. (RO)

H264_DMA_INTER_RRESP_ERR_CNT Represents the count of errors in the response for internal memory during AXI read operations. (RO)

H264_DMA_INTER_WRESP_ERR_CNT Represents the count of AXI write internal memory resp err. (RO)



H264_DMA_INTER_RD_FIFO_CNT Represents the count of cmd FIFO remain cmd in AXI read internal memory module. (RO)

H264_DMA_INTER_RD_BAK_FIFO_CNT Represents the count of backup cmd FIFO remain cmd in AXI read internal memory module.(RO)

H264_DMA_INTER_WR_FIFO_CNT Represents the count of cmd FIFO remain cmd in AXI write internal memory module. (RO)

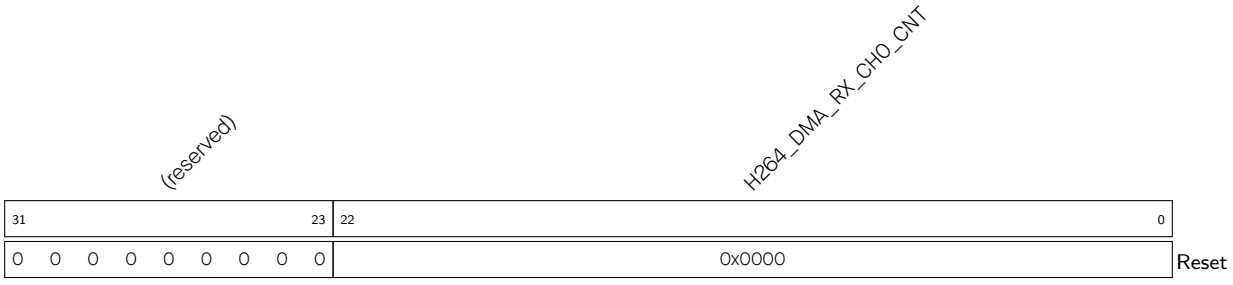
H264_DMA_INTER_WR_BAK_FIFO_CNT Represents the count of backup cmd FIFO remain cmd in AXI write internal memory module. (RO)

Register 41.332. H264_DMA_EXTER_AXI_ERR_REG (0x0B04)

H264_DMA_EXTER_RID_ERR_CNT Represents the count of errors in the external memory ID for AXI read. (RO)

H264_DMA_EXTER_RRESP_ERR_CNT Represents the count of errors in the response for external memory during AXI read operations. (RO)

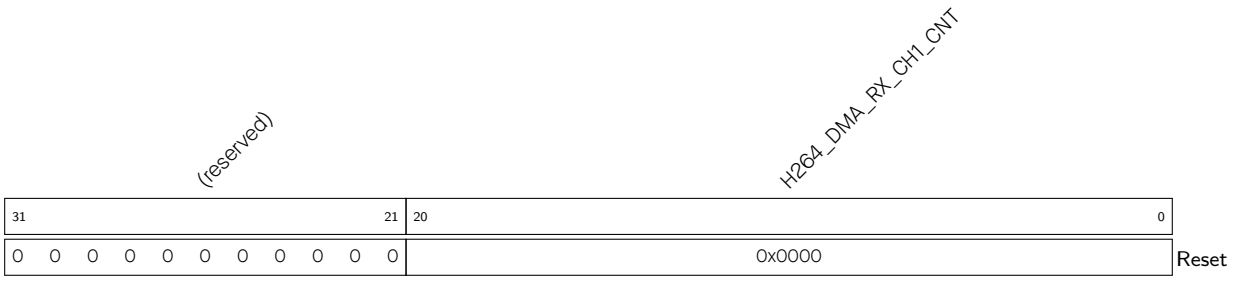
H264_DMA_EXTER_WRESP_ERR_CNT Represents the count of AXI write external memory resp err. (RO)



H264_DMA_EXTER_RD_FIFO_CNT Represents the count of cmd FIFO remain cmd in AXI read external memory module. (RO)

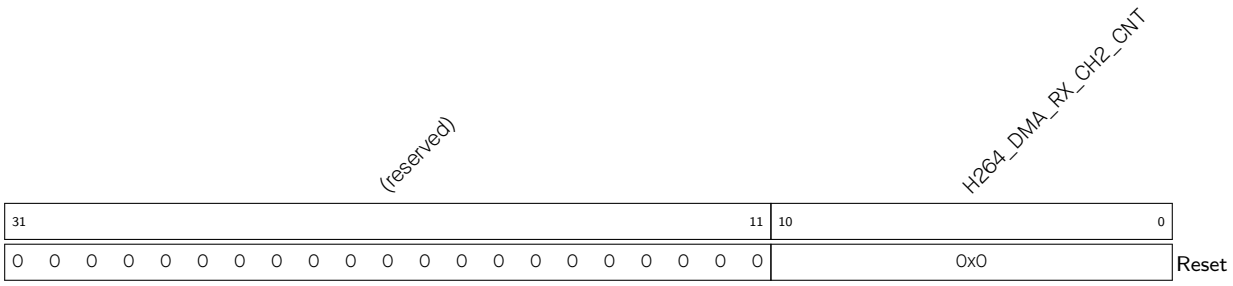
H264_DMA_EXTER_RD_BAK_FIFO_CNT Represents the count of backup cmd FIFO remain cmd in AXI read external memory module.(RO)

H264_DMA_EXTER_WR_FIFO_CNT Represents the count of cmd FIFO remain cmd in AXI write external memory module. (RO)



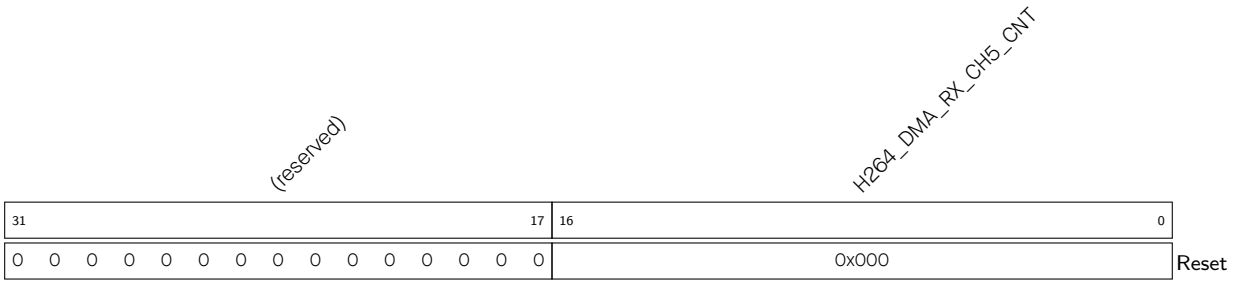
H264_DMA_EXTER_WR_BAK_FIFO_CNT Represents the count of backup cmd FIFO remain cmd in AXI write external memory module. (RO)

Register 41.333. H264_DMA_RX_CH0_COUNTER_REG (0x0B54)



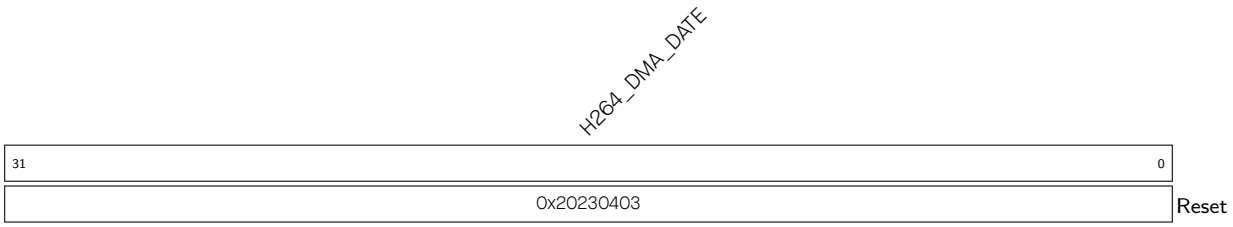
H264_DMA_RX_CH0_CNT Represents the RX channel 0 counter register. (RO)

Register 41.334. H264_DMA_RX_CH1_COUNTER_REG (0x0B58)



H264_DMA_RX_CH1_CNT Represents the RX channel 1 counter register. (RO)

Register 41.335. H264_DMA_RX_CH2_COUNTER_REG (0x0B5C)



H264_DMA_RX_CH2_CNT Represents the RX channel 2 counter register. (RO)

Register 41.336. H264_DMA_RX_CH5_COUNTER_REG (0x0B60)

H264_DMA_RX_CH5_CNT Represents the RX channel 5 counter register (RO)

Register 41.337. H264_DMA_DATE_REG (0x0B3C)

H264_DMA_DATE Version control register. (R/W)

Chapter 42

MIPI CSI

42.1 Introduction

The MIPI CSI module of ESP32-P4 provides a standard interface with camera modules for mobile devices, such as smartphones, tablets, and other portable electronics. It connects cameras to application processors in mobile devices, enabling high-speed data transfer and efficient communication between the camera and the host system.

ESP32-P4 MIPI CSI implements a MIPI RX D-PHY and a MIPI CSI-2 host controller. It provides one clock lane and two data lanes, supporting a data transmission of up to 1.5 Gbps per lane to communicate with camera sensors compliant with the MIPI CSI-2 specification.

Note:
The MIPI CSI-2 specification defines the communication between image application processors and cameras. It is part of the communication protocols defined by MIPI Alliance standards, designed for chip-to-chip communication in mobile systems.

42.2 Terminology

This section covers terminology used to describe the functionality of MIPI CSI.

MIPI CSI-2 MIPI Alliance Specification for Camera Serial Interface 2. It receives camera data through the PHY Protocol Interface (PPI) from the MIPI RX D-PHY and outputs data through a 32-bit image interface to the Image Signal Processor (ISP).

MIPI D-PHY MIPI Alliance Specification for the source synchronous physical layer. It implements the physical layer of universal lanes for the MIPI D-PHY interface, which receives clock and data from MIPI camera sensors through one clock lane and two data lanes.

PPI PHY Protocol Interface defined in MIPI Alliance Specification. It connects the CSI-2 host controller and D-PHY.

ISP Image Signal Processor, used to process images received from the camera. For more details about ISP, please refer to Chapter 38 *Image Signal Processor (ISP)*.

Transmitter The device that transmits data, usually a MIPI camera.

Receiver The device that receives data, in this chapter, the ESP32-P4 chip.

Clock lane The clock lane of the MIPI D-PHY interface, used to transmit high-speed differential clock signals.

Data lane	The data lane of the MIPI D-PHY interface, used to transmit data and commands.
Line	The line of the data lane of the MIPI D-PHY interface; each data lane consists of two lines: P and N.
Sequence	A string of state codes received through the data lane, controlling the MIPI RX D-PHY to enter other modes from Control mode.
Control mode	One of the operating modes of the MIPI RX D-PHY, used to receive requests from the transmitter. All other modes return to this mode.
High-Speed Data Reception mode	One of the operating modes of the MIPI RX D-PHY, used to receive data in burst mode.
Escape mode	One of the operating modes of the MIPI RX D-PHY, used to support low-speed asynchronous communication on the data lane to maintain a low-power state.
Ultra Low Power State (ULPS)	One of the operating modes of the MIPI RX D-PHY, in which the clock lane and data lane are in idle state, maintaining the lowest power consumption except for the Shut-Down state.
Test code	Specific control or configuration codes used to manage and test the MIPI D-PHY, such as setting operational mode.

42.3 Feature List

MIPI CSI in ESP32-P4 supports the following features:

- MIPI RX D-PHY compliant with MIPI D-PHY interface specification revision 1.1
- MIPI CSI-2 host compliant with MIPI CSI-2 specification
- Two data lanes, each with a rate ranging from 80 Mbps to 1.5 Gbps
- Ultra Low Power State in Escape mode
- 32-bit image interface with ISP
- Various input image formats:
  - RGB888/RGB666/RGB565
  - YUV422/YUV420
  - RAW8/RAW10/RAW12
- Error detection and correction at PHY level, packet level, line level, and frame level
- Electromagnetic Interference (EMI) mitigation by data scrambling

Note:
ESP32-P4 does not support different virtual channels defined in the MIPI specification, so virtual channel numbers in the packet header are ignored.

42.4 Architectural Overview

Figure 42.4-1 shows the architecture of MIPI CSI and its connection to other system components. The MIPI CSI consists of the following components:

- **MIPI RX D-PHY**: Implements the physical link layer, including one clock lane (CP/CN) and two data lanes (D0P/D0N and D1P/D1N) to connect with cameras.
- **MIPI CSI-2 host**: Implements the CSI-2 protocol, receives camera data from D-PHY, and outputs through the Image Interface, which includes:
  - **Pipeline**: Registers PPI signals.
  - **Descrambler**: Converts PPI scrambled data to its original values when enabled.
  - **PHY adaptation layer**: Manages the PHY interface, including PHY error handling.
  - **Packet analyzer**: Processes received data from lanes, including data lane merging, header decoding, and various error detection and correction.
  - **Image interface**: Reorders pixels into 32-bit Image Interface data and generates timing-accurate video synchronization signals.
  - **Error management**: Monitors and notifies about error conditions on the CSI-2 link.
  - **Register bank**: Provides access to configuration and control registers.
- **PPI interface**: Connects the MIPI RX D-PHY and the MIPI CSI-2 host controller.
- **Test code interface**: Sends configuration details from the MIPI CSI-2 host controller to the MIPI RX D-PHY.

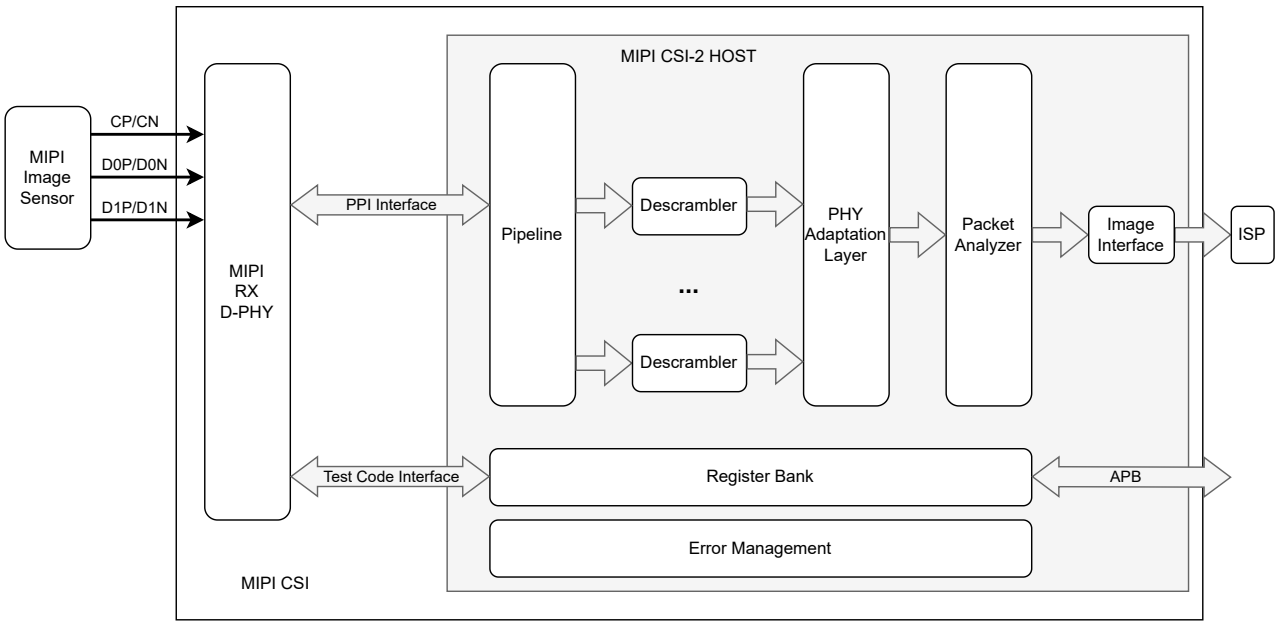


Figure 42.4-1. MIPI CSI Architecture

42.5 Functional Description

This section introduces the operating states and modes of the MIPI RX D-PHY and the major functions that facilitate the use of MIPI CSI. For detailed configurations, refer to Section 42.7 Programming Procedures.

42.5.1 Data Lane State

The functions of the transmitter determine the data lane state by driving certain line levels. During normal operation, either an HS-TX or an LP-TX is driving a lane.

- HS-TX: High-Speed transaction. An HS-TX always drives the lane differentially. It operates in two states: HS-0 and HS-1. When HS-TX drives the lane, the lane remains in High-Speed Data Reception mode.
  - HS-0: Transmits differential data 0 in High-Speed Data Reception mode.
  - HS-1: Transmits differential data 1 in High-Speed Data Reception mode.
- LP-TX: Low-Power transaction. The two LP-TXs drive the two lines of a lane independently and single-ended. It operates in four states: LP-00, LP-01, LP-10, and LP-11. When LP-TX drives the lane, the lane is in Control mode or Escape mode.
  - LP-00: A bridge state between other LP states (LP-01, LP-10, LP-11) in Control Mode or Escape Mode. When in Ultra Low Power State (ULPS), lanes are also in the LP-00 state.
  - LP-01: Transmits data 0 in Escape mode, or indicates entry into High-Speed Data Reception mode from Control mode.
    The complete sequence for entering High-Speed Data Reception mode is: LP-11 → LP-01 → LP-00
  - LP-10: Transmits data 1 in Escape mode, or indicates entry into Escape mode or Turnaround mode from Control mode.
    The complete sequence for entering Escape mode is: LP-11 → LP-10 → LP-00 → LP-01 → LP-00.
    The complete sequence for entering the Turnaround mode is: LP-11 → LP-10 → LP-00 → LP-10 → LP-00
  - LP-11: The stop state, i.e., the default idle state of a lane.

Note:
The Turnaround mode is used for switching the data transmission direction. This mode is not used in the ESP32-P4 MIPI CSI, and will not be further explained in this chapter.

Figure 42.5-1 shows the lane line levels for High-Speed (HS) and Low-Power (LP) transactions.

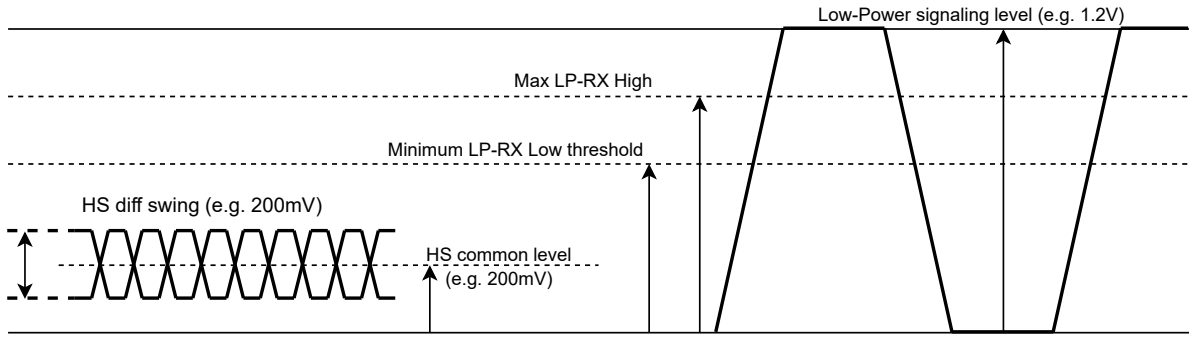

Figure 42.5-1. Level of MIPI Data Lane Lines

Table 42.5-1 shows the available line states.

Table 42.5-1. Lane State Descriptions

State Code	DP Line	DN Line	Corresponding State in Different Modes		
			High-Speed Data Reception Mode	Control Mode	Escape Mode
HS-0	HS Low	HS High	0	N/A	N/A
HS-1	HS High	HS Low	1	N/A	N/A
LP-00	LP Low	LP Low	N/A	Bridge	Space
LP-01	LP Low	LP High	N/A	HS-Rqst	0
LP-10	LP High	LP Low	N/A	LP-Rqst	1
LP-11	LP High	LP High	N/A	Stop	N/A

42.5.2 MIPI RX D-PHY Operation

Figure 42.5-2 illustrates the various states and modes of the MIPI RX D-PHY during initialization and active state. Detailed descriptions of each states and modes are presented in the following sections.

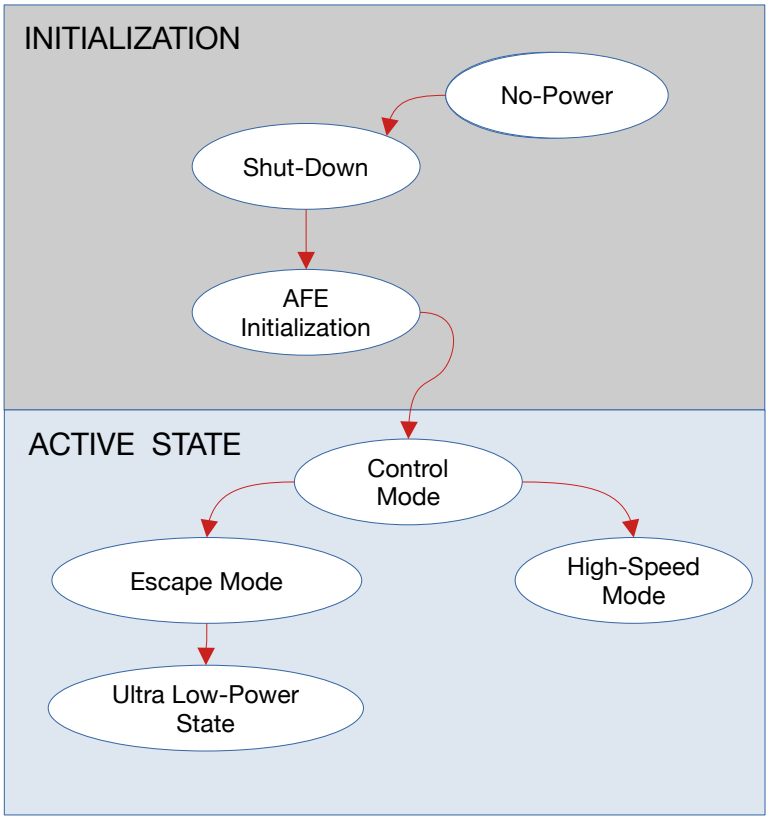

Figure 42.5-2. MIPI RX D-PHY Operating States and Modes

42.5.2.1 No-Power State

In the No-Power state, no supply voltage is applied to the PHY.

The MIPI RX D-PHY of MIPI CSI is in No-Power state when the power supply VDD_HP_*n* (n: 0-3) and VDD_MIPI_DPHY are off.

42.5.2.2 Shut-Down State

Shut-Down state refers to the idle state.

In Shut-Down state, the PHY disables all analog blocks, resets all digital logic, and sets the DOP/DON, D1P/D1N, and CP/CN lanes to high impedance (Hi-Z). Activating the Shut-Down state ensures the lowest power consumption. To enable the Shut-Down state of the PHY, set CSI_HOST_DPHY_RSTZ and CSI_HOST_PHY_SHUTDOWNZ to 0.

Before leaving the Shut-Down state, configure several parameters, including the lane number to be used and the lane operation frequency range.

The MIPI RX D-PHY consists of two data lanes. Configure CSI_HOST_N_LANES to select either one or both data lanes. These configurations should remain static or stable before exiting the Shut-Down state.

Depending on the specific requirements for the MIPI RX D-PHY, additional configuration steps might be necessary. By default, the PHY operates within a lower range of 80-110 Mbps. To accommodate higher bit rates, adjust the HS frequency ranges (the hsfreqrange field) in test code HS RX Control of lane 0 with the appropriate code. It is recommended to perform this adjustment in the Shut-Down state, as the control interface is independent of the rest of the MIPI RX D-PHY.

The different ranges supported are shown in Table 42.5-2. The hsfreqrange field indicates the HS operating frequency range and is accessible through test code 0x44. For detailed configuration, please refer to Section *42.5.3 MIPI RX D-PHY Configuration*.

Table 42.5-2. Frequency Ranges Supported by MIPI RX D-PHY

Frequency Range (Mbps)	hsfreqrange[5:0]
80-89	000000
90-99	010000
100-109	100000
110-129	000001
130-139	010001
140-149	100001
150-169	000010
170-179	010010
180-199	100010
200-219	000011
220-239	010011
240-249	100011
250-269	000100
270-299	010100
300-329	000101
330-359	010101
360-399	100101
400-449	000110
450-499	010110
500-549	000111
550-599	010111
600-649	001000
650-699	011000
700-749	001001
750-799	011001
800-849	101001
850-899	111001
900-949	001010
950-999	011010
1000-1049	101010
1050-1099	111010
1100-1149	001011
1150-1199	011011
1200-1249	101011
1250-1299	111011
1300-1349	001100
1350-1399	011100
1400-1449	101100

Frequency Range (Mbps)	hsfreqrange[5:0]
1450-1500	111100

When CSI_HOST_DPHY_RSTZ and CSI_HOST_PHY_SHUTDOWNZ are set to 1, the MIPI RX D-PHY leaves the Shut-Down state and starts the initialization procedure.

42.5.2.3 AFE Initialization

After releasing CSI_HOST_DPHY_RSTZ and CSI_HOST_PHY_SHUTDOWNZ, the PHY begins an initialization sequence for normal operation. It is recommended to release CSI_HOST_PHY_SHUTDOWNZ before CSI_HOST_DPHY_RSTZ. Additionally, ensure that CSI_DPHY_CFG_CLK (refer to Table 11.2-5 in Chapter 11 *Reset and Clock* for details) is available and stable at this point.

The initialization sequence includes several steps, such as enabling internal blocks and performing internal calibrations. Once completed, control transfers to the lanes, which manage power for LP/HS requests from the transmitter by enabling or disabling the corresponding receivers.

Set CSI_HOST_PHY_STOPSTATEDATA_*n* and CSI_HOST_PHY_STOPSTATECLK to 1 to perform all initialization steps. In this state, both clock and data lanes are in stop state (LP-11).

The initialization period (TINIT) is a protocol-dependent parameter with a minimum duration of 100 μs, as defined by the specification. After setting CSI_HOST_PHY_STOPSTATEDATA_*n* and CSI_HOST_PHY_STOPSTATECLK to 1, the software should wait more than 100 μs before starting camera data reception.

42.5.2.4 Control Mode

After completing AFE initialization, the MIPI RX D-PHY remains in Control mode by default. It receives the LP-11 state code (stop state) on the lines until a request is made. Upon receiving a request, the PHY enters either High-Speed Data Reception mode, Escape mode, or Ultra Low Power State. All requests must begin and end with the lanes in the stop state.

42.5.2.5 High-Speed Data Reception Mode

In High-Speed Data Reception mode, the PHY receives data in bursts. The lane operates in high-speed mode only during these bursts.

As shown in Figure 42.5-3, a burst consists of three parts: the low-power initialization sequence, the high-speed data payload, and the end of reception sequence.

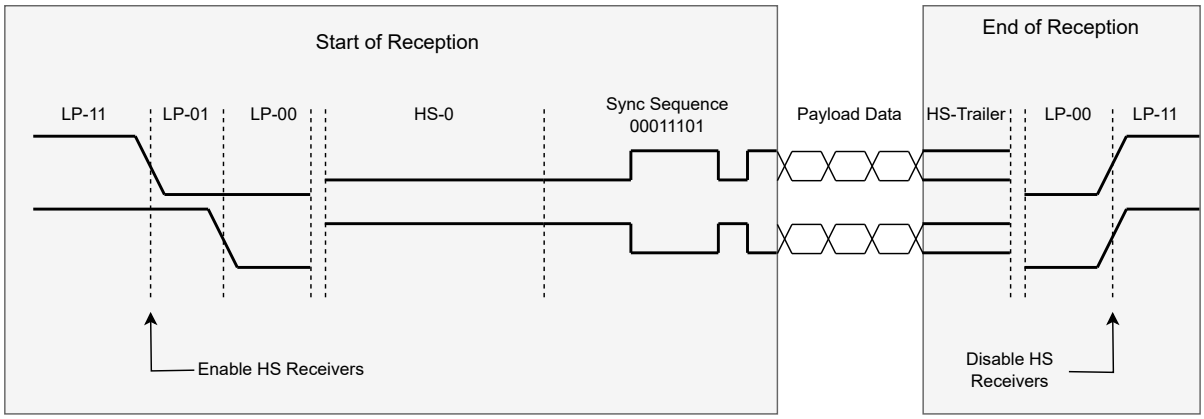

Figure 42.5-3. MIPI CSI HS Data Reception Sequence

The receiver enters high-speed mode following the low-power sequence of [LP-11 > LP-01 > LP-00]. Synchronization is achieved through a sync sequence of “00011101”. After synchronization, the PHY receives high-speed data until a transition from LP-00 to LP-11 is detected on the lane.

42.5.2.6 Escape Mode

Escape mode allows asynchronous communication using data lanes at low speed. During Escape mode, the lane remains in low-power state. A data lane enters this mode after Escape mode request sequence [LP-11 > LP-10 > LP-00 > LP-01 > LP-00]. If an LP-11 state code is detected before the lane reaches LP-00, the request will be aborted, and the lane will return to stop state. Upon entering Escape mode, the transmitter sends an 8-bit command to indicate a requested action.

MIPI CSI only supports Ultra Low Power State (ULPS) in escape mode. The 8-bit command to enter ULPS is “b00011110”. If the entry command is not valid, it will be ignored, and the receiver will wait until the transmitter returns to the stop state.

Ultra Low Power State

Ultra Low Power State involves the lowest power consumption, except for the Shut-Down state.

For data lanes, this mode is activated by sending an Ultra Low Power State entry command “00011110”. After that, the clock lane and data lanes enter the space state (LP-00).

Figure 42.5-4 shows the ULPS sequences for clock and data lanes.

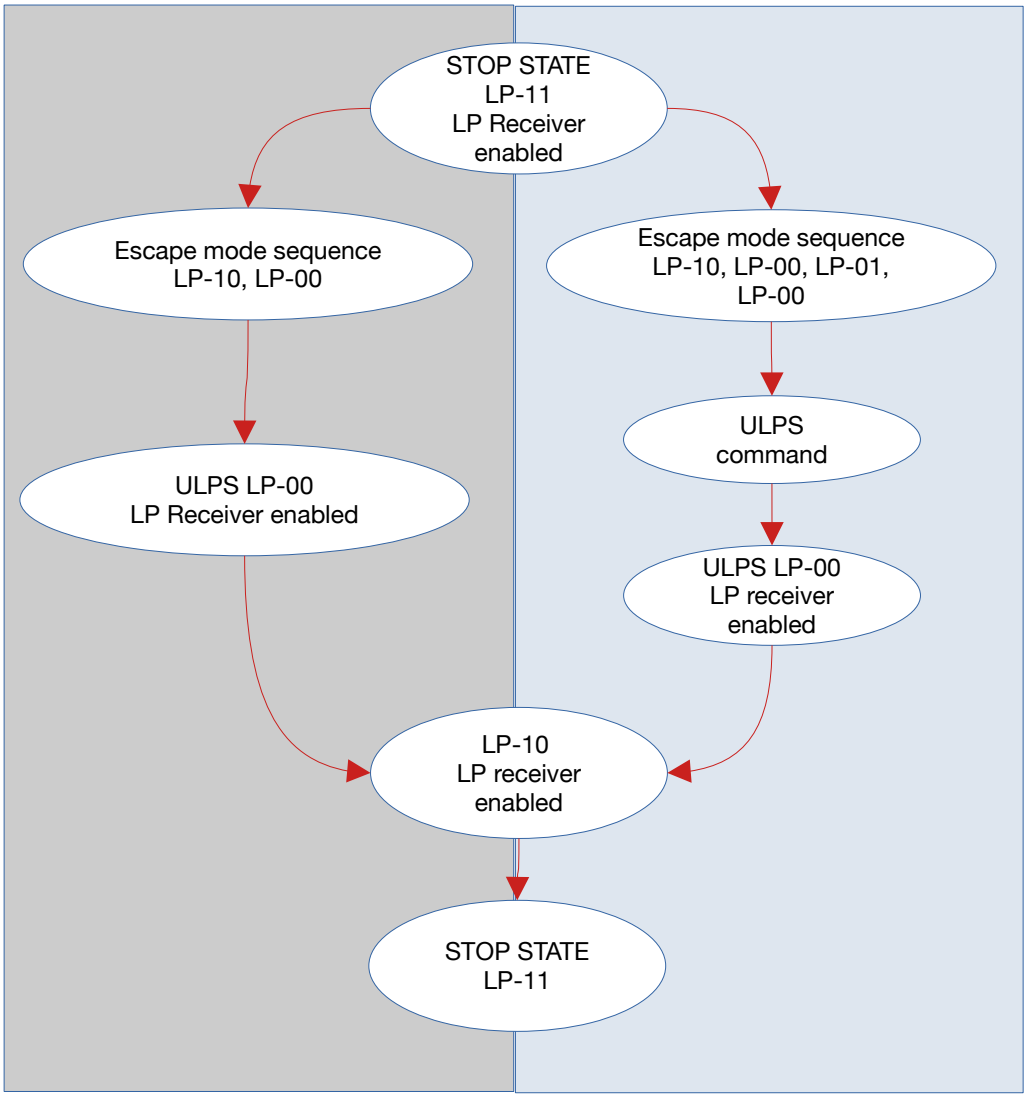

Figure 42.5-4. ULPS Sequences for Clock and Data Lanes

42.5.3 MIPI RX D-PHY Configuration

The MIPI RX D-PHY includes test codes for configuring MIPI RX D-PHY operation. Refer to Section 42.5.3.2 for all supported test codes.

42.5.3.1 MIPI RX D-PHY Programming Interface

The MIPI RX D-PHY test code programming involves two steps: first, program the test code into the registers; second, provide the test data to the tester's inputs.

Before configuring a test code, perform the following steps:

- Write 0 to CSI_HOST_PHY_SHUTDOWNZ and CSI_HOST_DPHY_RSTZ to shut down and reset the PHY.
- It is also recommended to set CSI_HOST_PHY_TESTCLR to 1 to apply a reset pulse before the first configuration of any test code.

Next, configure the test code by following these steps:

- Set the test code.

The test code loads when CSI_HOST_PHY_TESTEN is set to 1 and with the falling edge on CSI_HOST_PHY_TESTCLK.

- Ensure that CSI_HOST_PHY_TESTCLK is set to 1.
- Set CSI_HOST_PHY_TESTDIN to the 8-bit test code.
- Set CSI_HOST_PHY_TESTEN to 1.
- Set CSI_HOST_PHY_TESTCLK to 0. The falling edge on CSI_HOST_PHY_TESTCLK latches the value of CSI_HOST_PHY_TESTDIN[7:0] as the current test code.
- Set CSI_HOST_PHY_TESTEN to 0.

- Enter the test data.

  The test data programs to the latest loaded test code when CSI_HOST_PHY_TESTEN is 0 and with the rising edge on CSI_HOST_PHY_TESTCLK.

  - Set CSI_HOST_PHY_TESTCLK to 0, if not done already.
  - Set CSI_HOST_PHY_TESTDIN to the 8-bit test data.
  - Set CSI_HOST_PHY_TESTCLK to 1. The rising edge on CSI_HOST_PHY_TESTCLK programs the test data internally.
  - Repeat the above steps to add more test data for the same test code.

Set CSI_HOST_PHY_TESTCLR to 1 to reset a test code. This is necessary only before the first programming operation or if you wish to reset the PHY's configuration to its default value.

Figure 42.5-5 shows a timing diagram for the MIPI RX D-PHY control interface. After programming a test code, CSI_HOST_PHY_TESTDOUT asynchronously outputs the relevant data associated with the specific test code. This data may include read-back information or other meaningful signals.

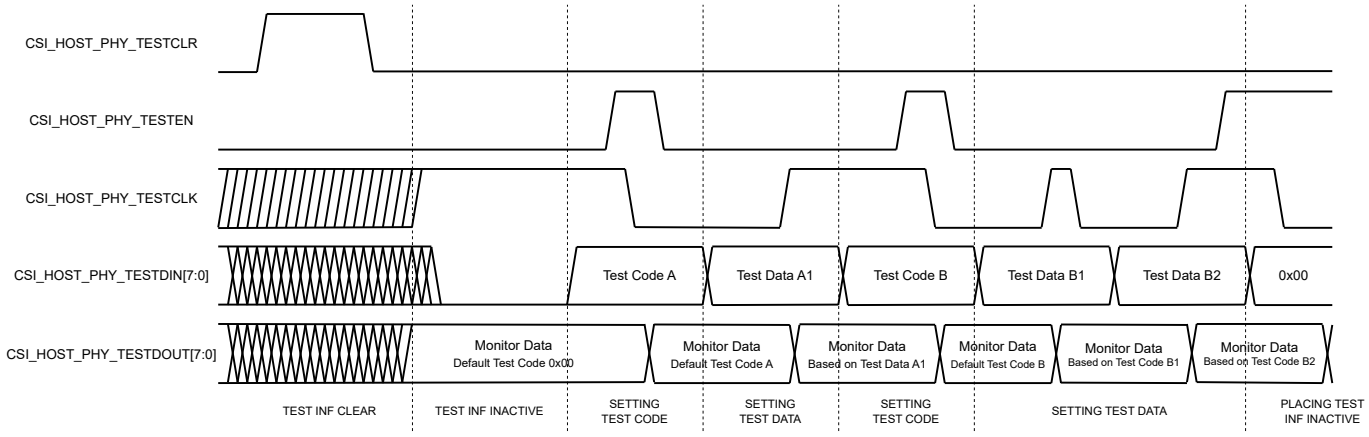

Figure 42.5-5. Control Interface Timing Diagram

Note:

Some test codes require two write data operations. In the first operation, the value of CSI_HOST_PHY_TESTCLK changes from 1 to 0. Ensure that the falling edge in the clock does not occur when CSI_HOST_PHY_TESTEN is set to 1. Otherwise, the current test data will be latched as an erroneous test code.

It is highly recommended to set the test interface to an inactive state by programming the test code 0x00 when not

used, as shown in the final sequence in Figure 42.5-5.

42.5.3.2 MIPI RX D-PHY Test Code

The MIPI RX D-PHY is configured through test codes via CSI_HOST_PHY_TEST_CTRL0_REG and CSI_HOST_PHY_TEST_CTRL1_REG. Refer to Section 42.5.3.1 *MIPI RX D-PHY Programming Interface* for more details.

Normal Operation

Use the following test code to enable normal operation of the PHY and the wake-up state of the test interface. In this mode, the test interface is inactive.

- **Test Code**: 0x00
- **Test Data**: None

HS RX Control of Lane 0

Use the following test code to select the HS operating frequency range (hsfreqrange).

- **Test Code**: 0x44
- **Test Data**:

Table 42.5-3. Test Data in HS RX Control of Lane 0

w-1'b0	w-6'b0	w-1'b0
Program Selector	HS operating frequency range selection (hsfreqrange)	Reserved

When Program Selector is 0, Test Data[6:1] programs hsfreqrange.

- **Test Dout:**

Table 42.5-4. Test Dout in HS RX Control of Lane 0

r-1'b0	r-6'b0	r-1'b0
1'b0	HS operating frequency range selection (hsfreqrange)	1'b0

When CSI_HOST_PHY_TESTDIN[7] is 0, Test Dout[6:1] reflects the value of the programmed hsfreqrange.

Others

Other test codes are reserved.

42.5.4 Descrambler

Data scrambling uses randomization techniques to mitigate electromagnetic interference (EMI) and radio frequency (RF) self-interference. This spreads the transmission energy of the link across a wider frequency band.

The transmitted data is scrambled with a Pseudo-Random-Bit-Stream (PRBS) to reduce the likelihood of repetitive patterns on a lane basis. The PRBS is generated using a Linear Feedback Shift Register (LFSR) that implements the generator polynomial:

$$G(x) = x^{16} + x^5 + x^4 + x^3 + 1 \tag{42.1}$$

Each data lane has an instance of the de-scrambling block. Set CSI_HOST_SCRAMBLE_ENABLE to 1 to enable this block. Each lane can be configured with a different 16-bit LFSR seed value via CSI_HOST_SCRAMBLE_SEED_LANE*n*.

The default seed values after resetting the controller are listed in 42.5-5.

Table 42.5-5. Scrambler PRBS Initial Seed Values for Lane 1 and Lane 2

Lane	Initial Seed Value
1	0x1008
2	0x1188

42.5.5 Error Management

The MIPI CSI-2 host analyzes received packets to identify protocol errors. Possible errors are listed in Table 42.5-6. These errors serve as interrupt sources and can generate the CSI_INTR signal. See Section 42.6 *Interrupts* for more details.

Table 42.5-6. Detectable Errors by MIPI CSI-2 Host

Error/Interrupt Source	Description	Corresponding Register Field
PHY_ERRSOTSYNCHS_*n* (*n*: 0-1)	Start-of-transmission error (no synchronization achieved) on data lane *n*	CSI_HOST_ST_PHY_ERRSOTSYNCHS_*n* (*n*: 0-1)
ERR_ECC_DOUBLE	Header ECC contains at least two errors (unrecoverable)	CSI_HOST_ST_ERR_ECC_DOUBLE
SHORTER_PAYLOAD	Reported word count exceeds received word count (unrecoverable)	CSI_HOST_ST_SHORTER_PAYLOAD
ERR_F_BNDRY_MATCH_VC*n* (*n*: 0-15)	Error matching frame start with frame end for virtual channel *n*	CSI_HOST_ST_ERR_F_BNDRY_MATCH_VC*n* (*n*: 0-15)
ERR_F_SEQ_VC*n* (*n*: 0-15)	Incorrect frame sequence detected on virtual channel *n*	CSI_HOST_ST_ERR_F_SEQ_VC*n* (*n*: 0-15)
ERR_FRAME_DATA_VC*n* (*n*: 0-15)	At least one CRC error in the last received frame on virtual channel *n*	CSI_HOST_ST_ERR_FRAME_DATA_VC*n* (*n*: 0-15)
ERR_CRC_VC*n* (*n*: 0-15)	Payload CRC error detected on virtual channel *n*	CSI_HOST_ST_ERR_CRC_VC*n* (*n*: 0-15)
ERR_ID_VC*n* (*n*: 0-15)	Unrecognized or unimplemented data type detected on virtual channel *n*	CSI_HOST_ST_ERR_ID_VC*n* (*n*: 0-15)

ERR_ECC_CORRECTED_VC*n* (*n*: 0-15)	Checksum error detected on virtual channel *n*	CSI_HOST_ST_ERR_ECC_CORRECTED_VC*n* (*n*: 0-15)
PHY_ERRSOTHS_*n* (*n*: 0-1)	Start-of-transmission error (synchronization can still be achieved) on data lane *n*	CSI_HOST_ST_PHY_ERRSOTHS_*n* (*n*: 0-1)
PHY_ERRESC_*n* (*n*: 0-1)	Escape entry error (ULPS) on data lane *n*	CSI_HOST_ST_PHY_ERRESC_*n* (*n*: 0-1)

Note:
MIPI CSI does not support virtual channel interleaving. Before starting transmission, verify which virtual channel is in use. Additionally, read error information from the specified virtual channel to detect any errors.

A reset is recommended for all errors in "*_FATAL_REG" registers.

42.6 Interrupts

ESP32-P4's MIPI CSI can generate the CSI_INTR interrupt signal that will be sent to the Interrupt Matrix.

The CSI_HOST_INT_ST_<group> registers report error conditions and trigger the CSI_INTR interrupt signal.

You can mask the interrupt pin by using the CSI_HOST_INT_MSK_<group> registers. All errors are masked by default. Set any bit of these registers to 1 to enable the specific error interrupt. The error asserts the respective bit in the CSI_HOST_INT_ST_<group> register. The CSI_HOST_INT_ST_<group> registers clear after a read operation.

Setting any bit of the Interrupt Force registers (CSI_HOST_INT_FORCE_<group>) to 1 triggers the corresponding interrupt without needing to activate the error conditions. These registers are for test purposes.

Figure42.6-1 shows the interrupt mechanism:

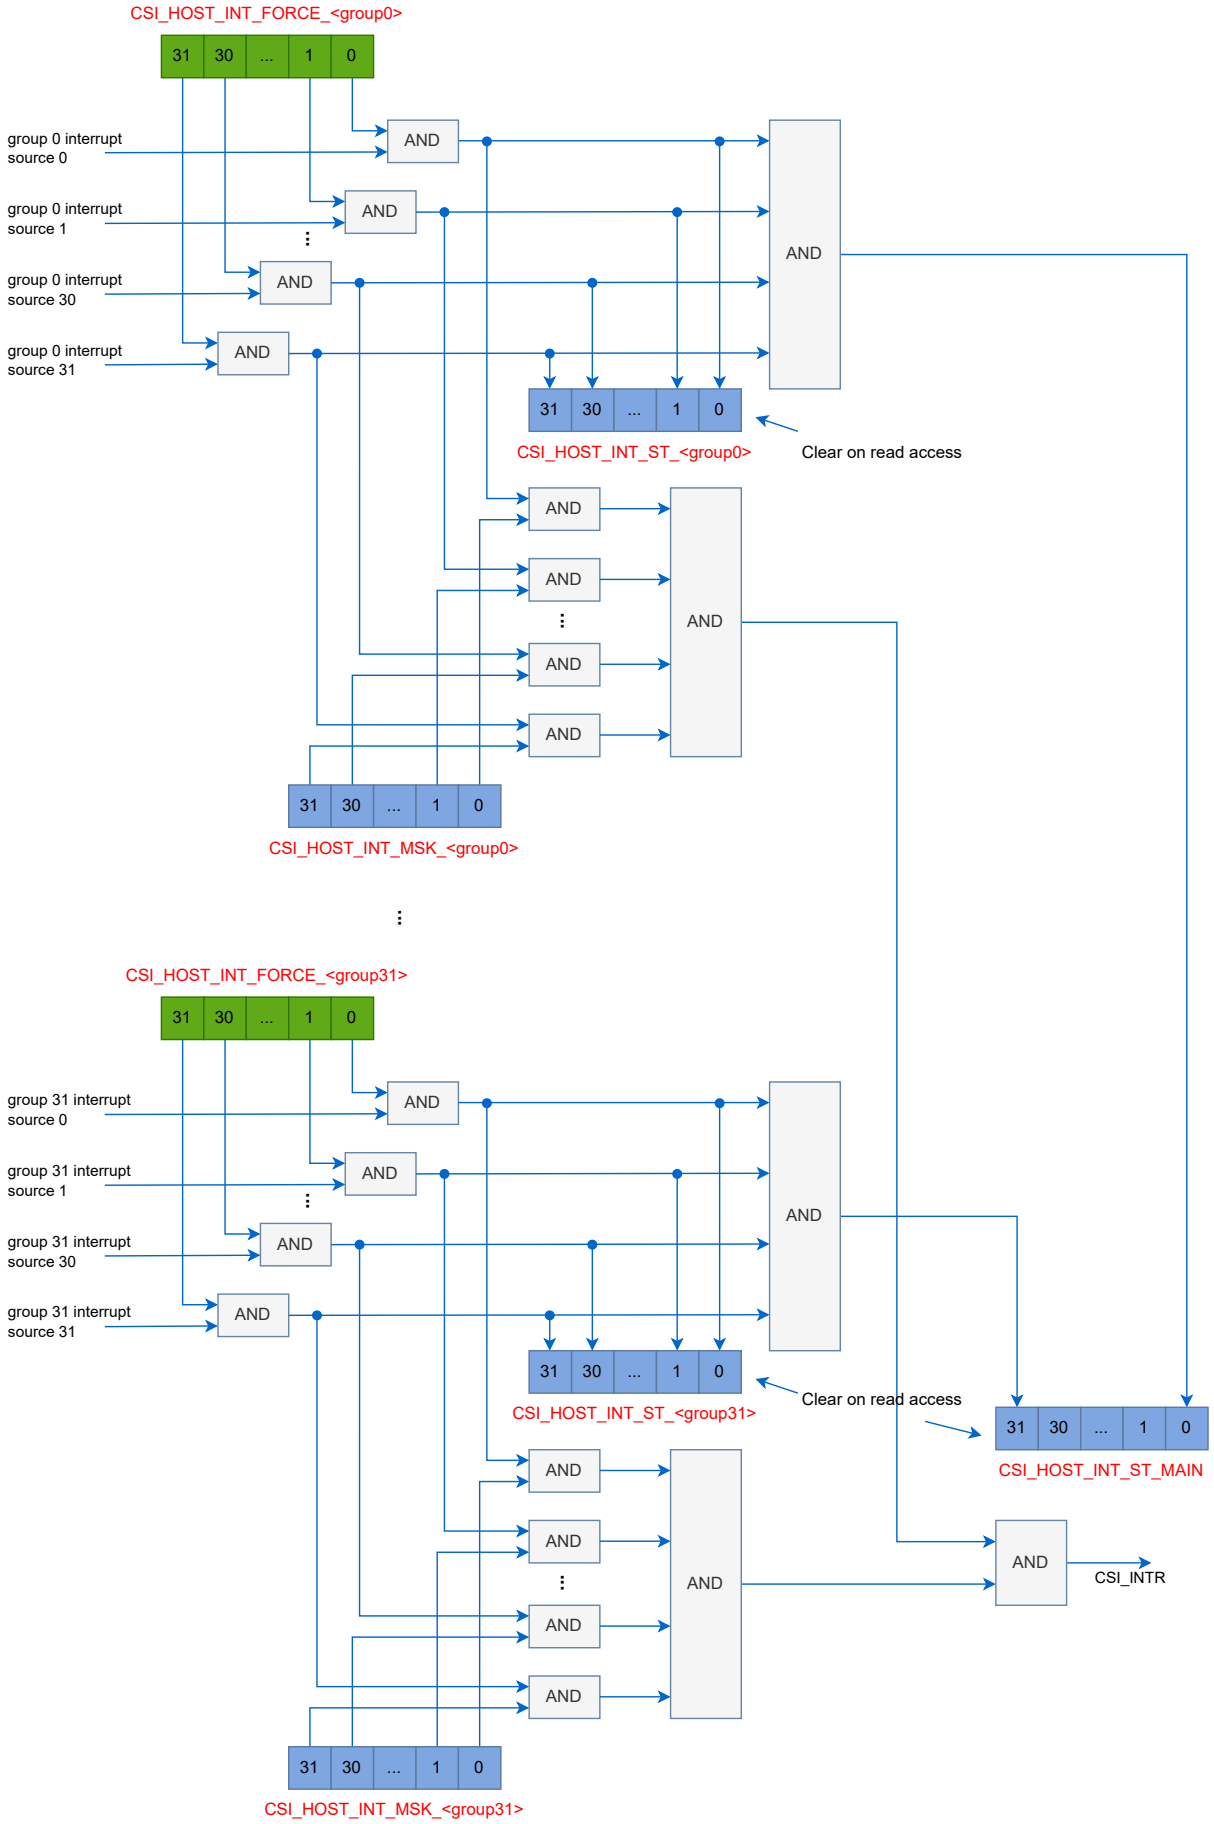

Figure 42.6-1. MIPI CSI Interrupt Mechanism

The interrupt signal CSI_INTR can be generated by the following internal interrupt sources (see Table 42.5-6 *Detectable Errors by MIPI CSI-2 Host* for details interrupt source description):

- PHY Fatal Interrupt:
  - PHY_ERRSOTSYNCHS_*n* (*n*: 0-1)
- Packet Fatal Interrupt:
  - ERR_ECC_DOUBLE
  - SHORTER_PAYLOAD
- Boundary Frame Fatal Interrupt:
  - ERR_F_BNDRY_MATCH_VC*n* (*n*: 0-15)
- Sequence Frame Fatal Interrupt:
  - ERR_F_SEQ_VC*n* (*n*: 0-15)
- CRC Frame Fatal Interrupt:
  - ERR_FRAME_DATA_VC*n* (*n*: 0-15)
- Payload CRC Fatal Interrupt:
  - ERR_CRC_VC*n* (*n*: 0-15)
- Data ID Interrupt:
  - ERR_ID_VC*n* (*n*: 0-15)
- ECC Corrected Interrupt:
  - ERR_ECC_CORRECTED_VC*n* (*n*: 0-15)
- PHY Interrupt:
  - PHY_ERRSOTHS_*n* (*n*: 0-1)
  - PHY_ERRESC_*n* (*n*: 0-1)

Note:
For definitions of *interrupt*, *interrupt signal*, *interrupt source*, and their correlations, please refer to Chapter 13 *Interrupt Matrix* > Section 13.2 *Interrupt Terminology in ESP32-P4*.

42.7 Programming Procedures

This section describes how to configure the MIPI RX D-PHY and the MIPI CSI-2 host for image data reception. MIPI CSI receives image data only in high-speed data reception mode.

42.7.1 Start High-Speed Data Reception

42.7.1.1 Clock and Reset

- Set HP_SYS_CLKRST_CSI_HOST_SYS_CLK_EN to 1 to enable the MIPI CSI clock.

- Set HP_SYS_CLKRST_RST_EN_CSI_HOST to 0 to release the MIPI CSI reset.
- Configure HP_SYS_CLKRST_MIPI_CSI_DPHY_CLK_SRC_SEL to select a proper clock source for the MIPI RX D-PHY configuration clock.
- Set HP_SYS_CLKRST_MIPI_CSI_DPHY_CFG_CLK_EN to 1 to enable the MIPI RX D-PHY configuration clock.
- Set HP_SYS_CLKRST_RST_EN_CSI_BRG to 1 to release the CSI_Bridge module of the ISP and reset the ISP.

42.7.1.2 MIPI RX D-PHY and MIPI Host Initialization

- Clear CSI_HOST_CSI2_RESETN to reset the CSI_HOST controller logic.
- Set CSI_HOST_PHY_TESTCLR to 1, then clear CSI_HOST_PHY_TESTCLR to reset the test code logic.
- Configure the MIPI RX D-PHY frequency range in test code 0x44 using the MIPI RX D-PHY programming interface.
- Configure CSI_HOST_N_LANES to define the number of active lanes in the system.
- Set CSI_HOST_PHY_SHUTDOWNZ and CSI_HOST_DPHY_RSTZ to 1 to release the MIPI RX D-PHY from the reset state.
- Set the corresponding bit in the CSI_HOST_INT_MSK_*_REG register to 1 to enable the error interrupt.
- Configure the descrambler function if needed.
- Set CSI_HOST_CSI2_RESETN to 1 to release the CSI_HOST reset.
- Wait until CSI_HOST_PHY_STOPSTATEDATA_*n* and CSI_HOST_PHY_STOPSTATECLK are 1.
- Start the camera image capture.

42.7.2 Stop High-Speed Data Reception

- Disable related channels in . Wait until is disabled. Refer to Chapter 7 *VDMA Controller (VDMA)*.
- Reset the ISP. Refer to Chapter 38 *Image Signal Processor (ISP)*.
- Set HP_SYS_CLKRST_RST_EN_CSI_HOST to 1 to reset the MIPI CSI.

42.8 Register Summary

The addresses in this section are relative to CSI Host base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Version Register			
CSI_HOST_VERSION_REG	CSI_HOST version control register	0x0000	RO
Configuration Registers			
CSI_HOST_N_LANES_REG	Active lane number configuration register	0x0004	R/W
CSI_HOST_CSI2_RESETN_REG	CSI_HOST reset control register	0x0008	R/W
CSI_HOST_PHY_SHUTDOWNZ_REG	RX D-PHY Shut-Down state control register	0x0040	R/W
CSI_HOST_DPHY_RSTZ_REG	RX D-PHY reset control register	0x0044	R/W
CSI_HOST_PHY_RX_REG	RX D-PHY RX-related signal status register	0x0048	RO
CSI_HOST_PHY_TEST_CTRL0_REG	RX D-PHY test code interface control register 0	0x0050	R/W
CSI_HOST_PHY_TEST_CTRL1_REG	RX D-PHY test code interface control register 1	0x0054	varies
CSI_HOST_SCRAMBLING_REG	Descrambler enable register	0x0300	R/W

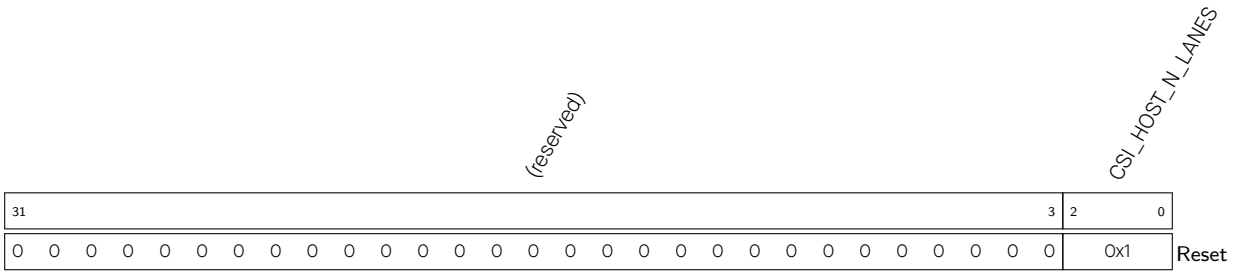
42.9 Registers

The addresses in this section are relative to CSI Host base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



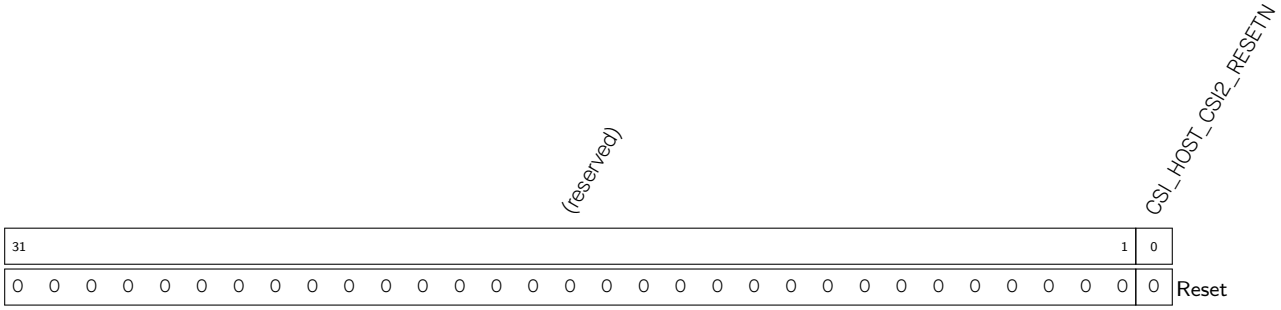
For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 42.1. CSI_HOST_VERSION_REG (0x0000)

CSI_HOST_VERSION Version control register. (RO)

Register 42.2. CSI_HOST_N_LANES_REG (0x0004)

CSI_HOST_N_LANES Configures the number of active lanes that the MIPI CSI-2 host uses to receive the camera device data. This can only be updated when the RX D-PHY lane is in stop state.



0: Data lane 0 is active

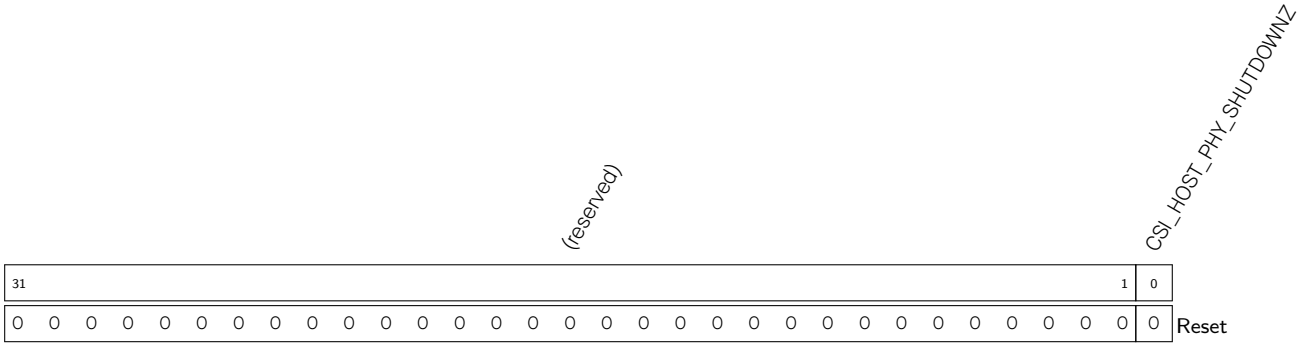
1: Both data lane 0 and data lane 1 are active

Other values: Invalid

(R/W)

Register 42.3. CSI_HOST_CSI2_RESETN_REG (0x0008)

CSI_HOST_CSI2_RESETN Configures whether to reset the internal logic of the MIPI CSI-2 host controller.



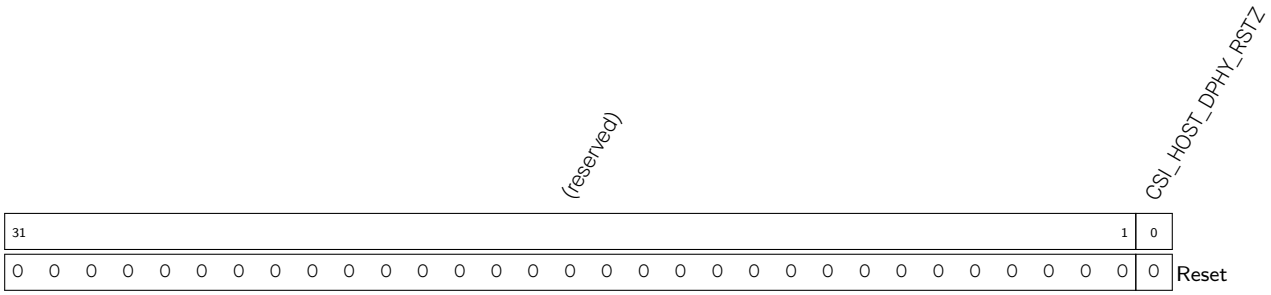
0: Reset

1: Release the reset

This register only affects the internal logic of the controller. It will not reset the configuration to default values.

(R/W)

Register 42.4. CSI_HOST_PHY_SHUTDOWNZ_REG (0x0040)



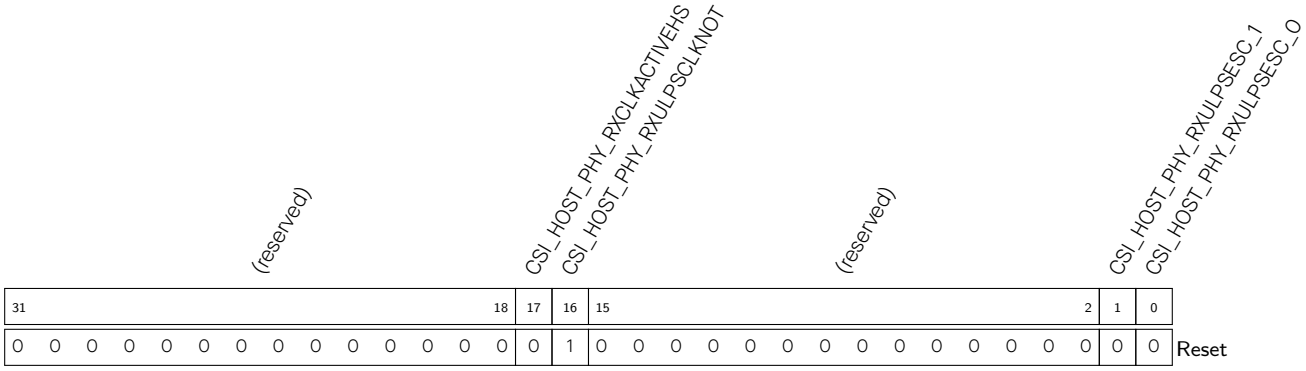
CSI_HOST_PHY_SHUTDOWNZ Configures whether to enable the Shut-Down state of the RX D-PHY.

0: Enable

1: Disable

(R/W)

Register 42.5. CSI_HOST_DPHY_RSTZ_REG (0x0044)



CSI_HOST_DPHY_RSTZ Configures whether to reset the RX D-PHY digital circuitry.

0: Reset

1: Release the reset

(R/W)

Register 42.6. CSI_HOST_PHY_RX_REG (0x0048)

CSI_HOST_PHY_RXULPSESC_*n* (*n*: 0-1) Represents whether data lane *n* has entered the Ultra Low Power State.

0: Entered

1: Not entered

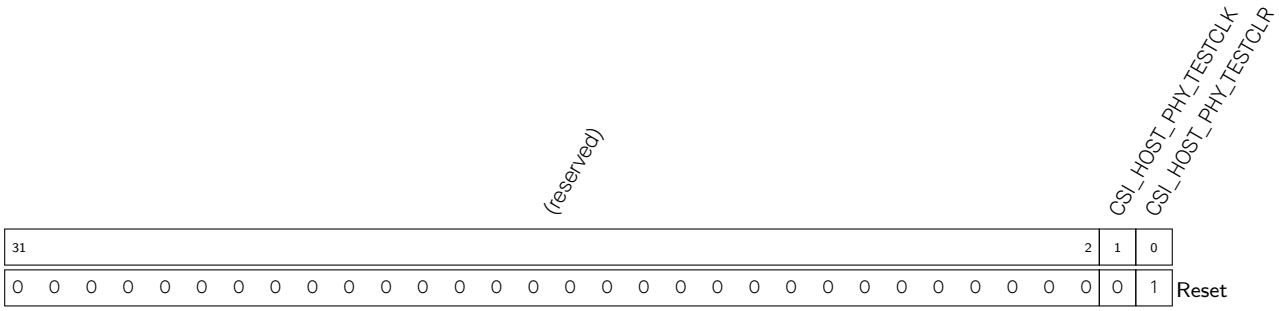
(RO)

CSI_HOST_PHY_RXULPSCLKNOT Represents whether RX D-PHY clock lane has entered the Ultra Low Power State.

0: Entered

1: Not entered

(RO)



CSI_HOST_PHY_RXCLKACTIVEHS Represents whether RX D-PHY clock lane is actively receiving a DDR clock.

0: Not actively receiving

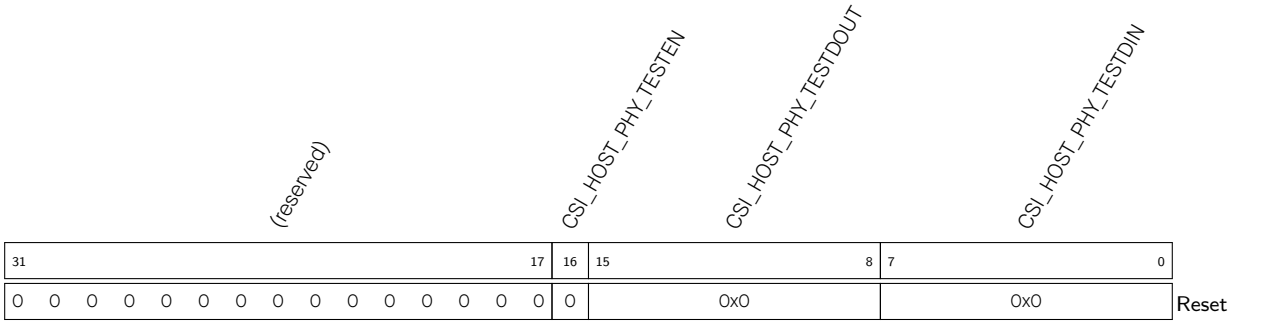
1: Actively receiving

(RO)

Register 42.7. CSI_HOST_PHY_TEST_CTRL0_REG (0x0050)

CSI_HOST_PHY_TESTCLR Configures whether to initialize the test code interface.

0: Not initialize



1: Initialize

To ensure the analog programmability default values are preset, this bit must be set to 1 then clear to 0 after power-up.

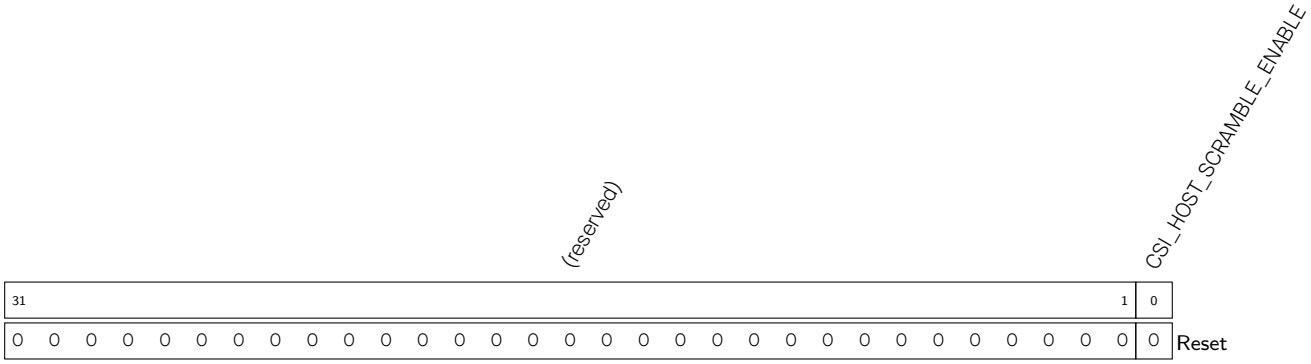
(R/W)

CSI_HOST_PHY_TESTCLK Configures clock to capture CSI_HOST_PHY_TESTDIN bus contents into D-PHY test code logic, with CSI_HOST_PHY_TESTEN controlling the operation selection. (R/W)

Register 42.8. CSI_HOST_PHY_TEST_CTRL1_REG (0x0054)

CSI_HOST_PHY_TESTDIN Configures the 8-bit data input of the test code interface for programming internal registers and accessing test functionalities. (R/W)

CSI_HOST_PHY_TESTDOUT Represents the 8-bit data output of the test code interface for reading data and other probing functionalities. (RO)



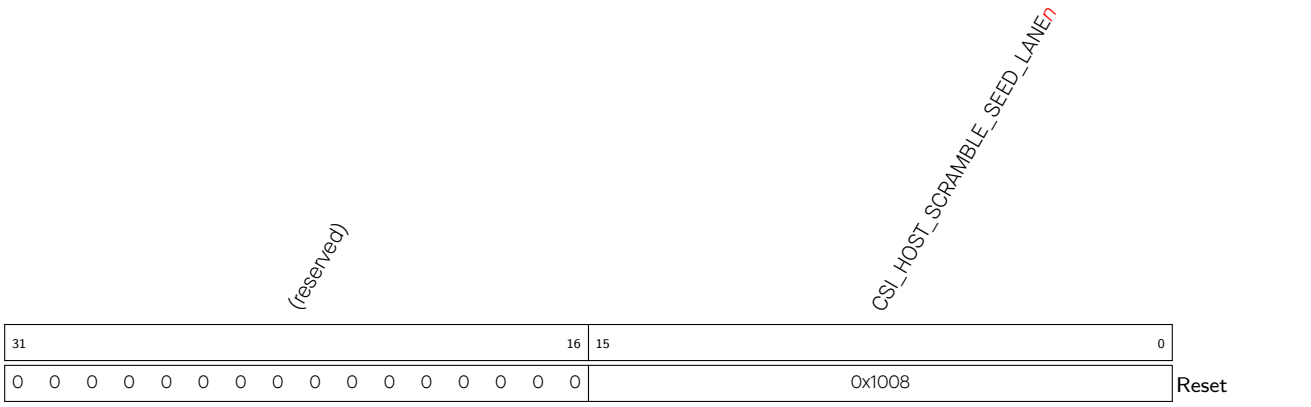
CSI_HOST_PHY_TESTEN Configures whether to performs the test data write operation of the test code interface on the rising edge or the falling edge of CSI_HOST_PHY_TESTCLK.

0: On the rising edge

1: On the falling edge

(R/W)

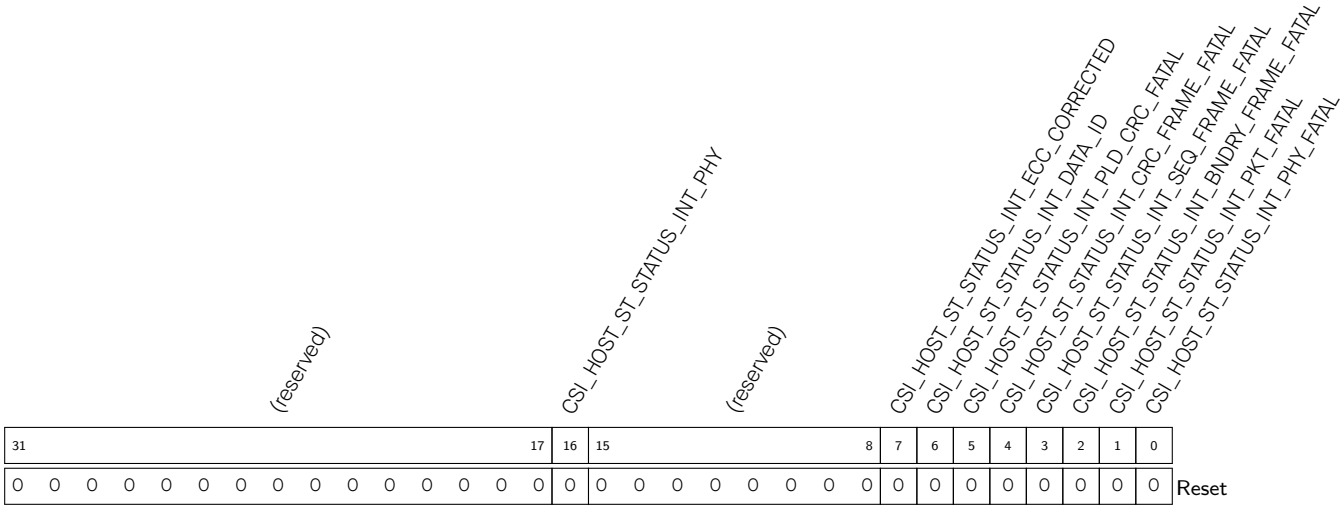
Register 42.9. CSI_HOST_SCRAMBLING_REG (0x0300)



CSI_HOST_SCRAMBLE_ENABLE Configures whether to enable the descrambler.

0: Disable

1: Enable



(R/W)

Register 42.10. CSI_HOST_SCRAMBLING_SEED*n*_REG (*n*: 1-2) (0x0300 + 0x04**n*)

CSI_HOST_SCRAMBLE_SEED_LANE*n-1* Configures the seed value used by the descrambler for lane *n-1*. (R/W)

Register 42.11. CSI_HOST_INT_ST_MAIN_REG (0x000C)

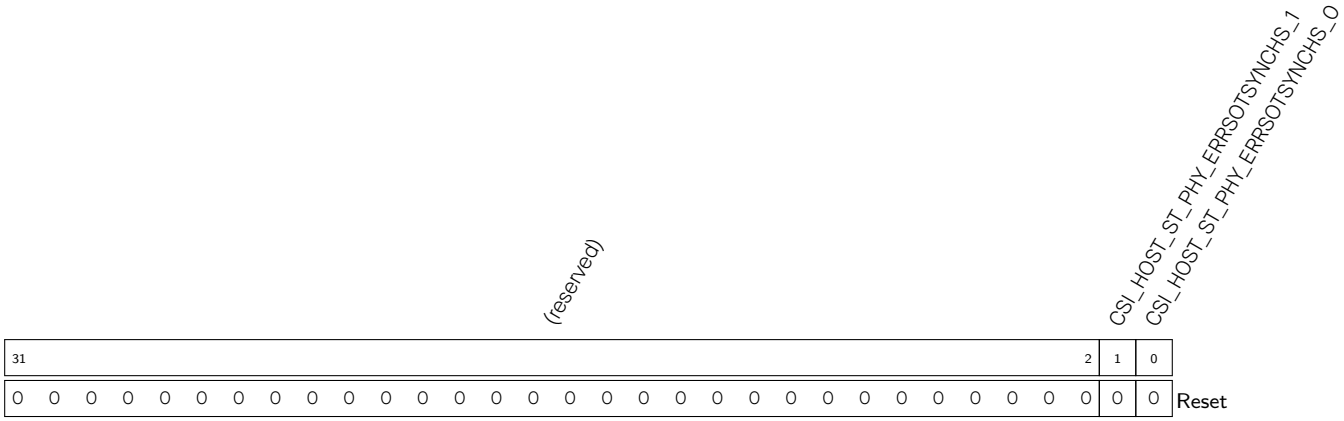
CSI_HOST_ST_STATUS_INT_PHY_FATAL Represents the status of CSI_HOST_INT_ST_PHY_FATAL_REG. (RC)

CSI_HOST_ST_STATUS_INT_PKT_FATAL Represents the status of CSI_HOST_INT_ST_PKT_FATAL_REG. (RC)

CSI_HOST_ST_STATUS_INT_BNDRY_FRAME_FATAL Represents the status of CSI_HOST_INT_ST_BNDRY_FRAME_FATAL_REG. (RC)

CSI_HOST_ST_STATUS_INT_SEQ_FRAME_FATAL Represents the status of CSI_HOST_INT_ST_SEQ_FRAME_FATAL_REG. (RC)

CSI_HOST_ST_STATUS_INT_CRC_FRAME_FATAL Represents the status of CSI_HOST_INT_ST_CRC_FRAME_FATAL_REG. (RC)



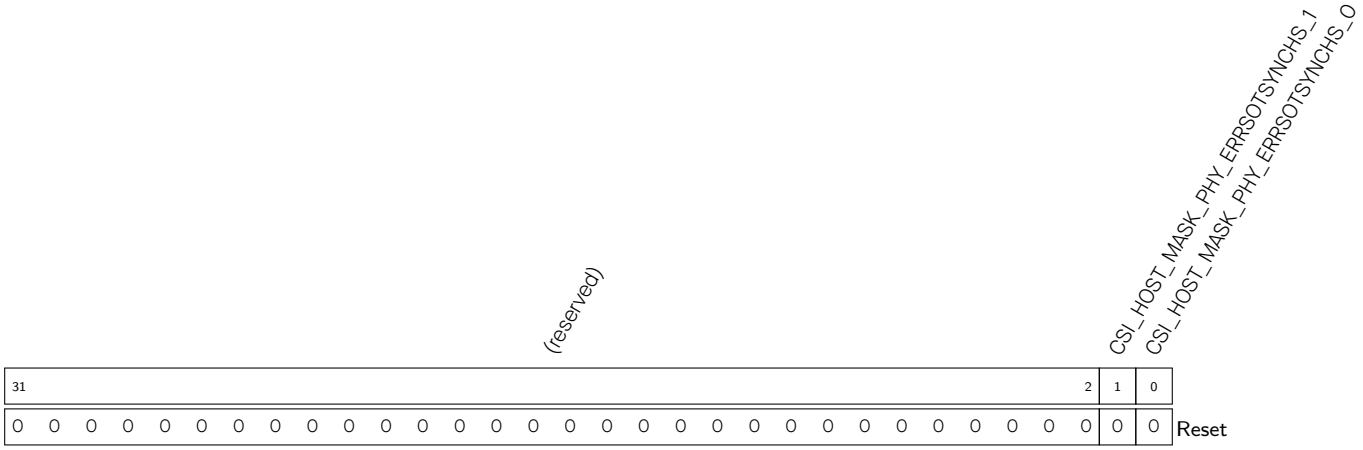
CSI_HOST_ST_STATUS_INT_PLD_CRC_FATAL Represents the status of CSI_HOST_INT_ST_PLD_CRC_FATAL_REG. (RC)

CSI_HOST_ST_STATUS_INT_DATA_ID Represents the status of CSI_HOST_INT_ST_DATA_ID_REG. (RC)

CSI_HOST_ST_STATUS_INT_ECC_CORRECTED Represents the status of CSI_HOST_INT_ST_ECC_CORRECTED_REG. (RC)

CSI_HOST_ST_STATUS_INT_PHY Represents the status of CSI_HOST_INT_PHY_REG. (RC)

Register 42.12. CSI_HOST_INT_ST_PHY_FATAL_REG (0x00E0)



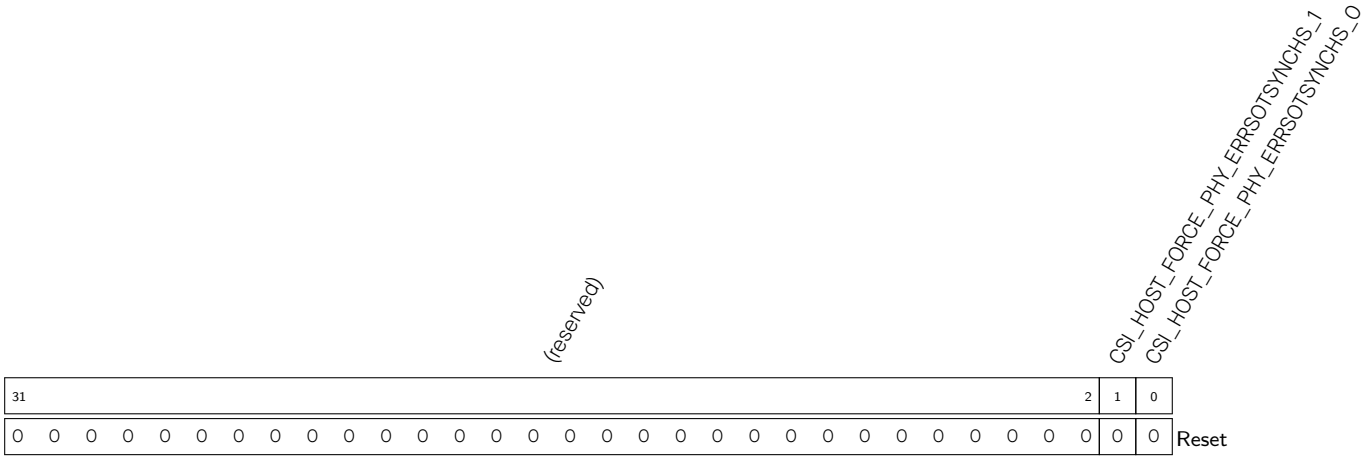
CSI_HOST_ST_PHY_ERRSOTSYNCHS_*n* (*n*: 0-1) Represents whether the PHY_ERRSOTSYNCHS_*n* error occurs.

0: Do not occur

1: Occur

(RC)

Register 42.13. CSI_HOST_INT_MSK_PHY_FATAL_REG (0x00E4)



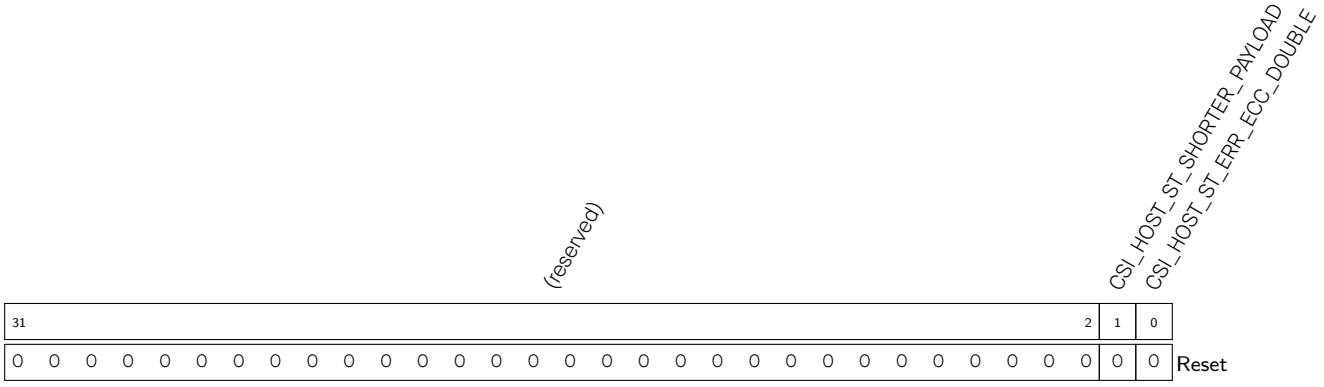
CSI_HOST_MASK_PHY_ERRSOTSYNCHS_*n* (*n*: 0-1) Configures whether to mask CSI_HOST_ST_PHY_ERRSOTSYNCHS_*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

Register 42.14. CSI_HOST_INT_FORCE_PHY_FATAL_REG (0x00E8)



CSI_HOST_FORCE_PHY_ERRSOTSYNCHS_*n* (*n*: 0-1) Configures whether to force set CSI_HOST_ST_PHY_ERRSOTSYNCHS_*n* to 1.

0: Do not force set

1: Force set

(R/W)

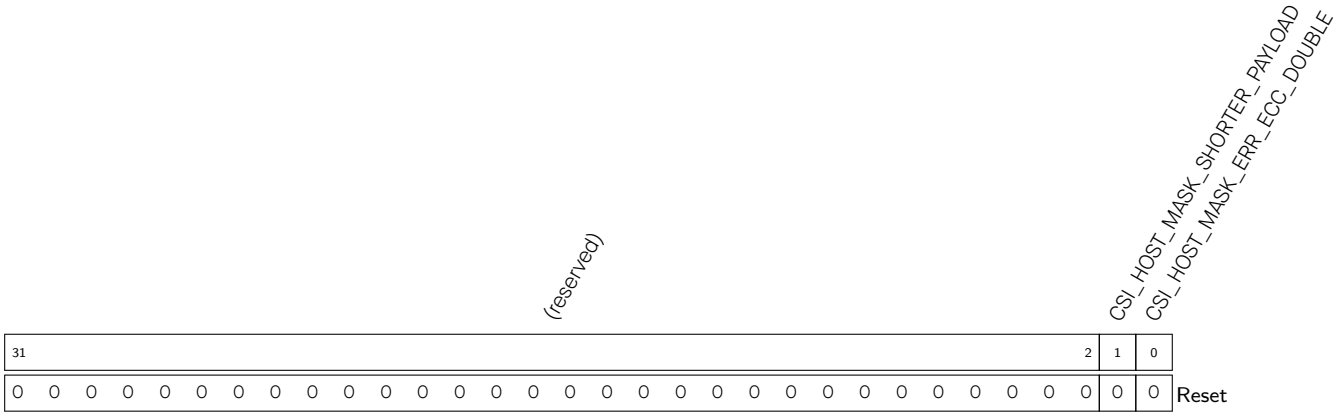
Register 42.15. CSI_HOST_INT_ST_PKT_FATAL_REG (0x00F0)

CSI_HOST_ST_ERR_ECC_DOUBLE Represents whether the ERR_ECC_DOUBLE error occurs.

0: Do not occur

1: Occur

(RC)



CSI_HOST_ST_SHORTER_PAYLOAD Represents whether the SHORTER_PAYLOAD error occurs.

0: Do not occur

1: Occur

(RC)

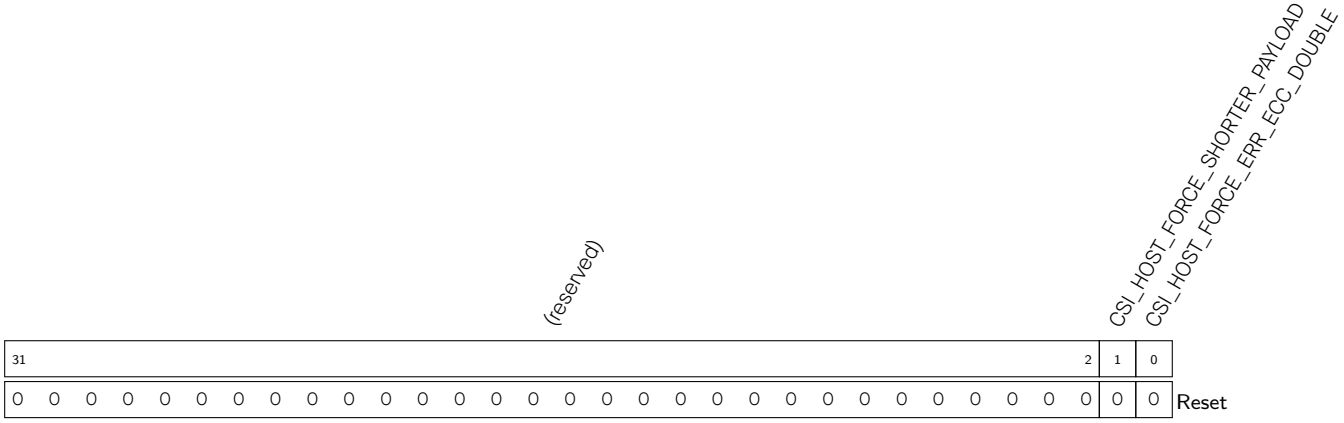
Register 42.16. CSI_HOST_INT_MSK_PKT_FATAL_REG (0x00F4)

CSI_HOST_MASK_ERR_ECC_DOUBLE Configures whether to mask CSI_HOST_ST_ERR_ECC_DOUBLE.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)



CSI_HOST_MASK_SHORTER_PAYLOAD Configures whether to mask CSI_HOST_ST_SHORTER_PAYLOAD.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

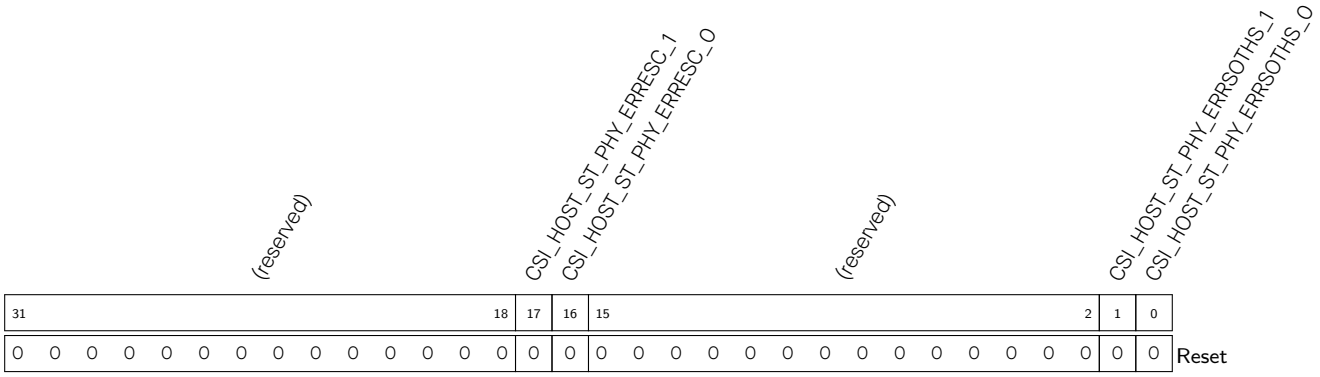
Register 42.17. CSI_HOST_INT_FORCE_PKT_FATAL_REG (0x00F8)

CSI_HOST_FORCE_ERR_ECC_DOUBLE Configures whether to force set CSI_HOST_ST_ERR_ECC_DOUBLE to 1.

0: Do not force set

1: Force set

(R/W)



CSI_HOST_FORCE_SHORTER_PAYLOAD Configures whether to force set CSI_HOST_ST_SHORTER_PAYLOAD to 1.

0: Do not force set

1: Force set

(R/W)

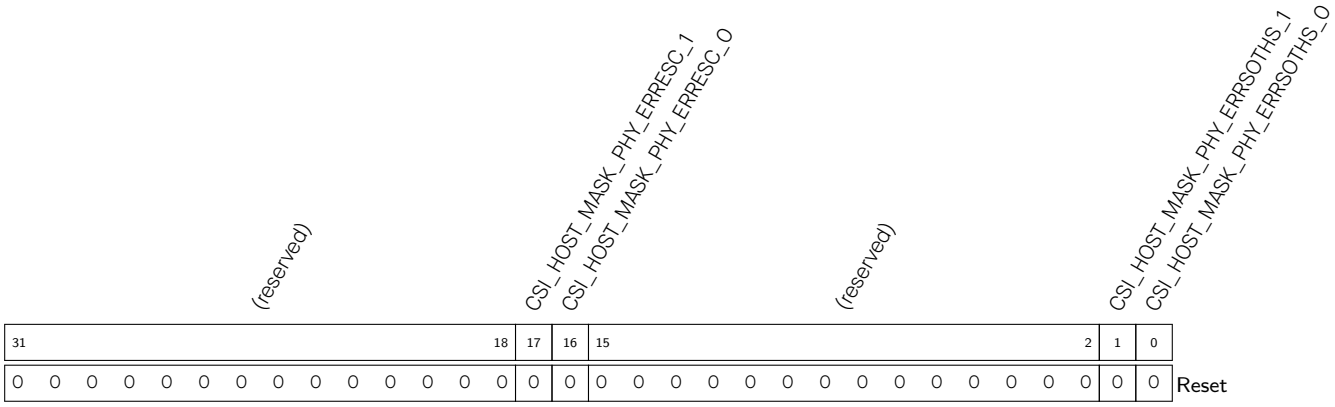
Register 42.18. CSI_HOST_INT_ST_PHY_REG (0x0110)

CSI_HOST_ST_PHY_ERRSOTHS_*n* (*n*: 0-1) Represents whether the PHY_ERRSOTHS_*n* error occurs.

0: Do not occur

1: Occur

(RC)



CSI_HOST_ST_PHY_ERRESC_*n* (*n*: 0-1) Represents whether the PHY_ERRESC_*n* error occurs.

0: Do not occur

1: Occur

(RC)

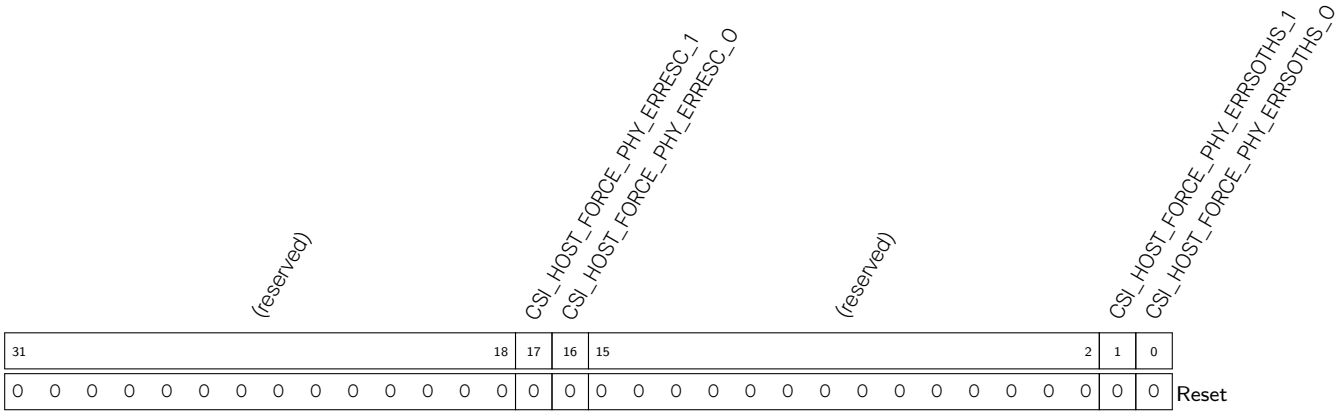
Register 42.19. CSI_HOST_INT_MSK_PHY_REG (0x0114)

CSI_HOST_MASK_PHY_ERRSOTHS_*n* (*n*: 0-1) Configures whether to mask CSI_HOST_ST_PHY_ERRSOTHS_*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)



CSI_HOST_MASK_PHY_ERRESC_*n* (*n*: 0-1) Configures whether to mask CSI_HOST_ST_PHY_ERRESC_*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

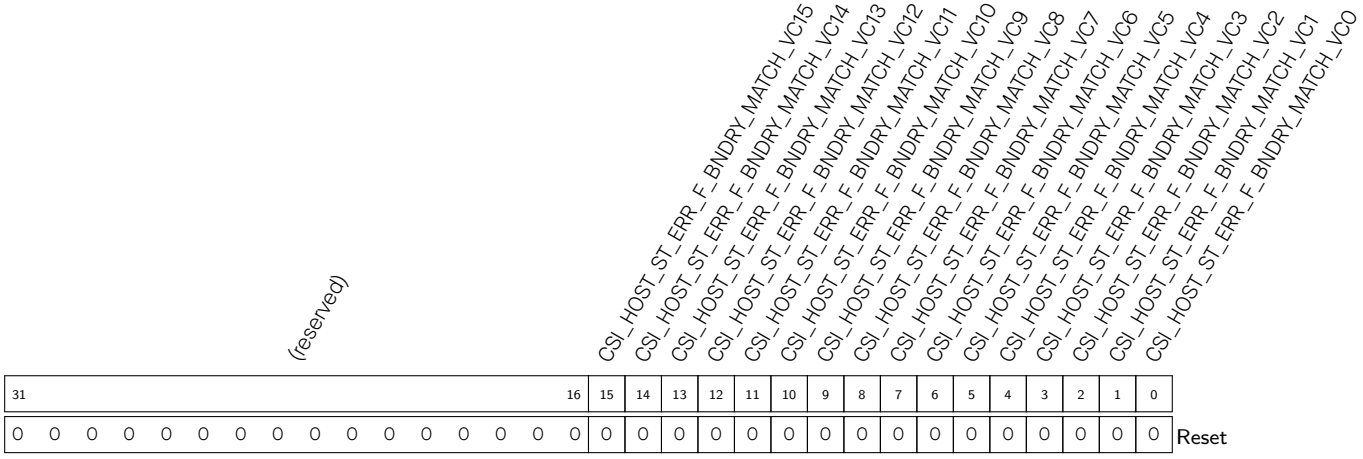
Register 42.20. CSI_HOST_INT_FORCE_PHY_REG (0x0118)

CSI_HOST_FORCE_PHY_ERRSOTHS_*n* (*n*: 0-1) Configures whether to force set CSI_HOST_ST_PHY_ERRSOTHS_*n* to 1.

0: Do not force set

1: Force set

(R/W)



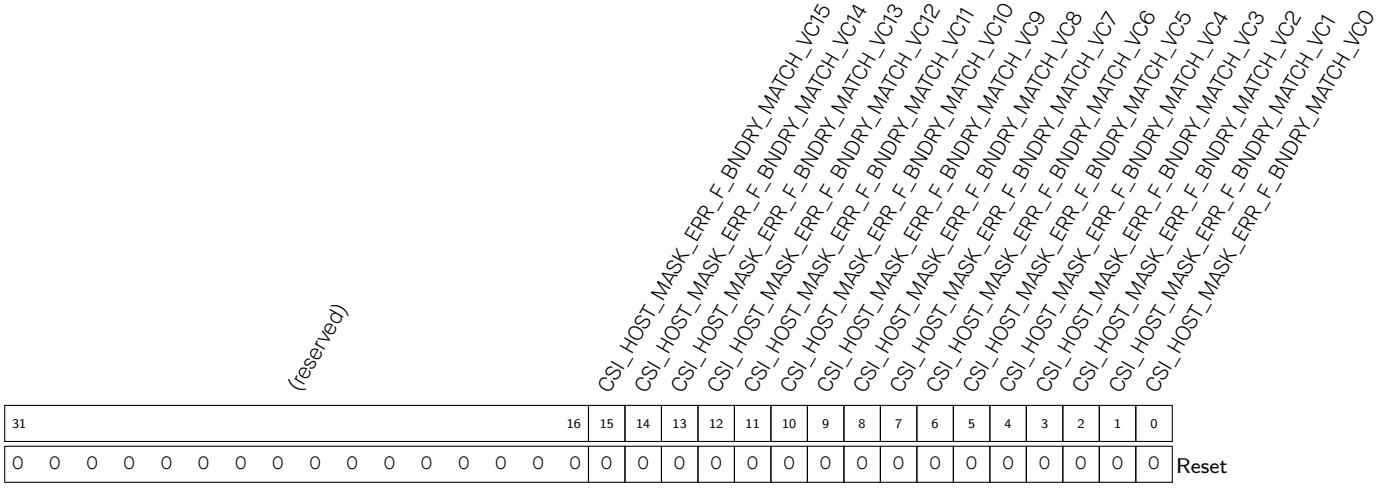
CSI_HOST_FORCE_PHY_ERRESC_*n* (*n*: 0-1) Configures whether to force set CSI_HOST_ST_PHY_ERRESC_*n* to 1.

0: Do not force set

1: Force set

(R/W)

Register 42.21. CSI_HOST_INT_ST_BNDRY_FRAME_FATAL_REG (0x0280)



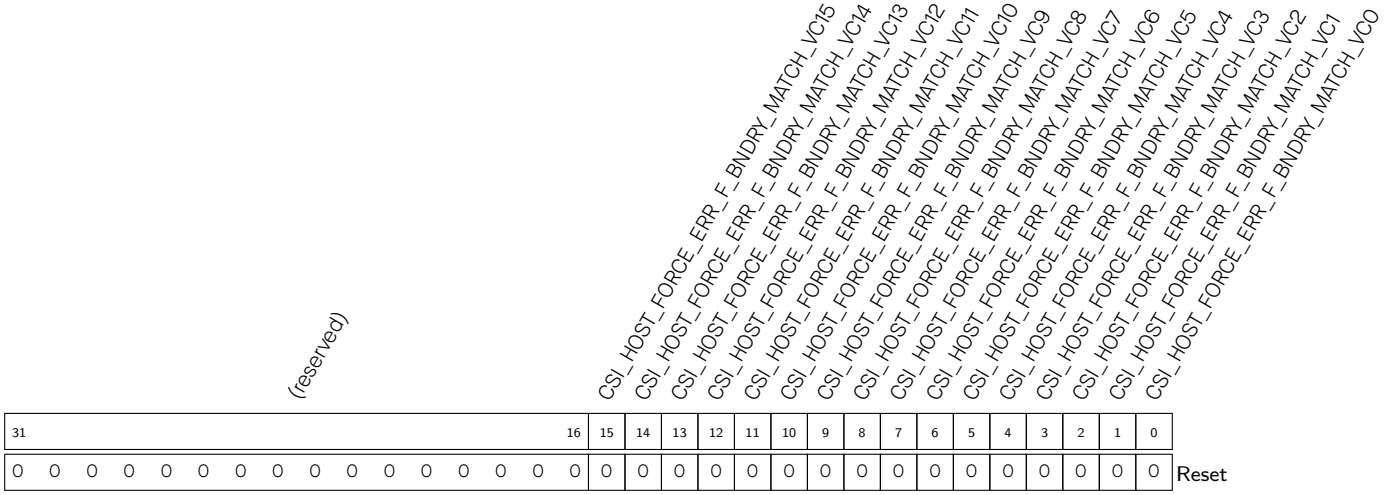
CSI_HOST_ST_ERR_F_BNDRY_MATCH_VC*n* (*n*: 0-15) Represents whether the ERR_F_BNDRY_MATCH_VC*n* error occurs.

0: Do not occur

1: Occur

(RC)

Register 42.22. CSI_HOST_INT_MSK_BNDRY_FRAME_FATAL_REG (0x0284)



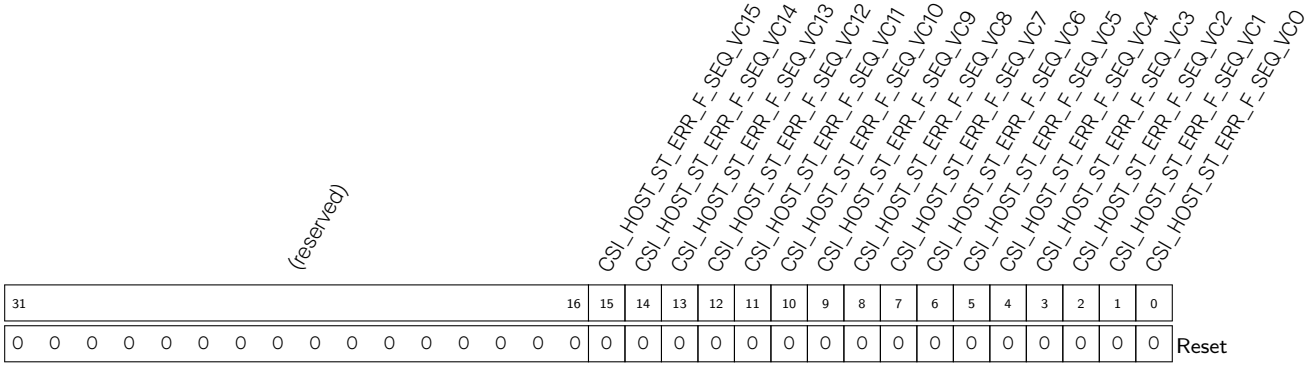
CSI_HOST_MASK_ERR_F_BNDRY_MATCH_VC*n* (*n*: 0-15) Configures whether to mask CSI_HOST_ST_ERR_F_BNDRY_MATCH_VC*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

Register 42.23. CSI_HOST_INT_FORCE_BNDRY_FRAME_FATAL_REG (0x0288)



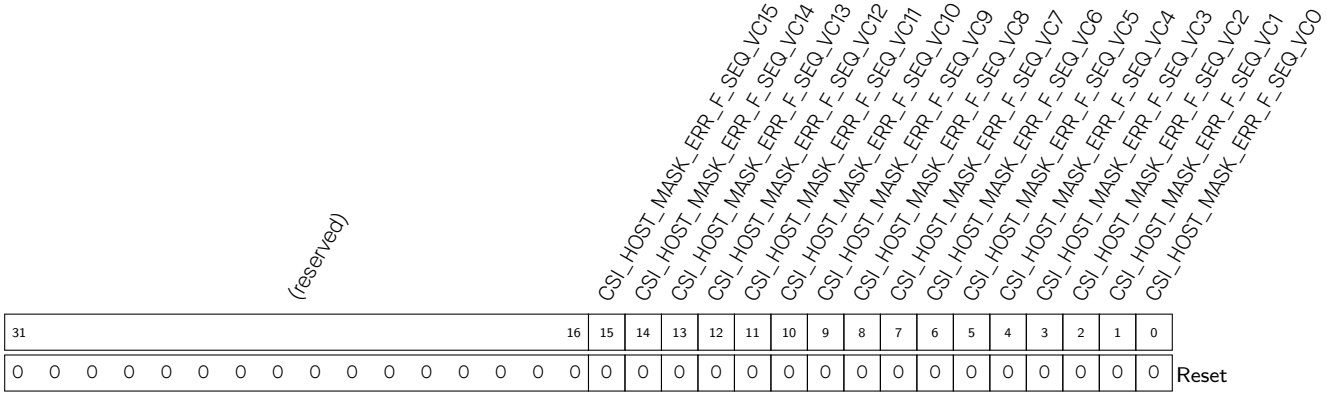
CSI_HOST_FORCE_ERR_F_BNDRY_MATCH_VC*n* (*n*: 0-15) Configures whether to force set CSI_HOST_ST_ERR_F_BNDRY_MATCH_VC*n* to 1.

0: Do not force set

1: Force set

(R/W)

Register 42.24. CSI_HOST_INT_ST_SEQ_FRAME_FATAL_REG (0x0290)



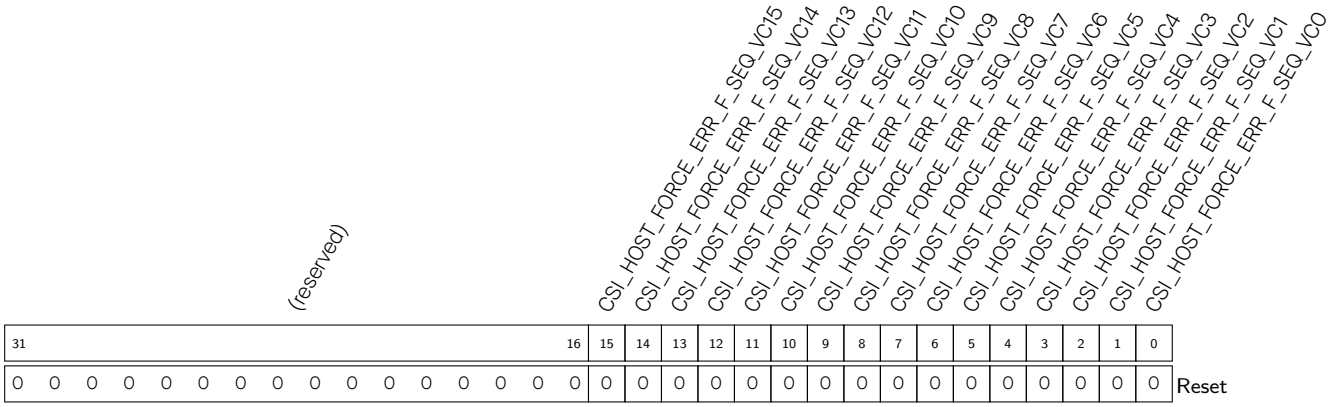
CSI_HOST_ST_ERR_F_SEQ_VC*n* (*n*: 0-15) Represents whether the ERR_F_SEQ_VC*n* error occurs.

0: Do not occur

1: Occur

(RC)

Register 42.25. CSI_HOST_INT_MSK_SEQ_FRAME_FATAL_REG (0x0294)



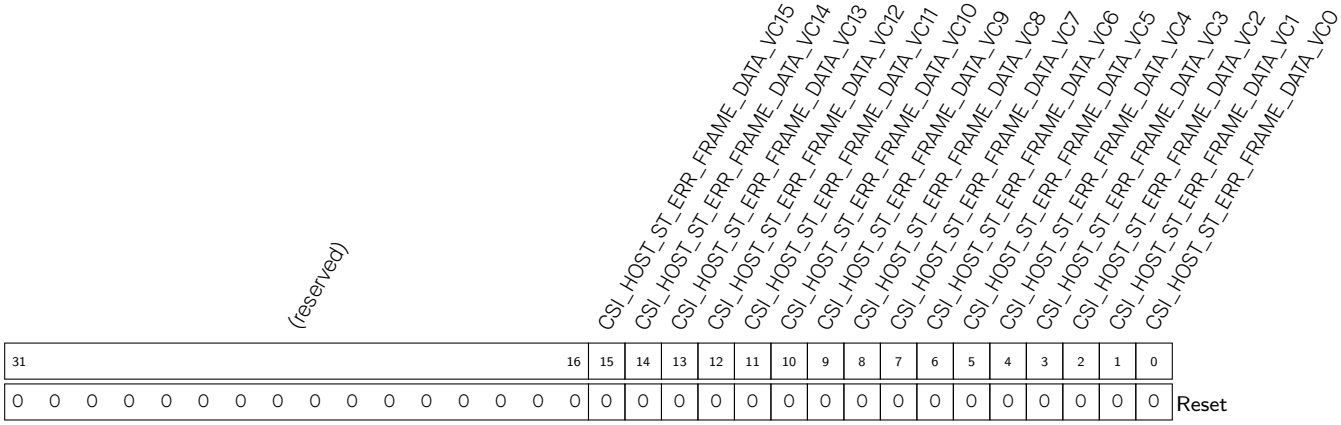
CSI_HOST_MASK_ERR_F_SEQ_VC*n* (*n*: 0-15) Configures whether to mask CSI_HOST_ST_ERR_F_SEQ_VC*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

Register 42.26. CSI_HOST_INT_FORCE_SEQ_FRAME_FATAL_REG (0x0298)



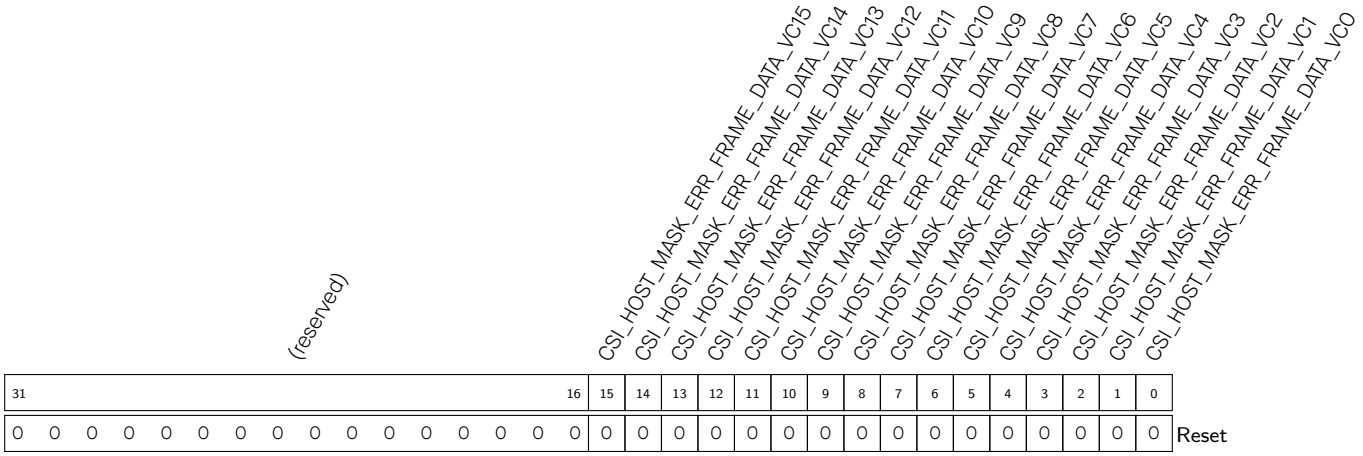
CSI_HOST_FORCE_ERR_F_SEQ_VC*n* (*n*: 0-15) Configures whether to force set CSI_HOST_ST_ERR_F_SEQ_VC*n* to 1.

0: Do not force set

1: Force set

(R/W)

Register 42.27. CSI_HOST_INT_ST_CRC_FRAME_FATAL_REG (0x02A0)



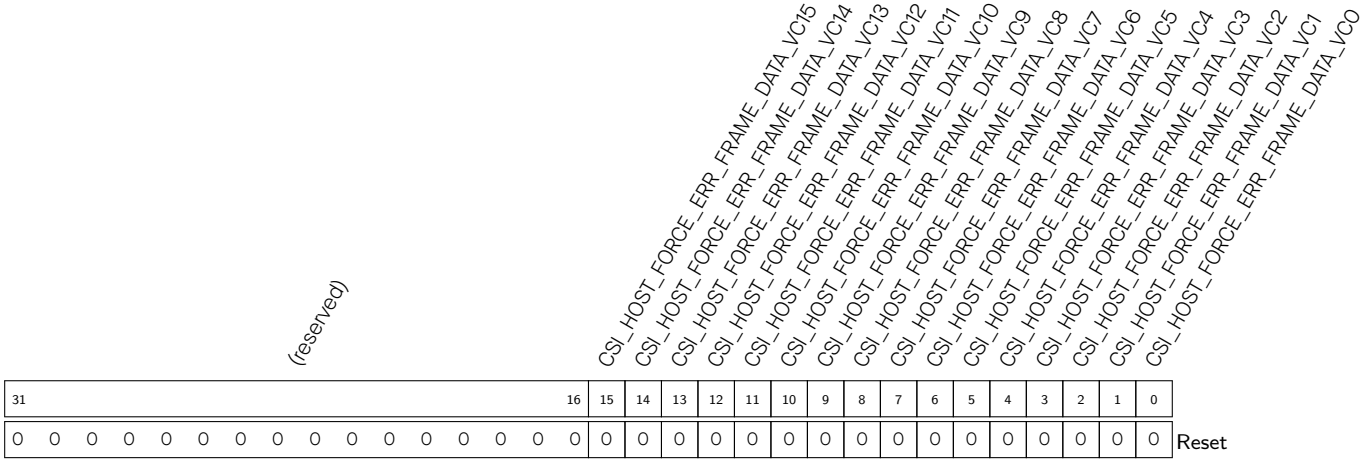
CSI_HOST_ST_ERR_FRAME_DATA_VC*n* (*n*: 0-15) Represents whether the ERR_FRAME_DATA_VC*n* error occurs.

0: Do not occur

1: Occur

(RC)

Register 42.28. CSI_HOST_INT_MSK_CRC_FRAME_FATAL_REG (0x02A4)



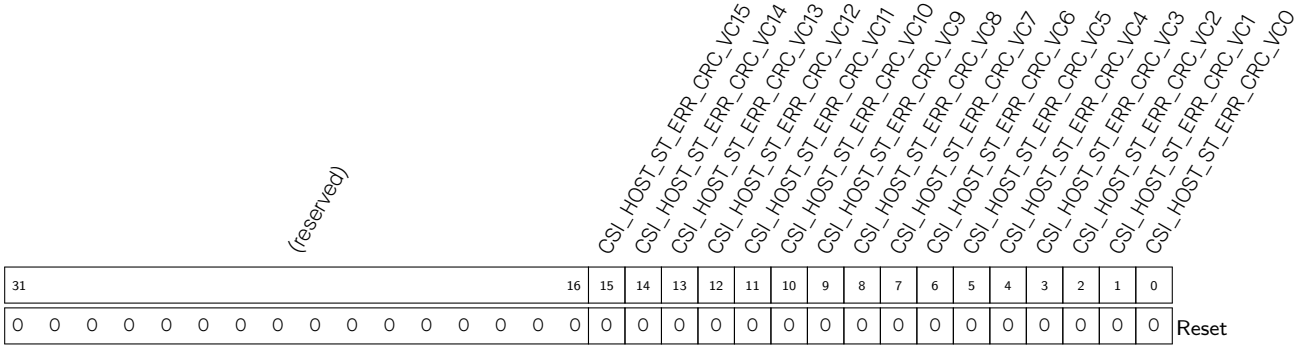
CSI_HOST_MASK_ERR_FRAME_DATA_VC*n* (*n*: 0-15) Configures whether to mask CSI_HOST_ST_ERR_FRAME_DATA_VC*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

Register 42.29. CSI_HOST_INT_FORCE_CRC_FRAME_FATAL_REG (0x02A8)



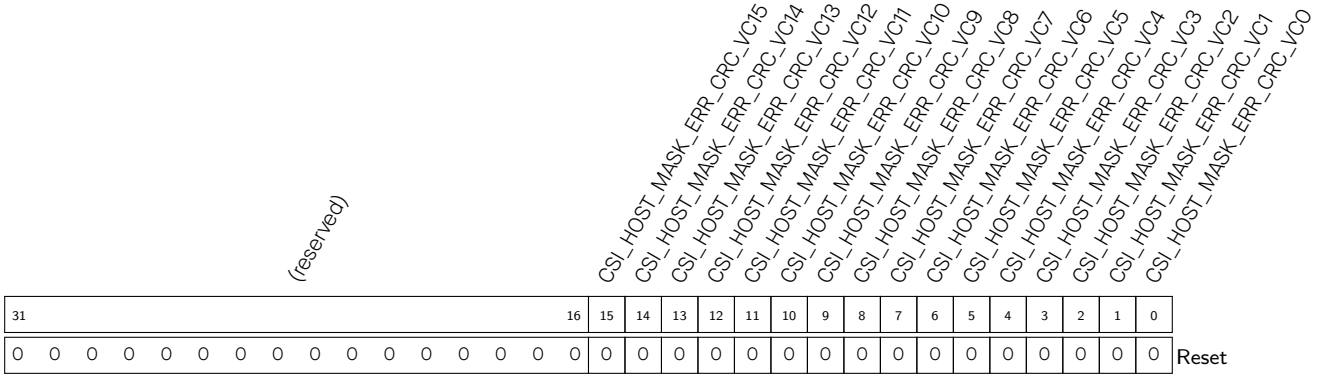
CSI_HOST_FORCE_ERR_FRAME_DATA_VC*n* (*n*: 0-15) Configures whether to force set CSI_HOST_ST_ERR_FRAME_DATA_VC*n* to 1.

0: Do not force set

1: Force set

(R/W)

Register 42.30. CSI_HOST_INT_ST_PLD_CRC_FATAL_REG (0x02B0)



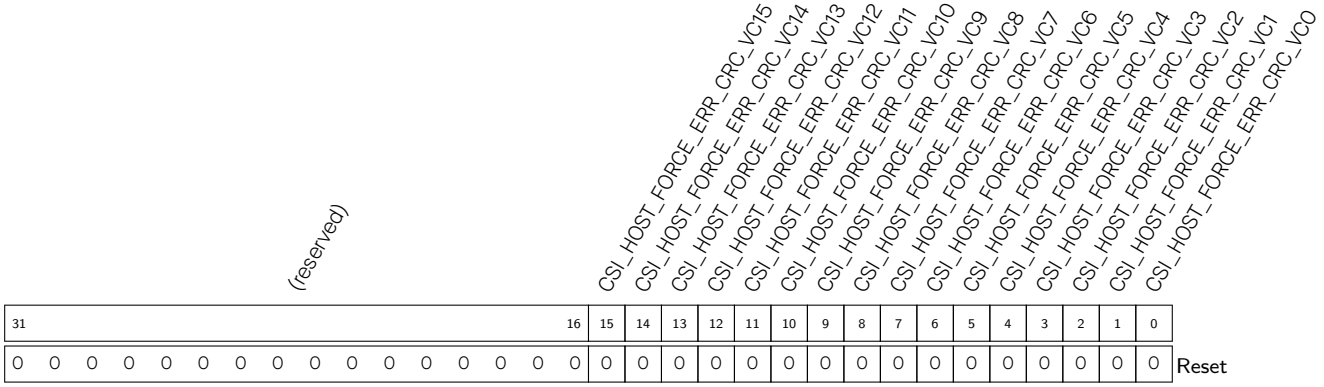
CSI_HOST_ST_ERR_CRC_VC*n* (*n*: 0-15) Represents whether the ERR_CRC_VC*n* error occurs.

0: Do not occur

1: Occur

(RC)

Register 42.31. CSI_HOST_INT_MSK_PLD_CRC_FATAL_REG (0x02B4)



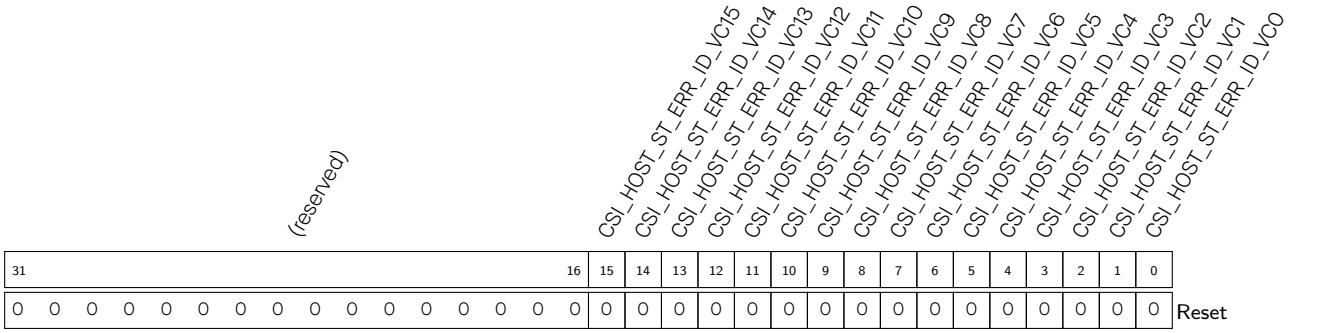
CSI_HOST_MASK_ERR_CRC_VC*n* (*n*: 0-15) Configures whether to mask CSI_HOST_ST_ERR_CRC_VC*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

Register 42.32. CSI_HOST_INT_FORCE_PLD_CRC_FATAL_REG (0x02B8)



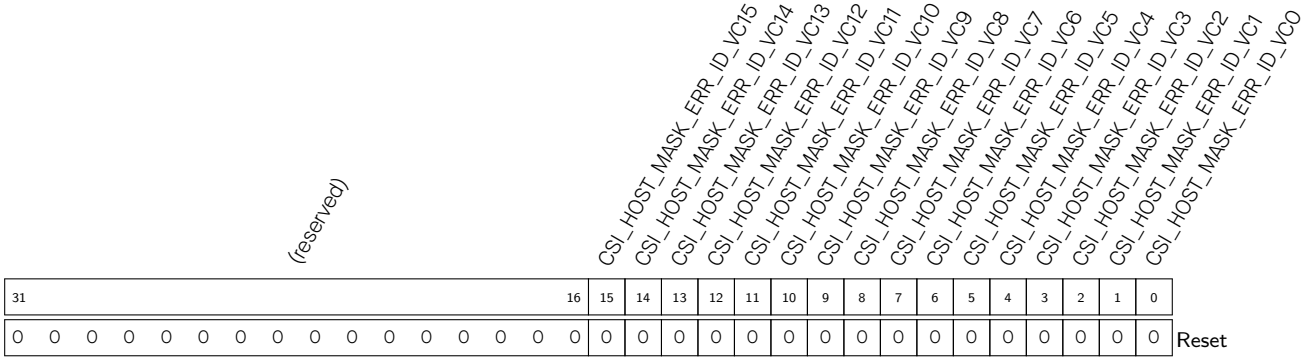
CSI_HOST_FORCE_ERR_CRC_VC*n* (*n*: 0-15) Configures whether to force set CSI_HOST_ST_ERR_CRC_VC*n* to 1.

0: Do not force set

1: Force set

(R/W)

Register 42.33. CSI_HOST_INT_ST_DATA_ID_REG (0x02C0)



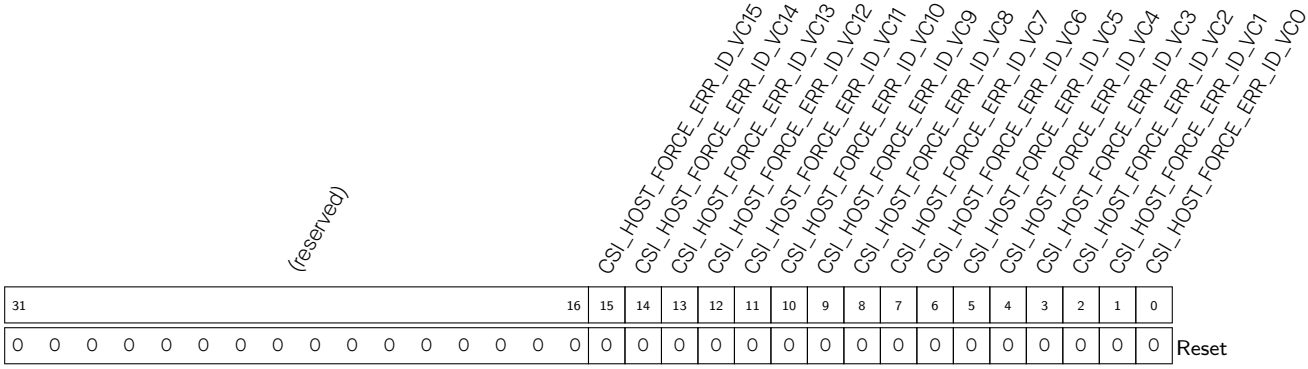
CSI_HOST_ST_ERR_ID_VC*n* (*n*: 0-15) Represents whether the ERR_ID_VC*n* error occurs.

0: Do not occur

1: Occur

(RC)

Register 42.34. CSI_HOST_INT_MSK_DATA_ID_REG (0x02C4)



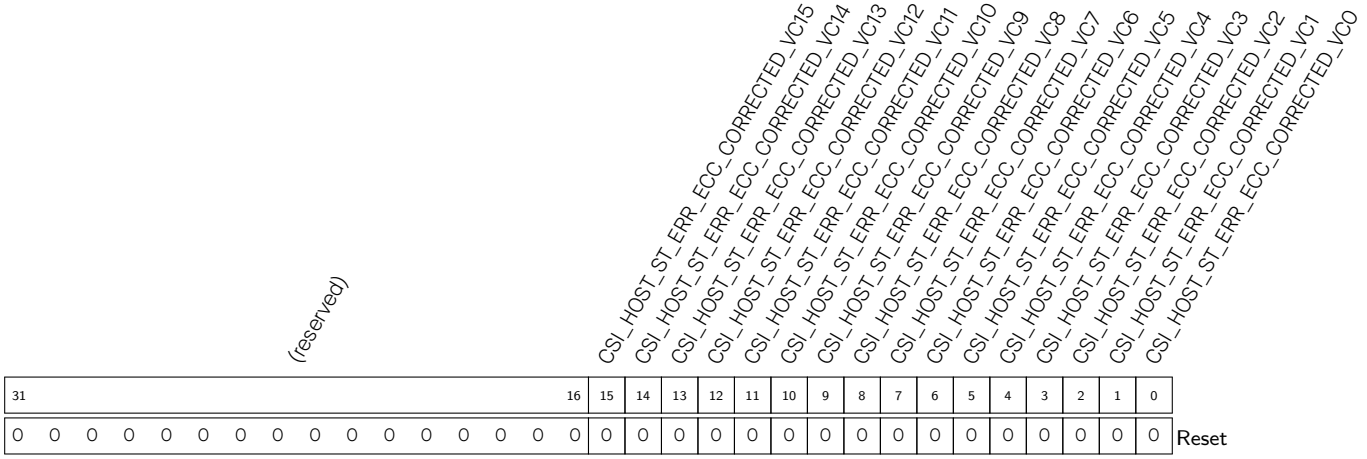
CSI_HOST_MASK_ERR_ID_VC*n* (*n*: 0-15) Configures whether to mask CSI_HOST_ST_ERR_ID_VC*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

Register 42.35. CSI_HOST_INT_FORCE_DATA_ID_REG (0x02C8)



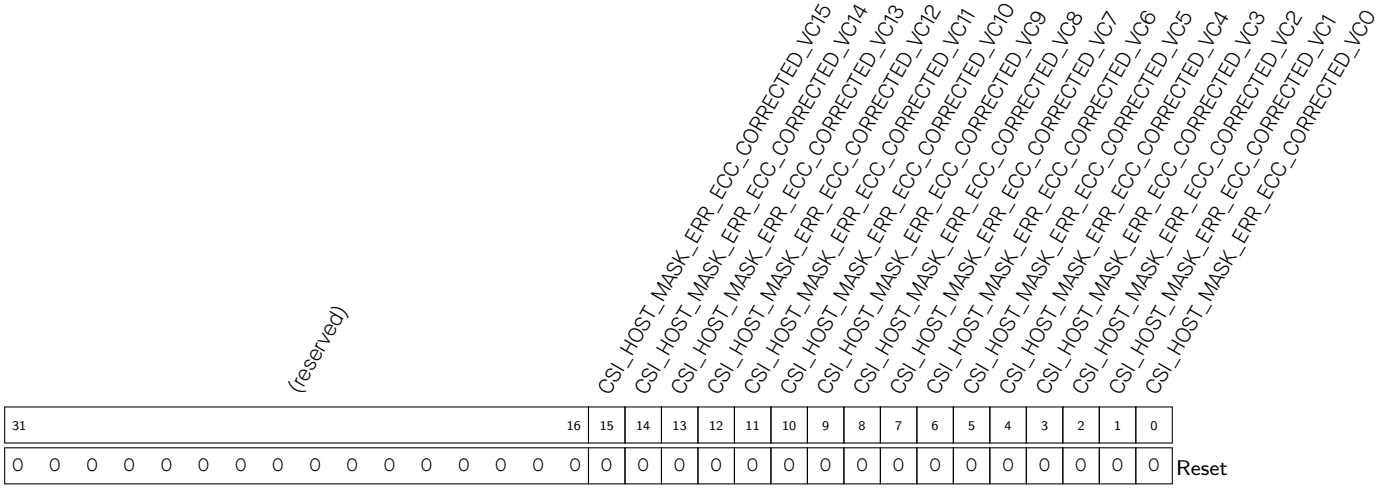
CSI_HOST_FORCE_ERR_ID_VC*n* (*n*: 0-15) Configures whether to force set CSI_HOST_ST_ERR_ID_VC*n* to 1.

0: Do not force set

1: Force set

(R/W)

Register 42.36. CSI_HOST_INT_ST_ECC_CORRECTED_REG (0x02D0)



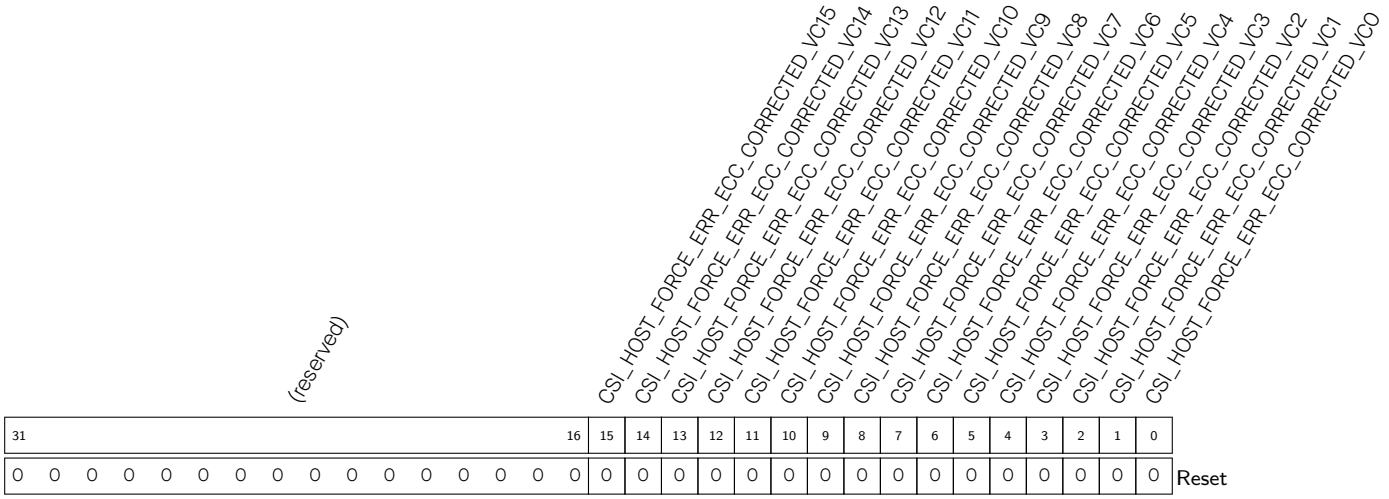
CSI_HOST_ST_ERR_ECC_CORRECTED_VC*n* (*n*: 0-15) Represents whether the ERR_ECC_CORRECTED_VC*n* error occurs.

0: Do not occur

1: Occur

(RC)

Register 42.37. CSI_HOST_INT_MSK_ECC_CORRECTED_REG (0x02D4)



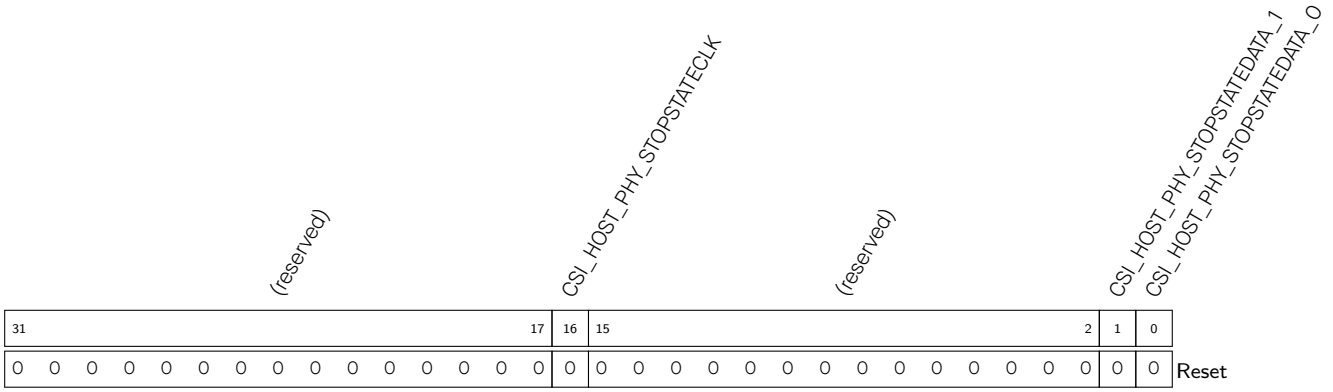
CSI_HOST_MASK_ERR_ECC_CORRECTED_VC*n* (*n*: 0-15) Configures whether to mask CSI_HOST_ST_ERR_ECC_CORRECTED_VC*n*.

0: Mask the error interrupt

1: Enable the error interrupt

(R/W)

Register 42.38. CSI_HOST_INT_FORCE_ECC_CORRECTED_REG (0x02D8)



CSI_HOST_FORCE_ERR_ECC_CORRECTED_VC*n* (*n*: 0-15) Configures whether to force set CSI_HOST_ST_ERR_ECC_CORRECTED_VC*n* to 1.

0: Do not force set

1: Force set

(R/W)

Register 42.39. CSI_HOST_PHY_STOPSTATE_REG (0x004C)

CSI_HOST_PHY_STOPSTATEDATA_*n* (*n*: 0-1) Represents whether data lane *n* is in stop state.

0: Not in stop state

1: In stop state

(RO)

CSI_HOST_PHY_STOPSTATECLK Represents whether clock lane in stop state.

0: Not in stop state

1: In stop state

(RO)

Chapter 43

MIPI DSI

43.1 Introduction

MIPI DSI stands for Mobile Industry Processor Interface Display Serial Interface. It is a standard interface protocol for connecting displays to mobile devices, such as smartphones, tablets, and other embedded systems. MIPI DSI in ESP32-P4 consists of three parts: a DSI Bridge, an MIPI DSI Host Controller, and an MIPI Bidirectional D-PHY. It provides one clock lane and two data lanes, and supports a maximum bit rate of 1.5 Gbps per lane for communication with a DSI-compliant display. DSI (Display Serial Interface) is part of a group of communication protocols defined by the MIPI Alliance.

The DSI Bridge provides an interface between system memory and the MIPI DSI Host Controller. It receives image data through VDMA from system memory, and outputs image data through the Display Pixel Interface (DPI) to the MIPI DSI Host Controller.

The MIPI DSI Host Controller implements the protocol functions defined in the MIPI DSI Specification. It receives image data from the DSI Bridge and outputs image data through the PHY-Protocol Interface (PPI) to the MIPI Bidirectional D-PHY.

The MIPI Bidirectional D-PHY implements the physical layer of bidirectional universal lanes for the MIPI D-PHY interface, which provides one clock lane and two data lanes. The PHY is only used as master.

43.2 Feature List

MIPI DSI in ESP32-P4 supports the following features:

- Configuration of DSI bridge or VDMA as flow controller when reading image data from memory
- Configurable DPI video timing in DSI Bridge
- Various input image formats: RGB888, RGB666, RGB565, YUV422, YUV420, GRAY
- Various DPI image output formats: RGB888, RGB666, RGB565
- Maximum DPI frequency: 240 MHz
- MIPI DSI Host compliant with MIPI DSI specification
- PHY compliant with MIPI D-PHY interface specification, revision 1.1
- The PHY attached with a PLL
- continuous and non-continuous clock lanes
- Escape Mode through data lane 0
- Lane operation ranging from 80 Mbps to 1.5 Gbps in HP TX

- burst and non-burst Video Modes
- Command Mode through APB interface to access display registers
- Supports commands defined in MIPI Alliance specification for Display Command Set (DCS)
- Video pattern generator
- Supports Ultra Low-Power mode

43.3 Architectural Overview

Figure 43.3-1 shows the architecture of MIPI DSI.

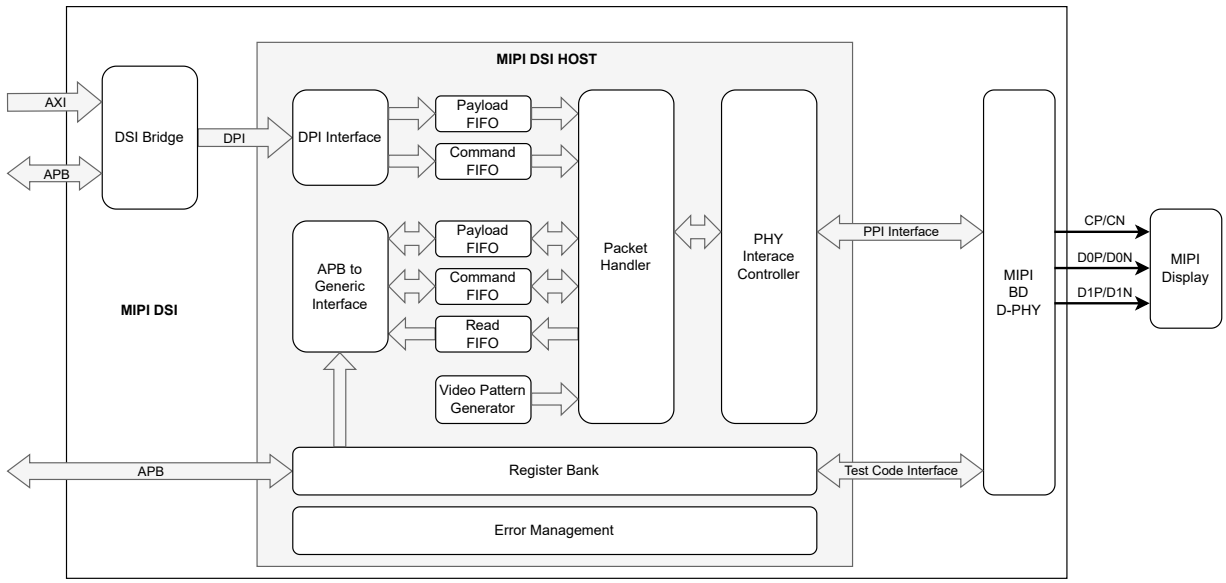


Figure 43.3-1. MIPI DSI architecture

- **DSI Bridge**: The DSI Bridge receives image data from system memory through VDMA, converts it to the DPI data format, and then outputs it to the MIPI DSI Host.
- **MIPI DSI Host**: The MIPI DSI Host receives image data from two sources: the DSI Bridge, or the video pattern generator. Then the received image data is packaged by the Packet Handler according to the MIPI DSI Specification and sent to the PHY Interface Controller. Finally, the image data is converted to the PPI data format and output to the MIPI DSI Bidirectional D-PHY, which includes:
  - **DPI Interface**: Receives pixel data from the DSI Bridge and buffers it to a FIFO.
  - **Register Bank**: Provides access to configuration and control registers.
  - **APB to Generic Interface**: Converts APB operations into Generic Commands.
  - **Video Pattern Generator**: Generates video test patterns.
  - **Packet Handler**: Schedules activities inside the link, including packet building, generating ECC CRC codes, packet reception, and so on.
  - **PHY Interface Controller**: Manages the PHY PPI interfaces, including enabling low-power(LP) transmission/reception, high-speed(HS) transmission, and so on.

  - **Error Management**: Monitors and notifies error conditions on the DSI link.

- **MIPI DSI D-PHY**: The MIPI DSI Bidirectional D-PHY implements the physical layer with one clock lane and two data lanes, connecting to the external display driver. MIPI DSI Bidirectional D-PHY also includes a PLL to generate the HS TX clock.

43.4 Functional Description

This section introduces different operating states and modes of MIPI Bi-Direction (BD) D-PHY and some major functions that facilitate the use of MIPI DSI.

43.4.1 DSI Bridge

DSI Bridge receives image data from system memory through VDMA. The data transfer flow controller can be configured to VDMA or DSI Bridge through DSI_BRG_DSI_DMA_FLOW_CONTROLLER. It is recommended to use VDMA as the flow controller for better performance.

When receiving image data with VDMA as the flow controller, the image can be split into multiple block transfers. To enable this functionality, set DSI_BRG_DMA_MULTIBLK_EN to 1 and configure DSI_BRG_DMA_FLOW_MULTIBLK_NUM with the desired block number. For a detailed explanation of block transfers, refer to *Transfer Hierarchy* in 7 *VDMA Controller (VDMA)*.

DSI Bridge supports the following input data types: RGB888, RGB666, RGB565, YUV422, YUV420, and GRAY. For YUV422, DSI Bridge supports 8 different pixel arrangements. To select whether the input data type is YUV, configure the DSI_BRG_DATA_IN_TYPE register, then use DSI_BRG_RAW_TYPE to specify the exact input format. For the output format sent to DSI Host, use DSI_BRG_DPI_TYPE to specify the RGB format.

All supported input pixel arrangements is list in table 43.4-1.

Table 43.4-1. input pixel arrangement

43.4.2 DSI Host

43.4.2.1 Video Transmission

DSI Host uses DPI as input interface. It is used to transmit a real-time pixel stream from HOST to peripherals in Video Mode.

There are two kinds of video transmission modes:

- **Burst Mode**: In Burst Mode, one pixel line is buffered in FIFO and transmitted in one single packet without any interruptions. It allows the pixel line be sent in a short time and then return to lane LP state, which can reduce power consumption and enable more time for other data transmission.
- **Non-Burst Mode**: In Non-Burst Mode, one pixel line is divided into several packets. It is used to match pixel bandwidth with DSI link bandwidth, and reduce the memory requirement for both host and peripheral. There are two kinds of Non-Burst mode:
  - Non-Burst mode with sync pulse: allows the peripheral to accurately reconstruct original video timing, including sync pulse widths.
  - Non-Burst mode with sync event: accurate reconstruction of sync pulse is not required.

If the host and peripheral meet the following requirements, it is recommended to select Burst Mode. Otherwise, the pixel data may be lost, causing malfunction of the display peripheral.

- The display peripheral supports receiving a full pixel line in one single block and the reception buffer won't overflow.
- The DSI output bandwidth is much higher than the DPI input bandwidth, which allows the lane to go to LP state after each line.

If any of the requirements cannot be met, Non-Burst Mode should be selected. In Non-Burst Mode, the DSI host should be configured to match DSI output ratio and DPI input ratio. The following equation shows how the transmission parameters should be configured (The left side represents the DSI output ratio, and the right side represents the DPI input ratio):

- If null packets are enabled (DSI_HOST_VID_NULL_SIZE $\neq$ 0):

$$\begin{aligned} & lanebyteclk_period \times DSI_HOST_VID_NUM_CHUNKS \\ & \quad \times (DSI_HOST_VID_PKT_SIZE \times bytes_per_pixel + 12 \\ & \quad + DSI_HOST_VID_NULL_SIZE)/number_of_lanes \\ & = dpiclk_period \times pixels_per_line \end{aligned}$$

- If null packets are disabled (DSI_HOST_VID_NULL_SIZE $=$ 0):

$$\begin{aligned} & lanebyteclk_period \times DSI_HOST_VID_NUM_CHUNKS \\ & \quad \times (DSI_HOST_VID_PKT_SIZE \times bytes_per_pixel + 6) \\ & /number_of_lanes = dpiclk_period \times pixels_per_line \end{aligned}$$

Refer to 43.4.4 for the definitions of lanebyteclk and dpiclk.

43.4.2.2 Command Transmission

DSI Host allows the transmission of generic commands described in DSI specification as manufacturer-specific in Command Mode through APB Slave Interface.

The command packets are built using the APB registers:

- DSI_HOST_GEN_PLD_DATA_REG: Writing to this register sends the data as the payload of a command packet. Reading this register returns the payload of read-back packets.
- DSI_HOST_GEN_HDR_REG: Contains the command packet header type and header data. Writing to this register triggers a command transmission.

The valid packets are as follows:

- Generic Write Short Packet 0 Parameters
- Generic Write Short Packet 1 Parameters
- Generic Write Short Packet 2 Parameters
- Generic Read Short Packet 0 Parameters
- Generic Read Short Packet 1 Parameters
- Generic Read Short Packet 2 Parameters
- Maximum Read Packet Configuration
- Generic Long Write Packet

Command packets can be transmitted in lane HS or LP states, while in video mode Blanking or Low-Power periods (BLLP). BLLP corresponds to the shaded areas in figure 43.4-1.

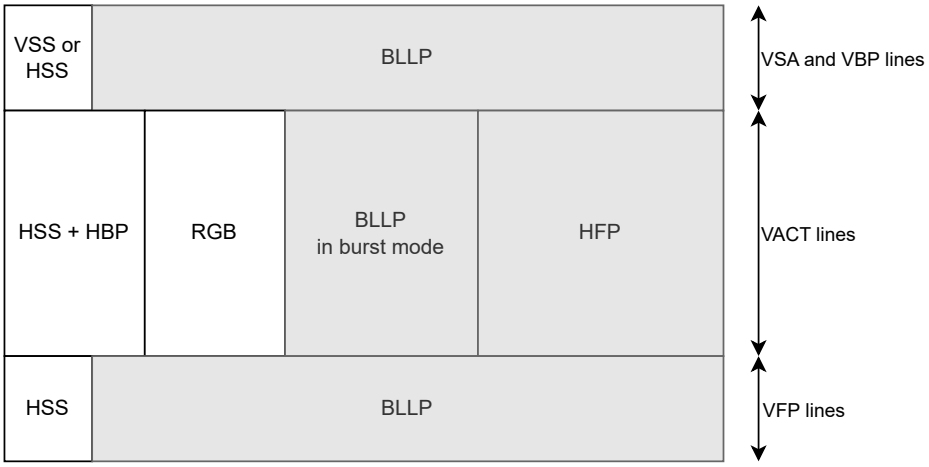

Figure 43.4-1. Command Transmission Periods

43.4.2.2.1 Command Transmission in LP mode

To enable sending commands in LP state during video transmission, set DSI_HOST_LP_CMD_EN to 1. In this case, even if bits 8 to 13 of DSI_HOST_VID_MODE_CFG_REG are set to 0, commands can still be sent during these periods.

- DSI_HOST_OUTVACT_LPCMD_TIME configures the time available (in bytes) to transmit commands in LP mode (based on escape clock) during VSA, VBP, and VFP. The outvact_lpcmd_time for Non-Burst with

Sync Pulse is shown in figure 43.4-2, and the outvact_lpcmd_time for Burst or Non-Burst with Sync Event is shown in figure 43.4-3.

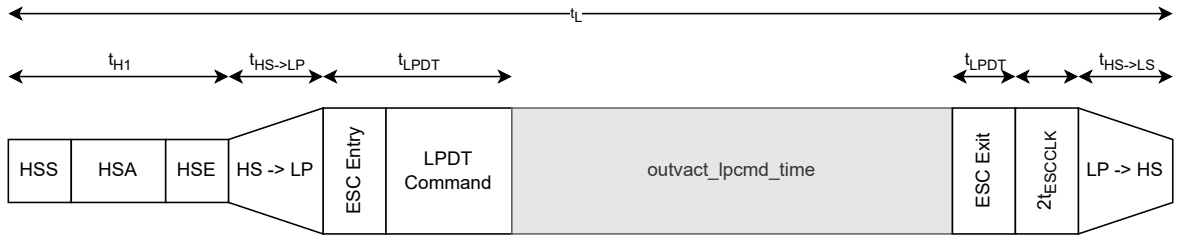

Figure 43.4-2. outvact_lpcmd_time for Non-Burst with Sync Pulse

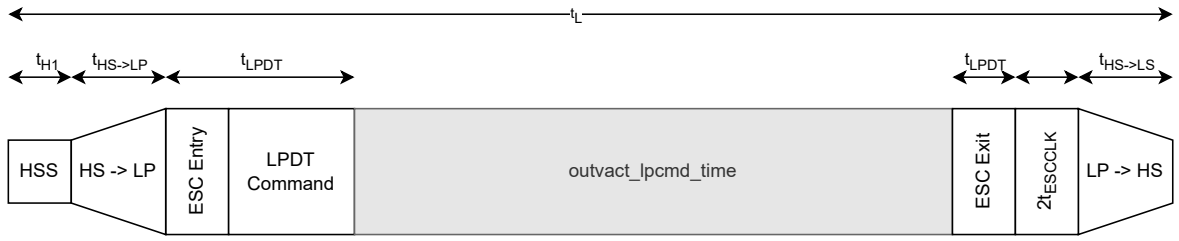

Figure 43.4-3. outvact_lpcmd_time for Burst or Non-Burst with Sync Event

The outvact_lpcmd_time is calculated by:

$$outvact_lpcmd_time = t_L - (t_{H1} + t_{HS \rightarrow LP} + t_{LP \rightarrow HS} + t_{LPDT} + 2 \times t_{ESCCLK}) / (2 \times 8 \times t_{ESCCLK})$$

- DSI_HOST_INVACT_LPCMD_TIME configures the time available (in bytes) to transmit commands in LP mode (based on escape clock) during HFP. The invact_lpcmd_time for Non-Burst with Sync Pulse is shown in figure 43.4-4; and the invact_lpcmd_time for Non-Burst with Sync Event is shown in figure 43.4-5.

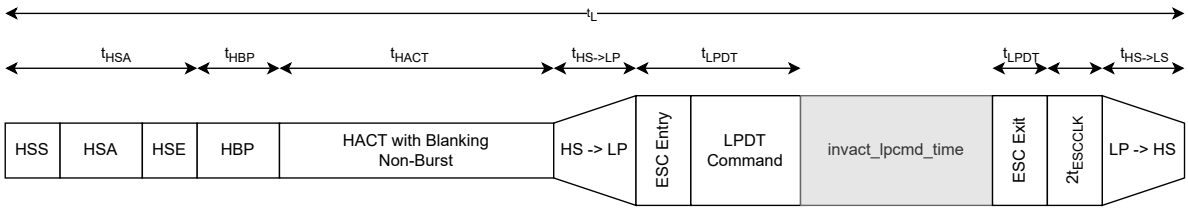

Figure 43.4-4. invact_lpcmd_time for Non-Burst with Sync Pulse

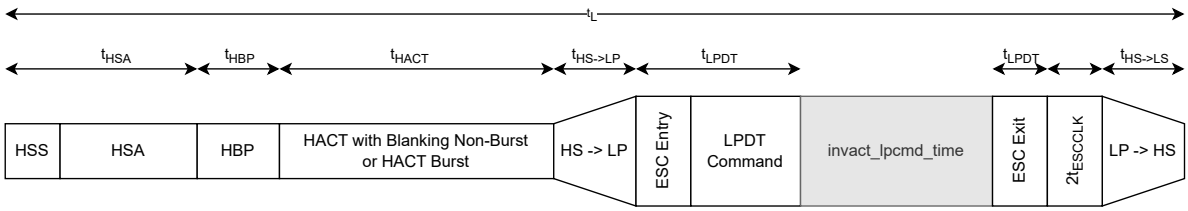

Figure 43.4-5. invact_lpcmd_time for Burst or Non-Burst with Sync Event

The invact_lpcmd_time is calculated by:

$$invact_lpcmd_time = t_L - (t_{HSA} + t_{HBP} + t_{HACT} + t_{HS \to LP} + t_{LP \to HS} + t_{LPDT} + 2 \times t_{ESCCLK}) / (2 \times 8 \times t_{ESCCLK})$$

43.4.2.2.2 Command Transmission in HS mode

If DSI_HOST_LP_CMD_EN is set to 0, the commands are sent in HS mode during video transmission. In this case, no programming is required.

43.4.2.3 Video Pattern Generator

The Video Pattern Generator can output horizontal or vertical color bar or BER testing pattern. For the pattern resolution, refer to Clocks and Display Resolution. The following register fields are used to configure the Video Pattern Generator:

- DSI_HOST_VPG_ORIENTATION: Indicates the orientation of the color bar
- DSI_HOST_VPG_MODE: Selects the pattern
- DSI_HOST_VPG_EN: Enables the video pattern generator

43.4.2.3.1 Color Bar Pattern

The color bar pattern has eight color bars: white, yellow, cyan, green, magenta, red, blue, and black. Each color width can be calculated by dividing the pattern size by eight. If the size is not divisible by eight, the last color black contains the remaining size. Figure 43.4-6 and 43.4-7 show the vertical and horizontal color bars.

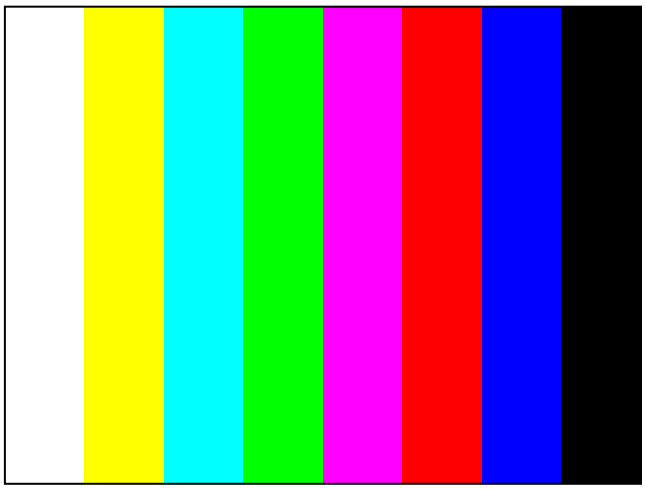

Figure 43.4-6. Vertical Color Bar

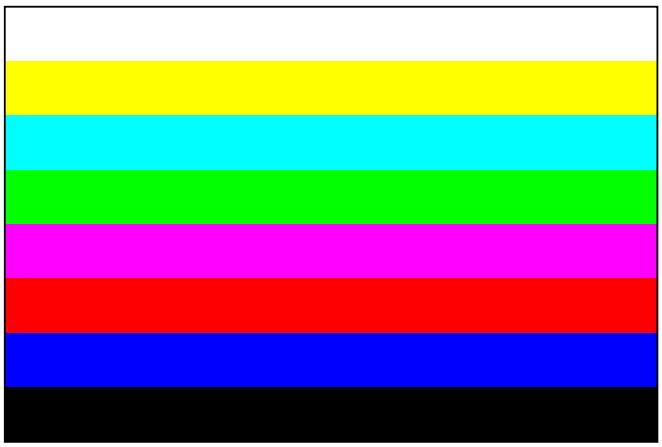

Figure 43.4-7. Horizontal Color Bar

Table 43.4-3 shows the color bar pattern RGB coding.

Table 43.4-3. Color Bar Coding

	White	Yellow	Cyan	Green	Magenta	Red	Blue	Black
R	High	High	Low	Low	High	High	Low	Low
G	High	High	High	High	Low	Low	Low	Low
B	High	Low	High	Low	High	Low	High	Low

43.4.2.3.2 BER Testing Pattern

The BER testing pattern tests whether the device RX PHY receives data correctly. The following data patterns are generated:

- X bytes of 0xAA (high-frequency pattern)
- X bytes of 0x33 (mid-frequency pattern)
- X bytes of 0xF0 (low-frequency pattern)
- X bytes of 0x7F (lone 0 pattern)
- X bytes of 0x55 (high-frequency pattern)
- X bytes of 0xCC (mid-frequency pattern)
- X bytes of 0x0F (low-frequency pattern)
- Y bytes of 0x80 (lone 1 pattern)

X and Y depend on pattern resolution, and Y equals X in most cases. With RGB888 color coding and horizontal resolution in multiples of eight, Figure 43.4-8 shows the pattern that appears on the DSI display:

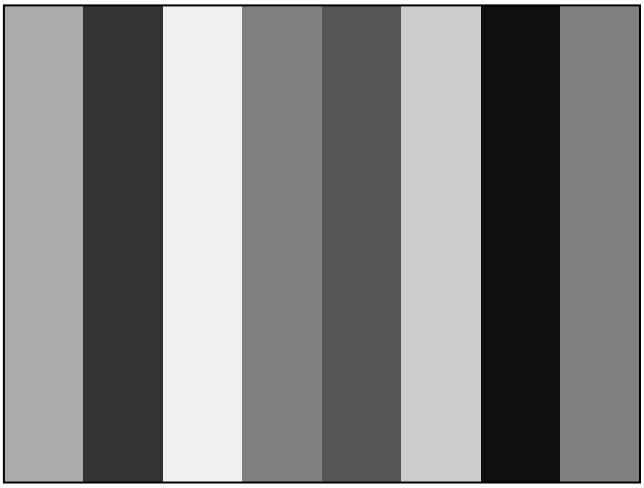

Figure 43.4-8. RGB888 BER Testing Pattern

43.4.2.4 Errors

The DSI_HOST_INT_ST0/1_REG registers indicate the DSI Host error reports. These registers can also trigger an interrupt to notify the system. To trigger the error interrupt, the corresponding bit in mask registers DSI_HOST_INT_MSK0/1_REG should be cleared. The DSI_HOST_INT_ST0/1_REG will be cleared after a read operation.

43.4.3 D-PHY

This section describes the D-PHY operating modes and PLL configurations.

43.4.3.1 D-PHY Operating Modes

Figure 43.4-9 shows the PHY initialization and active operating modes.

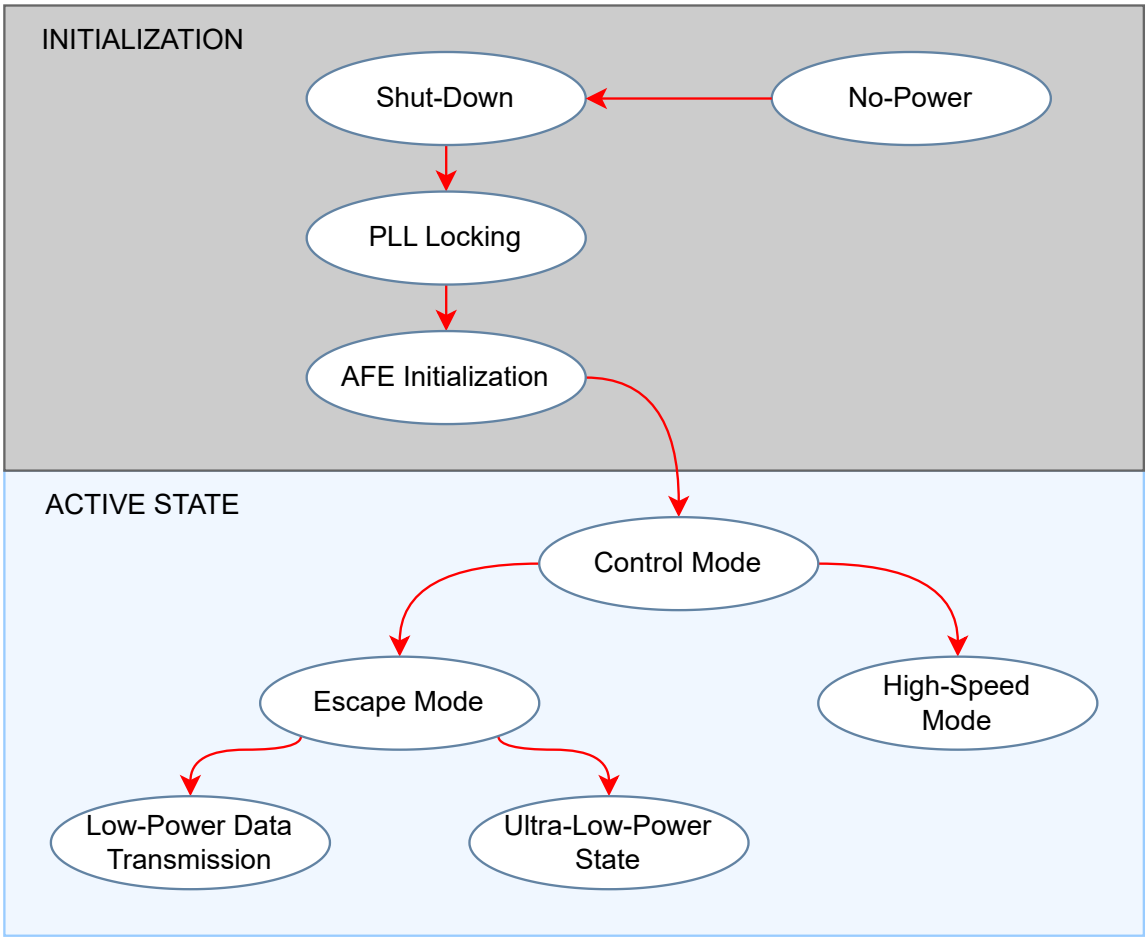

Figure 43.4-9. PHY operating modes

43.4.3.1.1 No Power State

No-Power state is characterized by the absence of any supply voltage applied to the PHY.

For ESP32-P4's MIPI DSI, MIPI BD D-PHY is in No Power state when the power supply VDD_HP_*n* (n: 0-3) and VDD_MIPI_DPHY are off.

43.4.3.1.2 Shutdown State

In Shutdown state, all analog blocks are disabled, all digital logic is reset, and DP/DN and CP/CN lane are high impedance (Hi-Z). To enable shutdown Mode of the PHY, clear DSI_HOST_PHY_RSTZ and DSI_HOST_PHY_SHUTDOWNZ to 0.

Before leaving the Shutdown state, some parameters should be configured, including the number of lanes to be used, the lane operation frequency range, the PLL configurations.

The MIPI BD D-PHY consists of two data lanes. Configure DSI_HOST_N_LANES to select either one or both data lanes for use.

By default, the PHY is set to operate within a lower range of 80-110 Mbps. To accommodate higher bit rates,

you can adjust the HS frequency ranges (the hsfreqrange field) in test code test code 0x44 with the proper code. It is recommended to perform this adjustment in Shutdown state if the PHY works always at the same bit rate, as the control interface is independent of the rest of the MIPI BD D-PHY. The supported ranges are shown in table 43.4-4:

Table 43.4-4. Frequency Ranges Supported by MIPI BD D-PHY

Frequency Range (Mbps)	hsfreqrange[5:0]*
80-89	000000
90-99	010000
100-109	100000
110-129	000001
130-139	010001
140-149	100001
150-169	000010
170-179	010010
180-199	100010
200-219	000011
220-239	010011
240-249	100011
250-269	000100
270-299	010100
300-329	000101
330-359	010101
360-399	100101
400-449	000110
450-499	010110
500-549	000111
550-599	010111
600-649	001000
650-699	011000
700-749	001001
750-799	011001
800-849	101001
850-899	111001
900-949	001010
950-999	011010
1000-1049	101010
1050-1099	111010
1100-1149	001011
1150-1199	011011
1200-1249	101011
1250-1299	111011
1300-1349	001100
1350-1399	011100

Continued on next page

Table 43.4-4 – continued from previous page

Frequency Range (Mbps)	hsfreqrange[5:0]*
1400-1449	101100
1450-1500	111100

It is also necessary to configure PLL input and output frequency through test code interface. Refer to PLL parameters for detailed description of PLL parameters.

When DSI_HOST_PHY_RSTZ and DSI_HOST_PHY_SHUTDOWNZ are set to 1, the MIPI BD D-PHY leaves the Shutdown state and starts an initialization procedure.

43.4.3.1.3 PLL-Locking and AFE Initialization

After DSI_HOST_PHY_RSTZ and DSI_HOST_PHY_SHUTDOWNZ are released, the PHY begins an initialization sequence to enable its normal operation. It is recommended to release DSI_HOST_PHY_SHUTDOWNZ before releasing DSI_HOST_PHY_RSTZ. Additionally, ensure that DSI_DPHY_CFG_CLK and DSI_DPHY_PLL_REFCLK (refer to Table 11.2-5 in Chapter 11 *Reset and Clock* for details) are available and stable at this point.

After that, the PLL becomes active and the PHY waits for the PLL lock which is indicated by DSI_HOST_PHY_LOCK.

Following the PLL lock, AFE Initialization is performed. All initialization steps are done when DSI_HOST_PHY_STOPSTATECLKLANE DSI_HOST_PHY_STOPSTATEnLANE are asserted and the lanes are in stop state (LP-11).

43.4.3.1.4 Control Mode

After the AFE initialization is completed, the MIPI BD D-PHY remains in Control mode by default while driving the stop state LP-11 on the lines until a request is made. Any request must start from and end in this state. After a request, a lane can enter High-Speed Data Transfer mode, Escape mode, Ultra Low Power state, or turnaround.

43.4.3.1.5 High-Speed Data Transfer

DSI HOST sends a request for High-Speed Data Transfer after receiving data from DSI Bridge. In High-Speed Data Reception mode, the PHY transmits image data in bursts. The lane operates in high-speed mode only during these bursts.

As shown in Figure 43.4-10, a burst on lane consists of three parts: the low-power initialization sequence, the high-speed data payload, and the end of reception sequence.

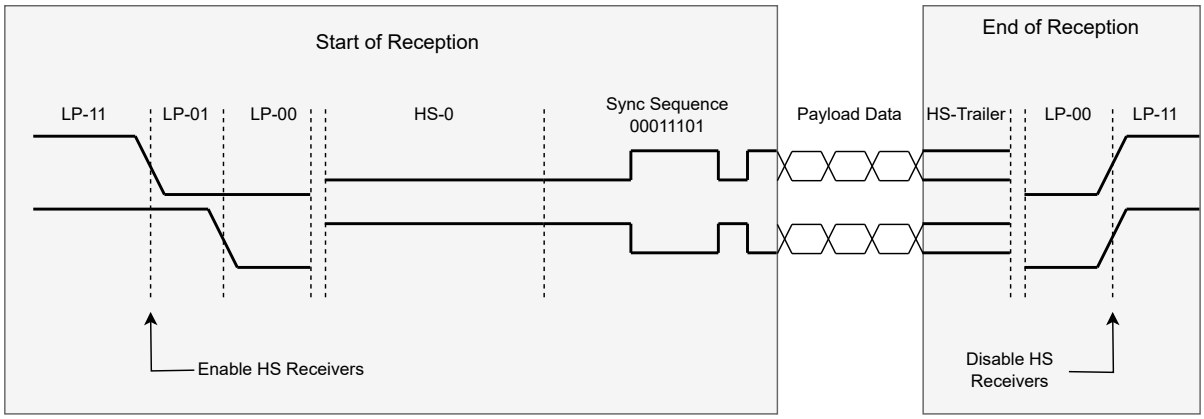

Figure 43.4-10. MIPI DSI HS Data Reception Sequence

43.4.3.1.6 Escape Mode

Escape mode allows asynchronous communication over data lanes at low speed. During Escape mode, the lane remains in low-power state. MIPI DSI in ESP32-P4 supports Low-Power Data Transmission (LPDT) and Ultra Low Power State (ULPS) in Escape mode.

Commands will be sent in LPDT if DSI_HOST_LP_CMD_EN is set to 1.

You can drive the PHY into ULPS through DSI_HOST_PHY_ULPS_CTRL_REG when DSI is idle to save power. The lane state can be observed through DSI_HOST_PHY_STATUS_REG.

43.4.3.1.7 Turnaround

The PHY can swap transmission direction through turnaround. This is used to receive command response from DSI devices.

43.4.3.2 PLL Parameters

The VCO output frequency of the PLL is a function of the frequency of input reference clock DSI_DPHY_PLL_REFCLK, as well as the multiplication ratio M, and the division ratio N:

$$f_{VCO} = \frac{M}{N} \times f_{REFCLK}$$

And the following limit must be met:

$$40\,\text{MHz} \geq \frac{f_{REFCLK}}{N} \geq 5\,\text{MHz}$$

Additionally, M must be an even number. The values of M and N can be programmed through test code 0x17 and test code 0x18. The programmed value is equal to the actual value minus 1, as shown in table 43.4-5. After that, bit-5 and bit-4 of test code 0x19 should be set to 1 to make the M and N configuration valid.

Table 43.4-5. M and N ratios

m[8:0] = M-1	M	n[6:0] = N-1	N
9'h1	2	7'h0	1
9'h3	4	7'h1	2
...	...	...	...

The VCO range of f_{VCO} can also be selected through test code 0x10. The valid VCO ranges are in table 43.4-6.

Table 43.4-6. VCO ranges

vcorange[2:0]	VCO Frequency (MHz)
000	80-200
001	200-300
010	300-500
011	500-700
100	700-900
101	900-1100
110	1100-1300
111	1300-1500

The loop bandwidth should be configured through test code interface depending on the output frequency to ensure proper operation of the PLL. The related parameters are listed below, and the valid value are listed in table 43.4-7.

- VCO capacitance (vcocap[1:0]), program through test code 0x10.
- CP current (icpctrl[3:0]), program through test code 0x11.
- LPF characteristic (lpfctrl[5:0]), program through test code 0x12.

Table 43.4-7. PLL CP and LPF Control Bits

VCO fmin (MHz)	VCO fmax (MHz)	vcorange[2:0]	icpctrl[3:0]	lpfctrl[5:0]	vcocap[1:0]
80	110	000	0100	010000	00
110	150		1000	001000	00
150	200		1100	001000	00
200	250	001	1100	001000	00
250	300		0010	001000	00
300	400	010	0101	001000	00

600	700		0110	000100	00
700	900	100	0110	000100	00
900	1100	101	0111	010000	00
1100	1300	110	0111	001000	00

Continued on next page

Table 43.4-7 – continued from previous page

VCO fmin (MHz)	VCO fmax (MHz)	vcorange[2:0]	icpctrl[3:0]	lpfctrl[5:0]	vcocap[1:0]
1300	1500	111	0111	001000	00

Note:

vcorange, icpctrl, lpfctrl are automatically set to the default values for the corresponding hsfreqrange, if the corresponding bit is 0.

- test code 0x10, bit7, clear to 0 to bypass vcorange
- test code 0x12, bit7, clear to 0 to bypass icpctrl
- test code 0x12, bit6, clear to 0 to bypass lpfctrl

43.4.3.3 Test Codes

The MIPI BD D-PHY provides a set of test codes for configuring MIPI BD D-PHY operation. The configuration can be done through Test Code Interface using DSI_HOST_PHY_TST_CTRL0_REG and DSI_HOST_PHY_TST_CTRL1_REG. For details of the Test Code Interface, refer to section 42.5.3.1 in Chapter 42 *MIPI CSI*.

All supported Test Codes are:

43.4.3.3.1 Normal Operation

This mode represents the normal operation of the PHY and also the wake up state of the test interface. In this mode, the test interface is inactive.

- **Test Code**: 0x00
- **Test Data**: None

43.4.3.3.2 PLL Bias Current Selector / Filter Capacitance Control / VCO Control

Controls the biasing of the PLL and the VCO transfer function.

- **Test Code**: 0x10
- **Test Data**:

Table 43.4-8. Test Data of 0x10

w-1'b0	w-1'b0	w-3'b000	w-2'b00	w-1'b1
Bypass VCO range	Reserved	VCO range control	VCO internal capacitance control	Reference bias current selector

  - Bit 7: Bypass VCO range
    * 0 - VCO range is programmed with the default value for the corresponding hsfreqrange
    * 1 - VCO range is programmed with bits 5-3

- Bit 6: Reserved
- Bits 5-3: VCO range control, refer to table 43.4-6 for details
- Bits 2-1: VCO internal capacitance control
  * 00 - Default capacitance
  * 01 - Low capacitance (four times lower than default value)
  * 10 - High capacitance (double of the default value)
  * 11 - Not allowed
- Bit 0: Reference bias current selector
  * 0 - Internal biasing
  * 1 - Clean external current source of 20uA

- **Test Dout**:

43.4.3.3.5 PLL Input Divider Ratio

Controls the PLL's input divider N. $N = n + 1$, where N is the actual divider ratio, and n is the programmed value in the test code.

to enable the programmed value, ensure that bit-4 of test code 0x19 is set to 1.

- **Test Code**: 0x17

43.4.4 Clocks and Display Resolution

The clock architecture of DSI is shown in figure 43.4-11. All clocks are:

- **PCLK**: the apb bus clock
- **ACLK**: the axi bus clock
- **DSI_DPICLK**: dpi interface clock
- **DSI_DPHY_CFG_CLK**: DPHY configuration clock
- **DSI_DPHY_PLL_REFCLK**: DPHY PLL input reference clock
- **TX_HS_CLK**: DPHY PLL output clock
- **TX_BYTE_CLK**: High-Speed (HS) transfer byte clock, TX_HS_CLK divided by 8.
- **TX_ESC_CLK**: Low-Power (LP) escape mode transfer clock, divided from TX_BYTE_CLK. The divider ratio can be configured through DSI_HOST_TO_CLK_DIVISION, and the allowed max-frequency is 20 MHz.

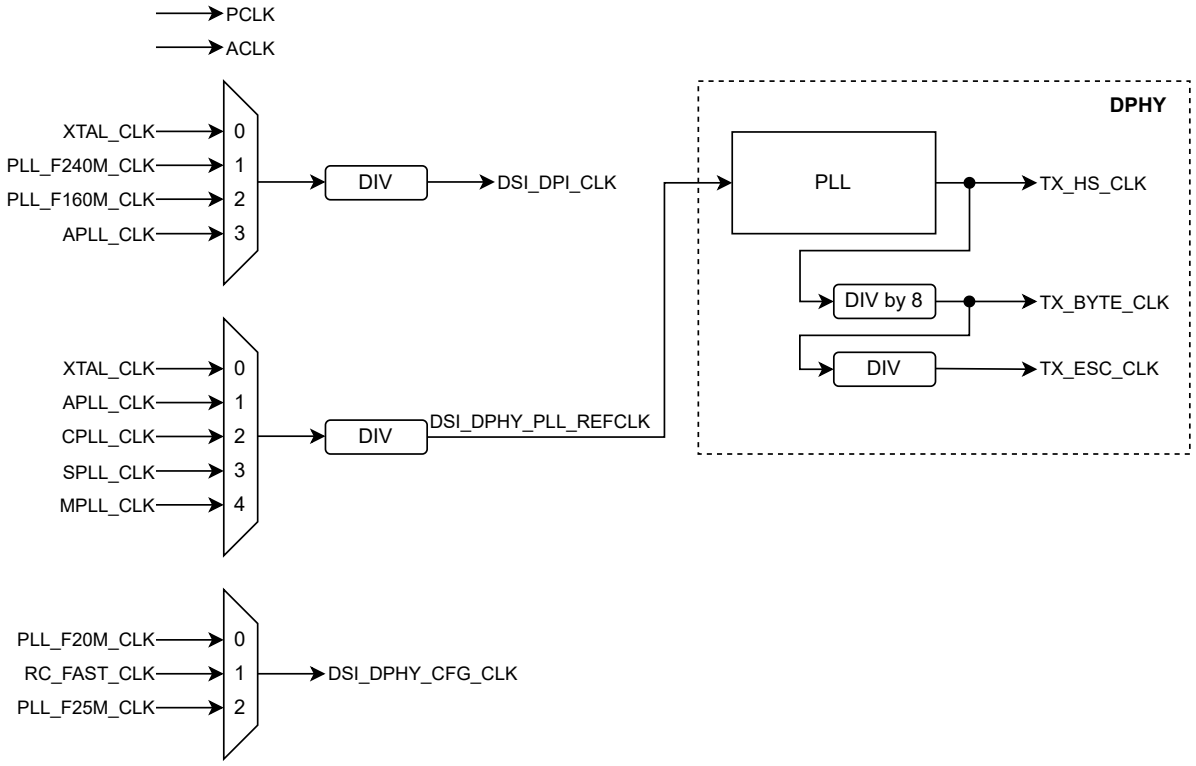

Figure 43.4-11. MIPI DSI clock architectural

DSI supports continuous and non-continuous clock lane

- For continuous clock, set DSI_HOST_AUTO_CLKLANE_CTRL to 1, set DSI_HOST_PHY_TXREQUESTCLKHS to 1
- For non-continuous clock, set DSI_HOST_AUTO_CLKLANE_CTRL to 0, set DSI_HOST_PHY_TXREQUESTCLKHS to 1

In video mode transmission, the video timing parameters are shown in figure 43.4-12.

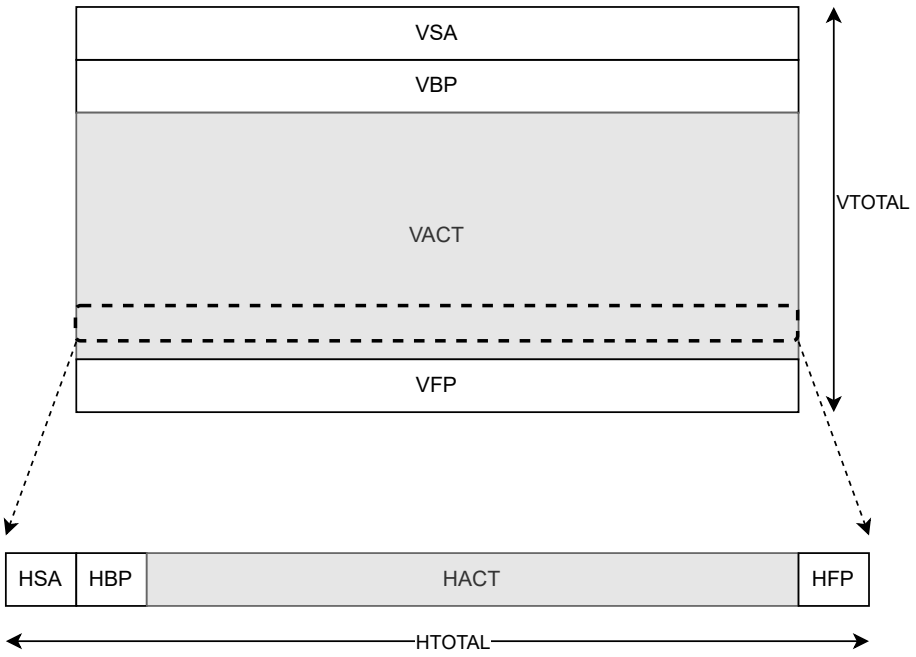

Figure 43.4-12. Video Timing

For DPI, the video timing and resolution can be configured through the following DSI Bridge register fields. After that, write 1 to DSI_BRG_DPI_CONFIG_UPDATE to make the configuration valid.

- DSI_BRG_HTOTAL: The HTOTAL length measured in DSI_DPICLK
- DSI_BRG_HDISP: The HACT length measured in DSI_DPICLK
- DSI_BRG_HBANK: The HBP length measured in DSI_DPICLK
- DSI_BRG_HSYNC: The HSA length measured in DSI_DPICLK
- DSI_BRG_VTOTAL: The VTOTAL length measured in lines
- DSI_BRG_VDISP: The VACT length measured in lines
- DSI_BRG_VBANK: The VBP length measured in lines
- DSI_BRG_VSYNC: The VSA length measured in lines

Similar configuration for video timing and resolution is required for DSI, and the related registers fields are listed below:

- DSI_HOST_VID_HSA_TIME: The HSA length measured in TX_BYTE_CLK
- DSI_HOST_VID_HBP_TIME: The HBP length measured in TX_BYTE_CLK
- DSI_HOST_VID_HLINE_TIME: The HTOTAL length measured in TX_BYTE_CLK
- DSI_HOST_VSA_LINES: The VSA length measured in lines
- DSI_HOST_VBP_LINES: The VBP length measured in lines
- DSI_HOST_VFP_LINES: The VFP length measured in lines
- DSI_HOST_VACTIVE_LINES: The VACT length measured in lines

The video timing configuration of DPI and DSI should match to avoid line buffer overflow. The actual timing of each line in DPI and DSI should be the same.

43.5 Interrupts

ESP32-P4's MIPI DSI can generate the following interrupt signals, which will be sent to the Interrupt Matrix.

- dsi_bridge_interrupt
- dsi_interrupt

The following interrupt sources can generate the dsi_bridge_interrupt interrupt signal:

Table 43.5-1. DSI Bridge interrupts

Interrupt Source	Detail
DSI_BRG_UNDERRUN_INT	Triggered when DSI Bridge buffer underruns.

The following interrupt sources can generate the dsi_interrupt interrupt signal:

Table 43.5-2. DSI Host Interrupts

Interrupt	Cause of Interrupt	Recommended Handing Method
DSI_HOST_ACK_WITH_ERR_0	SoT error from the Acknowledge error report	Transmit the packet again if the packet is critical
DSI_HOST_ACK_WITH_ERR_1	SoT Sync error from the Acknowledge error report	Transmit the packet again
DSI_HOST_ACK_WITH_ERR_2	EoT Sync error from the Acknowledge error report	Transmit the packet again
DSI_HOST_ACK_WITH_ERR_3	Escape Mode Entry Command error from the Acknowledge error report, the device does not recognize the Escape Mode Entry code	Check the device capability
DSI_HOST_ACK_WITH_ERR_4	Low-power Transmit Sync error from the Acknowledge error report	Transmit the packet again

Continued on the next page...

Table 43.5-2 – ...Continued from the previous page

Error Name	Cause of the Error	Recommended Method of Handing the Error
DSI_HOST_ACK_WITH_ERR_5	Peripheral Timeout error from the Acknowledge error report	Check whether the Host timeout counter configuration is consistent with the Device specifications; Host timeout counter configuration should be longer than the Deivice. This error is automatically recovered, but with no guarantee that the transmission or reception is complete
DSI_HOST_ACK_WITH_ERR_6	False Control error from the Acknowledge error report	Reset the DSI Host and DPHY
DSI_HOST_ACK_WITH_ERR_7	Reserved (specific to device) from the Acknowledge error report	Check the Device capabilities and connectivity and transmit again
DSI_HOST_ACK_WITH_ERR_8	ECC error, single-bit (detected and corrected) from the Acknowledge error report	No action is required. Analyze the signal integrity or the noise conditions of the link if this error is recurrent
DSI_HOST_ACK_WITH_ERR_9	ECC error, multi-bit (detected, not corrected) from the Acknowledge error report	Transmit the packets again if the packets are critical. Analyze the signal integrity or the nosie conditions of the link if this error is recurrent
DSI_HOST_ACK_WITH_ERR_10	Checksum error (long packet only) from the Acknowledge error report	Transmit the packets again if the packets are critical. Analyze the connectivity if this error is recurrent
DSI_HOST_ACK_WITH_ERR_11	Not recognized DSI data type from the Acknowledge error report. Some packets may not be supported	Check the Device capabilities
DSI_HOST_ACK_WITH_ERR_13	Invalid transmission length from the Acknowledge error report	Transmit the packets again. Analyze the connectivity if this error is recurrent
DSI_HOST_ACK_WITH_ERR_14	Reserved (specific to device) from the Acknowledge error report	Check the Device specification for possible reason and actions

Continued on the next page...

Table 43.5-2 – ...Continued from the previous page

Error Name	Cause of the Error	Recommended Method of Handing the Error
DSI_HOST_ACK_WITH_ERR_15	DSI protocol violation from the Acknowledge error report	Check the display specification. With this error, the Device should have another read-back command which reports additional error information
DSI_HOST_DPHY_ERRORS_0	ErrEsc escape entry error from Lane 0. The Escape Entry Code is not recognized	Repeat the reception
DSI_HOST_DPHY_ERRORS_1	ErrSyncEsc low-power data transmission synchronization error from Lane 0	Reset DSI Host and repeat the transmission
DSI_HOST_DPHY_ERRORS_2	Control error ErrControl from Lane 0	Reset DSI Host and DPHY
DSI_HOST_DPHY_ERRORS_3	LP0 contention error ErrContentionLP0 from Lane 0	Reset DSI Host and repeat the transmission
DSI_HOST_DPHY_ERRORS_4	LP1 contention error ErrContentionLP1 from Lane 0	Reset DSI Host and repeat the transmission
DSI_HOST_TO_HS_TX	High-speed transmission timeout error	Check the timeout configuration. Host timeout counter configuration should be longer than the Deivice
DSI_HOST_TO_LP_RX	Low-power reception timeout error	Check the timeout configuration. Host timeout counter configuration should be longer than the Deivice
DSI_HOST_ECC_SINGLE_ERR	ECC single error has been detected and corrected in a received packet	No action is required
DSI_HOST_ECC_MILTI_ERR	ECC multiple error has been detected in a received packet	Repeat the transmission
DSI_HOST_CRC_ERR	CRC error has been detected in the received packet payload	Reset DSI Host and repeat the transmission
DSI_HOST_PKT_SIZE_ERR	Packet size error has been detected during the packet reception	Reset DSI Host and repeat the transmission
DSI_HOST_EOPT_ERR	EoTp packet has not been received at the end of the incoming peripheral transmission	This error is not critical for data integrity of the received packet. Check if the Device supports EoTp packets

Continued on the next page...

Table 43.5-2 – ...Continued from the previous page

Error Name	Cause of the Error	Recommended Method of Handing the Error
DSI_HOST_DPI_PLD_WR_ERR	During a DPI pixel line storage, the payload FIFO becomes full and the data stored is corrupted	Check Video Mode configuration, and reset DSI Host and re-initiate the video transmission
DSI_HOST_GEN_CMD_WR_ERR	The system tried to write a command through the Generic interface and the FIFO is full. Therefore, the command is not written	Reset DSI Host and repeat the transmission
DSI_HOST_GEN_PLD_WR_ERR	The system tried to write a payload data through the Generic interface and the FIFO is full. Therefore, the payload is not written	Reset DSI Host and repeat the transmission
DSI_HOST_GEN_PLD_SEND_ERR	During a Generic interface packet build, the payload FIFO beomes empty and corrupt data is sent	Reset DSI Host and repeat the transmission
DSI_HOST_GEN_PLD_RD_ERR	During a DCS read data, the payload FIFO becomes empty and the data sent to the interface is corrupted	Reset DSI Host and repeat the transmission
DSI_HOST_GEN_PLD_RECEV_ERR	During a Generic interface packet read back, the payload FIFO becomes full and the received data is corrupted	Reset DSI Host and repeat the transmission
DSI_HOST_DPI_BUFF_PLD_UNDER	An underflow has occurred when reading payload to build DSI packet for video mode	Reset DSI Host and repeat the transmission

43.6 Programming Procedures

43.6.1 DSI Bridge Configuration

- Configure DSI Bridge clock and release reset.
- Configure input and output color mode. Refer to DSI Bridge for details.
- Configure video timing. Refer to Clocks and Display Resolution for details.
- Write 0 to DSI_BRG_DSI_DMA_FLOW_CONTROLLER to set VDMA as flow controller.
- Configure DSI_BRG_DMA_BURST_LEN to set the DMA burst length to match VDMA configuration.
- Configure DSI_BRG_DSI_RAW_BUF_ALMOST_EMPTY_THRD to

$1024 - DSI_BRG_DMA_BURST_LEN$ for better performance.

- Write 1 to DSI_BRG_DPI_EN to enable DPI.
- Write 1 to DSI_BRG_DSI_EN to enable DSI Bridge.
- Configure VDMA and set VDMA as flow controller. Refer to 7 for details.

43.6.2 D-PHY configuration

- Set DSI_HOST_PHY_SHUTDOWNZ and DSI_HOST_PHY_RSTZ to 0, set DSI_HOST_PHY_TESTCLR to 1.
- Apply an appropriate DSI_DPHY_CFG_CLK and DSI_DPHY_PLL_REFCLK.
- Configure the hsfreqrange through test code 0x44. Refer to table 43.4-4 for detailed value.
- Configure PLL parameters. Refer to PLL Parameters for details.
- Configure DSI_HOST_TO_CLK_DIVISION to apply an appropriate TX_ESC_CLK divider ratio.
- Set DSI_HOST_PHY_SHUTDOWNZ and DSI_HOST_PHY_RSTZ to 1.
- Waits for DSI_HOST_PHY_STOPSTATE0LANE and DSI_HOST_PHY_STOPSTATE1LANE asserted.

43.6.3 MIPI DSI common configuration

- Release global reset.
- Configure DSI_HOST_N_LANES to define the number of lanes to be used.
- Configure video timing settings. Refer to Clocks and Display Resolution for details.
- Initialize the DPHY through D-PHY configuration.
- Write DSI_HOST_SHUTDOWNZ to 1 to release DSI Host from shutdown.

43.6.4 System memory data output flow configuration

- Configure DSI Bridge through DSI Bridge configuration.
- Configure DSI Host through MIPI DSI common configuration.

43.6.5 Video pattern output flow configuration

- Configure pattern through register field DSI_HOST_VPG_ORIENTATION, DSI_HOST_VPG_MODE, and DSI_HOST_VPG_EN. Refer to Video Pattern Generator for details.
- Configure DSI Host through MIPI DSI common configuration.

43.6.6 Using DCS command to operate Display register

- Write to Display
  - Write packet payload to DSI_HOST_GEN_PLD_DATA_REG.
  - Write packet header to DSI_HOST_GEN_HDR_REG.
- Read from Display

- Write packet header to DSI_HOST_GEN_HDR_REG.
- Read response data from DSI_HOST_GEN_PLD_DATA_REG.

43.7 Register Summary

43.7.1 MIPI DSI Bridge Register Summary

The addresses in this section are relative to the MIPI DSI Bridge base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Configuration Registers			
DSI_BRG_CLK_EN_REG	DSI Bridge clock enable register	0x0000	R/W
DSI_BRG_EN_REG	DSI Bridge enable register	0x0004	R/W
DSI_BRG_DMA_REQ_CFG_REG	DSI Bridge DMA burst length register	0x0008	R/W
DSI_BRG_RAW_NUM_CFG_REG	DSI Bridge raw pixel count control register	0x000C	varies
DSI_BRG_RAW_BUF_CREDIT_CTL_REG	DSI Bridge raw buffer credit register	0x0010	R/W
DSI_BRG_PIXEL_TYPE_REG	DSI Bridge DPI pixel type control register	0x0018	R/W
DSI_BRG_DMA_BLOCK_INTERVAL_REG	DSI Bridge DMA block interval control register	0x001C	R/W
DSI_BRG_DMA_REQ_INTERVAL_REG	DSI Bridge DMA request interval control register	0x0020	R/W
DSI_BRG_DPI_LCD_CTL_REG	DSI Bridge DPI signal control register	0x0024	R/W
DSI_BRG_DPI_RSV_DPI_DATA_REG	DSI Bridge DPI reserved data register	0x0028	R/W
DSI_BRG_DPI_V_CFG0_REG	DSI Bridge DPI vertical timing config register 0	0x0030	R/W
DSI_BRG_DPI_V_CFG1_REG	DSI Bridge DPI vertical timing config register 1	0x0034	R/W
DSI_BRG_DPI_H_CFG0_REG	DSI Bridge DPI horizontal timing config register 0	0x0038	R/W
DSI_BRG_DPI_H_CFG1_REG	DSI Bridge DPI horizontal timing config register 1	0x003C	R/W
DSI_BRG_DPI_MISC_CONFIG_REG	DSI Bridge DPI miscellaneous config register	0x0040	R/W
DSI_BRG_DPI_CONFIG_UPDATE_REG	DSI Bridge DPI config update register	0x0044	WT
DSI_BRG_HOST_TRIGGER_REV_REG	DSI Bridge host trigger reverse control register	0x0064	R/W
DSI_BRG_BLK_RAW_NUM_CFG_REG	DSI Bridge block raw pixel count control register	0x0068	varies
DSI_BRG_DMA_FRAME_INTERVAL_REG	DSI Bridge DMA frame interval control register	0x006C	R/W
DSI_BRG_MEM_AUX_CTRL_REG	DSI Bridge memory auxiliary control register	0x0070	R/W
DSI_BRG_RDN_ECO_LOW_REG	DSI Bridge RDN ECO low register	0x0078	R/W
DSI_BRG_RDN_ECO_HIGH_REG	DSI Bridge RDN ECO high register	0x007C	R/W
DSI_BRG_HOST_CTRL_REG	DSI Bridge host control register	0x0080	R/W
DSI_BRG_MEM_CLK_CTRL_REG	DSI Bridge memory clock force-on control register	0x0084	R/W
DSI_BRG_DMA_FLOW_CTRL_REG	DSI Bridge DMA flow controller register	0x0088	R/W
DSI_BRG_RAW_BUF_ALMOST_EMPTY_THRD_REG	DSI Bridge raw buffer almost-empty threshold register	0x008C	R/W
DSI_BRG_YUV_CFG_REG	DSI Bridge YUV format config register	0x0090	R/W
DSI_BRG_PHY_LP_LOOPBACK_CTRL_REG	DSI PHY LP loopback test control register	0x0094	varies
DSI_BRG_PHY_HS_LOOPBACK_CTRL_REG	DSI PHY HS loopback test control register	0x0098	varies
DSI_BRG_PHY_LOOPBACK_CNT_REG	DSI PHY loopback test counter register	0x009C	R/W

Name	Description	Address	Access
Status Registers			
DSI_BRG_FIFO_FLOW_STATUS_REG	DSI Bridge FIFO flow status register	0x0014	RO
DSI_BRG_HOST_BIST_CTL_REG	DSI Bridge host BIST control register	0x0060	varies
DSI_BRG_RDN_ECO_CS_REG	DSI Bridge RDN ECO chip select register	0x0074	varies
Interrupt Registers			
DSI_BRG_INT_ENA_REG	DSI Bridge interrupt enable register	0x0050	R/W
DSI_BRG_INT_CLR_REG	DSI Bridge interrupt clear register	0x0054	WT
DSI_BRG_INT_RAW_REG	DSI Bridge raw interrupt status register	0x0058	R/ WTC/ SS
DSI_BRG_INT_ST_REG	DSI Bridge masked interrupt status register	0x005C	RO
Version Register			
DSI_BRG_VER_DATE_REG	DSI Bridge version date register	0x0100	R/W

43.7.2 MIPI DSI Host Register Summary

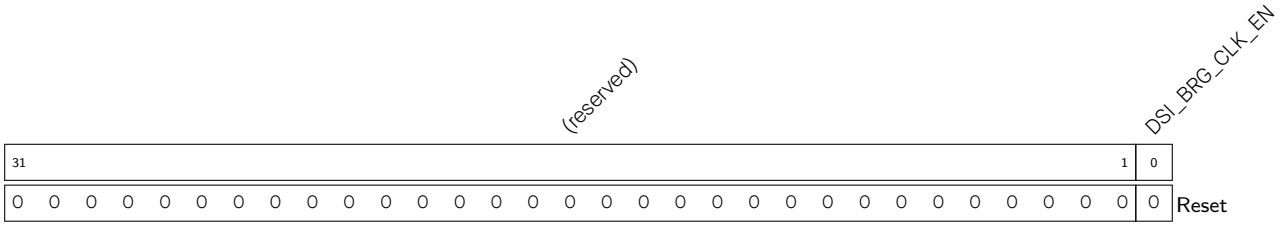
The addresses in this section are relative to MIPI DSI Host base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Version Register			
DSI_HOST_VERSION_REG	Version register	0x0000	RO
Configuration Registers			
DSI_HOST_PWR_UP_REG	DSI Host power up control register	0x0004	R/W
DSI_HOST_CLKMGR_CFG_REG	Internal divider control register	0x0008	R/W
DSI_HOST_DPI_VCID_REG	Virtual channel ID for DPI configuration register	0x000C	R/W
DSI_HOST_DPI_COLOR_CODING_REG	DPI color coding register	0x0010	R/W
DSI_HOST_DPI_CFG_POL_REG	DPI signal polarity register	0x0014	R/W
DSI_HOST_DPI_LP_CMD_TIM_REG	low-power command timing configuration register	0x0018	R/W
DSI_HOST_PCKHDL_CFG_REG	Packet header configuration register, configures how EoTp, BTA, CRC, ECC are to be used	0x002C	R/W
DSI_HOST_GEN_VCID_REG	Virtual channel ID of READ response for Generic Interface configuration register	0x0030	R/W
DSI_HOST_MODE_CFG_REG	Video or Command Mode configuration register	0x0034	R/W
DSI_HOST_VID_MODE_CFG_REG	Video Mode configuration register	0x0038	R/W
DSI_HOST_VID_PKT_SIZE_REG	Video packet size configuration register	0x003C	R/W
DSI_HOST_VID_NUM_CHUNKS_REG	Chunk number configuration register	0x0040	R/W
DSI_HOST_VID_NULL_SIZE_REG	Null packet size configuration register	0x0044	R/W
DSI_HOST_VID_HSA_TIME_REG	HSA configuration register	0x0048	R/W
DSI_HOST_VID_HBP_TIME_REG	HBP configuration register	0x004C	R/W
DSI_HOST_VID_HLINE_TIME_REG	HTOTAL configuration register	0x0050	R/W

Name	Description	Address	Access
DSI_HOST_VID_VSA_LINES_REG	VSA configuration register	0x0054	R/W
DSI_HOST_VID_VBP_LINES_REG	VBP configuration register	0x0058	R/W
DSI_HOST_VID_VFP_LINES_REG	VFP configuration register	0x005C	R/W
DSI_HOST_VID_VACTIVE_LINES_REG	VACT configuration register	0x0060	R/W
DSI_HOST_CMD_MODE_CFG_REG	Command Mode configuration register	0x0068	R/W
DSI_HOST_GEN_HDR_REG	Generic Interface packet header register	0x006C	R/W
DSI_HOST_GEN_PLD_DATA_REG	Generic Interface packet payload register	0x0070	R/W
DSI_HOST_TO_CNT_CFG_REG	Time out counter register	0x0078	R/W
DSI_HOST_HS_RD_TO_CNT_REG	HS read time out counter register	0x007C	R/W
DSI_HOST_LP_RD_TO_CNT_REG	LP read time out counter register	0x0080	R/W
DSI_HOST_HS_WR_TO_CNT_REG	HS write time out counter register	0x0084	R/W
DSI_HOST_LP_WR_TO_CNT_REG	LP write time out counter register	0x0088	R/W
DSI_HOST_BTA_TO_CNT_REG	Bus Turnaround time out counter register	0x008C	R/W
DSI_HOST_LPCLK_CTRL_REG	Non-continuous clock configuration register	0x0094	R/W
DSI_HOST_PHY_TMR_LPCLK_CFG_REG	Time of CLK lane switch between HS and LP configuration register	0x0098	R/W
DSI_HOST_PHY_TMR_CFG_REG	Time of DATA lane switch between HS and LP configuration register	0x009C	R/W
DSI_HOST_PHY_RSTZ_REG	DPHY reset control register	0x00A0	R/W
DSI_HOST_PHY_IF_CFG_REG	DPHY lane number and stop state configuration register	0x00A4	R/W
DSI_HOST_PHY_ULPS_CTRL_REG	DPHY ULPS control register	0x00A8	R/W
DSI_HOST_PHY_TX_TRIGGERS_REG	DPHY trigger register	0x00AC	R/W
DSI_HOST_PHY_TST_CTRL0_REG	DPHY test code clk and clear control register	0x00B4	R/W
DSI_HOST_PHY_TST_CTRL1_REG	DPHY test code data and enable control register	0x00B8	varies
DSI_HOST_PHY_CAL_REG	DPHY skew calibration control register	0x00CC	R/W
DSI_HOST_PHY_TMR_RD_CFG_REG	DPHY read timer configuration register	0x00F4	R/W
DSI_HOST_VID_SHADOW_CTRL_REG	DPI shadow control register	0x0100	R/W
Status Registers			
DSI_HOST_CMD_PKT_STATUS_REG	Generic Interface FIFO status register	0x0074	RO
DSI_HOST_PHY_STATUS_REG	DPHY status register	0x00B0	RO
DSI_HOST_DPI_VCID_ACT_REG	Actual VCID value register	0x010C	RO
DSI_HOST_DPI_COLOR_CODING_ACT_REG	Actual DPI_COLOR_CODING value register	0x0110	RO
DSI_HOST_DPI_LP_CMD_TIM_ACT_REG	Actual DPI_LP_CMD_TIM value register	0x0118	RO
DSI_HOST_VID_MODE_CFG_ACT_REG	Actual VID_MODE_CFG value register	0x0138	RO
DSI_HOST_VID_PKT_SIZE_ACT_REG	Actual VID_PKT_SIZE value register	0x013C	RO
DSI_HOST_VID_NUM_CHUNKS_ACT_REG	Actual VID_NUM_CHUNKS value register	0x0140	RO
DSI_HOST_VID_NULL_SIZE_ACT_REG	Actual VID_NULL_SIZE value register	0x0144	RO
DSI_HOST_VID_HSA_TIME_ACT_REG	Actual HSA value register	0x0148	RO
DSI_HOST_VID_HBP_TIME_ACT_REG	Actual HBP value register	0x014C	RO
DSI_HOST_VID_HLINE_TIME_ACT_REG	Actual HLINE value register	0x0150	RO
DSI_HOST_VID_VSA_LINES_ACT_REG	Actual VSA value register	0x0154	RO

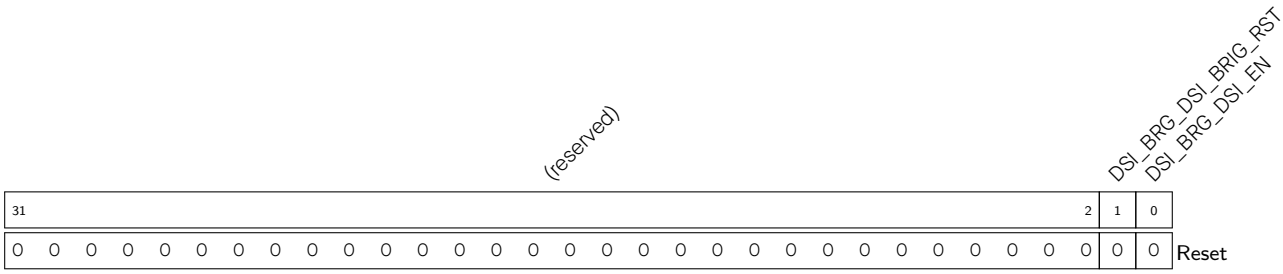
Name	Description	Address	Access
DSI_HOST_VID_VBP_LINES_ACT_REG	Actual VBP value register	0x0158	RO
DSI_HOST_VID_VFP_LINES_ACT_REG	Actual VFP value register	0x015C	RO
DSI_HOST_VID_VACTIVE_LINES_ACT_REG	Actual VACT value register	0x0160	RO
DSI_HOST_VID_PKT_STATUS_REG	DPI FIFO status register	0x0168	RO
Interrupt Registers			
DSI_HOST_INT_ST0_REG	Interrupt status register	0x00BC	RO
DSI_HOST_INT_ST1_REG	Interrupt status register	0x00C0	RO
DSI_HOST_INT_MSK0_REG	Interrupt mask register	0x00C4	R/W
DSI_HOST_INT_MSK1_REG	Interrupt mask register	0x00C8	R/W



43.8 Registers

43.8.1 MIPI DSI Bridge Register

The addresses in this section are relative to MIPI DSI Bridge base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.



For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 43.1. DSI_BRG_CLK_EN_REG (0x0000)

DSI_BRG_CLK_EN Configures force_on of dsi_bridge register clock gate. (R/W)

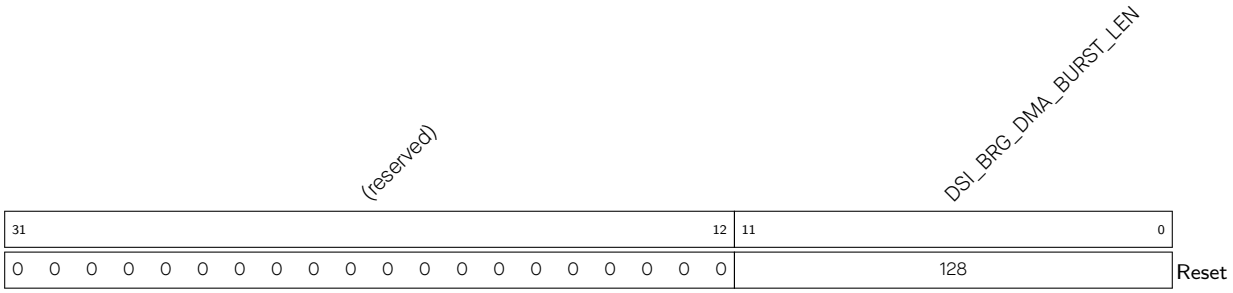
Register 43.2. DSI_BRG_EN_REG (0x0004)

DSI_BRG_DSI_EN Configures module enable of dsi_bridge.

0: disable

1: enable

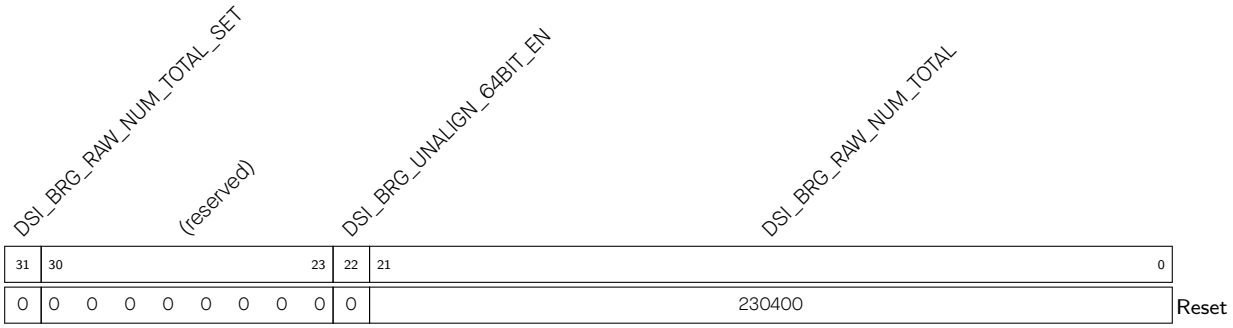
(R/W)



DSI_BRG_DSI_BRIG_RST Configures software reset of dsi_bridge.

0: release reset

1: reset



(R/W)

Register 43.3. DSI_BRG_DMA_REQ_CFG_REG (0x0008)

DSI_BRG_DMA_BURST_LEN Configures the number of 64-bit in one DMA burst transfer, valid only when dsi_bridge as flow controller. (R/W)

Register 43.4. DSI_BRG_RAW_NUM_CFG_REG (0x000C)

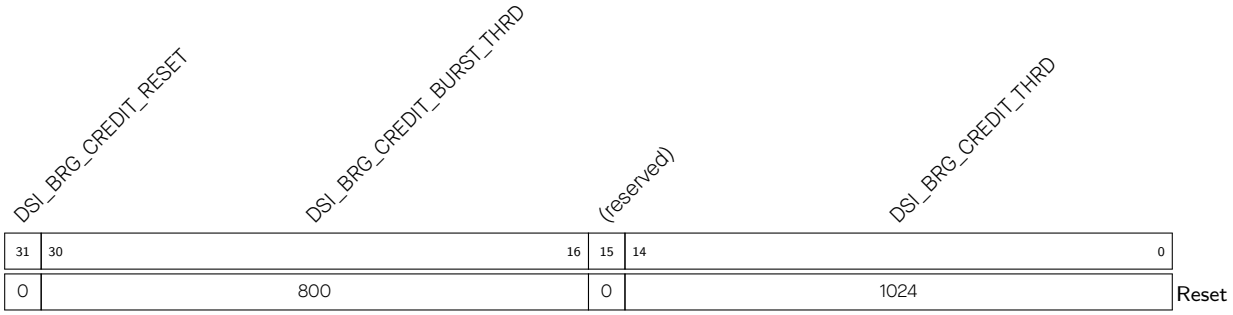
DSI_BRG_RAW_NUM_TOTAL Configures number of total pix bits/64. (R/W)

DSI_BRG_UNALIGN_64BIT_EN Configures whether the total pix bits is a multiple of 64bits.

0: align to 64-bit

1: unalign to 64-bit

(R/W)



DSI_BRG_RAW_NUM_TOTAL_SET Configures enable of reloading reg_raw_num_total to the internal counter, valid only when dsi_bridge as flow controller.

0: disable

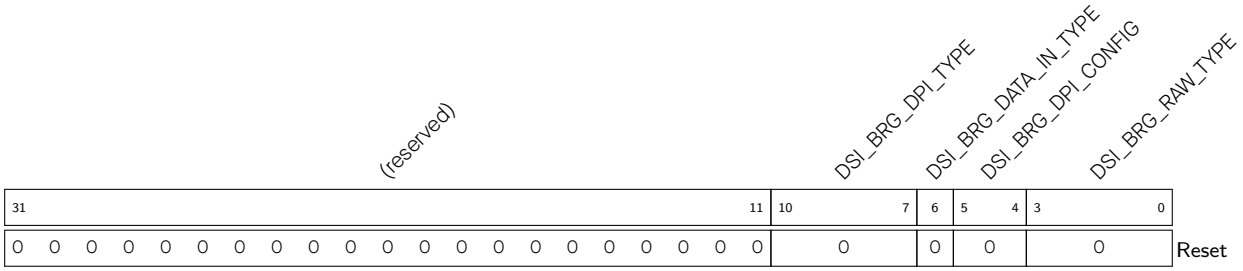
1: enable

(WT)

Register 43.5. DSI_BRG_RAW_BUF_CREDIT_CTL_REG (0x0010)

DSI_BRG_CREDIT_THRD Configures the threshold whether dsi_bridge FIFO can receive one more 64-bit, valid only when dsi_bridge as flow controller. (R/W)

DSI_BRG_CREDIT_BURST_THRD Configures the threshold whether dsi_bridge FIFO can receive one more DMA burst, valid only when dsi_bridge as flow controller. (R/W)



DSI_BRG_CREDIT_RESET Configures internal credit counter clear, valid only when dsi_bridge as flow controller.

0: no operation

1: reset

(R/W)

Register 43.6. DSI_BRG_PIXEL_TYPE_REG (0x0018)

DSI_BRG_RAW_TYPE Configures the input pixel type.

0: RGB888

1: RGB666

2: RGB565

8: YUV444

9: YUV422

10: YUV420

12: GRAY

(R/W)

DSI_BRG_DPI_CONFIG Configures the pixel arrange type of DPI interface. (R/W)

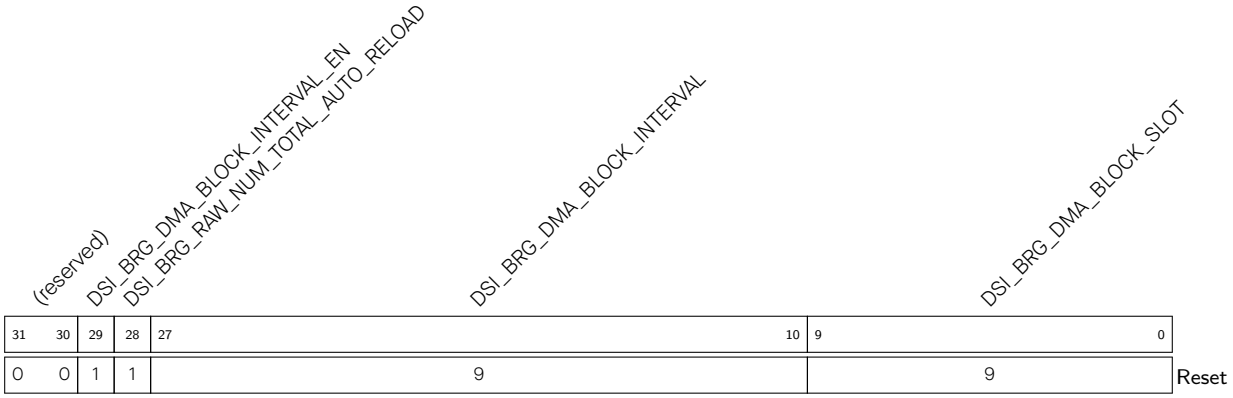
DSI_BRG_DATA_IN_TYPE Configures input data type.

0: RGB

1: YUV

(R/W)

DSI_BRG_DPI_TYPE Configures the DPI output pixel type.



0: RGB888

1: RGB666

2: RGB565

(R/W)

Register 43.7. DSI_BRG_DMA_BLOCK_INTERVAL_REG (0x001C)

DSI_BRG_DMA_BLOCK_SLOT Configures the max block_slot_cnt. (R/W)

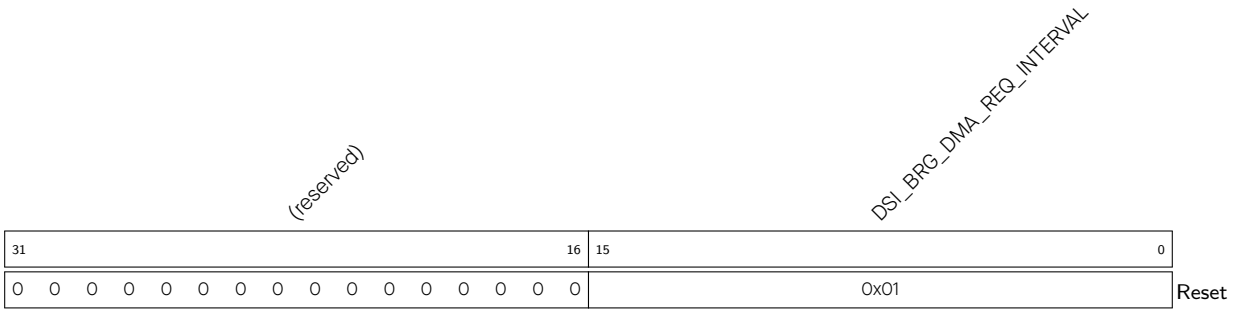
DSI_BRG_DMA_BLOCK_INTERVAL Configures the max block_interval_cnt, block_interval_cnt increased by 1 when block_slot_cnt if full. (R/W)

DSI_BRG_RAW_NUM_TOTAL_AUTO_RELOAD Configures enable of auto reload reg_raw_num_total.

0: disable

1: enable

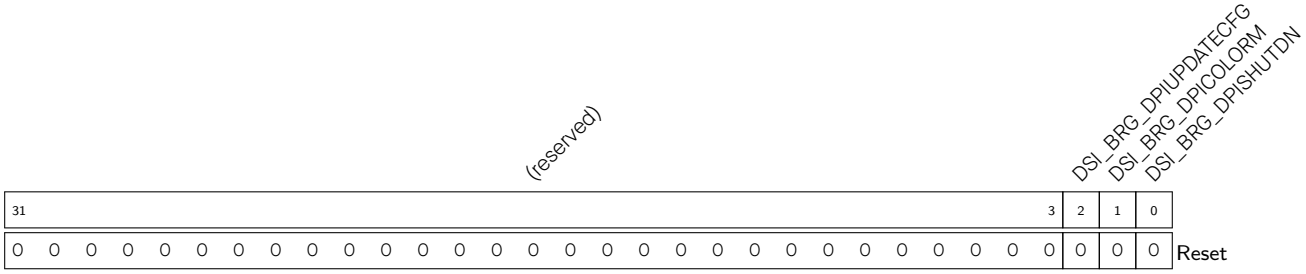
(R/W)



DSI_BRG_DMA_BLOCK_INTERVAL_EN Configures the DMA block transfer interval enable.

0: disable

1: enable

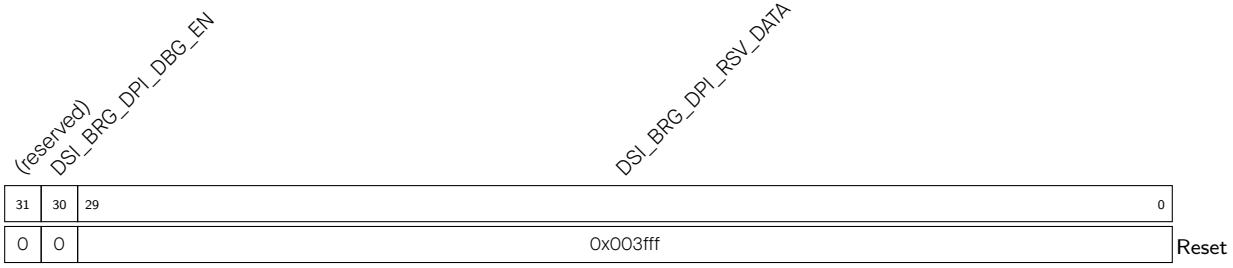


(R/W)

Register 43.8. DSI_BRG_DMA_REQ_INTERVAL_REG (0x0020)

DSI_BRG_DMA_REQ_INTERVAL Configures the interval between DMA request events. (R/W)

Register 43.9. DSI_BRG_DPI_LCD_CTL_REG (0x0024)



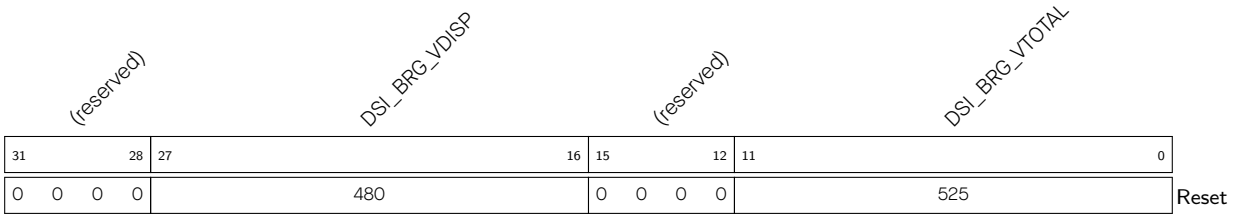
DSI_BRG_DPISHUTDN Configures dpishutdn signal in DPI interface. (R/W)

DSI_BRG_DPICOLORM Configures dpicolorm signal in DPI interface. (R/W)

DSI_BRG_DPIUPDATECFG Configures dpiupdatecfg signal in DPI interface. (R/W)

Register 43.10. DSI_BRG_DPI_RSV_DPI_DATA_REG (0x0028)

DSI_BRG_DPI_RSV_DATA Configures the pixel data sent to dsi_host when dsi_bridge FIFO underflow. (R/W)

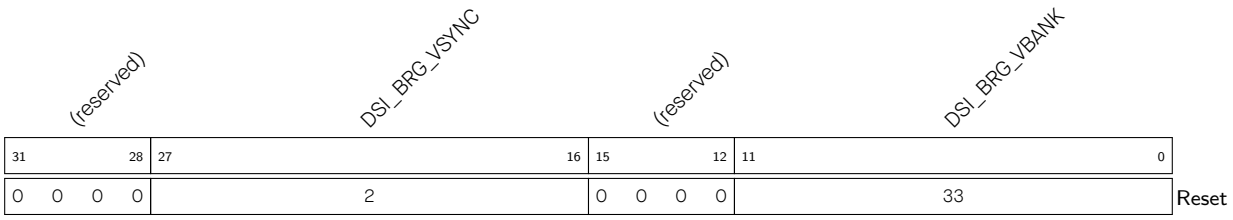


DSI_BRG_DPI_DBG_EN Configures data debug feature enable.

0: disable

1: enable

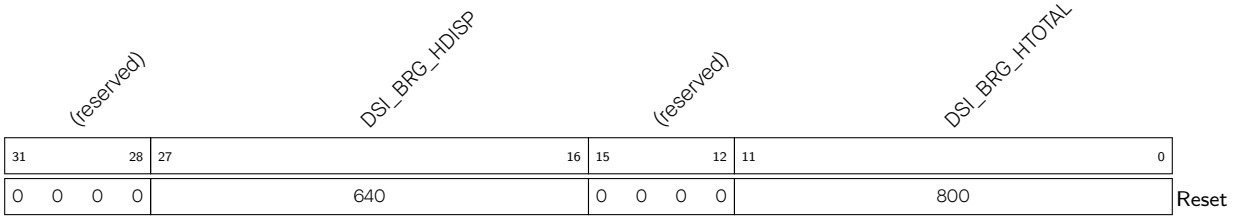
(R/W)



Register 43.11. DSI_BRG_DPI_V_CFG0_REG (0x0030)

DSI_BRG_VTOTAL Configures the total length of one frame (by line) for DPI output, must meet: reg_vtotal > reg_vdisp+reg_vsync+reg_vbank. (R/W)

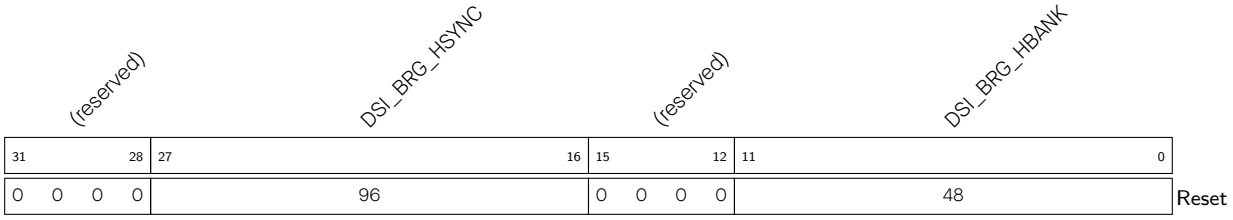
DSI_BRG_VDISP Configures the length of valid line (by line) for DPI output. (R/W)



Register 43.12. DSI_BRG_DPI_V_CFG1_REG (0x0034)

DSI_BRG_VBANK Configures the length between vsync and valid line (by line) for DPI output. (R/W)

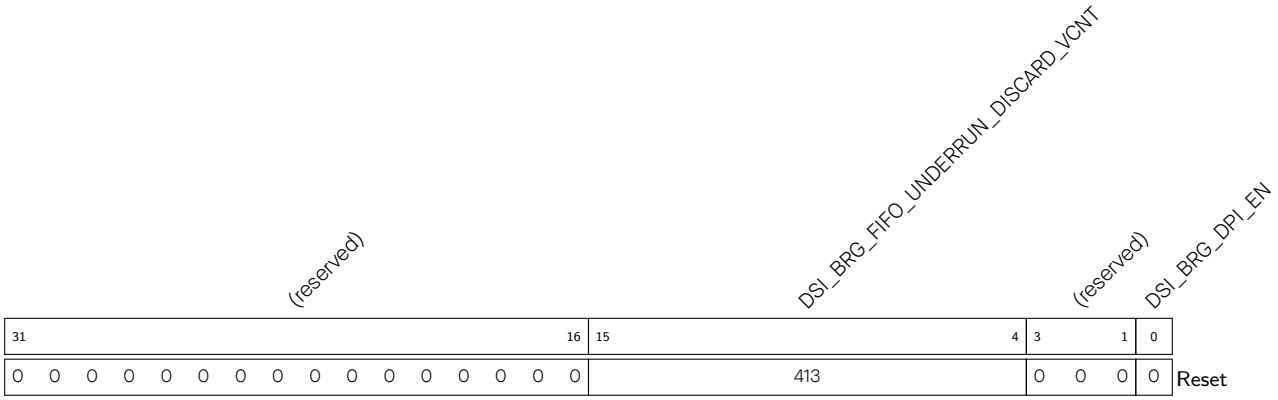
DSI_BRG_VSYNC Configures the length of vsync (by line) for DPI output. (R/W)



Register 43.13. DSI_BRG_DPI_H_CFG0_REG (0x0038)

DSI_BRG_HTOTAL Configures the total length of one line (by pixel count) for DPI output, must meet: reg_htotal > reg_hdisp+reg_hsync+reg_hbank. (R/W)

DSI_BRG_HDISP Configures the length of valid pixel data (by pixel count) for DPI output. (R/W)



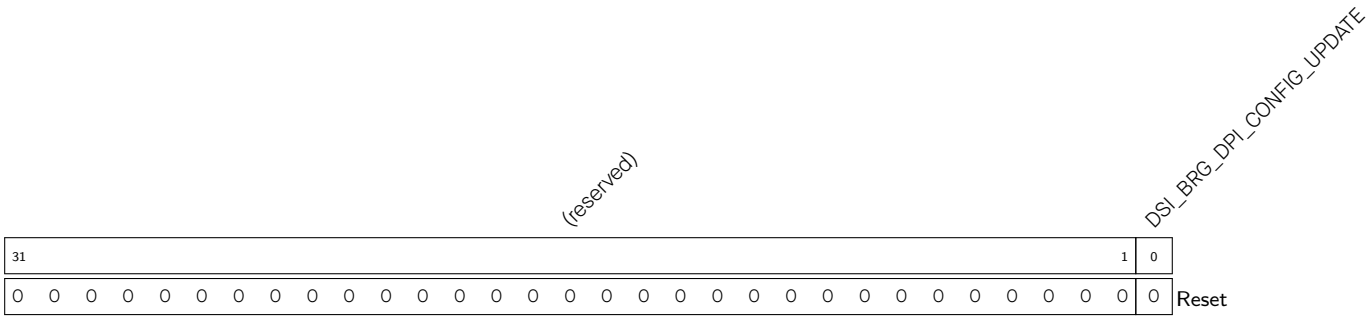
Register 43.14. DSI_BRG_DPI_H_CFG1_REG (0x003C)

DSI_BRG_HBANK Configures the length between hsync and pixel data valid (by pixel count) for DPI output. (R/W)

DSI_BRG_HSYNC Configures the length of hsync (by pixel count) for DPI output. (R/W)

Register 43.15. DSI_BRG_DPI_MISC_CONFIG_REG (0x0040)

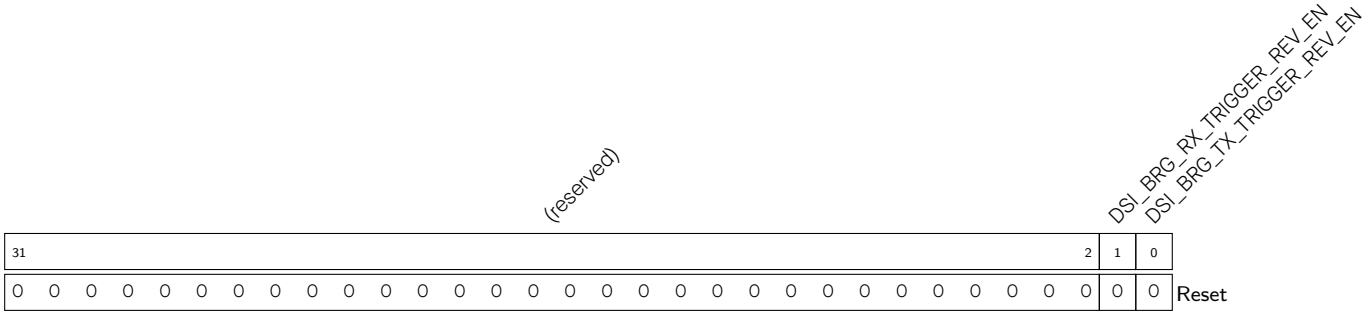
DSI_BRG_DPI_EN Configures DPI output enable.



0: disable

1: enable

(R/W)



DSI_BRG_FIFO_UNDERRUN_DISCARD_VCNT Configures the underrun interrupt mask; when underrun occurs and line count is less than this field, the interrupt is suppressed. (R/W)

Register 43.16. DSI_BRG_DPI_CONFIG_UPDATE_REG (0x0044)

DSI_BRG_DPI_CONFIG_UPDATE Write 1 to update DPI config register MIPI_DSI_BRG_DPI_*. (WT)

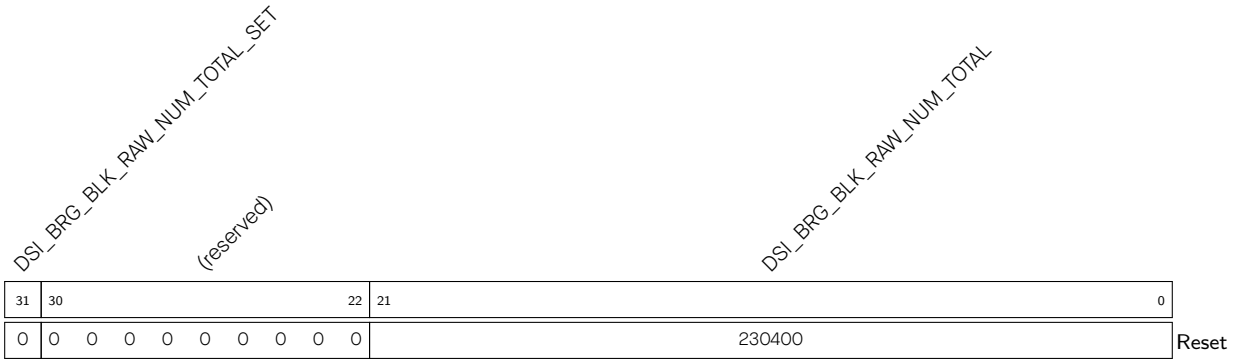
Register 43.17. DSI_BRG_HOST_TRIGGER_REV_REG (0x0064)

DSI_BRG_TX_TRIGGER_REV_EN Configures DSI tx_trigger reverse.

0: disable

1: enable

(R/W)

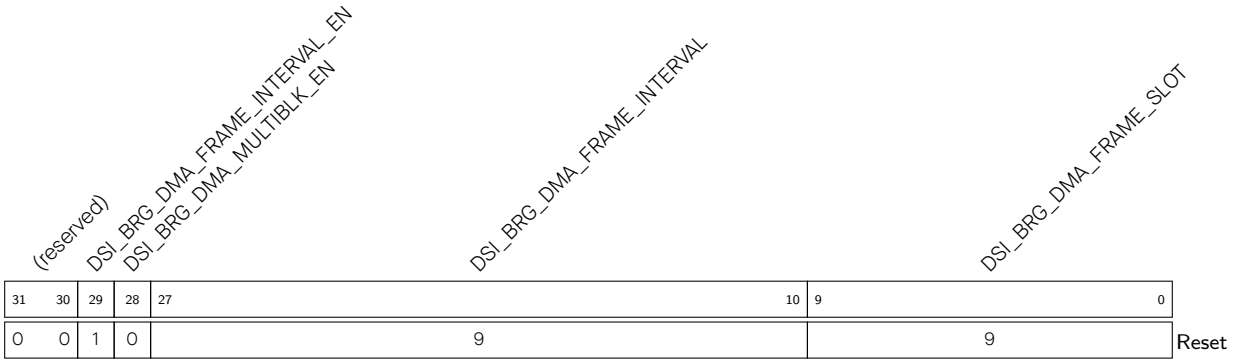


DSI_BRG_RX_TRIGGER_REV_EN Configures DSI rx_trigger reverse.

0: disable

1: enable

(R/W)



Register 43.18. DSI_BRG_BLK_RAW_NUM_CFG_REG (0x0068)

DSI_BRG_BLK_RAW_NUM_TOTAL Configures number of total block pix bits/64. (R/W)

DSI_BRG_BLK_RAW_NUM_TOTAL_SET Write 1 to reload reg_blk_raw_num_total to the internal counter. (WT)

Register 43.19. DSI_BRG_DMA_FRAME_INTERVAL_REG (0x006C)

DSI_BRG_DMA_FRAME_SLOT Configures the max frame_slot_cnt. (R/W)

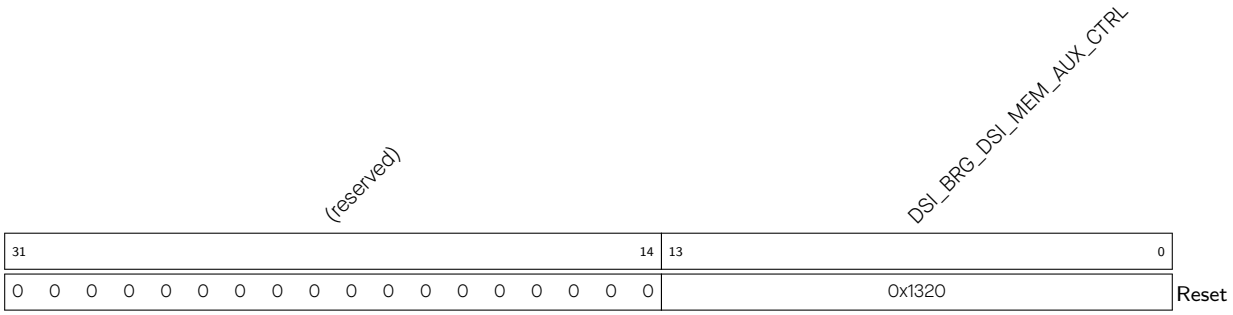
DSI_BRG_DMA_FRAME_INTERVAL Configures the max frame_interval_cnt, frame_interval_cnt increased by 1 when frame_slot_cnt if full. (R/W)

DSI_BRG_DMA_MULTIBLK_EN Configures multi-block transfer enable.

0: disable

1: enable

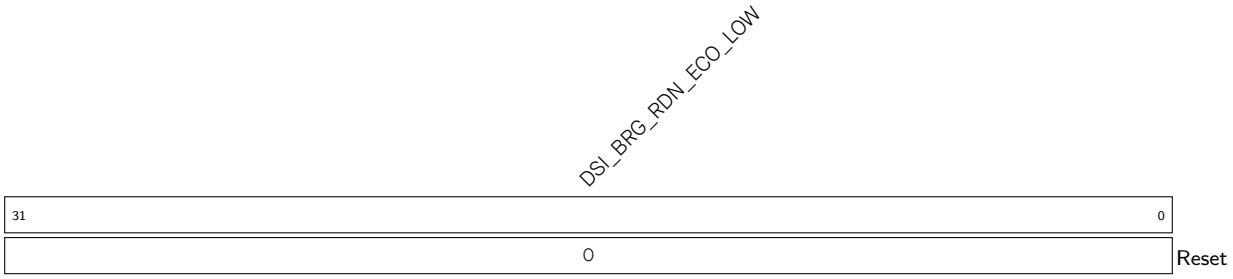
(R/W)



DSI_BRG_DMA_FRAME_INTERVAL_EN Configures enable interval between frame transfer.

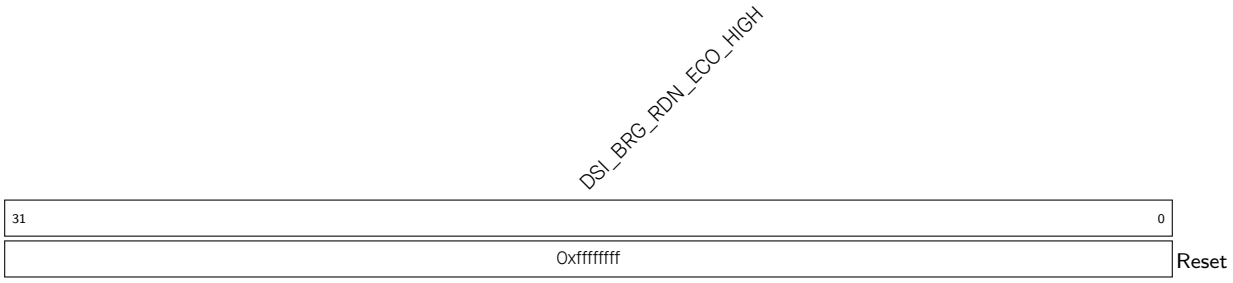
0: disable

1: enable



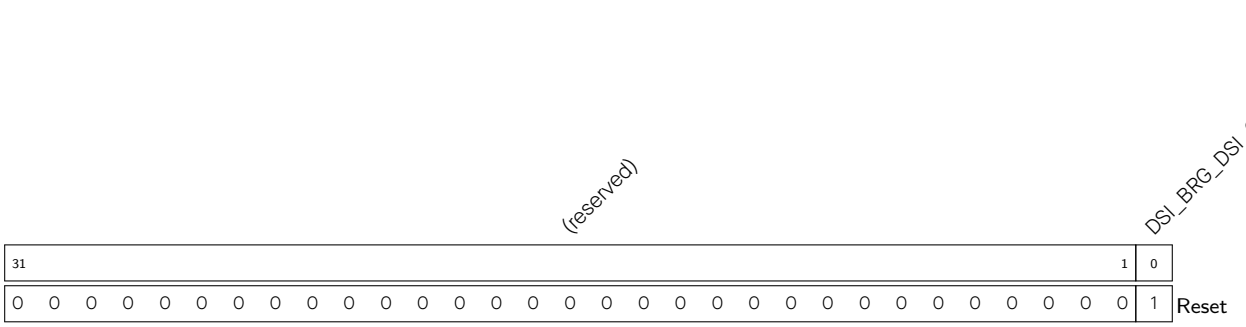
(R/W)

Register 43.20. DSI_BRG_MEM_AUX_CTRL_REG (0x0070)



DSI_BRG_DSI_MEM_AUX_CTRL Configures dsi_bridge FIFO FIFO memory auxiliary control. (R/W)

Register 43.21. DSI_BRG_RDN_ECO_LOW_REG (0x0078)

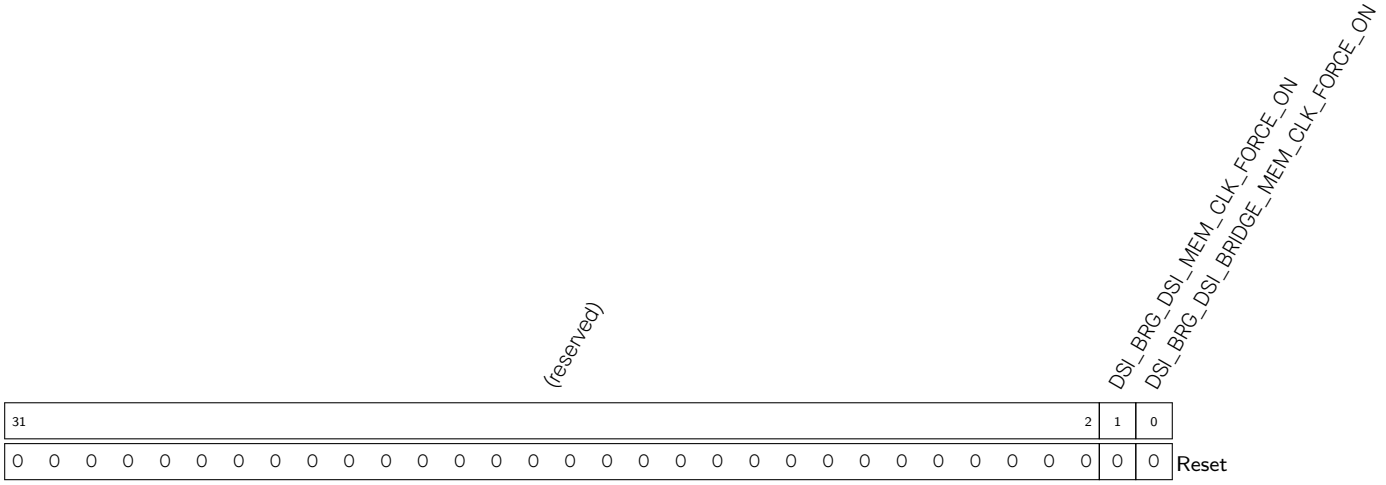


DSI_BRG_RDN_ECO_LOW RDN ECO low register value. (R/W)

Register 43.22. DSI_BRG_RDN_ECO_HIGH_REG (0x007C)

DSI_BRG_RDN_ECO_HIGH RDN ECO high register value. (R/W)

Register 43.23. DSI_BRG_HOST_CTRL_REG (0x0080)



DSI_BRG_DSI_CFG_REF_CLK_EN Configures the clk enable refclk and cfg_clk of dsi_host.

0: disable

1: enable

(R/W)

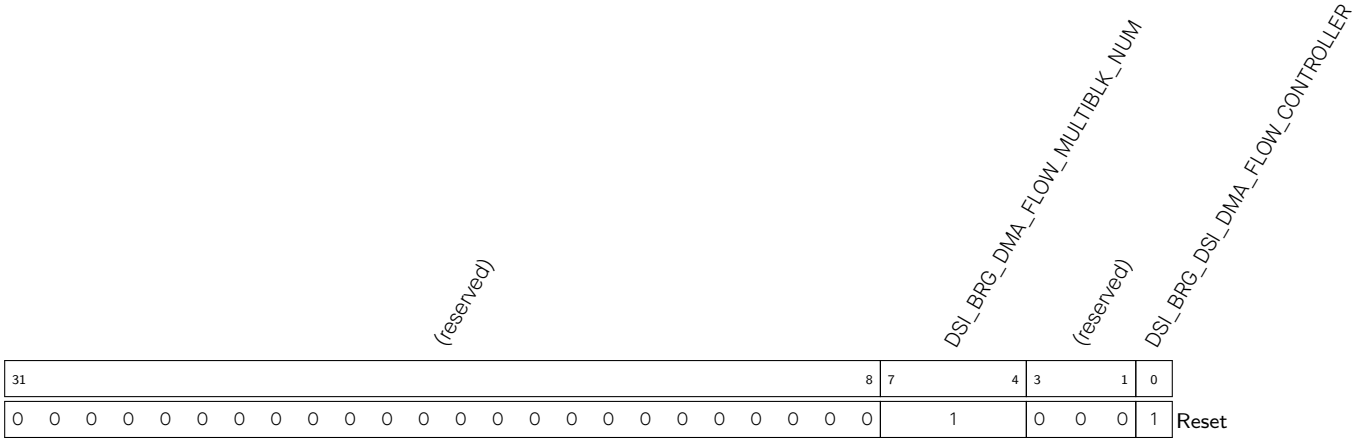
Register 43.24. DSI_BRG_MEM_CLK_CTRL_REG (0x0084)

DSI_BRG_DSI_BRIDGE_MEM_CLK_FORCE_ON Configures the clock force on of dsi_bridge FIFO memory.

0: disable

1: force on

(R/W)



DSI_BRG_DSI_MEM_CLK_FORCE_ON Configures the clock force on of DPI FIFO memory.

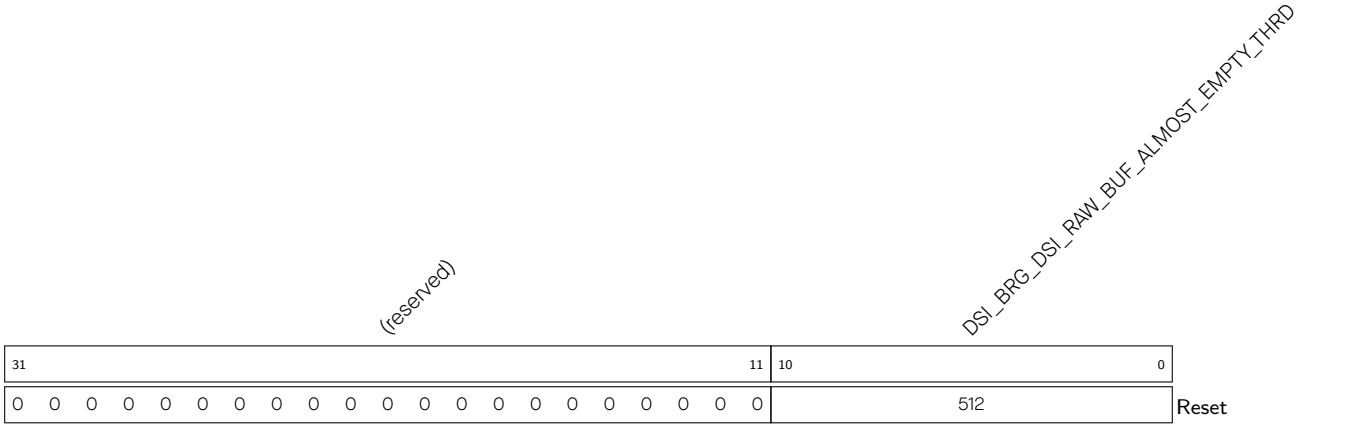
0: disable

1: force on

(R/W)

Register 43.25. DSI_BRG_DMA_FLOW_CTRL_REG (0x0088)

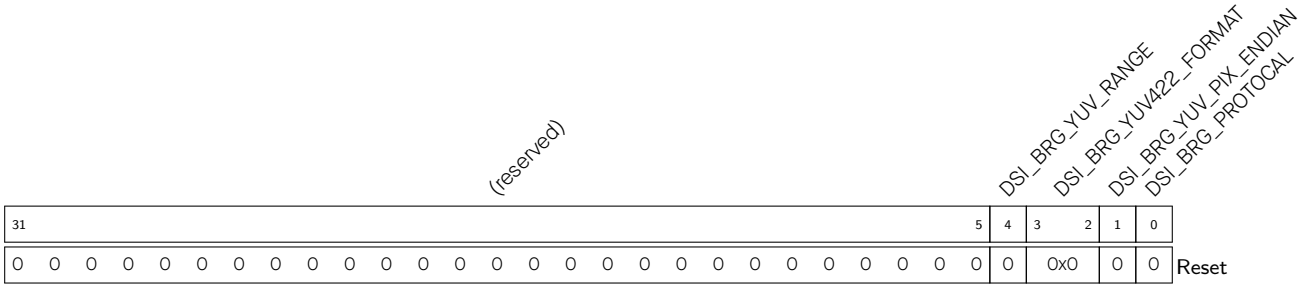
DSI_BRG_DSI_DMA_FLOW_CONTROLLER Configures the flow controller.



0: DMAC as flow controller

1: dsi_bridge as flow controller

(R/W)



DSI_BRG_DMA_FLOW_MULTIBLK_NUM Configures the number of blocks when multi-block mode is enabled and DMAC is the flow controller. (R/W)

Register 43.26. DSI_BRG_RAW_BUF_ALMOST_EMPTY_THRD_REG (0x008C)

DSI_BRG_DSI_RAW_BUF_ALMOST_EMPTY_THRD Configures the FIFO almost empty threshold, valid only when DMAC as flow controller. (R/W)

Register 43.27. DSI_BRG_YUV_CFG_REG (0x0090)

DSI_BRG_PROTOCAL Configures YUV to RGB protocol.

0: BT.601

1: BT.709

(R/W)

DSI_BRG_YUV_PIX_ENDIAN Configures YUV pixel endian.

0: Y0U0Y1V1Y2U2Y3V3

1: Y3U3Y2V2Y1U1Y0V0

(R/W)

DSI_BRG_YUV422_FORMAT Configures YUV422 store format.

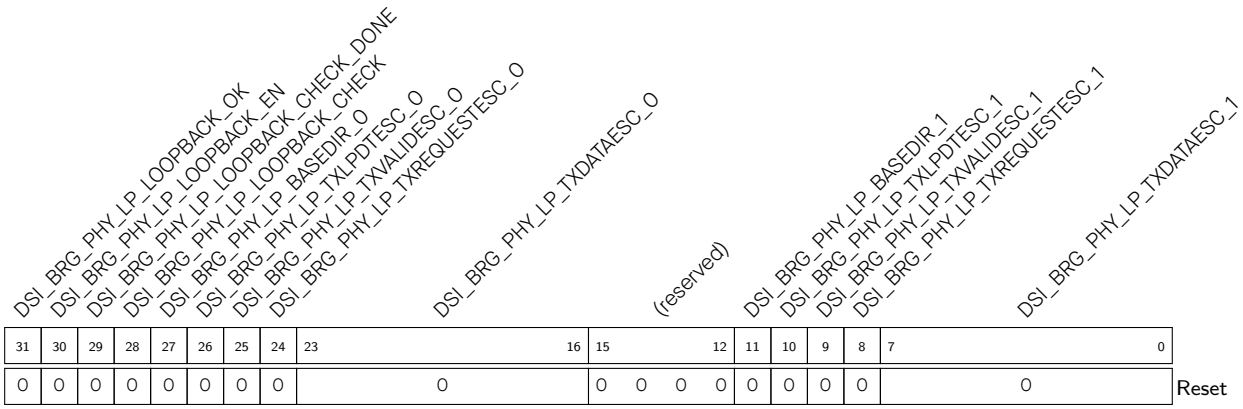
0: YUYV

1: YVYU

2: UYVY

3: VYUY

(R/W)



DSI_BRG_YUV_RANGE Configures YUV pixel range.

0: limit range

1: full range

(R/W)

Register 43.28. DSI_BRG_PHY_LP_LOOPBACK_CTRL_REG (0x0094)

DSI_BRG_PHY_LP_TXDATAESC_1 txdataesc_1 ctrl when enable DSI PHY lp_loopback_test. (R/W)

DSI_BRG_PHY_LP_TXREQUESTESC_1 txrequestesc_1 ctrl when enable DSI PHY lp_loopback_test. (R/W)

DSI_BRG_PHY_LP_TXVALIDESC_1 txvalidesc_1 ctrl when enable DSI PHY lp_loopback_test. (R/W)

DSI_BRG_PHY_LP_TXLPDTESC_1 txlpdtesc_1 ctrl when enable DSI PHY lp_loopback_test. (R/W)

DSI_BRG_PHY_LP_BASEDIR_1 basedir_1 ctrl when enable DSI PHY lp_loopback_test. (R/W)

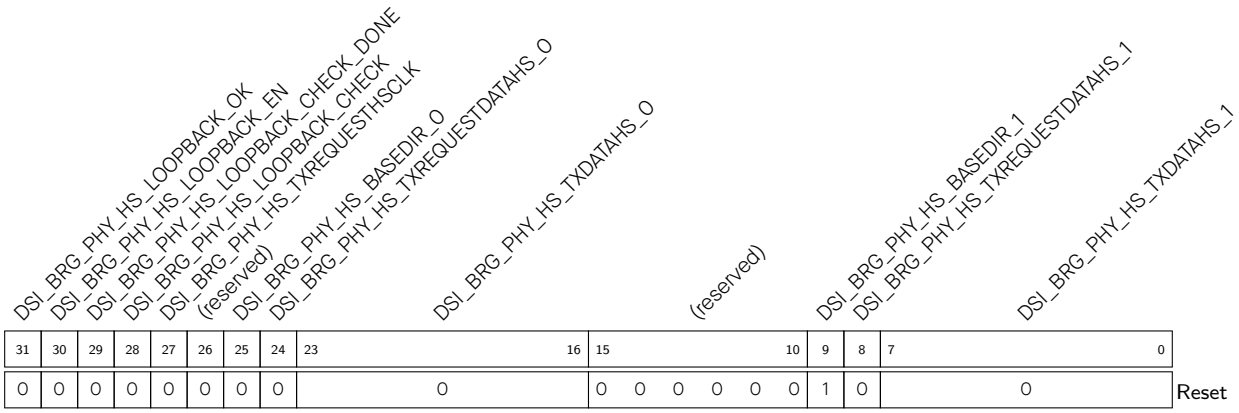
DSI_BRG_PHY_LP_TXDATAESC_0 txdataesc_0 ctrl when enable DSI PHY lp_loopback_test. (R/W)

DSI_BRG_PHY_LP_TXREQUESTESC_0 txrequestesc_0 ctrl when enable DSI PHY lp_loopback_test. (R/W)

DSI_BRG_PHY_LP_TXVALIDESC_0 txvalidesc_0 ctrl when enable DSI PHY lp_loopback_test. (R/W)

DSI_BRG_PHY_LP_TXLPDTESC_0 txlpdtesc_0 ctrl when enable DSI PHY lp_loopback_test. (R/W)

DSI_BRG_PHY_LP_BASEDIR_0 basedir_0 ctrl when enable DSI PHY lp_loopback_test. (R/W)



DSI_BRG_PHY_LP_LOOPBACK_CHECK DSI PHY lp_loopback test start check. (WT)

DSI_BRG_PHY_LP_LOOPBACK_CHECK_DONE DSI PHY lp_loopback test check done. (RO)

DSI_BRG_PHY_LP_LOOPBACK_EN DSI PHY LP loopback control enable. (R/W)

DSI_BRG_PHY_LP_LOOPBACK_OK result of DSI PHY lp_loopback test. (RO)

Register 43.29. DSI_BRG_PHY_HS_LOOPBACK_CTRL_REG (0x0098)

DSI_BRG_PHY_HS_TXDATAHS_1 txdatahs_1 ctrl when enable DSI PHY hs_loopback_test. (R/W)

DSI_BRG_PHY_HS_TXREQUESTDATAHS_1 txrequestdatahs_1 ctrl when enable DSI PHY hs_loopback_test. (R/W)

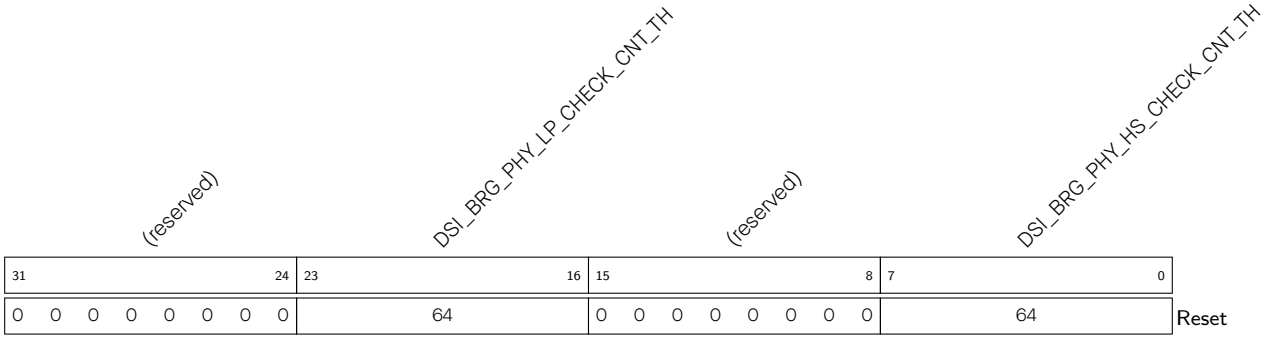
DSI_BRG_PHY_HS_BASEDIR_1 basedir_1 ctrl when enable DSI PHY hs_loopback_test. (R/W)

DSI_BRG_PHY_HS_TXDATAHS_0 txdatahs_0 ctrl when enable DSI PHY hs_loopback_test. (R/W)

DSI_BRG_PHY_HS_TXREQUESTDATAHS_0 txrequestdatahs_0 ctrl when enable DSI PHY hs_loopback_test. (R/W)

DSI_BRG_PHY_HS_BASEDIR_0 basedir_0 ctrl when enable DSI PHY hs_loopback_test. (R/W)

DSI_BRG_PHY_HS_TXREQUESTHSCLK txrequesthsclk when enable DSI PHY hs_loopback_test. (R/W)

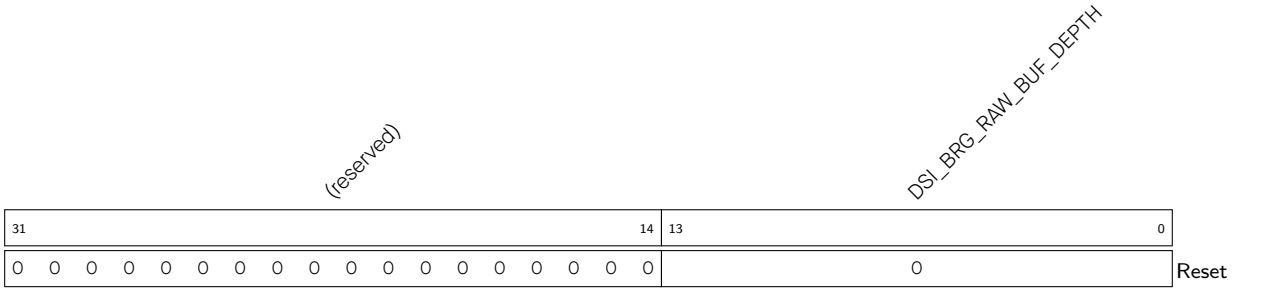


DSI_BRG_PHY_HS_LOOPBACK_CHECK DSI PHY hs_loopback test start check. (WT)

DSI_BRG_PHY_HS_LOOPBACK_CHECK_DONE DSI PHY hs_loopback test check done. (RO)

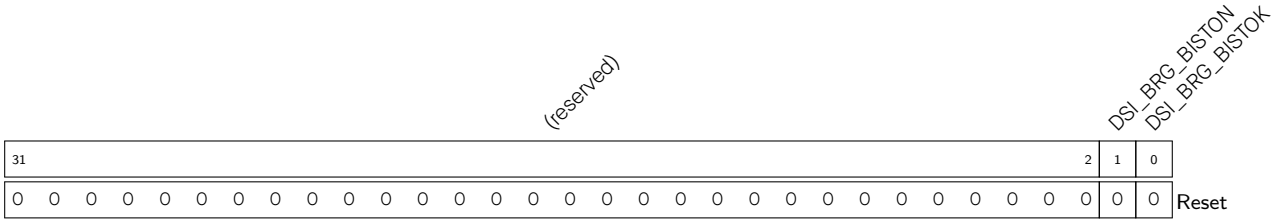
DSI_BRG_PHY_HS_LOOPBACK_EN DSI PHY HS loopback control enable. (R/W)

DSI_BRG_PHY_HS_LOOPBACK_OK result of DSI PHY hs_loopback test. (RO)



Register 43.30. DSI_BRG_PHY_LOOPBACK_CNT_REG (0x009C)

DSI_BRG_PHY_HS_CHECK_CNT_TH hs_loopback test check count. (R/W)



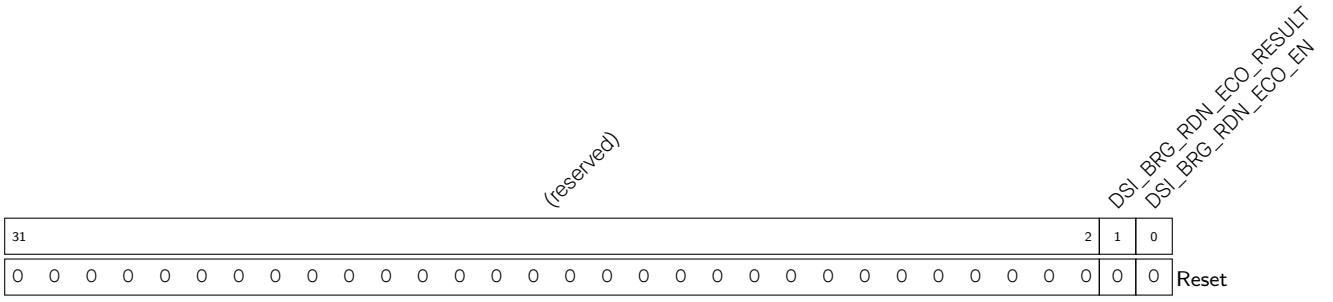
DSI_BRG_PHY_LP_CHECK_CNT_TH lp_loopback test check count. (R/W)

Register 43.31. DSI_BRG_FIFO_FLOW_STATUS_REG (0x0014)

DSI_BRG_RAW_BUF_DEPTH Represents the current depth of dsi_bridge FIFO. (RO)

Register 43.32. DSI_BRG_HOST_BIST_CTL_REG (0x0060)

DSI_BRG_BISTOK BIST result indicator. (RO)



DSI_BRG_BISTON Configures BIST enable.

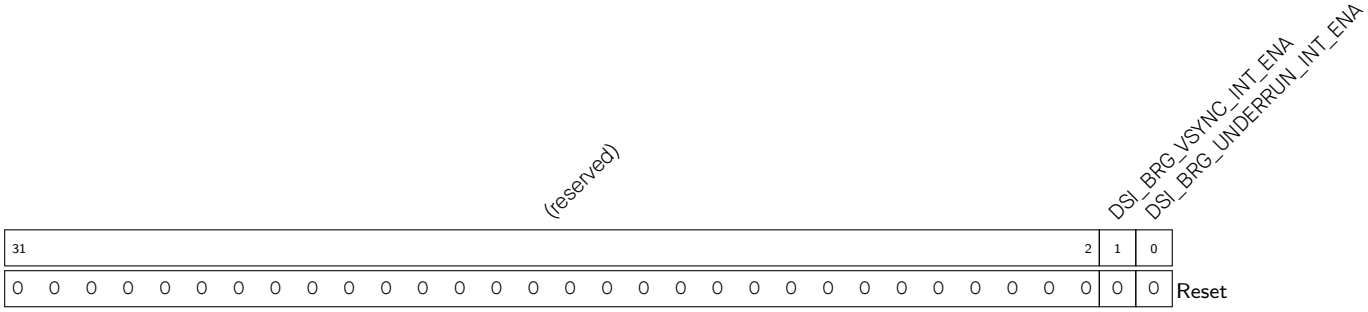
0: disable

1: enable

(R/W)

Register 43.33. DSI_BRG_RDN_ECO_CS_REG (0x0074)

DSI_BRG_RDN_ECO_EN Configures RDN ECO enable.



0: disable

1: enable

(R/W)

DSI_BRG_RDN_ECO_RESULT RDN ECO result. (RO)

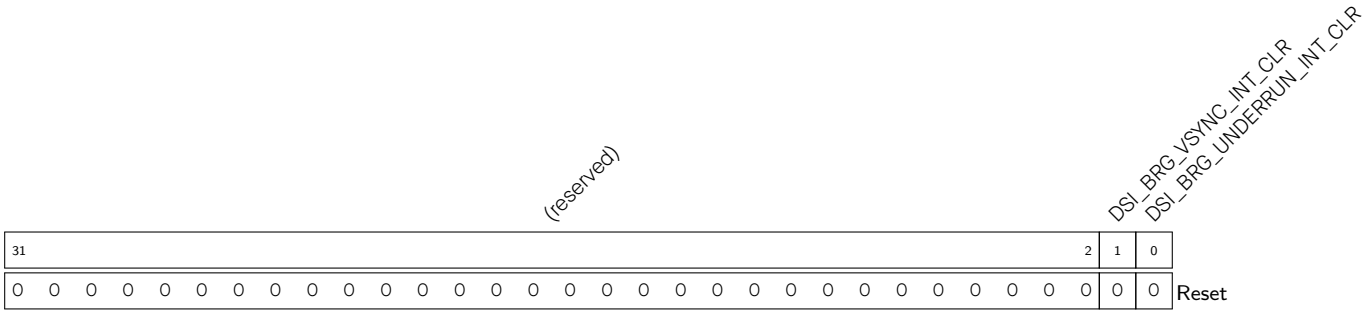
Register 43.34. DSI_BRG_INT_ENA_REG (0x0050)

DSI_BRG_UNDERRUN_INT_ENA Configures DSI_BRG_UNDERRUN_INT enable.

0: disable

1: enable

(R/W)

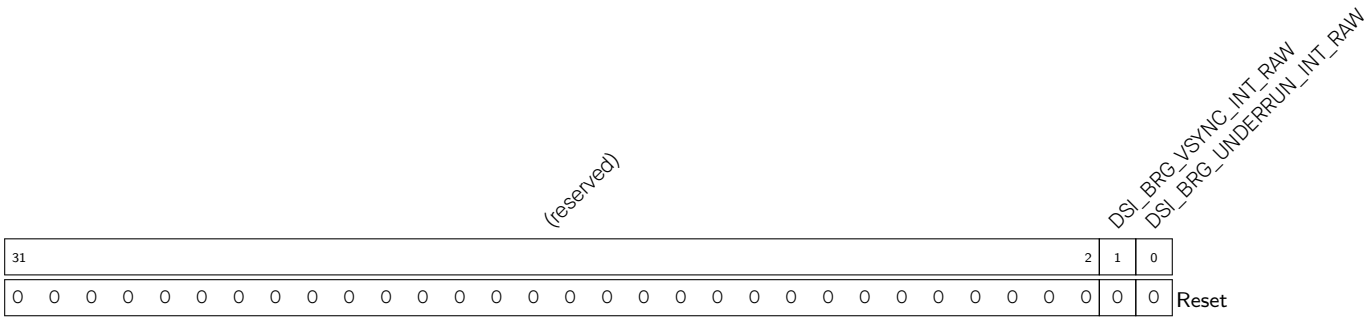


DSI_BRG_VSYNC_INT_ENA Configures DSI_BRG_VSYNC_INT enable.

0: disable

1: enable

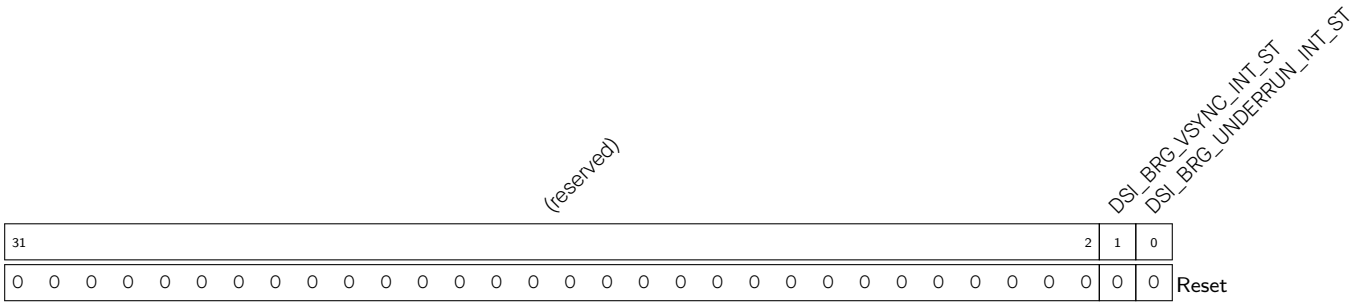
(R/W)



Register 43.35. DSI_BRG_INT_CLR_REG (0x0054)

DSI_BRG_UNDERRUN_INT_CLR write 1 to clear dpi_underrun_int_raw field of MIPI_DSI_BRG_INT_RAW_REG. (WT)

DSI_BRG_VSYNC_INT_CLR write 1 to clear dpi_vsync_int_raw field of MIPI_DSI_BRG_INT_RAW_REG. (WT)



Register 43.36. DSI_BRG_INT_RAW_REG (0x0058)

DSI_BRG_UNDERRUN_INT_RAW Represents raw interrupt status of dpi_underrun. (R/WTC/SS)

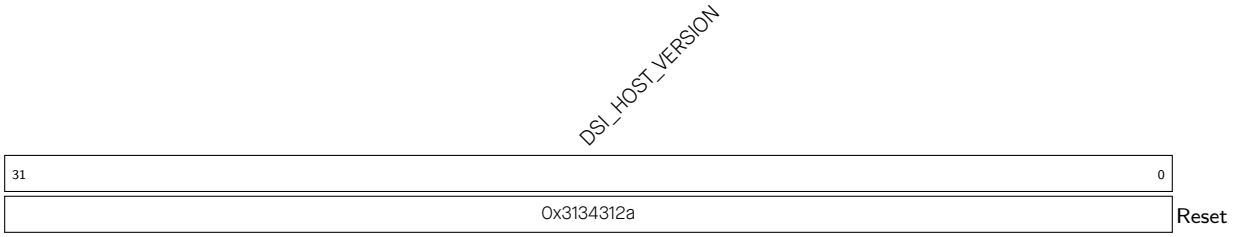
DSI_BRG_VSYNC_INT_RAW Represents raw interrupt status of dpi_vsync. (R/WTC/SS)

Register 43.37. DSI_BRG_INT_ST_REG (0x005C)

DSI_BRG_UNDERRUN_INT_ST Represents the masked interrupt status of dpi_underrun. (RO)

DSI_BRG_VSYNC_INT_ST Represents the masked interrupt status of dpi_vsync. (RO)

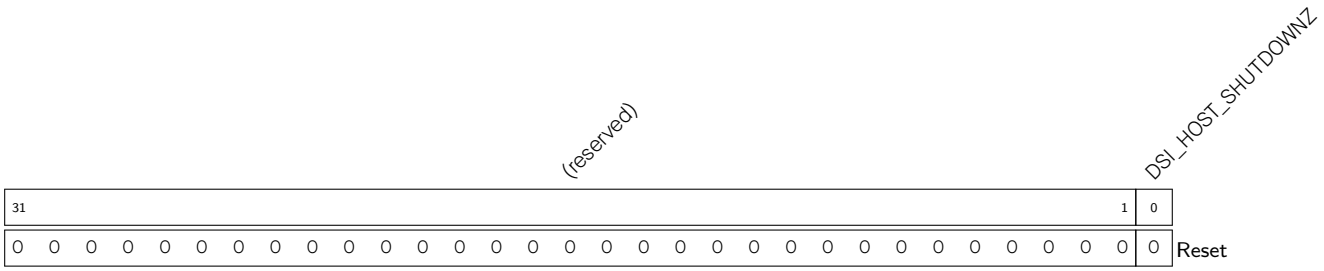
Register 43.38. DSI_BRG_VER_DATE_REG (0x0100)



DSI_BRG_VER_DATA Represents the CSV version date of this register file. (R/W)

43.8.2 MIPI DSI Host Register

The addresses in this section are relative to MIPI DSI Host base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

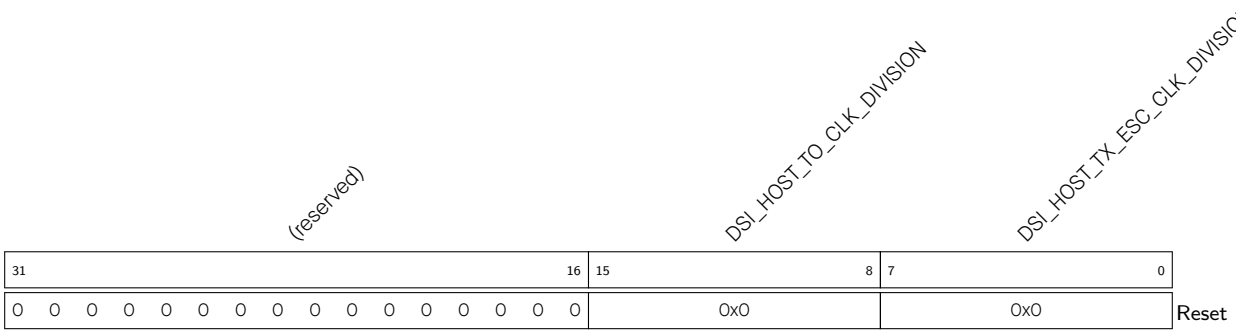


For how to program reserved fields, please refer to Section Programming Reserved Register Field.

Register 43.39. DSI_HOST_VERSION_REG (0x0000)

DSI_HOST_VERSION Represents DSI Host version. (RO)

Register 43.40. DSI_HOST_PWR_UP_REG (0x0004)

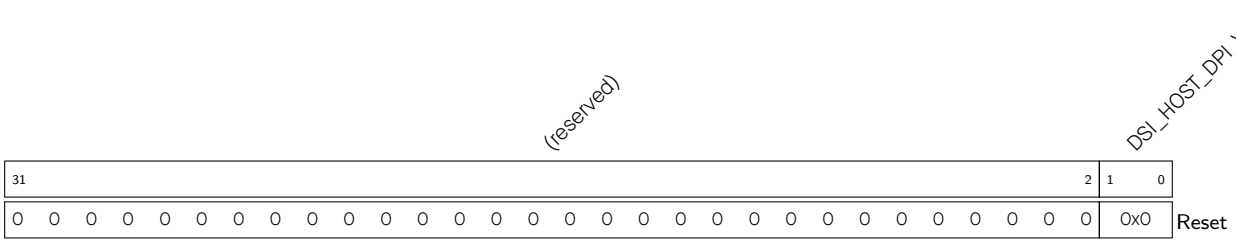


DSI_HOST_SHUTDOWNZ Configures DSI Host power.

0: reset

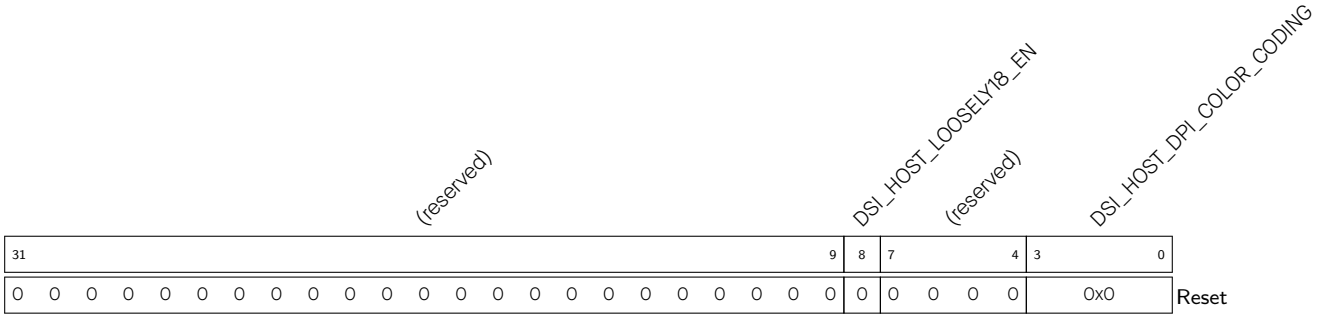
1: power up

(R/W)



Register 43.41. DSI_HOST_CLKMGR_CFG_REG (0x0008)

DSI_HOST_TX_ESC_CLK_DIVISION Configures the division factor of TX Escape clock. The values 0 or 1 will stop the TX Eacape clock. (R/W)



DSI_HOST_TO_CLK_DIVISION Configures the division factor of Time Out counter clock for HS to LP and LP to HS. (R/W)

Register 43.42. DSI_HOST_DPI_VCID_REG (0x000C)

DSI_HOST_DPI_VCID Configures the DPI virtual channel ID. (R/W)

Register 43.43. DSI_HOST_DPI_COLOR_CODING_REG (0x0010)

DSI_HOST_DPI_COLOR_CODING Configures the DPI color coding, refer to table 43.4-2 for details

0: RGB565 configuration 0

1: RGB565 configuration 1

2: RGB565 configuration 2

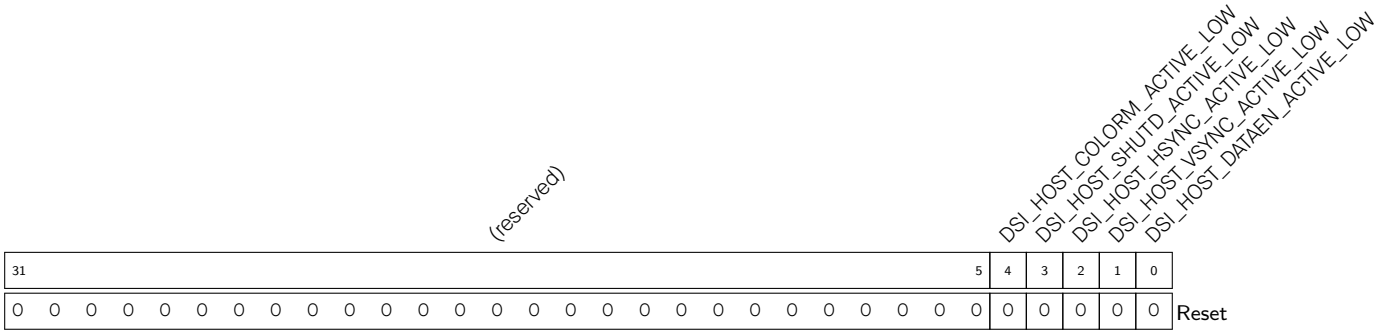
3: RGB666 configuration 0

4: RGB666 configuration 1

5: RGB888

others: reserved

(R/W)



DSI_HOST_LOOSELY18_EN Configures loosely packet for 18-bit configurations.

0:disable

1:enable

(R/W)

Register 43.44. DSI_HOST_DPI_CFG_POL_REG (0x0014)

DSI_HOST_DATAEN_ACTIVE_LOW Configures DPI dpidataen signal polarity.

0: active high

1: active low

(R/W)

DSI_HOST_VSYNC_ACTIVE_LOW Configures DPI dpivsync signal polarity.

0: active high

1: active low

(R/W)

DSI_HOST_HSYNC_ACTIVE_LOW Configures DPI dpihsync signal polarity.

0: active high

1: active low

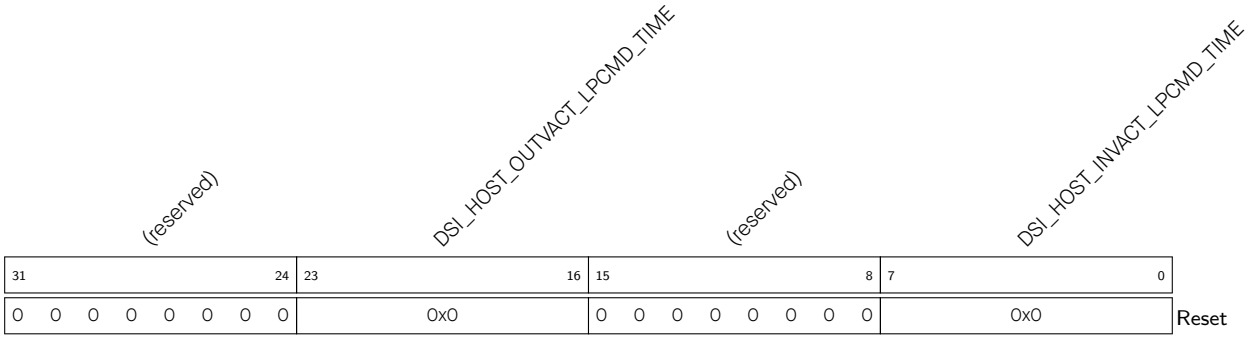
(R/W)

DSI_HOST_SHUTD_ACTIVE_LOW Configures DPI dpishutdn signal polarity.

0: active high

1: active low

(R/W)

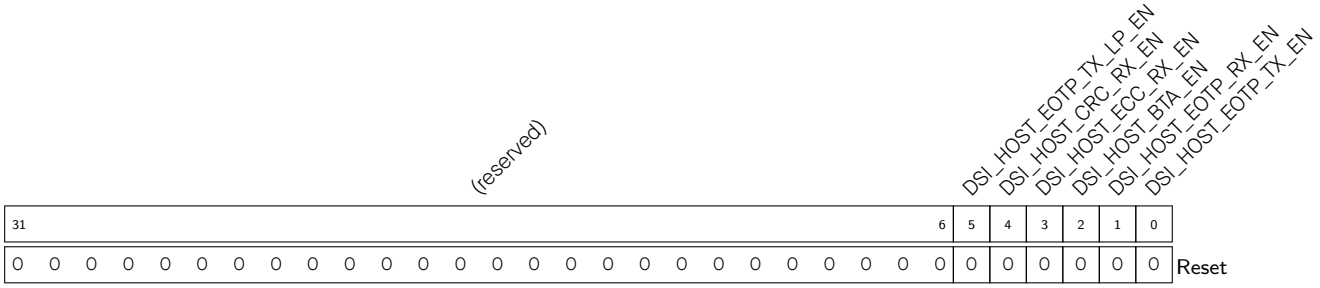


DSI_HOST_COLORM_ACTIVE_LOW Configures DPI dpicolorm signal polarity.

0: active high

1: active low

(R/W)



Register 43.45. DSI_HOST_DPI_LP_CMD_TIM_REG (0x0018)

DSI_HOST_INVACT_LPCMD_TIME Configures the size in bytes of the largest packet that can fit in a line during VACT region for LP command transmission. (R/W)

DSI_HOST_OUTVACT_LPCMD_TIME Configures the size in bytes of the largest packet that can fit in a line during VSA VBP VFP region for LP command transmission. (R/W)

Register 43.46. DSI_HOST_PCKHDL_CFG_REG (0x002C)

DSI_HOST_EOTP_TX_EN Configures the enable of the EoTp transmission in HS.

0: disable

1: enable

(R/W)

DSI_HOST_EOTP_RX_EN Configures the enable of the EoTp reception.

0: disable

1: enable

(R/W)

DSI_HOST_BTA_EN Configures the enable of the Bus Turn-Around (BTA) request.

0: disable

1: enable

(R/W)

DSI_HOST_ECC_RX_EN Configures the enable of ECC reception, error correction, and reporting.

0: disable

1: enable

(R/W)

DSI_HOST_CRC_RX_EN Configures the enable of CRC reception and error reporting.

0: disable

1: enable

(R/W)

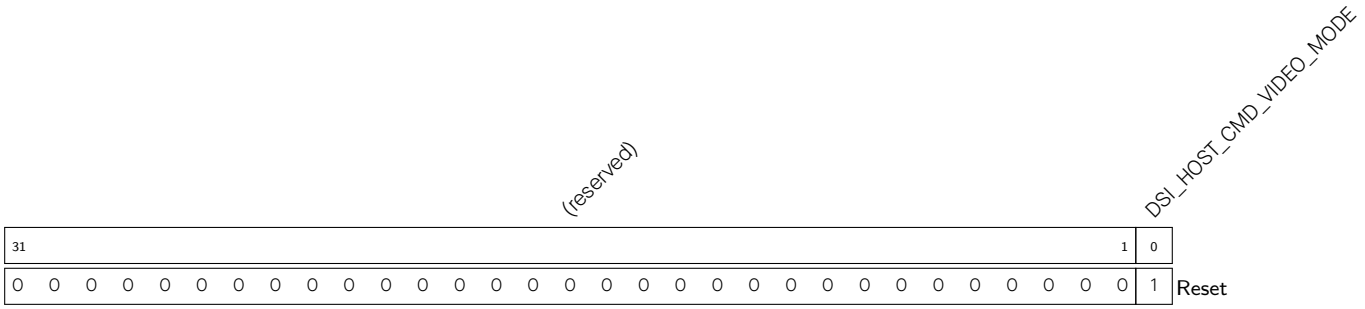
DSI_HOST_EOTP_TX_LP_EN Configures the enable of the EoTp transmission in LP.

0: disable

1: enable

(R/W)

Register 43.47. DSI_HOST_GEN_VCID_REG (0x0030)

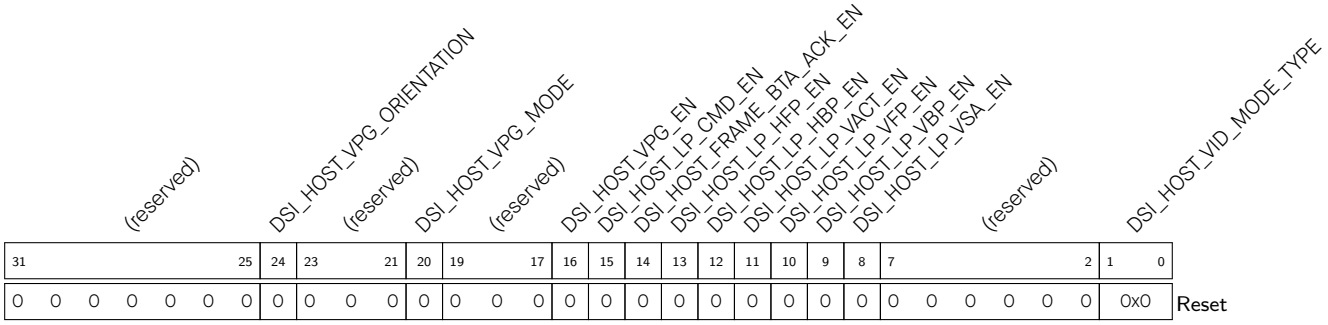


DSI_HOST_GEN_VCID_RX Configures Generic Interface read-back virtual channel ID. (R/W)

DSI_HOST_GEN_VCID_TEAR_AUTO Configures hardware TEA effect virtual channel ID. (R/W)

DSI_HOST_GEN_VCID_TX_AUTO Configures Generic Interface auto generated or transmitted packet virtual channel ID. (R/W)

Register 43.48. DSI_HOST_MODE_CFG_REG (0x0034)



DSI_HOST_CMD_VIDEO_MODE Configures operation mode.

0: video mode

1: command mode

(R/W)

Register 43.49. DSI_HOST_VID_MODE_CFG_REG (0x0038)

(reserved)
DSI_HOST_VPG_ORIENTATION
(reserved)
DSI_HOST_VPG_MODE
(reserved)
DSI_HOST_VPG_EN
DSI_HOST_LP_CMD_EN
DSI_HOST_FRAME_BTA_ACK_EN
DSI_HOST_LP_HFP_EN
DSI_HOST_LP_HBP_EN
DSI_HOST_LP_VACT_EN
DSI_HOST_LP_VFP_EN
DSI_HOST_LP_VBP_EN
DSI_HOST_LP_VSA_EN
(reserved)
DSI_HOST_VID_MODE_TYPE
31 25 24 23 21 20 19 17 16 15 14 13 12 11 10 9 8 7 2 1 0
0 0 0

Register 43.49. DSI_HOST_VID_MODE_CFG_REG (0x0038)

Continued from the previous page...

DSI_HOST_FRAME_BTA_ACK_EN Configures whether to enable the request for an acknowledge response at the end of a frame.

0: disable

1: enable

(R/W)

DSI_HOST_LP_CMD_EN Configures whether to enable the command transmission only in LP mode.

0: disable

1: enable

(R/W)

DSI_HOST_VPG_EN Configures the video pattern generator enable.

0: disable

1: enable

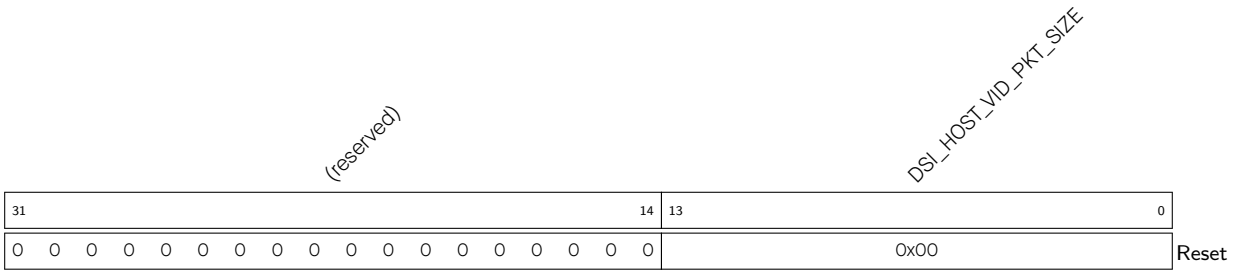
(R/W)

DSI_HOST_VPG_MODE Configures the pattern type.

0: color bar

1: ber pattern

(R/W)



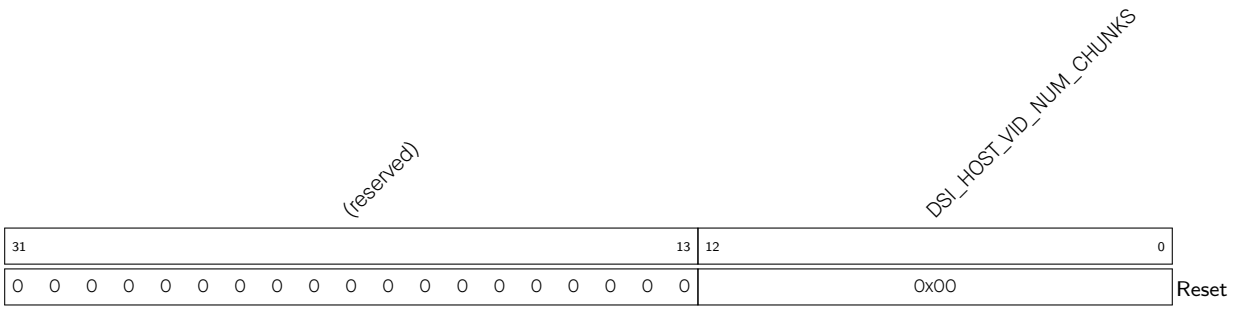
DSI_HOST_VPG_ORIENTATION Configures the color bar orientation.

0: vertical

1: horizontal

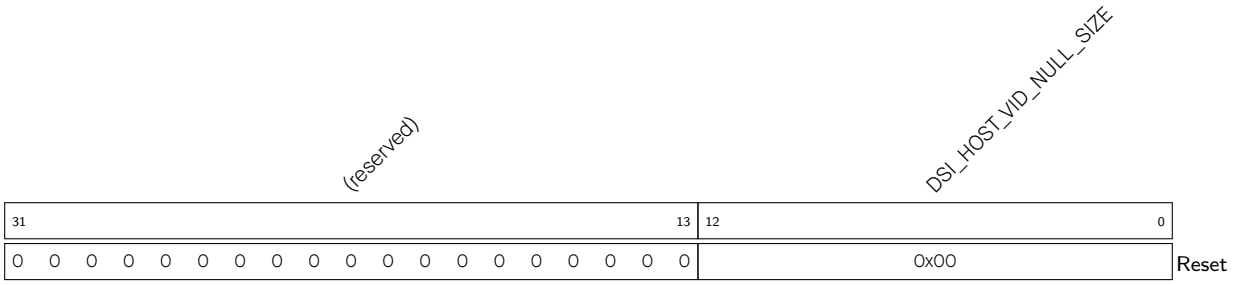
(R/W)

Register 43.50. DSI_HOST_VID_PKT_SIZE_REG (0x003C)



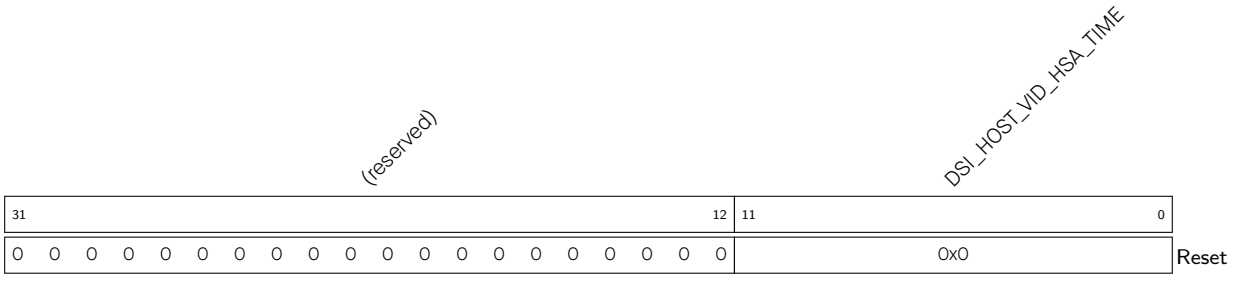
DSI_HOST_VID_PKT_SIZE Configures the number of pixels in a single video packet

For 18-bit not loosely packed data, the value must be a multiple of 4



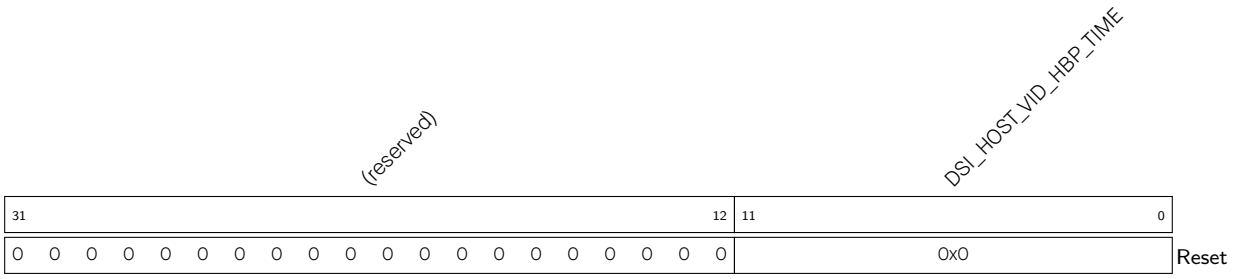
(R/W)

Register 43.51. DSI_HOST_VID_NUM_CHUNKS_REG (0x0040)



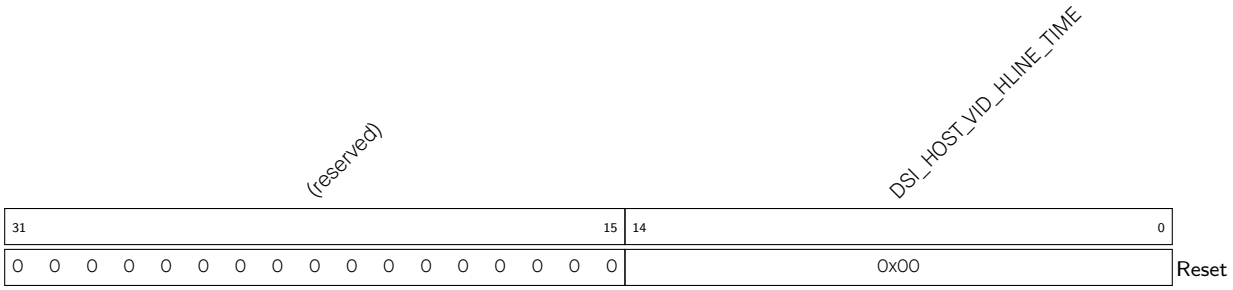
DSI_HOST_VID_NUM_CHUNKS Configures the number of chunks to be transmitted during a line. A chunk is a pair made of a video packet and a null packet. (R/W)

Register 43.52. DSI_HOST_VID_NULL_SIZE_REG (0x0044)



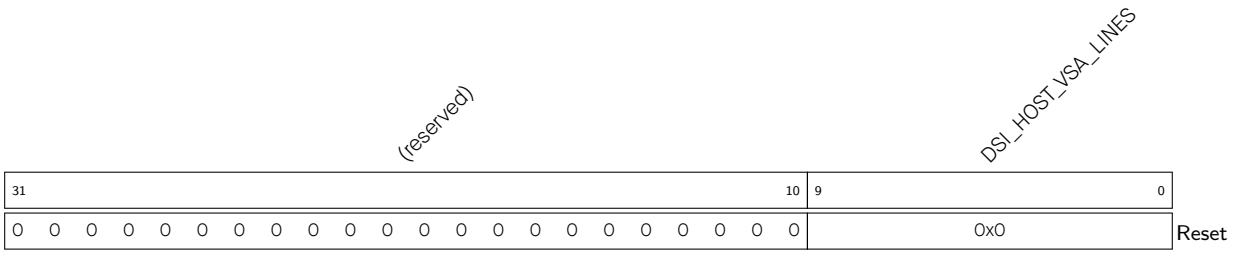
DSI_HOST_VID_NULL_SIZE Configures the number of bytes inside a null packet. Set to 0 to disable null packets. (R/W)

Register 43.53. DSI_HOST_VID_HSA_TIME_REG (0x0048)



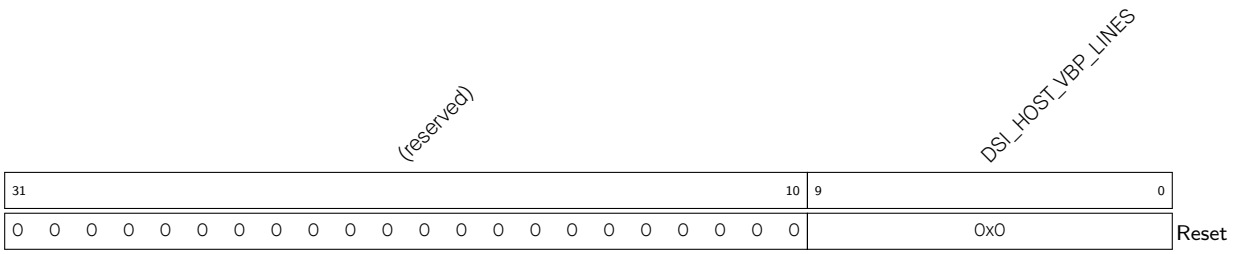
DSI_HOST_VID_HSA_TIME Configures the HSA period in lane byte clock cycles. (R/W)

Register 43.54. DSI_HOST_VID_HBP_TIME_REG (0x004C)



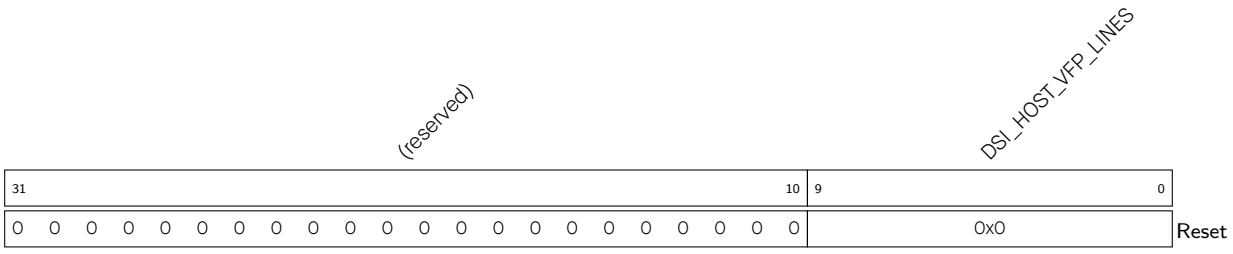
DSI_HOST_VID_HBP_TIME Configures the HBP period in lane byte clock cycles. (R/W)

Register 43.55. DSI_HOST_VID_HLINE_TIME_REG (0x0050)



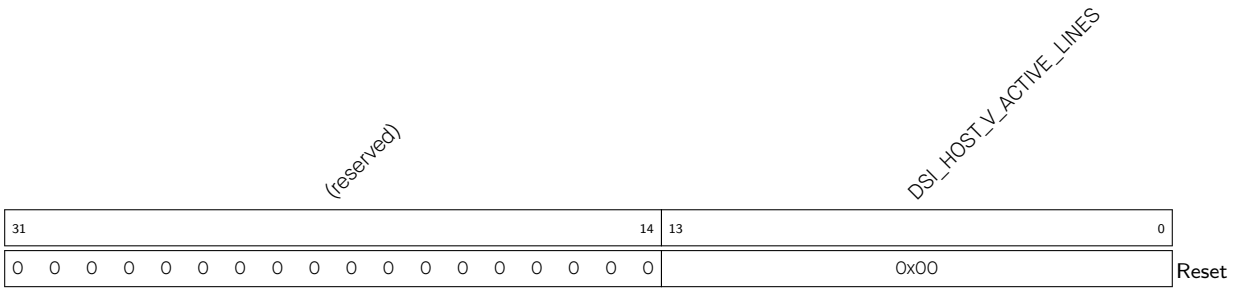
DSI_HOST_VID_HLINE_TIME Configures the HTOTAL time (HSA+HBP+HACT+HFP) in lane byte clock cycles. (R/W)

Register 43.56. DSI_HOST_VID_VSA_LINES_REG (0x0054)



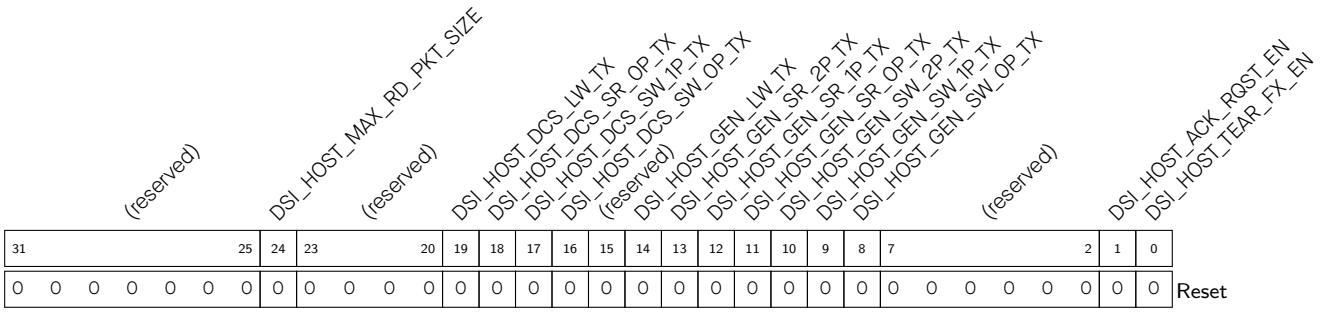
DSI_HOST_VSA_LINES Configures the VSA period in number of lines. (R/W)

Register 43.57. DSI_HOST_VID_VBP_LINES_REG (0x0058)



DSI_HOST_VBP_LINES Configures the VBP period in number of lines. (R/W)

Register 43.58. DSI_HOST_VID_VFP_LINES_REG (0x005C)



DSI_HOST_VFP_LINES Configures the VFP period in number of lines. (R/W)

Register 43.59. DSI_HOST_VID_VACTIVE_LINES_REG (0x0060)

DSI_HOST_V_ACTIVE_LINES Configures the VACT period in number of lines. (R/W)

Register 43.60. DSI_HOST_CMD_MODE_CFG_REG (0x0068)

(reserved)
DSI_HOST_MAX_RD_PKT_SIZE

Register 43.60. DSI_HOST_CMD_MODE_CFG_REG (0x0068)

Continued from the previous page...

DSI_HOST_GEN_SR_1P_TX Configures the Generic short read packet with one parameter command transmission type.
0: HS
1: LP
(R/W)

DSI_HOST_GEN_SR_2P_TX Configures the Generic short read packet with two parameter command transmission type.
0: HS
1: LP
(R/W)

DSI_HOST_GEN_LW_TX Configures the Generic long write packet command transmission type.
0: HS
1: LP
(R/W)

DSI_HOST_DCS_SW_0P_TX Configures the DCS short write packet with zero parameter command transmission type.
0: HS
1: LP
(R/W)

DSI_HOST_DCS_SW_1P_TX Configures the DCS short write packet with one parameter command transmission type.
0: HS
1: LP
(R/W)

DSI_HOST_DCS_SR_0P_TX Configures the DCS short read packet with zero parameter command transmission type.
0: HS
1: LP
(R/W)

DSI_HOST_DCS_LW_TX Configures the DCS long write packet command transmission type.
0: HS
1: LP
(R/W)

DSI_HOST_MAX_RD_PKT_SIZE Configures the max read packet size command transmission type.
0: HS
1: LP
(R/W)

Register 43.61. DSI_HOST_GEN_HDR_REG (0x006C)

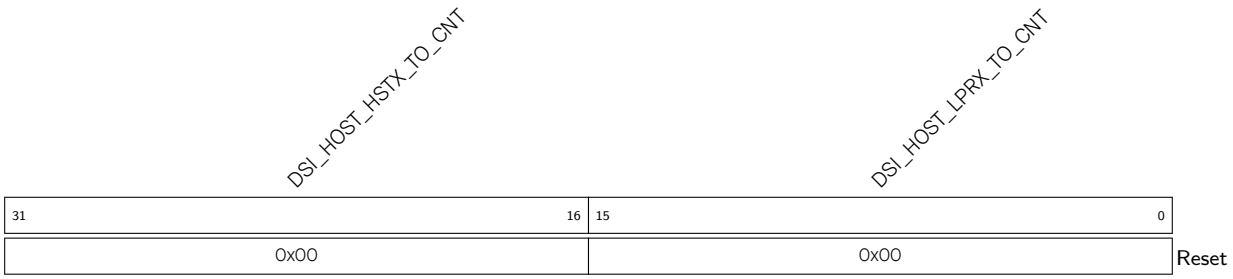
DSI_HOST_GEN_DT Configures the Data Type of packet header. (R/W)

DSI_HOST_GEN_VC Configures the Virtual Channel ID of packet header. (R/W)

DSI_HOST_GEN_WC_LSBYTE Configures the least significant byte of Word Count for long packets or data 0 for short packets of packet header. (R/W)

DSI_HOST_GEN_WC_MSBYTE Configures the most significant byte of Word Count for long packets or data 1 for short packets of packet header. (R/W)

Register 43.62. DSI_HOST_GEN_PLD_DATA_REG (0x0070)



DSI_HOST_GEN_PLD_B1 Configures the byte 1 of the packet payload. (R/W)

DSI_HOST_GEN_PLD_B2 Configures the byte 2 of the packet payload. (R/W)

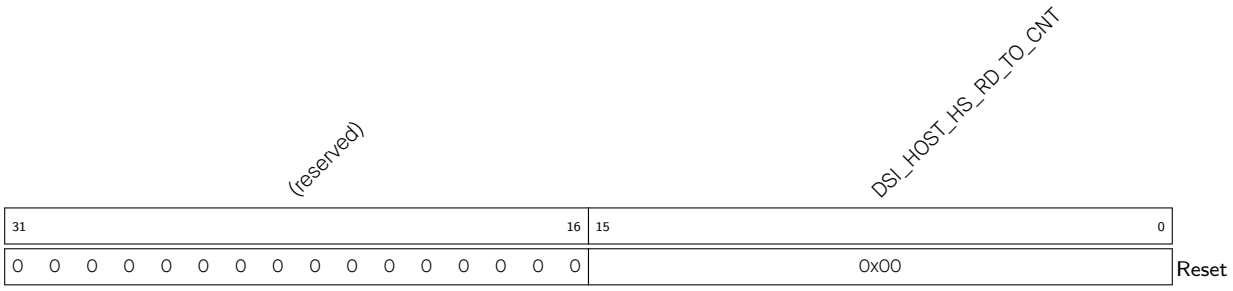
DSI_HOST_GEN_PLD_B3 Configures the byte 3 of the packet payload. (R/W)

DSI_HOST_GEN_PLD_B4 Configures the byte 4 of the packet payload. (R/W)

Register 43.63. DSI_HOST_TO_CNT_CFG_REG (0x0078)

DSI_HOST_LPRX_TO_CNT Configures the timeout counter that triggers a LP reception timeout contention detection (measured in TO_CLK_DIVISION cycles). (R/W)

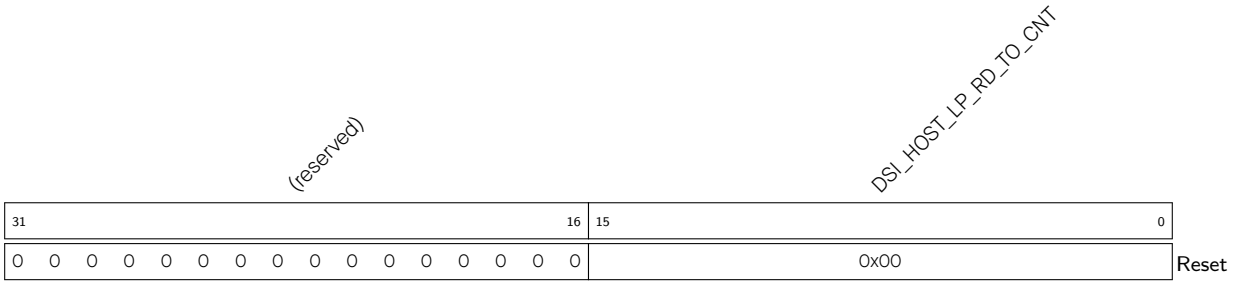
DSI_HOST_HSTX_TO_CNT Configures the timeout counter that triggers a HS transmission timeout contention detection (measured in TO_CLK_DIVISION cycles).
For non-burst mode, if there is not sufficient time to switch from HS to LP and back during HFP, the DSI link returns to LP once per frame. The configuration should meet:



$$\text{TO_CLK_DIVISION} \times \text{DSI_HOST_LPRX_TO_CNT} \times \text{lane_byte_clk_period} \geq 1.1 \times \text{frame data transmission time}$$

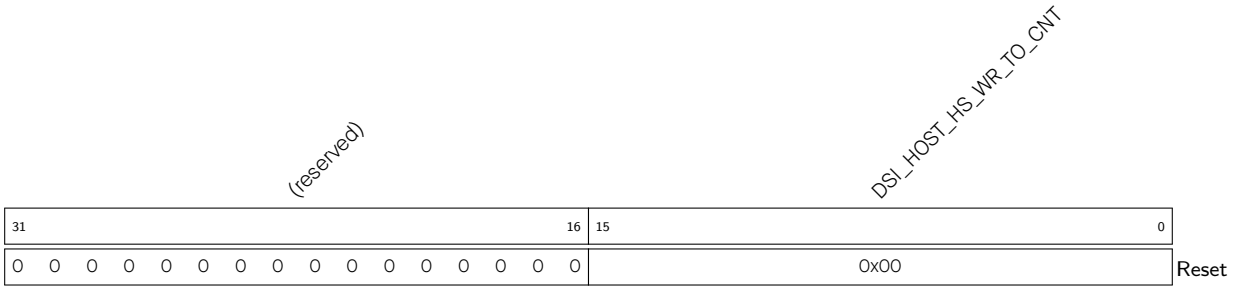
For burst mode, pixel packets are time-compressed, leaving more time during HFP to switch from HS to LP and back. If this mode is chosen, the configuration should meet:

$$\text{TO_CLK_DIVISION} \times \text{DSI_HOST_LPRX_TO_CNT} \times \text{lane_byte_clk_period} \geq 1.1 \times \text{line data transmission time}$$



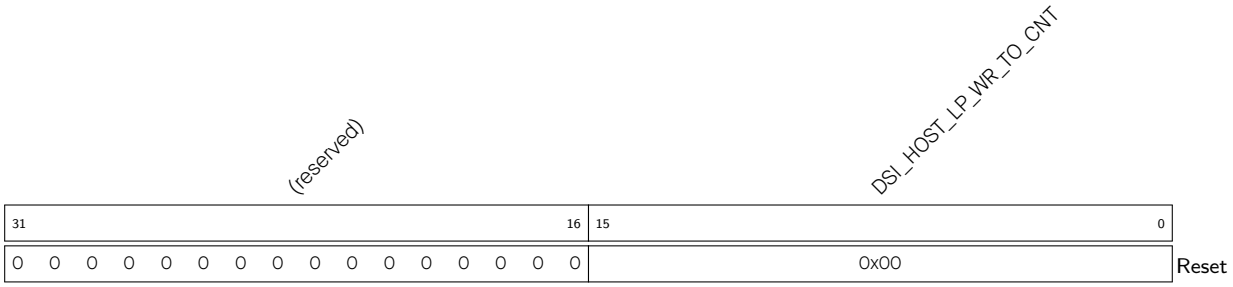
(R/W)

Register 43.64. DSI_HOST_HS_RD_TO_CNT_REG (0x007C)



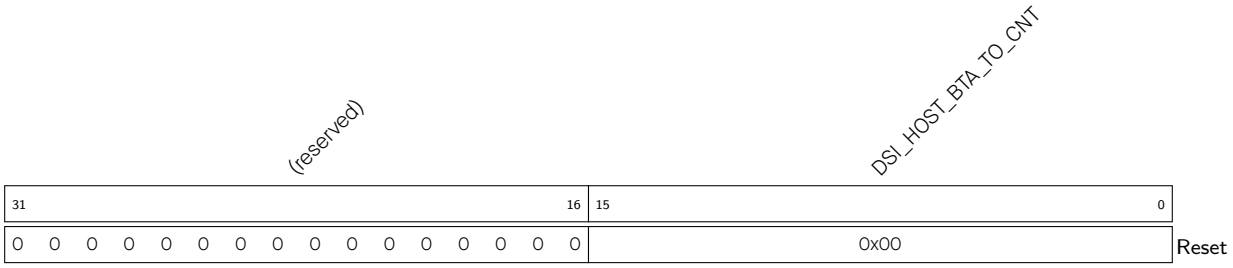
DSI_HOST_HS_RD_TO_CNT Configures the time that DSI Host keeps the link still after sending a HS read. Measured in lane byte clk cycles. Count starts when DPHY enters stop state and causes no interrupts. (R/W)

Register 43.65. DSI_HOST_LP_RD_TO_CNT_REG (0x0080)



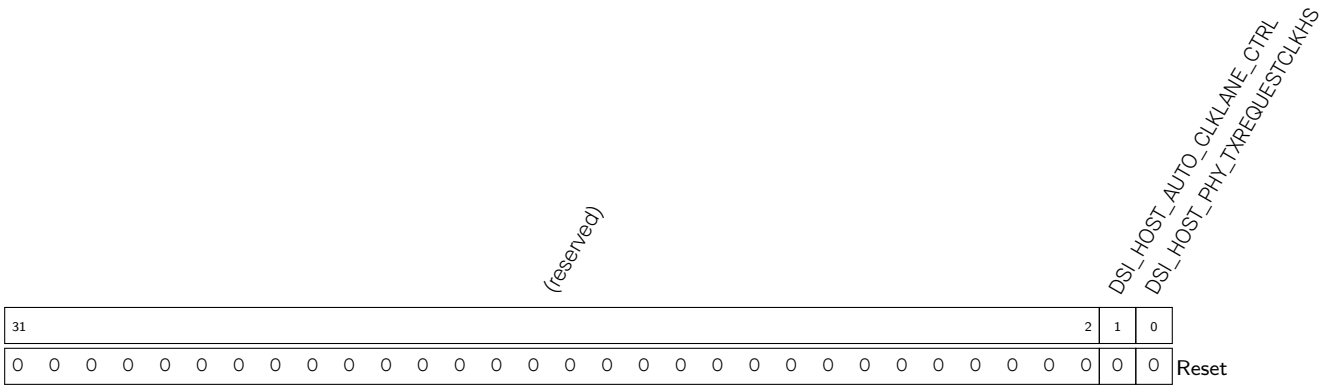
DSI_HOST_LP_RD_TO_CNT Configures the time that DSI Host keeps the link still after sending a LP read. Measured in lane byte clk cycles. Count starts when DPHY enters stop state and causes no interrupts. (R/W)

Register 43.66. DSI_HOST_HS_WR_TO_CNT_REG (0x0084)



DSI_HOST_HS_WR_TO_CNT Configures the time that DSI Host keeps the link still after sending a HS write. Measured in lane byte clk cycles. Count starts when DPHY enters stop state and causes no interrupts. (R/W)

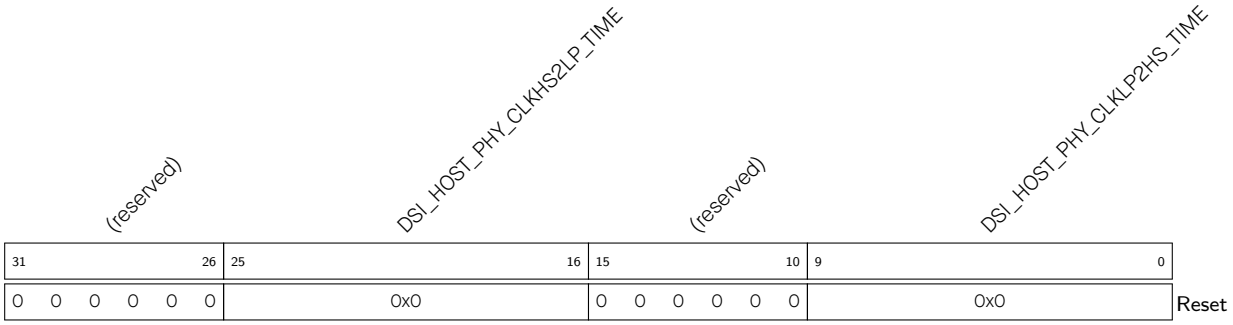
Register 43.67. DSI_HOST_LP_WR_TO_CNT_REG (0x0088)



DSI_HOST_LP_WR_TO_CNT Configures the time that DSI Host keeps the link still after sending a LP write. Measured in lane byte clk cycles. Count starts when DPHY enters stop state and causes no interrupts. (R/W)

Register 43.68. DSI_HOST_BTA_TO_CNT_REG (0x008C)

DSI_HOST_BTA_TO_CNT Configures the time that DSI Host keeps the link still after sending a BTA. Measured in lane byte clk cycles. Count starts when DPHY enters stop state and causes no interrupts. (R/W)



Register 43.69. DSI_HOST_LPCLK_CTRL_REG (0x0094)

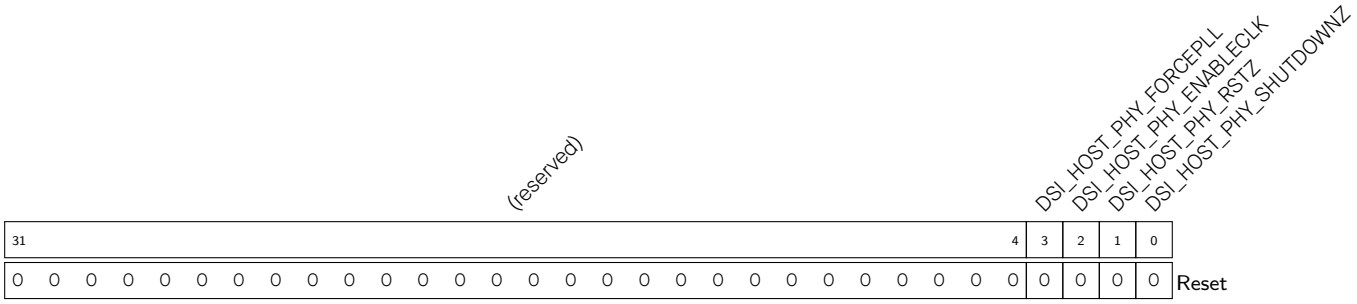
DSI_HOST_PHY_TXREQUESTCLKHS Controls the DPY PPI txrequestclkhs signal. (R/W)

DSI_HOST_AUTO_CLKLANE_CTRL Configures whether to enable the automatic mechanism to stop providing clock in the clock lane when time allows. (R/W)

Register 43.70. DSI_HOST_PHY_TMR_LPCLK_CFG_REG (0x0098)

DSI_HOST_PHY_CLKLP2HS_TIME Configures the max time that DPHY clock lane takes to go from LP to HS, mearured in lane byte clk cycles. (R/W)

DSI_HOST_PHY_CLKHS2LP_TIME Configures the max time that DPHY clock lane takes to go from HS to LP, mearured in lane byte clk cycles. (R/W)



Register 43.71. DSI_HOST_PHY_TMR_CFG_REG (0x009C)

DSI_HOST_PHY_LP2HS_TIME Configures the max time that DPHY data lane takes to go from LP to HS, mearured in lane byte clk cycles. (R/W)

DSI_HOST_PHY_HS2LP_TIME Configures the max time that DPHY data lane takes to go from HS to LP, mearured in lane byte clk cycles. (R/W)

Register 43.72. DSI_HOST_PHY_RSTZ_REG (0x00A0)

DSI_HOST_PHY_SHUTDOWNZ Configures DPHY macro power state.

0: power dowm

1: power up

(R/W)

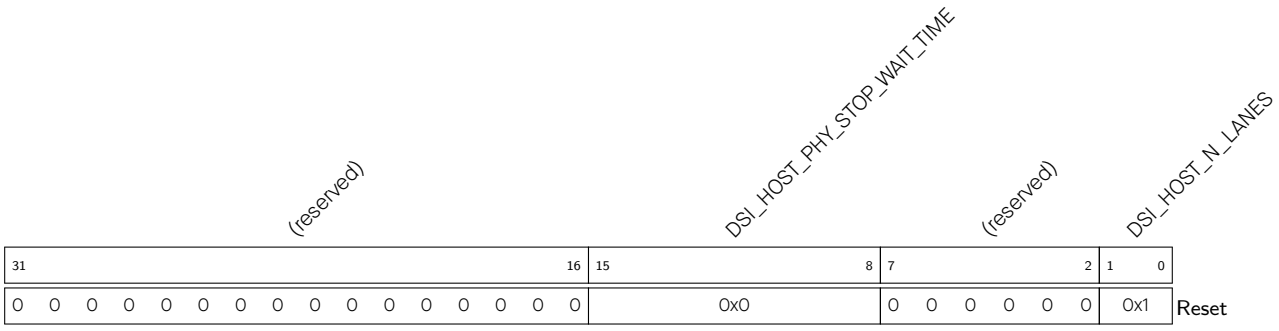
DSI_HOST_PHY_RSTZ Configures DPHY digital logic reset.

0: reset

1: release reset

(R/W)

DSI_HOST_PHY_ENABLECLK Configures DPHY clock lane module enable.



0: disable

1: enable

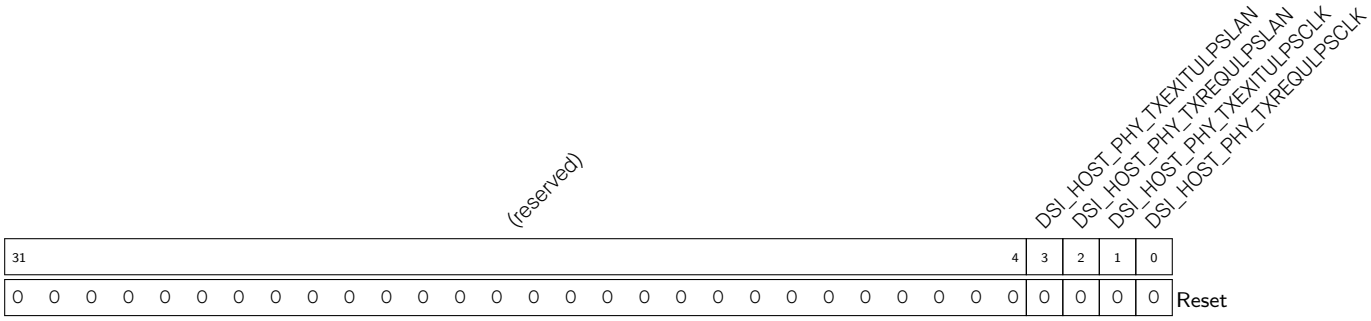
(R/W)

DSI_HOST_PHY_FORCEPLL Configures DPHY PLL when DPHY is in ULPS. (R/W)

Register 43.73. DSI_HOST_PHY_IF_CFG_REG (0x00A4)

DSI_HOST_N_LANES Configures the number of active data lane.

0: lane 0



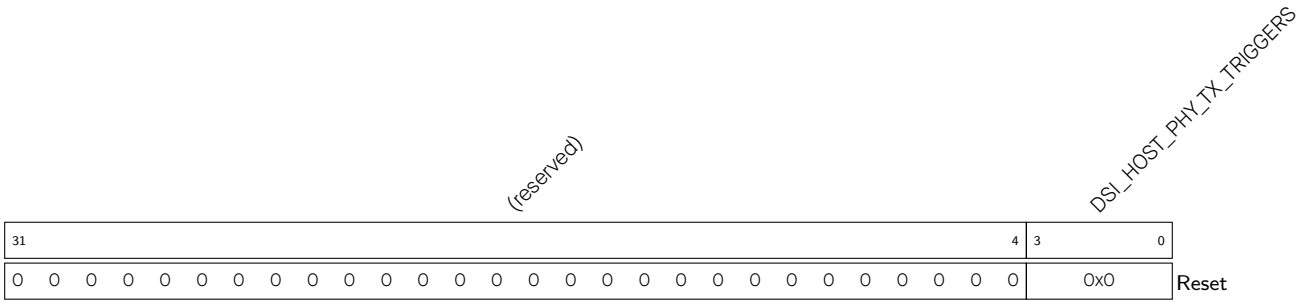
1: lane 0 and 1

others: reserved

(R/W)

DSI_HOST_PHY_STOP_WAIT_TIME NA. (R/W)

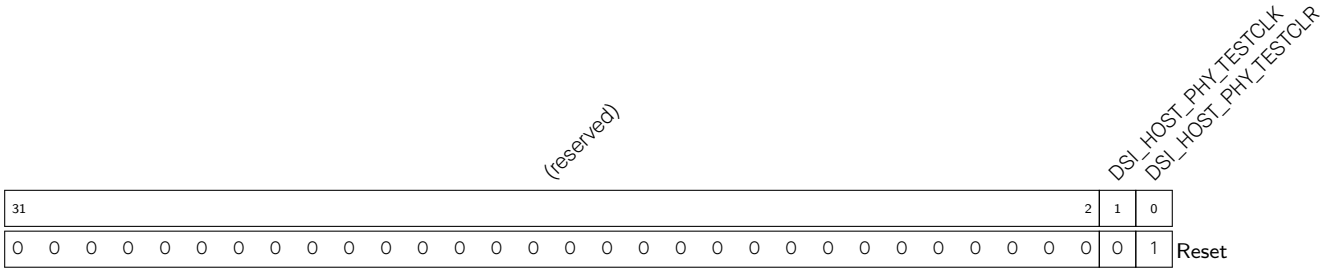
Register 43.74. DSI_HOST_PHY_ULPS_CTRL_REG (0x00A8)



DSI_HOST_PHY_TXREQULPSCLK Controls ULPS mode request on clock lane. (R/W)

DSI_HOST_PHY_TXEXITULPSCLK Controls ULPS mode exit on clock lane. (R/W)

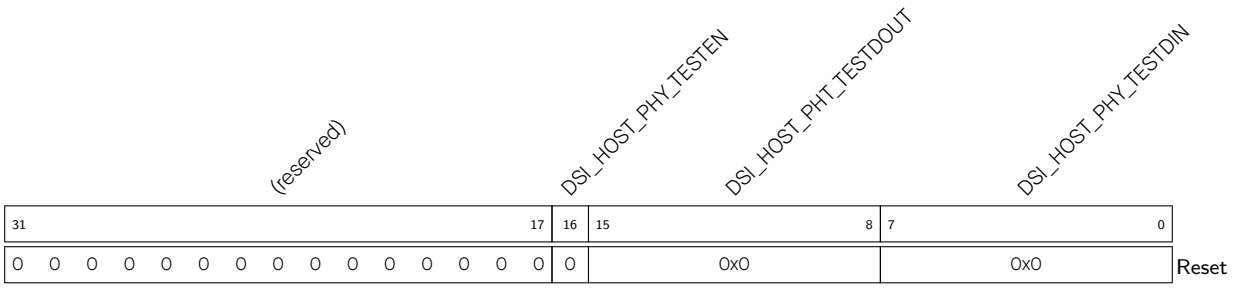
DSI_HOST_PHY_TXREQULPSLAN Controls ULPS mode request on all active data lane. (R/W)



DSI_HOST_PHY_TXEXITULPSLAN Controls ULPS mode exit on all active data lane. (R/W)

Register 43.75. DSI_HOST_PHY_TX_TRIGGERS_REG (0x00AC)

DSI_HOST_PHY_TX_TRIGGERS Controls the trigger transmission. (R/W)

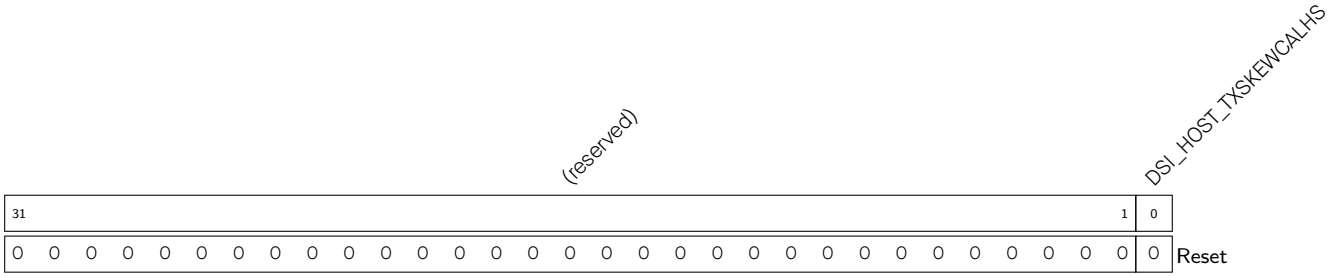


Register 43.76. DSI_HOST_PHY_TST_CTRL0_REG (0x00B4)

DSI_HOST_PHY_TESTCLR Controls test code interface TESTCLR. (R/W)

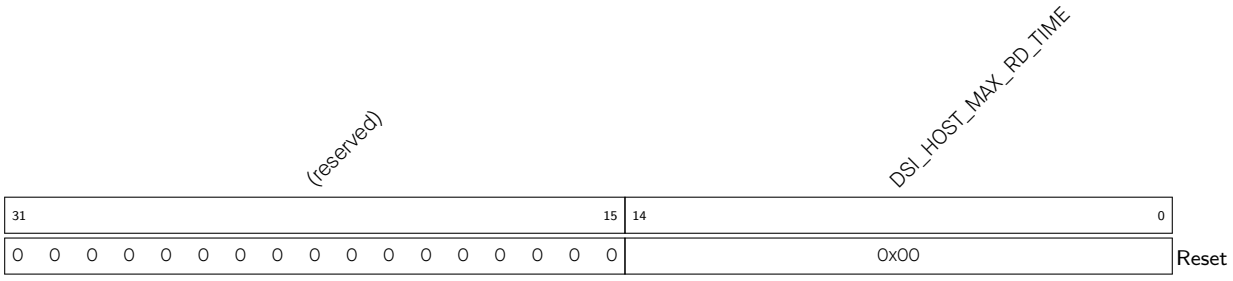
DSI_HOST_PHY_TESTCLK Controls test code interface TESTCLK. (R/W)

Register 43.77. DSI_HOST_PHY_TST_CTRL1_REG (0x00B8)



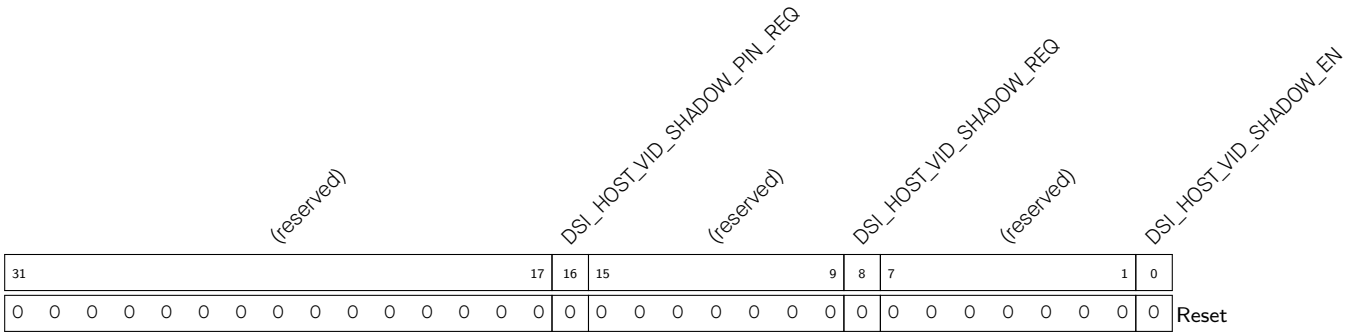
DSI_HOST_PHY_TESTDIN Controls test code interface TESTDIN. (R/W)

DSI_HOST_PHT_TESTDOUT Represents test code interface TESTDOUT. (RO)



DSI_HOST_PHY_TESTEN Controls test code interface TESTEN. (R/W)

Register 43.78. DSI_HOST_PHY_CAL_REG (0x00CC)

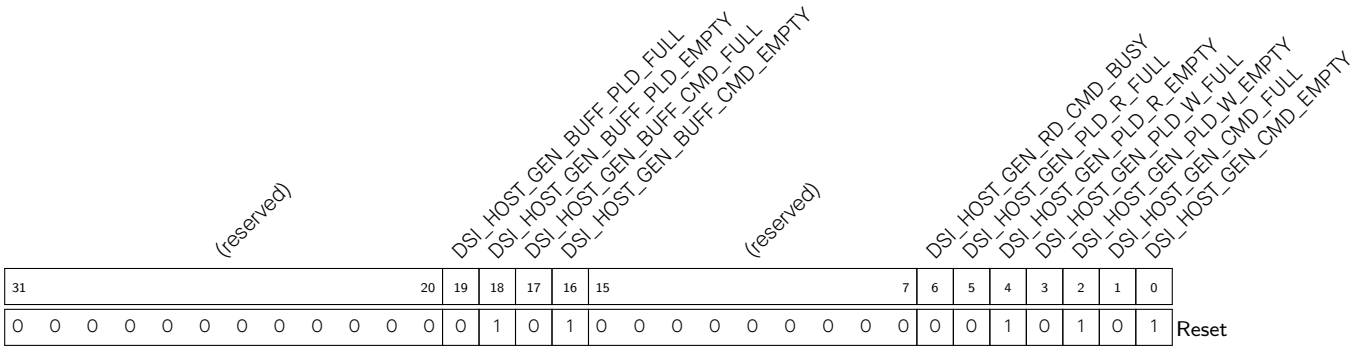


DSI_HOST_TXSKEWCALHS Configures HS skew calibration (assuming that DPHY is in stop state). (R/W)

Register 43.79. DSI_HOST_PHY_TMR_RD_CFG_REG (0x00F4)

DSI_HOST_MAX_RD_TIME Configures the max time required to perform a read command in lane byte clock cycle. This register can only be modified when no read command is in prograss. (R/W)

Register 43.80. DSI_HOST_VID_SHADOW_CTRL_REG (0x0100)



DSI_HOST_VID_SHADOW_EN Controls whether the DPI receives the active configuration from shadow register. (R/W)

DSI_HOST_VID_SHADOW_REQ Controls to update DPI register from regbank to shadow register. AUto cleared after request done. (R/W)

DSI_HOST_VID_SHADOW_PIN_REQ Controls the video request is done by external pin. When set to 1, DSI_HOST_VID_SHADOW_REQ is ignored. (R/W)

Register 43.81. DSI_HOST_CMD_PKT_STATUS_REG (0x0074)

DSI_HOST_GEN_CMD_EMPTY Represents the empty status of generic command FIFO. (RO)

DSI_HOST_GEN_CMD_FULL Represents the full status of generic command FIFO. (RO)

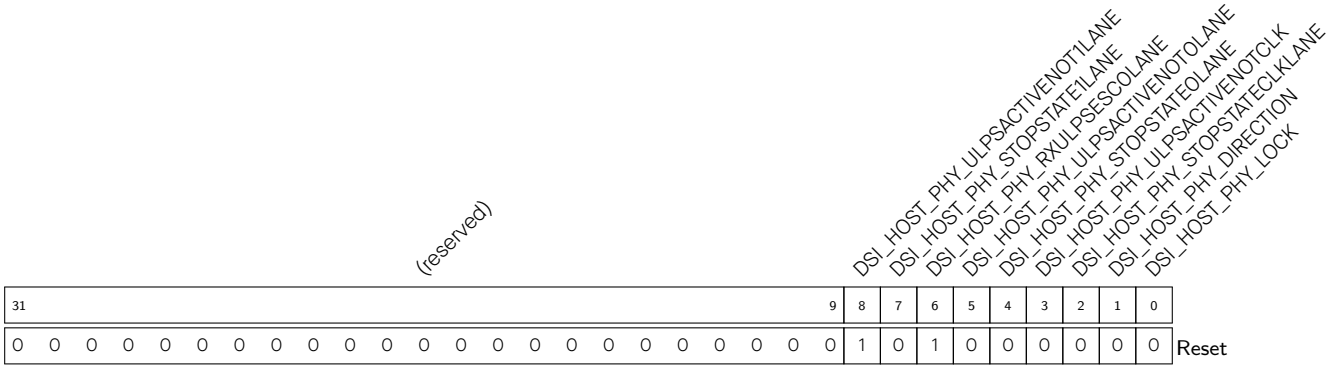
DSI_HOST_GEN_PLD_W_EMPTY Represents the empty status of generic write payload FIFO. (RO)

DSI_HOST_GEN_PLD_W_FULL Represents the full status of generic write payload FIFO. (RO)

DSI_HOST_GEN_PLD_R_EMPTY Represents the empty status of generic read payload FIFO. (RO)

DSI_HOST_GEN_PLD_R_FULL Represents the full status of generic read payload FIFO. (RO)

DSI_HOST_GEN_RD_CMD_BUSY Represents that a read command is issued and cleared when the entire response is stored in the FIFO for Generic Interface. (RO)



DSI_HOST_GEN_BUFF_CMD_EMPTY Represents the empty status of generic command internal buffer. (RO)

DSI_HOST_GEN_BUFF_CMD_FULL Represents the full status of generic command internal buffer. (RO)

DSI_HOST_GEN_BUFF_PLD_EMPTY Represents the empty status of generic payload internal buffer. (RO)

DSI_HOST_GEN_BUFF_PLD_FULL Represents the full status of generic payload internal buffer. (RO)

Register 43.82. DSI_HOST_PHY_STATUS_REG (0x00B0)

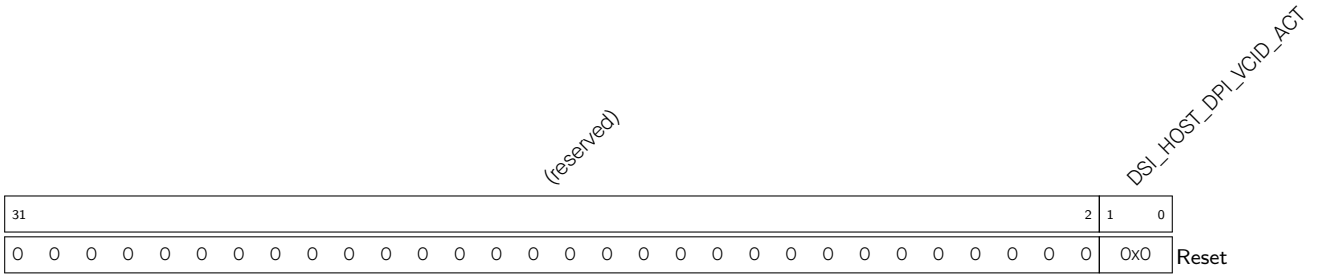
DSI_HOST_PHY_LOCK Represents the status of DPHY phylock. (RO)

DSI_HOST_PHY_DIRECTION Represents the status of phydirection. (RO)

DSI_HOST_PHY_STOPSTATECLKLANE Represents the status of DPHY phystopstateclklane. (RO)

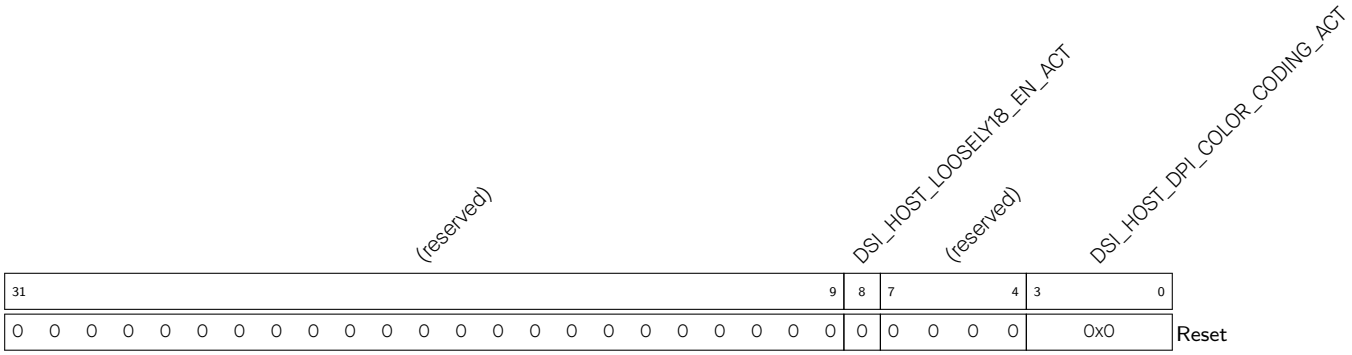
DSI_HOST_PHY_ULPSACTIVENOTCLK Represents the status of DPHY phyulpsactivenotclk. (RO)

DSI_HOST_PHY_STOPSTATEOLANE Represents the status of DPHY phystopstate0lane. (RO)



DSI_HOST_PHY_ULPSACTIVENOTOLANE Represents the status of DPHY ulpsactivenot0lane. (RO)

DSI_HOST_PHY_RXULPSESCOLANE Represents the status of DPHY rxulpsesc0lane. (RO)

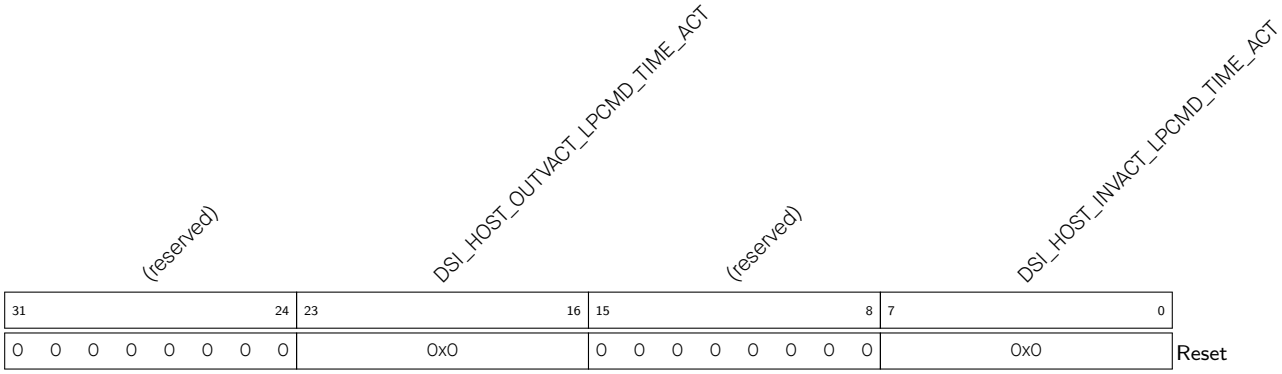


DSI_HOST_PHY_STOPSTATE1LANE Represents the status of DPHY phystopstate1lane. (RO)

DSI_HOST_PHY_ULPSACTIVENOT1LANE Represents the status of DPHY ulpsactivenot1lane. (RO)

Register 43.83. DSI_HOST_DPI_VCID_ACT_REG (0x010C)

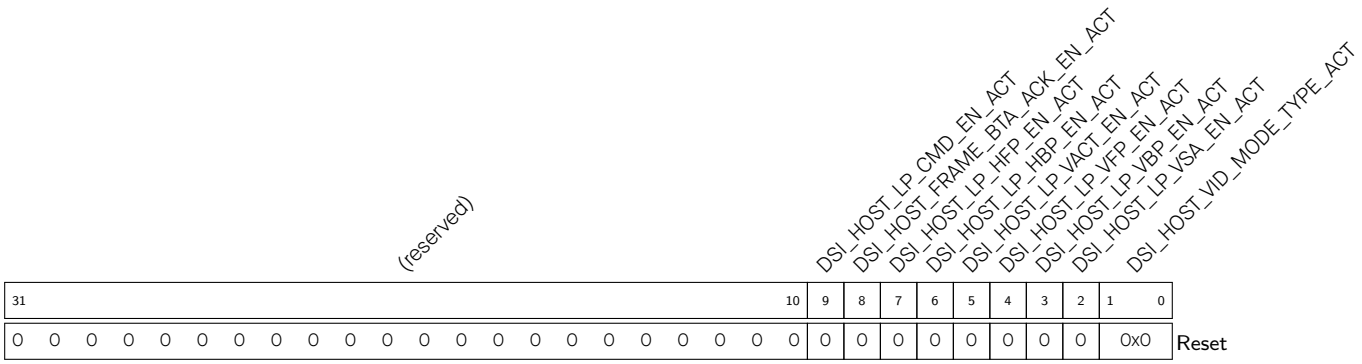
(reserved)
DSI_HOST_DPI_VCID_ACT
31 2 1 0
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0



Register 43.84. DSI_HOST_DPI_COLOR_CODING_ACT_REG (0x0110)

DSI_HOST_DPI_COLOR_CODING_ACT Represent the actual DPI color coding. (RO)

DSI_HOST_LOOSELY18_EN_ACT Represent the actual 18-bit loosely packed enable. (RO)



Register 43.85. DSI_HOST_DPI_LP_CMD_TIM_ACT_REG (0x0118)

DSI_HOST_INVACT_LPCMD_TIME_ACT Represents the actual value of INVACT_LPCMD_TIME. (RO)

DSI_HOST_OUTVACT_LPCMD_TIME_ACT Represents the actual value of OUT_VACT_LPCMD_TIME. (RO)

Register 43.86. DSI_HOST_VID_MODE_CFG_ACT_REG (0x0138)

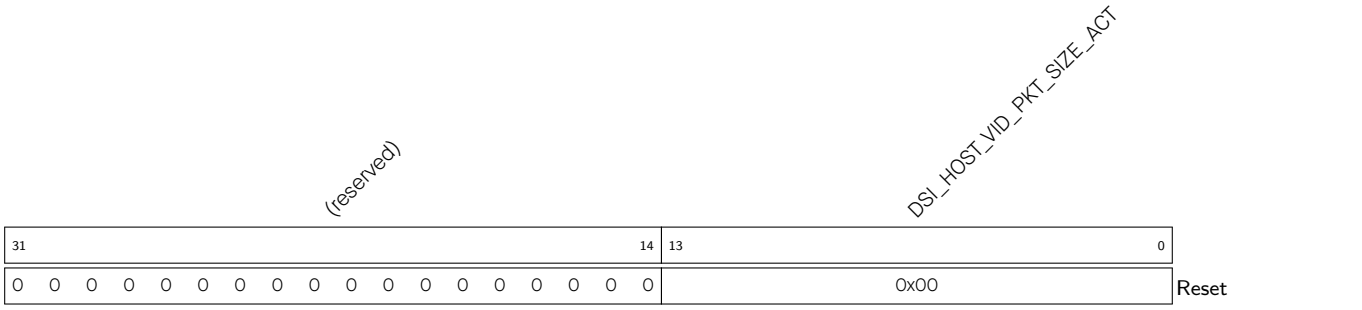
DSI_HOST_VID_MODE_TYPE_ACT Represents the actual value of VID_MODE_TYPE. (RO)

DSI_HOST_LP_VSA_EN_ACT Represents the actual value of LP_VSA_EN. (RO)

DSI_HOST_LP_VBP_EN_ACT Represents the actual value of LP_VBP_EN. (RO)

DSI_HOST_LP_VFP_EN_ACT Represents the actual value of LP_VFP_EN. (RO)

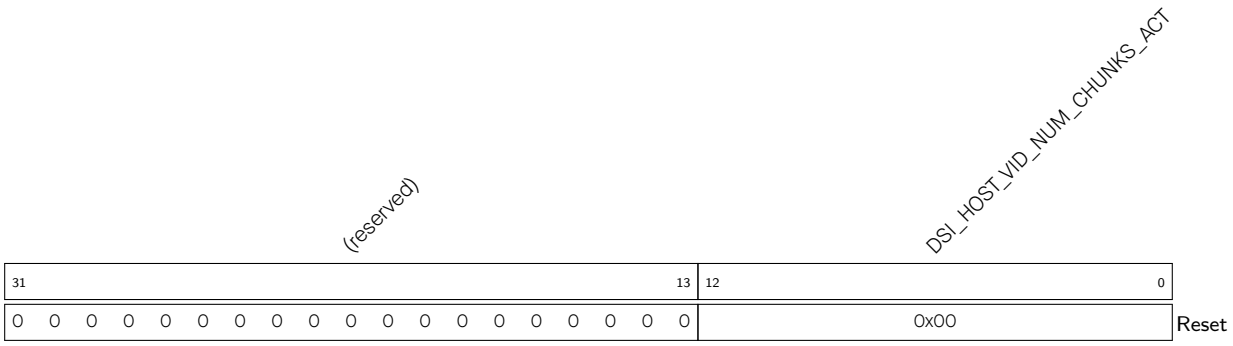
DSI_HOST_LP_VACT_EN_ACT Represents the actual value of LP_VACT_EN. (RO)



DSI_HOST_LP_HBP_EN_ACT Represents the actual value of LP_HBP_EN. (RO)

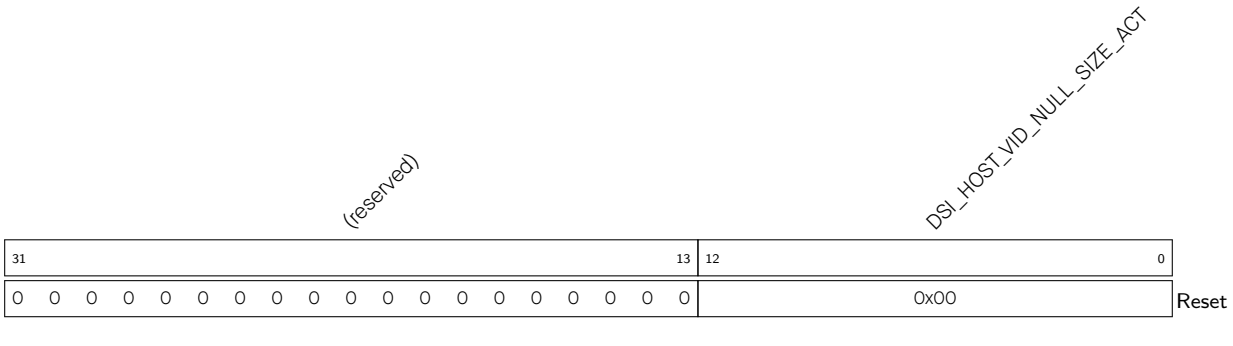
DSI_HOST_LP_HFP_EN_ACT Represents the actual value of LP_HFP_EN. (RO)

DSI_HOST_FRAME_BTA_ACK_EN_ACT Represents the actual value of FRAME_BTA_ACK_EN. (RO)



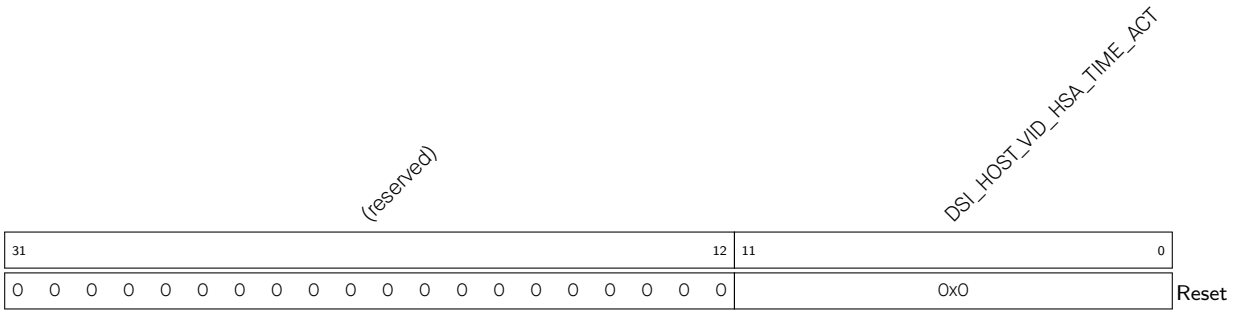
DSI_HOST_LP_CMD_EN_ACT Represents the actual value of LP_CMD_EN. (RO)

Register 43.87. DSI_HOST_VID_PKT_SIZE_ACT_REG (0x013C)



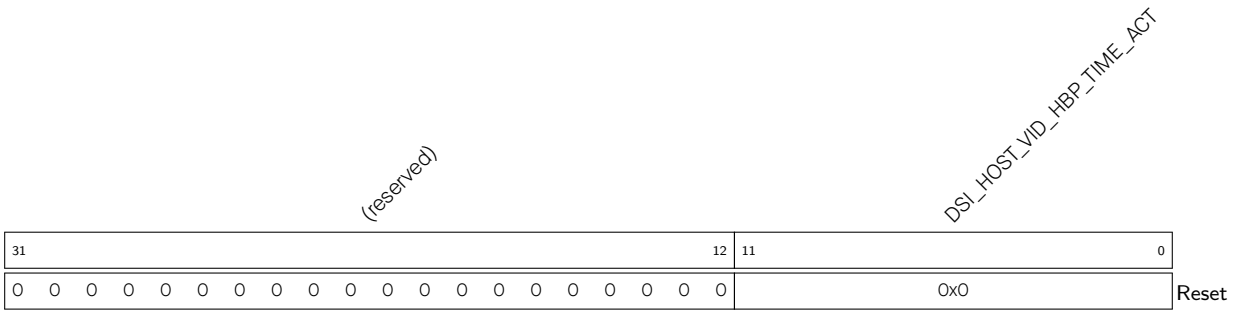
DSI_HOST_VID_PKT_SIZE_ACT Represents the actual value of VID_PKT_SIZE. (RO)

Register 43.88. DSI_HOST_VID_NUM_CHUNKS_ACT_REG (0x0140)



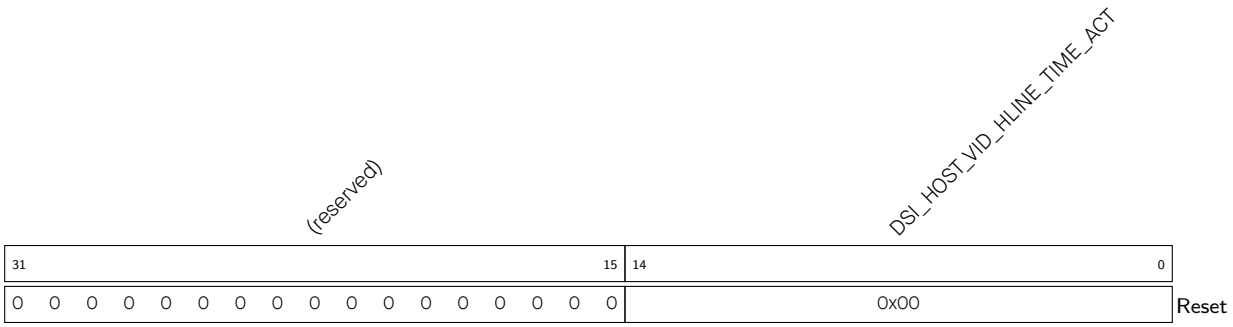
DSI_HOST_VID_NUM_CHUNKS_ACT Represents the actual value of VID_NUM_CHUNKS_ACT. (RO)

Register 43.89. DSI_HOST_VID_NULL_SIZE_ACT_REG (0x0144)



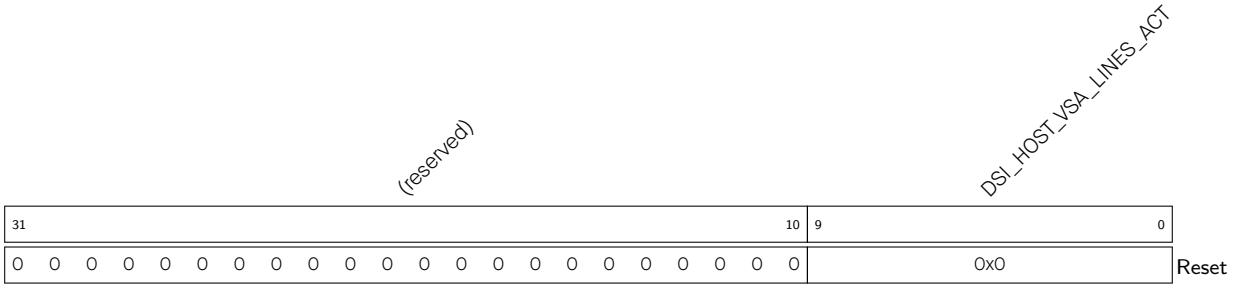
DSI_HOST_VID_NULL_SIZE_ACT Represents the actual value of VID_NULL_SIZE. (RO)

Register 43.90. DSI_HOST_VID_HSA_TIME_ACT_REG (0x0148)



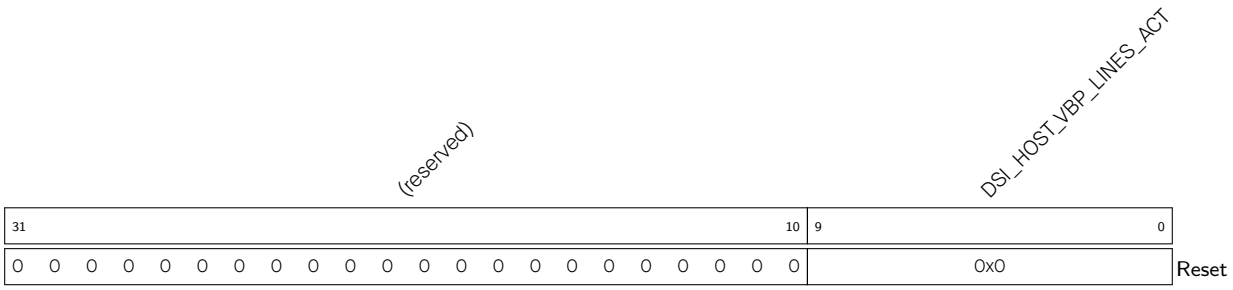
DSI_HOST_VID_HSA_TIME_ACT Represents the actual value of VID_HSA_TIME. (RO)

Register 43.91. DSI_HOST_VID_HBP_TIME_ACT_REG (0x014C)



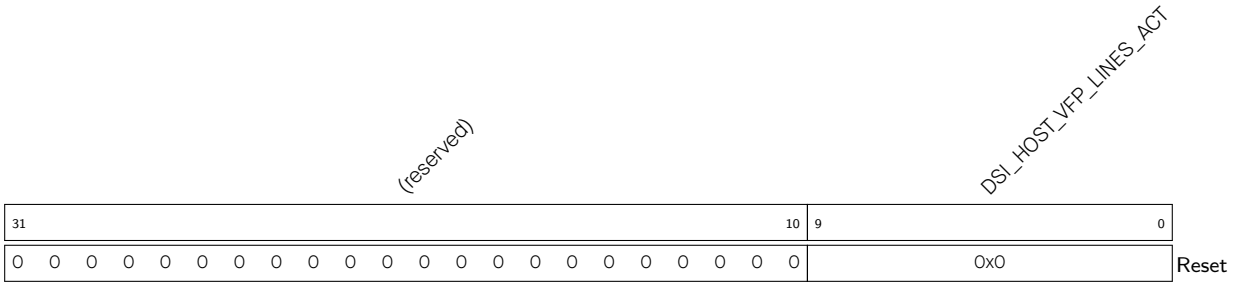
DSI_HOST_VID_HBP_TIME_ACT Represents the actual value of VID_HBP_TIME. (RO)

Register 43.92. DSI_HOST_VID_HLINE_TIME_ACT_REG (0x0150)



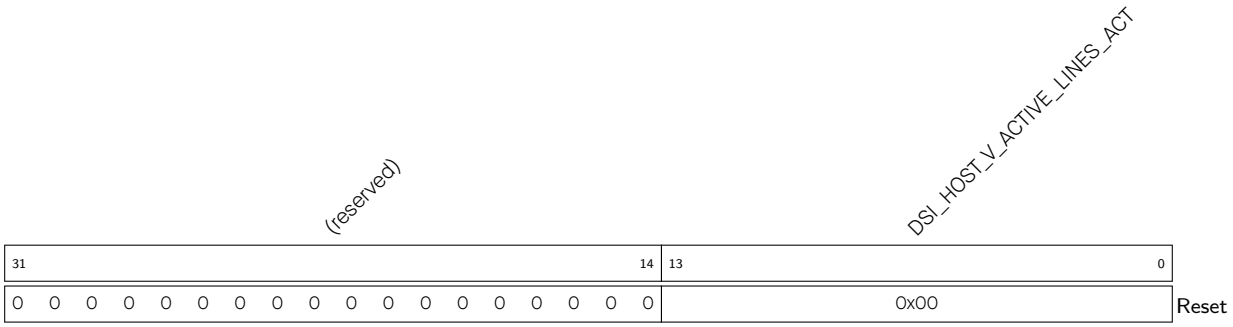
DSI_HOST_VID_HLINE_TIME_ACT Represents the actual value of VID_HLINE_TIME. (RO)

Register 43.93. DSI_HOST_VID_VSA_LINES_ACT_REG (0x0154)



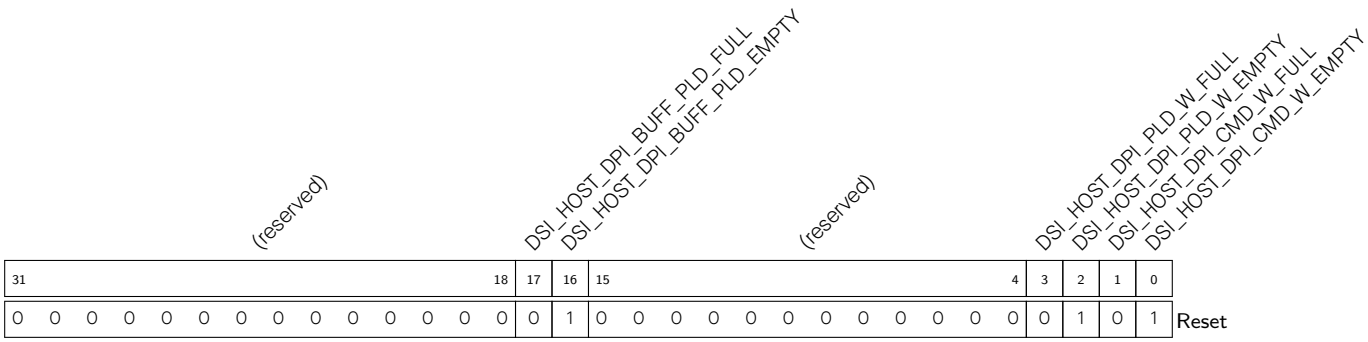
DSI_HOST_VSA_LINES_ACT Represents the actual value of VID_VSA_TIME. (RO)

Register 43.94. DSI_HOST_VID_VBP_LINES_ACT_REG (0x0158)



DSI_HOST_VBP_LINES_ACT Represents the actual value of VID_VBP_TIME. (RO)

Register 43.95. DSI_HOST_VID_VFP_LINES_ACT_REG (0x015C)



DSI_HOST_VFP_LINES_ACT Represents the actual value of VID_VFP_TIME. (RO)

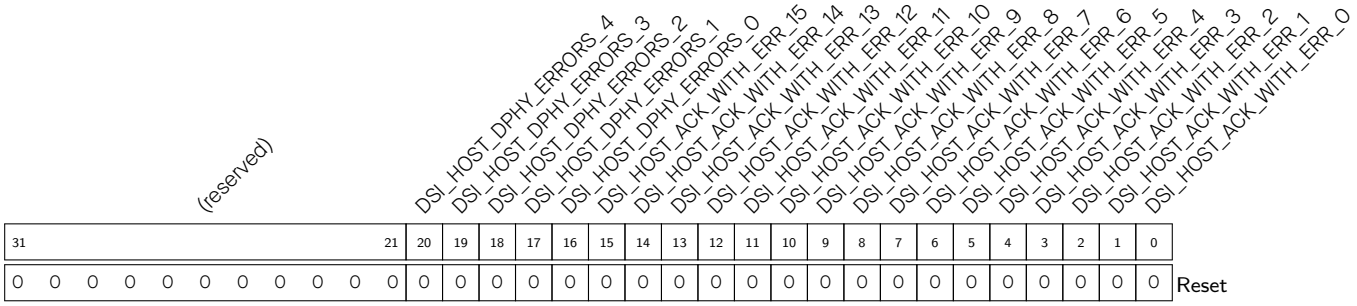
Register 43.96. DSI_HOST_VID_VACTIVE_LINES_ACT_REG (0x0160)

DSI_HOST_V_ACTIVE_LINES_ACT Represents the actual value of VID_VACTIVE_TIME. (RO)

Register 43.97. DSI_HOST_VID_PKT_STATUS_REG (0x0168)

DSI_HOST_DPI_CMD_W_EMPTY Represents the empty status of write command FIFO for video mode. (RO)

DSI_HOST_DPI_CMD_W_FULL Represents the full status of write command FIFO for video mode. (RO)



DSI_HOST_DPI_PLD_W_EMPTY Represents the empty status of write payload FIFO for video mode. (RO)

DSI_HOST_DPI_PLD_W_FULL Represents the full status of write payload FIFO for video mode. (RO)

DSI_HOST_DPI_BUFF_PLD_EMPTY Represents the empty status of payload internal buffer for video mode. (RO)

DSI_HOST_DPI_BUFF_PLD_FULL Represents the full status of payload internal buffer for video mode. (RO)

Register 43.98. DSI_HOST_INT_STO_REG (0x00BC)

DSI_HOST_ACK_WITH_ERR_0 Represents SoT error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_1 Represents SoT Sync error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_2 Represents EoT error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_3 Represents Escape Mode Entry Command error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_4 Represents LP Transmit Sync error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_5 Represents Periphal timeout error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_6 Represents False Control error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_7 Represents reserved from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_8 Represents ECCsingle-bit error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_9 Represents ECC multi-bit error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_10 Represents checksum error (long packet only) from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_11 Represents not recognized DSI data type error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_12 Represents invalid DSI VCID error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_13 Represents invalid transmission length error from the Acknowledge report. (RO)

DSI_HOST_ACK_WITH_ERR_14 Represents reserved from the Acknowledge report. (RO)

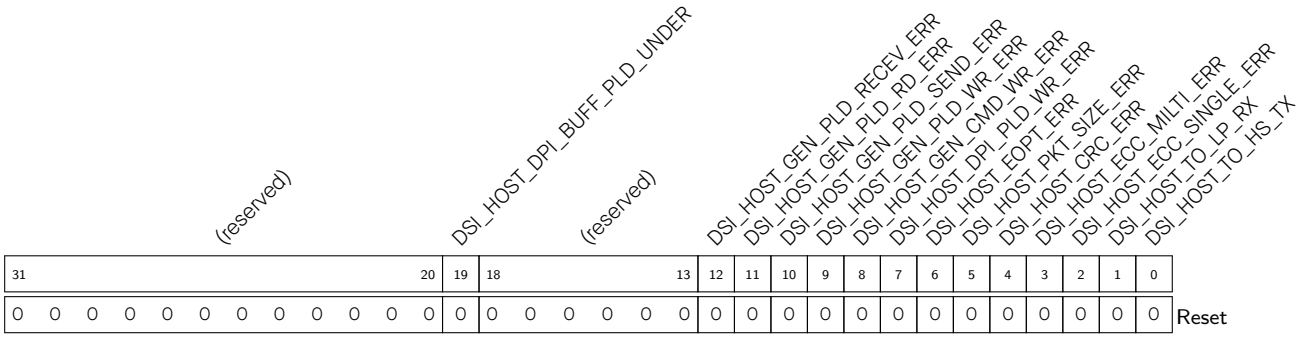
DSI_HOST_ACK_WITH_ERR_15 Represents DSI protocol violation error from the Acknowledge report. (RO)

Continued on the next page...

Register 43.98. DSI_HOST_INT_ST0_REG (0x00BC)

Continued from the previous page...

DSI_HOST_DPHY_ERRORS_0 Represents ErrEsc eacape entry error from Lane 0. (RO)



DSI_HOST_DPHY_ERRORS_1 Represents ErrSyncEsc LP data transmission synchronization error from Lane 0. (RO)

DSI_HOST_DPHY_ERRORS_2 Represents ErrControl control error from Lane 0. (RO)

DSI_HOST_DPHY_ERRORS_3 Represents ErrContentionLP0 LP0 contention error from Lane 0. (RO)

DSI_HOST_DPHY_ERRORS_4 Represents ErrContentionLP1 LP1 contention error from Lane 0. (RO)

Register 43.99. DSI_HOST_INT_ST1_REG (0x00C0)

DSI_HOST_TO_HS_TX Represents HP transmission timeout couinter reached the end and contention has been detected. (RO)

DSI_HOST_TO_LP_RX Represents LP reception timeout couinter reached the end and contention has been detected. (RO)

DSI_HOST_ECC_SINGLE_ERR Represents ECC single error has been detected and corrected in a received packet. (RO)

DSI_HOST_ECC_MILTI_ERR Represents ECC multiple error has been detected in a received packet. (RO)

DSI_HOST_CRC_ERR Represents CRC error has been detected in a received packet. (RO)

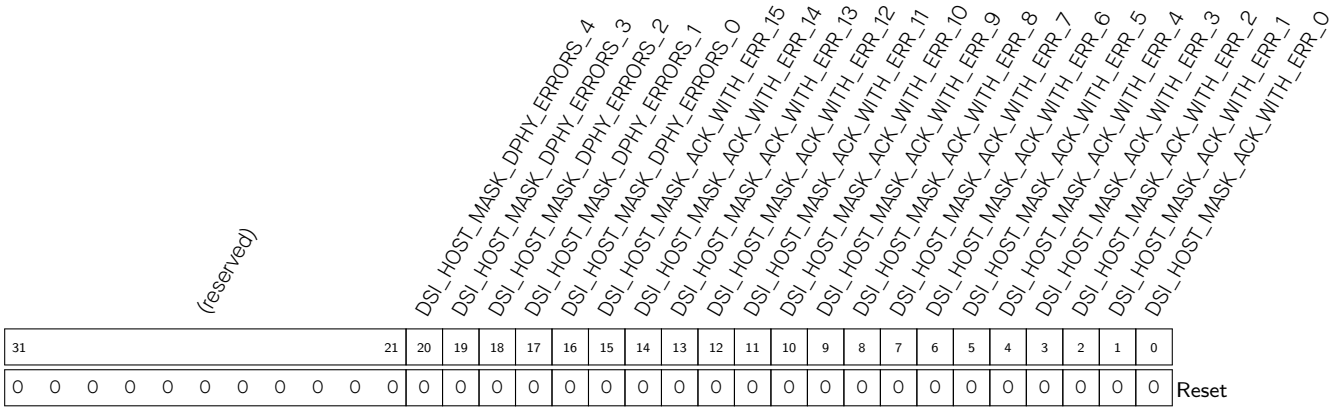
DSI_HOST_PKT_SIZE_ERR Represents the packet size error has been detected during packet reception. (RO)

DSI_HOST_EOPT_ERR Represents the EoTp packet has not been received at the end of the incommign peripheral transmission. (RO)

DSI_HOST_DPI_PLD_WR_ERR Represents payload FIFO becomes full and data corrupted during DPI pixel line storage. (RO)

DSI_HOST_GEN_CMD_WR_ERR Represents the system tried to write a command through Generic Interface and the FIFO is full. (RO)

DSI_HOST_GEN_PLD_WR_ERR Represents the system tried to write a payload data through Generic Interface and the FIFO is full. (RO)



DSI_HOST_GEN_PLD_SEND_ERR Represents the payload FIFO becomes empty and corrupted data is sent during Generic Interface packet build. (RO)

DSI_HOST_GEN_PLD_RD_ERR Represents that payload FIFO becomes empty and the data sent to the interface is corrupted during a DCS read data. (RO)

DSI_HOST_GEN_PLD_RECEV_ERR Represents the payload FIFO becomes full and the received data is corrupted during a Generic Interface packet read back. (RO)

DSI_HOST_DPI_BUFF_PLD_UNDER Represents an underflow has occued when reading payload to build DSI packet for video mode. (RO)

Register 43.100. DSI_HOST_INT_MSK0_REG (0x00C4)

DSI_HOST_MASK_ACK_WITH_ERR_0 Controls the mask for ACK_WITH_ERR_0. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_1 Controls the mask for ACK_WITH_ERR_1. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_2 Controls the mask for ACK_WITH_ERR_2. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_3 Controls the mask for ACK_WITH_ERR_3. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_4 Controls the mask for ACK_WITH_ERR_4. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_5 Controls the mask for ACK_WITH_ERR_5. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_6 Controls the mask for ACK_WITH_ERR_6. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_7 Controls the mask for ACK_WITH_ERR_7. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_8 Controls the mask for ACK_WITH_ERR_8. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_9 Controls the mask for ACK_WITH_ERR_9. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_10 Controls the mask for ACK_WITH_ERR_10. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_11 Controls the mask for ACK_WITH_ERR_11. (R/W)

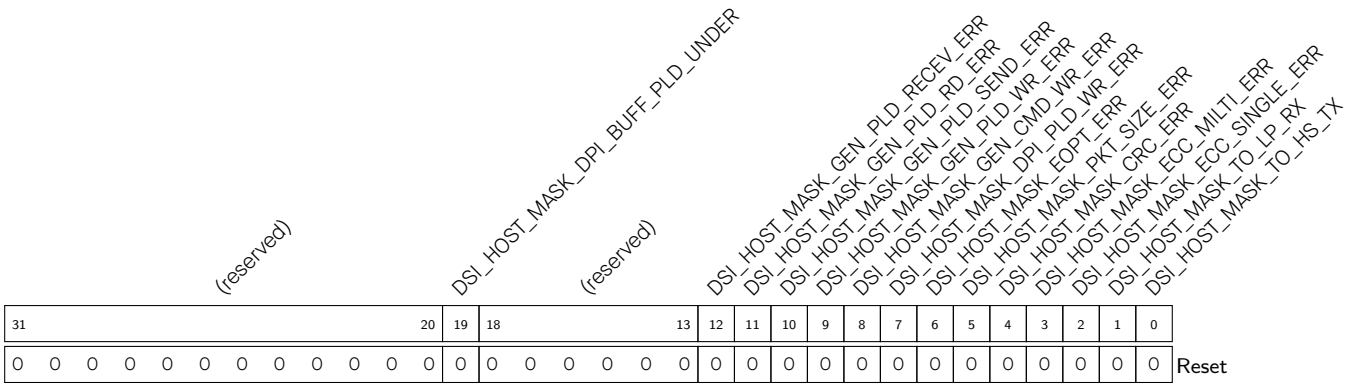
DSI_HOST_MASK_ACK_WITH_ERR_12 Controls the mask for ACK_WITH_ERR_12. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_13 Controls the mask for ACK_WITH_ERR_13. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_14 Controls the mask for ACK_WITH_ERR_14. (R/W)

DSI_HOST_MASK_ACK_WITH_ERR_15 Controls the mask for ACK_WITH_ERR_15. (R/W)

DSI_HOST_MASK_DPHY_ERRORS_0 Controls the mask for DPHY_ERRORS_0. (R/W)



DSI_HOST_MASK_DPHY_ERRORS_1 Controls the mask for DPHY_ERRORS_1. (R/W)

DSI_HOST_MASK_DPHY_ERRORS_2 Controls the mask for DPHY_ERRORS_2. (R/W)

DSI_HOST_MASK_DPHY_ERRORS_3 Controls the mask for DPHY_ERRORS_3. (R/W)

DSI_HOST_MASK_DPHY_ERRORS_4 Controls the mask for DPHY_ERRORS_4. (R/W)

Register 43.101. DSI_HOST_INT_MSK1_REG (0x00C8)

DSI_HOST_MASK_TO_HS_TX Controls the mask for TO_HS_TX. (R/W)

DSI_HOST_MASK_TO_LP_RX Controls the mask for TO_LP_RX. (R/W)

DSI_HOST_MASK_ECC_SINGLE_ERR Controls the mask for ECC_SINGLE_ERR. (R/W)

DSI_HOST_MASK_ECC_MILTI_ERR Controls the mask for ECC_MULTI_ERR. (R/W)

DSI_HOST_MASK_CRC_ERR Controls the mask for CRC_ERR. (R/W)

DSI_HOST_MASK_PKT_SIZE_ERR Controls the mask for PKT_SIZE_ERR. (R/W)

DSI_HOST_MASK_EOPT_ERR Controls the mask for EOPT_ERR. (R/W)

DSI_HOST_MASK_DPI_PLD_WR_ERR Controls the mask for DPI_PLD_WR_ERR. (R/W)

DSI_HOST_MASK_GEN_CMD_WR_ERR Controls the mask for GEN_CMD_WR_ERR. (R/W)

DSI_HOST_MASK_GEN_PLD_WR_ERR Controls the mask for GEN_PLD_WR_ERR. (R/W)

DSI_HOST_MASK_GEN_PLD_SEND_ERR Controls the mask for GEN_PLD_SEND_ERR. (R/W)

DSI_HOST_MASK_GEN_PLD_RD_ERR Controls the mask for GEN_PLD_RD_ERR. (R/W)

DSI_HOST_MASK_GEN_PLD_RECEV_ERR Controls the mask for GEN_PLD_RECEV_ERR. (R/W)

DSI_HOST_MASK_DPI_BUFF_PLD_UNDER Controls the mask for DPI_BUFF_PLD_UNDER. (R/W)

Chapter 44

Voice Activity Detection (VAD)

44.1 Introduction

ESP32-P4 integrates a Voice Activity Detection (VAD) module. This module facilitates the hardware implementation of the first-stage algorithm for voice wake-up and other multimedia functions. Additionally, it provides hardware support for low-power voice wake-up solutions.

44.2 Feature List

The VAD module has the following features:

- VAD algorithm processes voice data frame by frame, with each frame containing 256 data points. The data sampling rate is 8 kHz, and the bit width is 16 bits
- 2 KB buffer that stores up to 4 frames of data
- Independent system wake-up source
- Configurable interrupt sources
- Flexible configuration of algorithm parameters

44.3 Architectural Overview

Figure 44.3-1 is the block diagram of the ESP32-P4 VAD module. The VAD module includes:

- Energy threshold check
- FFT (Fast Fourier Transform) calculation
- LTSD (Long-Term Spectral Divergence) calculation

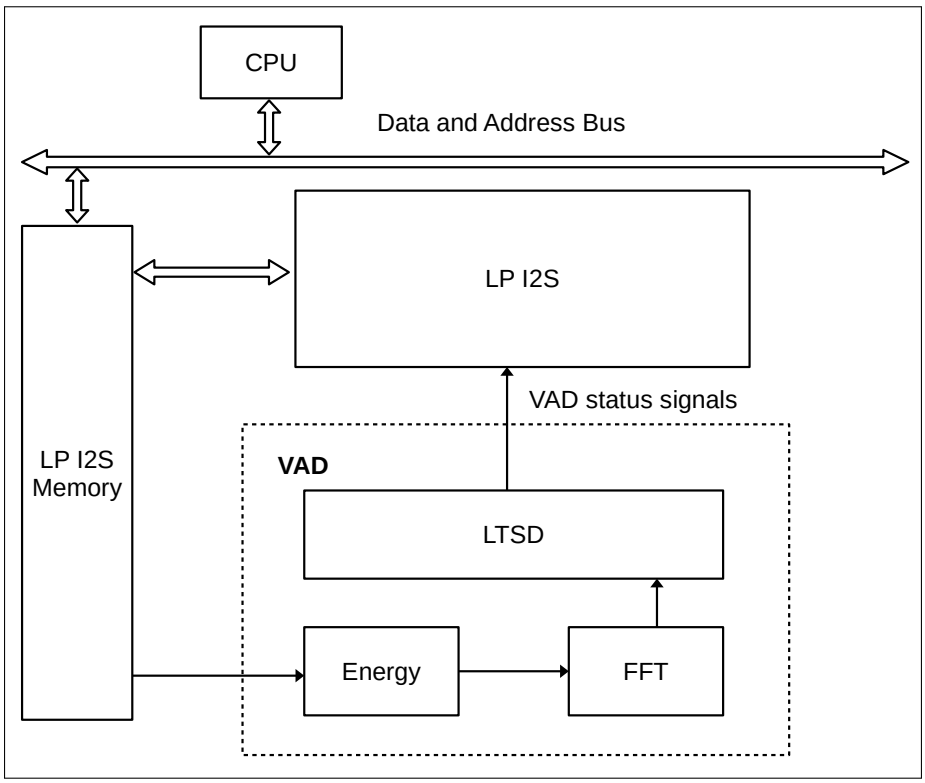


Figure 44.3-1. ESP32-P4 VAD Architecture

The VAD module reads 8 kHz, 16-bit wide audio data from LP I2S memory. It processes the data through three stages: energy detection, FFT, and LTSD. Then the module detects the voice activity status and sends the VAD status signal to the LP I2S module, which is used to generate the corresponding interrupt and wake-up signal.

44.4 Functional Description

The ESP32-P4's VAD module offers flexible and configurable functionality. Users can adjust algorithm parameters and wake-up sources to meet their specific needs.

44.4.1 Algorithm Parameter Configuration

Number of Initial Frames

When the VAD module starts running, it first enters an initialization phase before normal operation. During this phase, it automatically learns noise parameters. The duration of the initialization phase depends on the number of initial frames configured by the user. Proper setting of initial frames can effectively suppress noise and significantly reduce false positives. However, if the initialization phase is extended over too many frames, voice activity within these frames may be missed. Therefore, please configure an appropriate number of initial frames based on actual conditions.

It is recommended to place the device in the target environment noise during the initialization, and set the number of initial frames to 100-200 frames.

Users can configure the number of initial frames via LP_I2S_PARAM_INIT_FRAME_NUM.

Note:
It is recommended to let the VAD module learn noise parameters during the initialization. However, the VAD module will also continuously learn and update noise parameters during normal operation. Therefore, in scenarios where the false positive rate during initial frames is not a concern, the number of initial frames can be reduced, allowing the VAD module to enter the normal operation more quickly.

Energy Threshold

The VAD module sets an energy threshold before the voice activity detection. Setting the threshold can filter out low-energy voice activities (e.g., distant voices) from triggering a wake-up. Appropriate energy threshold setting can effectively reduce false positives and conserve power.

It defines the energy value of a speech frame as the mean square of one-frame data. The VAD module calculates the sum of squares of one-frame data in real-time. If this sum is less than the energy threshold multiplied by 256, subsequent calculations will not be performed. Users can configure the energy threshold via LP_I2S_PARAM_MIN_ENERGY.

Band Energy Check

The band energy check assesses the proportion of band energy within the overall frequency spectrum. Enabling the band energy check in varying environments can help reduce false positives; however, it may also reduce true positives. Users should determine whether to enable or disable the band energy check based on the environment.

Users can enable or disable the band energy check via LP_I2S_PARAM_SKIP_BAND_ENERGY.

- 0: Enable band energy check
- 1: Disable band energy check

Voice Activity Detection

The VAD module has two voice activity status: voice activity status and non-voice activity status, managed by voice frame counter speech_count and non-voice frame counter silent_count. These counters control transitions between the status as follows:

- **Non-voice activity status:**
  - When voice activities are detected in the current frame, the count value of speech_count increases by 1.
  - When voice activities are not detected in the current frame, the count value of speech_count decreases by 1 (down to a minimum of 0).
  - If the count value of speech_count is greater than LP_I2S_PARAM_HANGOVER_SPEECH, the VAD module enters the voice activity status and resets silent_count to 0.
  - Under the non-voice activity status, the VAD module continuously learns and updates noise information.
- **Voice activity status:**
  - When voice activities are detected in the current frame, the count value of speech_count increases by 1, and the count value of silent_count decreases by 1 (down to a minimum of 0).

- When voice activities are not detected in the current frame, the count value of silent_count increases by 1:
  - If the count value of speech_count is greater than LP_I2S_PARAM_MIN_SPEECH_COUNT, and
    - The count value of silent_count is greater than LP_I2S_PARAM_HANGOVER_SILENT, the VAD module transitions to the non-voice activity status and resets both speech_count and silent_count to 0;
    - The count value of silent_count is less than LP_I2S_PARAM_HANGOVER_SILENT, the VAD module maintains the voice activity status.
  - If the count value of speech_count is less than or equal to LP_I2S_PARAM_MIN_SPEECH_COUNT, the VAD module transitions directly to the non-voice activity status and resets speech_count to 0.
- Under the voice activity status, the VAD module pauses updating noise information. When the count value of speech_count exceeds LP_I2S_PARAM_MAX_SPEECH_COUNT, indicating stability in the new environment, it resumes learning and updating noise information.

Status Registers

The VAD module provides several key operational variables as status registers (read-only) to facilitate user debugging. The status registers include:

- LP_I2S_VAD_FLAG: Represents the current voice activity detection status. 1 represents the VAD module is in the voice activity status, while 0 represents it is in the non-voice activity status.
- LP_I2S_ENERGY_ENOUGH: Represents whether the current frame passes the energy threshold check. 1 represents the current frame passes the energy threshold check, while 0 represents not pass.
- LP_I2S_SPEECH_COUNT_OB: Represents the count value of the voice frame counter, speech_count.
- LP_I2S_SILENT_COUNT_OB: Represents the count value of the non-voice frame counter, silent_count.

44.4.2 Wake-up Source Configuration

When the VAD module is in the voice activity status, it triggers the wake-up source LP_I2S_WAKEUP. Users can configure the wake-up source (please refer to Chapter 50 *LP I2S Controller*), enabling the VAD to become one of the wake-up sources for ESP32-P4.

44.5 Interrupts

ESP32-P4's VAD module shares the same interrupt signal LP_I2S_INTR with the LP I2S module. The following interrupt sources can generate the interrupt signal:

- LP_I2S_VAD_DONE_INT: Triggered when the VAD completes processing one frame of data.
- LP_I2S_VAD_RESET_DONE_INT: Triggered when the VAD is reset.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 44.7 *Register Summary*.

44.6 Programming Procedure

44.6.1 Automatic Operation Mode

1. Configure the VAD parameters as described in Section 44.4.1.
2. Enable the VAD automatic detection mode by writing 1 to LP_I2S_VAD_EN.
3. Configure the LP I2S to operate in 16-bit receive mode and start receiving data in 16-bit format. The received data will be stored in the LP I2S memory.
4. The VAD module will automatically perform operations on each frame of data after the LP I2S receives the complete frame.
5. (Optional) When the VAD module triggers a wake-up source/interrupt signal, the LP I2S memory already contains the voice frame that triggered the VAD wake-up, along with the previous three voice frames. Users can read these four frames of voice data from the LP I2S memory via the LP core for subsequent processing. For details on the size of the LP I2S memory and data reading methods, please refer to Chapter 50 *LP I2S Controller* > Section 50.8.3 *Internal Memory*.

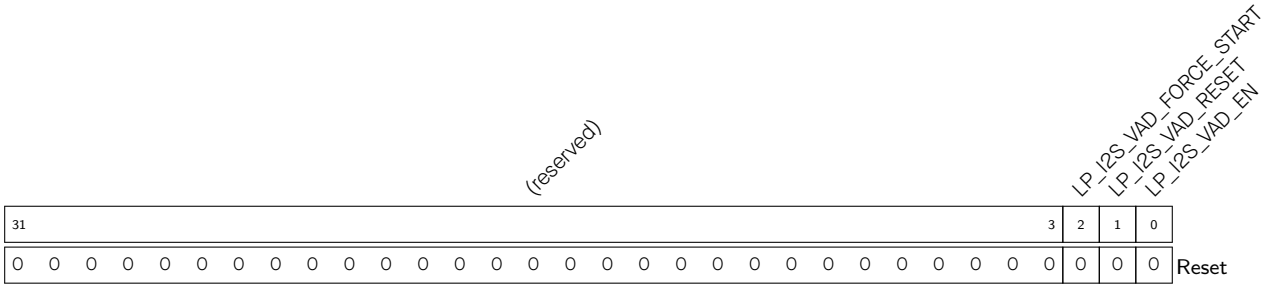
44.6.2 Manual Operation Mode

1. Configure the VAD parameters as described in Section 44.4.1.
2. Manually store the voice data in the LP I2S memory. For details, refer to Chapter 50 *LP I2S Controller* > Section 50.8.3 *Internal Memory*.
3. With all the voice data stored in the memory, write 1 to LP_I2S_VAD_FORCE_START, then the VAD will perform operations on one frame of data.
4. When the VAD module completes processing one frame of data, LP_I2S_VAD_DONE_INT interrupt will be generated.

44.7 Register Summary

The addresses in this section are relative to VAD base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.



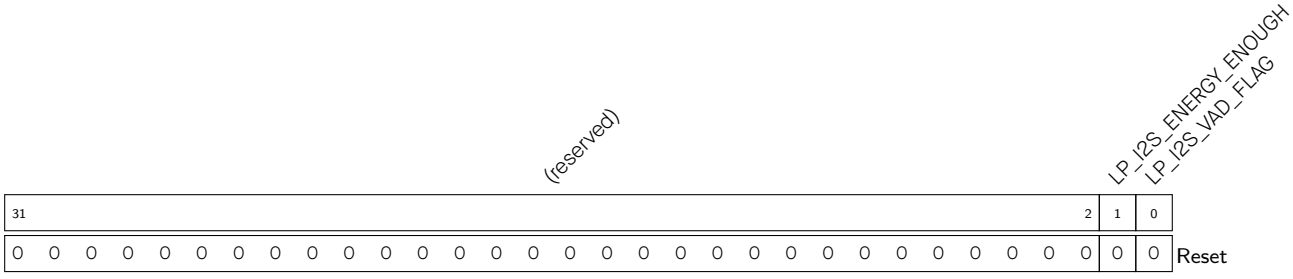
Name	Description	Address	Access
VAD Registers			
LP_I2S_VAD_CONF_REG	Operation control register	0x0000	varies
LP_I2S_VAD_RESULT_REG	Voice activity status register	0x0004	RO
LP_I2S_VAD_PARAM0_REG	Parameter configuration register 0	0x0080	R/W
LP_I2S_VAD_PARAM1_REG	Parameter configuration register 1	0x0084	R/W
LP_I2S_VAD_OBO_REG	Status register for key operational variables	0x00B0	RO

44.8 Registers

The addresses in this section are relative to VAD base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

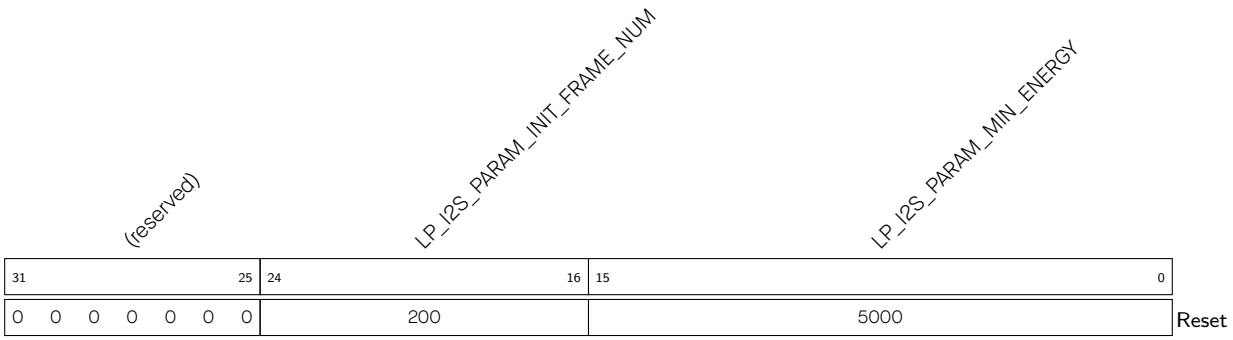
Register 44.1. LP_I2S_VAD_CONF_REG (0x0000)



LP_I2S_VAD_EN Configures whether to enable the automatic operation mode.
0: Disable
1: Enable
(R/W)

LP_I2S_VAD_RESET Configures whether to reset the VAD module.
0: Not reset
1: Reset
(WT)

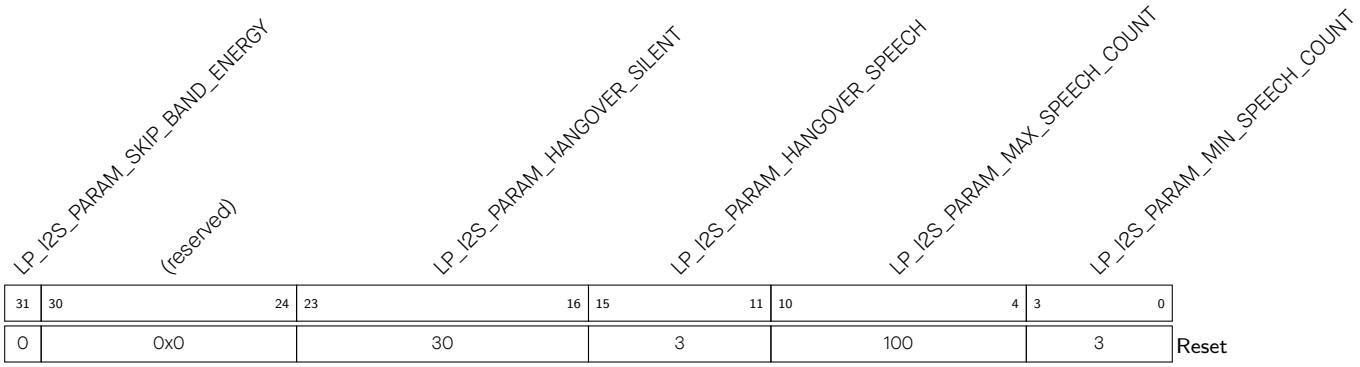
LP_I2S_VAD_FORCE_START Configures whether to trigger the manual operation on one frame of data.
0: Not trigger
1: Trigger
(WT)



Register 44.2. LP_I2S_VAD_RESULT_REG (0x0004)

LP_I2S_VAD_FLAG Represents the voice activity status. For details, see Section 44.4.1. (RO)

LP_I2S_ENERGY_ENOUGH Represents whether the current frame passes the energy threshold check. For details, see Section 44.4.1. (RO)



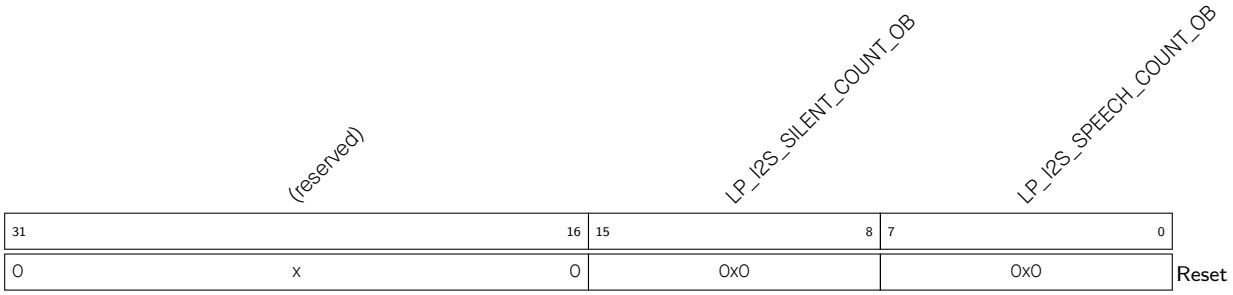
Register 44.3. LP_I2S_VAD_PARAM0_REG (0x0080)

LP_I2S_PARAM_MIN_ENERGY Configures the energy threshold. For details, see Section 44.4.1. (R/W)

LP_I2S_PARAM_INIT_FRAME_NUM Configures the number of initial frames. For details, see Section 44.4.1. (R/W)

Register 44.4. LP_I2S_VAD_PARAM1_REG (0x0084)

LP_I2S_PARAM_MIN_SPEECH_COUNT Configures the transition between voice activity status. For details, see Section 44.4.1. (R/W)



LP_I2S_PARAM_MAX_SPEECH_COUNT Configures the transition between voice activity status. For details, see Section 44.4.1. (R/W)

LP_I2S_PARAM_HANGOVER_SPEECH Configures the transition between voice activity status. For details, see Section 44.4.1. (R/W)

LP_I2S_PARAM_HANGOVER_SILENT Configures the transition between voice activity status. For details, see Section 44.4.1. (R/W)

LP_I2S_PARAM_SKIP_BAND_ENERGY Configures the transition between voice activity status. For details, see Section 44.4.1. (R/W)

Register 44.5. LP_I2S_VAD_OB0_REG (0x00B0)

LP_I2S_SPEECH_COUNT_OB Represents the count value of the voice frame counter, speech_count. For details, see Section 44.4.1. (RO)

LP_I2S_SILENT_COUNT_OB Represents the count value of the non-voice frame counter, silent_count. For details, see Section 44.4.1. (RO)

Part VII

Connectivity Interface

This part addresses the connectivity aspects of the system, describing components related to various communication interfaces like I2C, I2S, SPI, UART, USB, and more. The part also covers interfaces to generate signals used in remote control, motor control, LED control, etc.

Chapter 45

UART Controller (UART)

45.1 Overview

A UART is a character-oriented data link for asynchronous communication between devices. Such communication does not add clock signals to the data sent. Therefore, in order to communicate successfully, the transmitter and the receiver must operate at the same baud rate with the same stop bit(s) and parity bit(s).

A UART data frame usually begins with one start bit, followed by data bits, one parity bit (optional), and one or more stop bits. UART controllers on ESP32-P4 support various lengths of data bits and stop bits. These controllers also support software and hardware flow control as well as GDMA for high-speed data transfer. This allows developers to use multiple UART ports at minimal software cost.

ESP32-P4 has six UART controllers, including five regular UARTs and one low-power (LP) UART. These UARTs are compatible with various UART devices, and support Infrared Data Association (IrDA) and RS485 communication. In this chapter, the five regular UART controllers are referred to as UART*n*, in which *n* denotes 0, 1, 2, 3, or 4. LP UART is the cut-down version of the regular UART, with a separate group of registers. For differences between UART and LP UART, please refer to Table 45.2-1.

45.2 Features

Table 45.2-1 lists the feature comparison between UART and LP UART:

Table 45.2-1. UART and LP UART Feature Comparison

UART Feature	LP UART Feature
Programmable baud rate up to 5 MBaud	
128 x 8 bit RAM respectively for the TX channel and RX channel of a UART controller	20 x 8-bit RAM, shared by the TX FIFO and RX FIFO of LP UART
Full-duplex asynchronous communication	
Data bits (5 to 8 bits)	
Stop bits (1, 1.5, or 2 bits)	
Parity bit	
Special character AT_CMD detection	
RS485 protocol	—
IrDA protocol	—

Three prescalable clock sources: 1. XTAL_CLK 2. RC_FAST_CLK 3. PLL_F80M_CLK	Three prescalable clock sources 1. RC_FAST_CLK 2. XTAL_DIV_CLK 3. PLL_F8M_CLK

The following description mainly covers regular UART controllers.

45.3 UART Structure

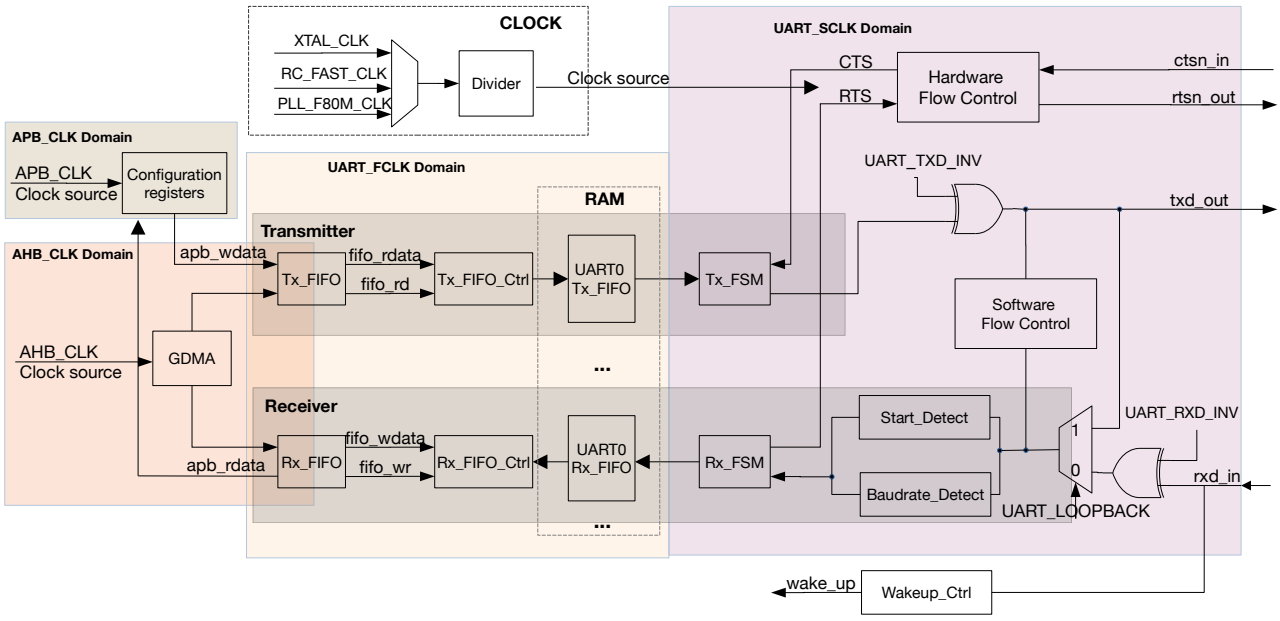

Figure 45.3-1. UART Structure

Figure 45.3-1 shows the basic structure of a UART controller. A UART controller works in four clock domains, namely APB_CLK, AHB_CLK, UART_SCLK, and UART_FCLK. APB_CLK and AHB_CLK are synchronized but with different frequencies (APB_CLK is derived from AHB_CLK by division), and likewise UART_SCLK and UART_FCLK are synchronized but with different frequencies (UART_SCLK is derived from UART_FCLK by division). UART_FCLK has three clock sources: PLL_F80M_CLK, RC_FAST_CLK, and crystal clock XTAL_CLK (for details, please refer to Chapter 11 *Reset and Clock*), which are selected by configuring HP_SYS_UART*n*_CLK_SRC_SEL. The selected clock source is divided by a divider to generate UART_SCLK clock signals. The divisor is configured by HP_SYS_CLKRST_UART*n*_SCLK_DIV_NUM for the integral part, HP_SYS_CLKRST_UART*n*_SCLK_DIV_DENOMINATOR for the denominator of the fractional part, and HP_SYS_CLKRST_UART*n*_SCLK_DIV_NUMERATOR for the numerator of the fractional part. The divisor ranges from 1 ~ 256. Only regular UART has such a divider; LP UART does not.

A UART controller can be broken down into two parts based on functions: a transmitter and a receiver.

The transmitter contains a TX FIFO (i.e., Tx_FIFO in Figure 45.3-1), which buffers data to be sent. Software can write data to Tx_FIFO via the APB bus, or move data to Tx_FIFO using GDMA. Tx_FIFO_Ctrl controls writing and reading Tx_FIFO. When Tx_FIFO is not empty, Tx_FSM reads data bits in the data frame via Tx_FIFO_Ctrl, and converts them into a bitstream. The levels of output bitstream signal txd_out can be inverted by configuring the UART_TXD_INV field.

The receiver contains an RX FIFO (i.e., Rx_FIFO in Figure 45.3-1), which buffers data to be processed. The input bitstream signal rxd_in is transferred to the UART controller, and its level can be inverted by configuring UART_RXD_INV field. Baudrate_Detect measures the baud rate of input bitstream signal rxd_in by detecting its minimum pulse width. Start_Detect detects the start bit in a data frame. If the start bit is detected, Rx_FSM stores data bits in the data frame into Rx_FIFO by Rx_FIFO_Ctrl. Software can read data from Rx_FIFO via the APB bus, or receive data using GDMA.

HW_Flow_Ctrl controls rxd_in and txd_out data flows by standard UART RTS and CTS flow control signals (rtsn_out and ctsn_in). SW_Flow_Ctrl controls data flows by adding special characters to outgoing data and detecting special characters in incoming data. When a UART controller is in Light-sleep mode (see Chapter 15 *Low-Power Management* for more details), a wake_up signal can be generated in four ways and sent to RTC, which then wakes up the ESP32-P4 chip. For more information about wakeup, please refer to Section 45.4.8.

45.4 Functional Description

45.4.1 Clock and Reset

UART controllers are asynchronous. Their register configuration module works in the APB_CLK domain. TX FIFO and RX FIFO work across the AHB_CLK and UART_FCLK domains. The UART RAM control unit works in the UART_FCLK domain. The UART transmission and reception control module works in the UART_SCLK domain, i.e., UART Core's clock domain.

When the frequency of the UART_SCLK is higher than the frequency needed to generate the baud rate, the UART Core can be clocked at a lower frequency by the divider, in order to reduce power consumption. Usually, the UART Core's clock frequency is lower than the APB_CLK's frequency, and can be divided by the largest divisor when higher than the frequency needed to generate the baud rate. The frequency of the UART Core's clock can also be at most twice higher than the APB_CLK. The clock for the UART transmitter and the UART receiver can be controlled independently. To enable the clock for the UART transmitter, UART_TX_SCLK_EN shall be set; to enable the clock for the UART receiver, UART_RX_SCLK_EN shall be set.

To ensure that the configured register values are synchronized from APB_CLK domain to the UART_SCLK domain, please follow the procedures in Section45.5.

To reset the whole UART, please:

- Enable the UART Core's clock by setting HP_SYS_CLKRST_UART*n*_CLK_EN to 1.
- Write 1 to HP_SYS_CLKRST_RST_EN_UART*n*_CORE.
- Clear HP_SYS_CLKRST_RST_EN_UART*n*_CORE to 0.

45.4.2 UART FIFO

The transmitter and the receiver on the UART controller each use a 128 x 8-bit RAM, and access their respective RAM through a separate 4 x 8-bit asynchronous FIFO interface. The RAM and asynchronous FIFO interface for the transmitter and the receiver are independent and cannot be shared.

UART Tx_FIFO is reset by setting UART_TXFIFO_RST. UART Rx_FIFO is reset by setting UART_RXFIFO_RST.

Data to be sent is written to TX FIFO via the APB bus or using GDMA, read automatically, and converted from a frame into a bitstream by hardware Tx_FSM. Data received is converted from a bitstream into a frame by hardware Rx_FSM, written into RX FIFO, and then stored into RAM via the APB bus or using GDMA. The five UART controllers share one GDMA channel.

The empty signal threshold for Tx_FIFO is configured by setting UART_TXFIFO_EMPTY_THRHD. When data stored in Tx_FIFO is less than UART_TXFIFO_EMPTY_THRHD, a UART_TXFIFO_EMPTY_INT interrupt is generated. The full signal threshold for Rx_FIFO is configured by setting UART_RXFIFO_FULL_THRHD. When data stored in Rx_FIFO is greater than or equal to UART_RXFIFO_FULL_THRHD, a UART_RXFIFO_FULL_INT interrupt is generated. In addition, when Rx_FIFO receives more data than its capacity, a UART_RXFIFO_OVF_INT interrupt is generated.

UART*n* can access FIFO via register UART_FIFO_REG. You can put data into TX FIFO by writing UART_RXFIFO_RD_BYTE, and get data in RX FIFO by reading UART_RXFIFO_RD_BYTE.

45.4.3 Baud Rate Generation and Detection

45.4.3.1 Baud Rate Generation

Before a UART controller sends or receives data, the baud rate should be configured by setting corresponding registers. The baud rate generator of a UART controller functions by dividing the input clock source. It can divide the clock source by a fractional amount. The divisor is configured by UART_CLKDIV_SYNC_REG: UART_CLKDIV for the integral part, and UART_CLKDIV_FRAG for the fractional part. When using the 80 MHz input clock, the UART controller supports a maximum baud rate of 5 MBaud.

The divisor of the baud rate divider is equal to

$$UART_CLKDIV + \frac{UART_CLKDIV_FRAG}{16}$$

meaning that the final baud rate is equal to

$$\frac{INPUT_FREQ}{UART_CLKDIV + \frac{UART_CLKDIV_FRAG}{16}}$$

where INPUT_FREQ is the frequency of UART Core's source clock. For example, if UART_CLKDIV = 694 and UART_CLKDIV_FRAG = 7, then the divisor value is

$$694 + \frac{7}{16} = 694.4375$$

When UART_CLKDIV_FRAG is 0, the baud rate generator is an integer clock divider where an output pulse is generated every UART_CLKDIV input pulses.

When UART_CLKDIV_FRAG is not 0, the divider is fractional and the output baud rate clock pulses are not strictly uniform. As shown in Figure 45.4-1, for every 16 output pulses, the generator divides either

(UART_CLKDIV + 1) input pulses or UART_CLKDIV input pulses per output pulse. A total of UART_CLKDIV_FRAG output pulses are generated by dividing (UART_CLKDIV + 1) input pulses, and the remaining (16 - UART_CLKDIV_FRAG) output pulses are generated by dividing UART_CLKDIV input pulses.

The output pulses are interleaved as shown in Figure 45.4-1 below, to make the output timing more uniform:

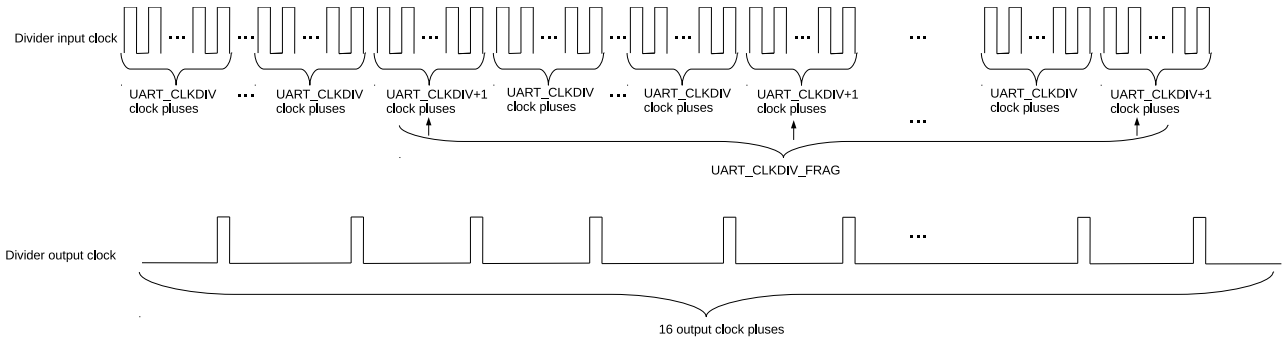

Figure 45.4-1. UART Controllers Division

To support IrDA (see Section 45.4.7 for details), the fractional clock divider for IrDA data transmission generates clock signals divided by 16 × UART_CLKDIV_SYNC_REG. This divider works similarly as the one elaborated above: it takes UART_CLKDIV/16 as the integer value and the lowest four bits of UART_CLKDIV as the fractional value.

45.4.3.2 Baud Rate Detection

Automatic baud rate detection (Autobaud) on UARTs is enabled by setting UART_AUTOBAUD_EN. The Baudrate_Detect module shown in Figure 45.4-2 filters any noise whose pulse width is shorter than UART_GLITCH_FILT.

Before communication starts, the transmitter could send random data to the receiver for baud rate detection. UART_LOWPULSE_MIN_CNT stores the minimum low pulse width, UART_HIGHPULSE_MIN_CNT stores the minimum high pulse width, UART_POSEDGE_MIN_CNT stores the minimum pulse width between two positive edges, and UART_NEGEDGE_MIN_CNT stores the minimum pulse width between two negative edges. These four fields are read by software to determine the transmitter's baud rate.

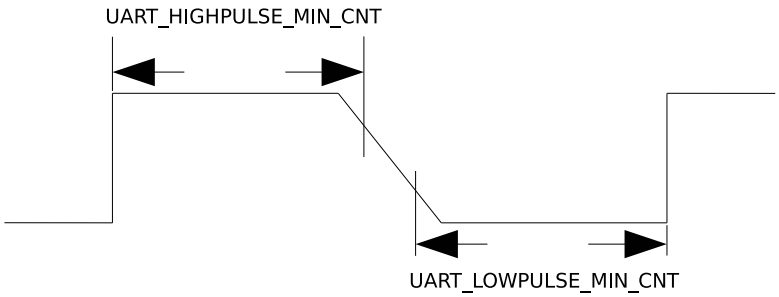

Figure 45.4-2. The Timing Diagram of Weak UART Signals Along Negative Edges

The baud rate can be determined in the following three ways:

1. Normally, to avoid sampling erroneous data along positive or negative edges in a metastable state, which results in the inaccuracy of UART_LOWPULSE_MIN_CNT or UART_HIGHPULSE_MIN_CNT, use a

weighted average of these two values to eliminate errors for 1-bit pulses. In this case, the baud rate is calculated as follows:

$$B_{uart} = \frac{f_{clk}}{(UART_LOWPULSE_MIN_CNT + UART_HIGHPULSE_MIN_CNT + 2)/2}$$

2. If UART signals are weak along negative edges as shown in Figure 45.4-2, which leads to an inaccurate average of UART_LOWPULSE_MIN_CNT and UART_HIGHPULSE_MIN_CNT, use UART_POSEDGE_MIN_CNT to determine the transmitter's baud rate as follows:

$$B_{uart} = \frac{f_{clk}}{(UART_POSEDGE_MIN_CNT + 1)/2}$$

3. If UART signals are weak along positive edges, use UART_NEGEDGE_MIN_CNT to determine the transmitter's baud rate as follows:

$$B_{uart} = \frac{f_{clk}}{(UART_NEGEDGE_MIN_CNT + 1)/2}$$

45.4.4 UART Data Frame

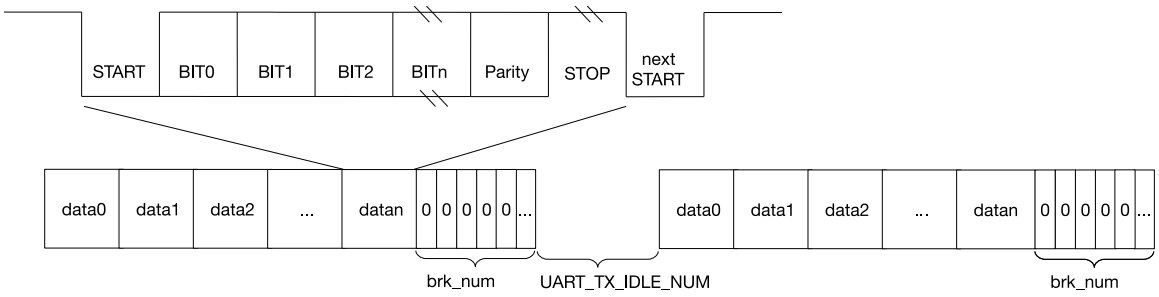

Figure 45.4-3. Structure of UART Data Frame

Figure 45.4-3 shows the basic structure of a data frame. A frame starts with one start bit, and ends with stop bits which can be 1, 1.5, or 2 bit-long, configured by UART_STOP_BIT_NUM (in RS485 mode turnaround delay may be added. See details in Section 45.4.6.2). The start bit is logical low, whereas stop bits are logical high.

The actual data length can be anywhere between 5 ~ 8 bit, configured by UART_BIT_NUM. When UART_PARITY_EN is set, a parity bit is added after data bits. UART_PARITY is used to choose even parity or odd parity. When the receiver detects a parity bit error in the data received, a UART_PARITY_ERR_INT interrupt is generated, and the data received will still be stored into RX FIFO. When the receiver detects a data frame error, a UART_FRM_ERR_INT interrupt is generated, and the data received by default is stored into RX FIFO.

If all data in Tx_FIFO has been sent, a UART_TX_DONE_INT interrupt is generated. After this, if the UART_TXD_BRK bit is set, then the transmitter will enter the break condition and send several NULL characters in which the TX data line is logical low. The number of NULL characters is configured by UART_TX_BRK_NUM. Once the transmitter has sent all NULL characters, a UART_TX_BRK_DONE_INT interrupt is generated. The minimum interval between data frames can be configured using UART_TX_IDLE_NUM. If the transmitter stays idle for UART_TX_IDLE_NUM or more time, a UART_TX_BRK_IDLE_DONE_INT interrupt is generated.

The receiver can also detect the Break conditions when the RX data line detects any low logical level for one NULL character transmission, and a UART_BRK_DET_INT interrupt will be triggered to detect when a break condition has been completed.

The receiver can detect the current bus state through the timeout interrupt UART_RXFIFO_TOUT_INT. The UART_RXFIFO_TOUT_INT interrupt will be triggered when the bus is in the idle state for more than UART_RX_TOUT_THRHD bit time on current baud rate after the receiver has received at least one byte. You can use this interrupt to detect whether all the data from the transmitter has been sent.

45.4.5 AT_CMD Character Structure

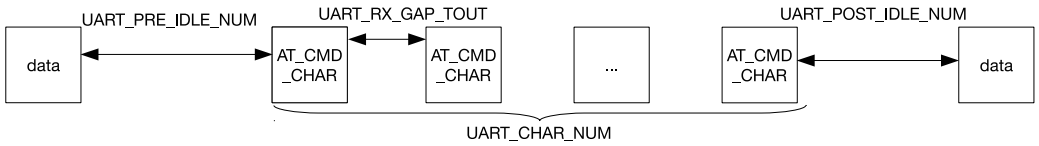

Figure 45.4-4. AT_CMD Character Structure

Figure 45.4-4 is the structure of a special character AT_CMD. If the receiver constantly receives AT_CMD_CHAR and the following conditions are met, a UART_AT_CMD_CHAR_DET_INT interrupt is generated.

- The interval between the first AT_CMD_CHAR and the last non-AT_CMD_CHAR character is at least UART_PRE_IDLE_NUM cycles.
- The interval between two AT_CMD_CHAR characters is less than UART_RX_GAP_TOUT in the unit of baud rate cycles.
- The number of AT_CMD_CHAR characters is equal to or greater than UART_CHAR_NUM.
- The interval between the last AT_CMD_CHAR character and next non-AT_CMD_CHAR character is at least UART_POST_IDLE_NUM cycles.

Note: Given that the interval between AT_CMD_CHAR characters is less than UART_RX_GAP_TOUT in the unit of baud rate cycles, the APB_CLK frequency is suggested not to be lower than 8 MHz.

45.4.6 RS485

The five regular UART controllers support RS485 communication mode. In this mode differential signals are used to transmit data, so it can communicate over longer distances at higher bit rates than RS232. RS485 has two-wire half-duplex and four-wire full-duplex options. UART controllers support two-wire half-duplex transmission and bus snooping.

45.4.6.1 Driver Control

As shown in Figure 45.4-5, in a two-wire multidrop network, an external RS485 transceiver is needed for differential to single-ended conversion or the other way around. An RS485 transceiver contains a driver and a receiver. When a UART controller is not in transmitter mode, the connection to the differential line can be broken by disabling the driver. When DE is 1, the driver is enabled; when DE is 0, the driver is disabled.

The UART receiver converts differential signals to single-ended signals via an external receiver. RE is the enable control signal for the receiver. When RE is 0, the receiver is enabled; when RE is 1, the receiver is disabled. If RE is configured as 0, the UART controller is allowed to snoop data on the bus, including the data sent by itself.

DE can be controlled by either software or hardware. To reduce the cost of software, in our design DE is controlled by hardware. As shown in Figure 45.4-5, DE is connected to dtrn_out of UART (please refer to Section 45.4.9.1 for more details).

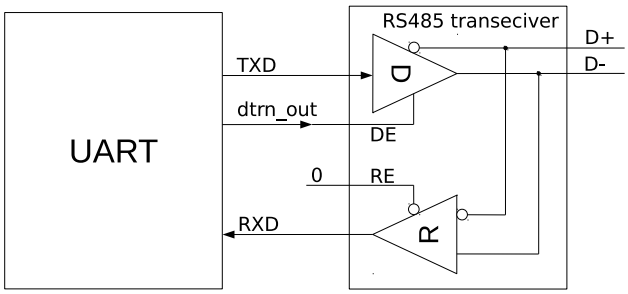

Figure 45.4-5. Driver Control Diagram in RS485 Mode

45.4.6.2 Turnaround Delay

By default, the UART controllers work in receiver mode. When a UART controller is switched from transmitter mode to receiver mode, the RS485 protocol requires a turnaround delay of one cycle after the stop bit. The UART transmitter supports adding a turnaround delay of one cycle before the start bit or after the stop bit. When UART_DL0_EN is set, a turnaround delay of one cycle is added before the start bit; when UART_DL1_EN is set, a turnaround delay of one cycle is added after the stop bit.

45.4.6.3 Bus Snooping

In a two-wire multidrop network, UART controllers support bus snooping if RE of the external RS485 transceiver is 0. By default, a UART controller is not allowed to transmit and receive data simultaneously. If UART_RS485TX_RX_EN is set and the external RS485 transceiver is configured as in Figure 45.4-5, a UART controller may receive data in transmitter mode and snoop the bus. If UART_RS485RXBY_TX_EN is set, a UART controller may transmit data in receiver mode.

The two UART controllers can snoop the data sent by themselves. In transmitter mode, when a UART controller monitors a collision between the data sent and the data received, a UART_RS485_CLASH_INT is generated; when a UART controller monitors a data frame error, a UART_RS485_FRM_ERR_INT interrupt is generated; when a UART controller monitors a parity bit error, a UART_RS485_PARITY_ERR_INT is generated.

45.4.7 IrDA

IrDA protocol consists of three layers, namely the physical layer, the link access protocol, and the link management protocol. The UART controllers implement IrDA's physical layer. In IrDA encoding, a UART controller supports data rates up to 115.2 kbit/s (SIR, or serial infrared mode). As shown in Figure 45.4-6, the IrDA encoder converts a non-return to zero code (NRZ) signal to a return to zero inverted code (RZI) signal and sends it to the external driver and infrared LED. This encoder uses modulated signals whose pulse width is 3/16 bits to indicate logic "0", and low levels to indicate logic "1". The IrDA decoder receives signals from the infrared receiver and converts them to NRZ signals. In most cases, the receiver is high when it is idle, and the parity bit of the encoder output is opposite to that of the decoder input. If a low pulse is detected, it indicates that a start bit has been received.

When IrDA function is enabled, one bit is divided into 16 clock cycles. If the bit to be sent is zero, then the 9th, 10th, and 11th clock cycle are high.

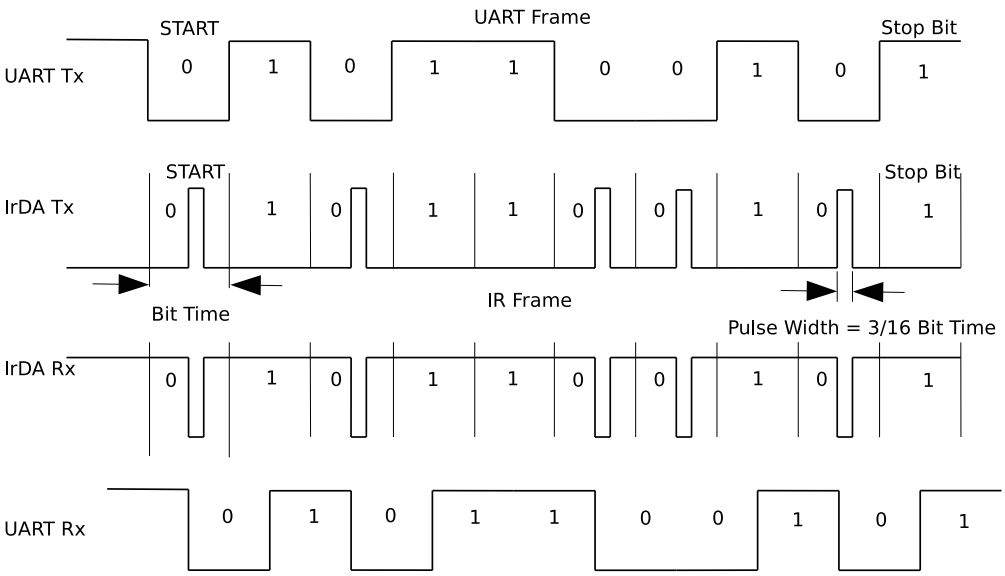

Figure 45.4-6. The Timing Diagram of Encoding and Decoding in SIR mode

The IrDA transceiver is half-duplex, meaning that it cannot send and receive data simultaneously. As shown in Figure 45.4-7, IrDA function is enabled by setting UART_IRDA_EN. When UART_IRDA_TX_EN is set to 1, the IrDA transceiver is enabled to send data and not allowed to receive data; when UART_IRDA_TX_EN is reset to 0, the IrDA transceiver is enabled to receive data and not allowed to send data.

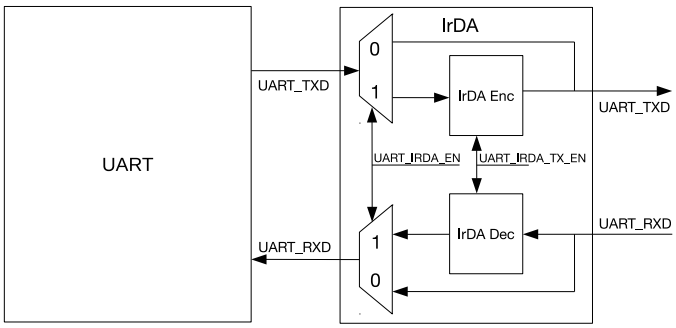

Figure 45.4-7. IrDA Encoding and Decoding Diagram

45.4.8 Wakeup

UART can be set as wakeup source. When a UART controller is in Light-sleep mode, a wake_up signal can be generated in four ways and be sent to the RTC module, which then wakes up ESP32-P4.

- UART_WK_MODE_SEL = 0: When all the clocks are disabled, the chip can be woken up by reverting RXD for multiple cycles until the number of positive edges is greater than or equal to UART_ACTIVE_THRESHOLD + 3.
- UART_WK_MODE_SEL = 1: UART Core keeps working, so the UART receiver can still receive data and store the received data in RX FIFO. When the number of data bytes in RX FIFO is greater than UART_RX_WAKE_UP_THRHD, the chip can be woken up from the Light-sleep mode.
- UART_WK_MODE_SEL = 2: When the UART receiver detects a start bit, the chip will be woken up.

- UART_WK_MODE_SEL = 3: When the UART receiver receives a specific character sequence, the chip will be woken up. The wakeup characters can be defined by configuring UART_WK_CHAR0, UART_WK_CHAR1, UART_WK_CHAR2, UART_WK_CHAR3, and UART_WK_CHAR4. These characters can be formed into different character sequences by configuring UART_CHAR_NUM and UART_WK_CHAR_MASK, as shown in Table 45.4-1. Once the sequence is detected, the chip will be woken up. For the last configuration in Table 45.4-1, UART will detect for CHAR0 ~ CHAR4 in order.

Table 45.4-1. UART_CHAR_WAKEUP Mode Configuration

UART_CHAR_NAME	UART_WP_CHAR_MASK	Character Sequence
1	0xF	CHAR4
2	0x7	CHAR3/CHAR4
3	0x3	CHAR2/CHAR3/CHAR4
4	0x1	CHAR1/CHAR2/CHAR3/CHAR4
5	0x0	CHAR0/CHAR1/CHAR2/CHAR3/CHAR4

After the chip is woken up by UART, it is necessary to clear the wake_up signal by transmitting data to UART in Active mode or resetting the whole UART, otherwise the number of rising edges required for the next wakeup will be reduced.

45.4.9 Flow Control

UART controllers have two ways to control data flow, namely hardware flow control and software flow control. Hardware flow control is achieved using output signal rtsn_out and input signal ctsn_in. Software flow control is achieved by inserting special characters in the data flow sent and detecting special characters in the data flow received.

45.4.9.1 Hardware Flow Control

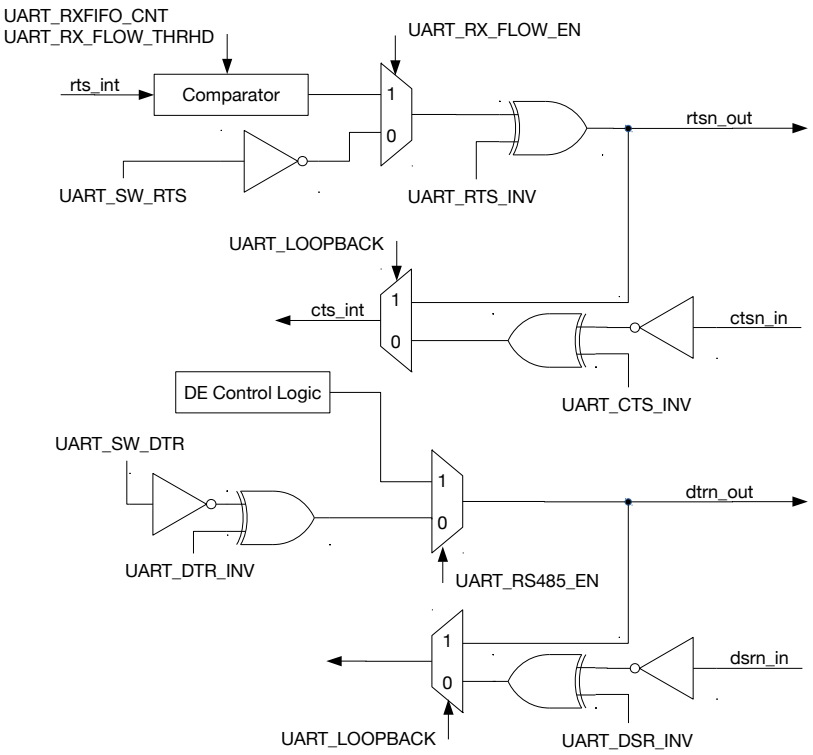

Figure 45.4-8. Hardware Flow Control Diagram

Figure 45.4-8 shows the hardware flow control of a UART controller. Hardware flow control uses output signal rtsn_out and input signal dsrn_in. Figure 45.4-9 illustrates how these signals are connected between UART on ESP32-P4 (hereinafter referred to as IUO) and the external UART (hereinafter referred to as EUO).

When rtsn_out of IUO is low, EUO is allowed to send data. When rtsn_out of IUO is high, EUO is notified to stop sending data until rtsn_out of IUO returns to low. The output signal rtsn_out can be controlled in two ways.

- Software control: Enter this mode by clearing UART_RX_FLOW_EN to 0. In this mode, the level of rtsn_out is changed by configuring UART_SW_RTS.
- Hardware control: Enter this mode by setting UART_RX_FLOW_EN to 1. In this mode, rtsn_out is pulled high when data in Rx_FIFO exceeds UART_RX_FLOW_THRHD.

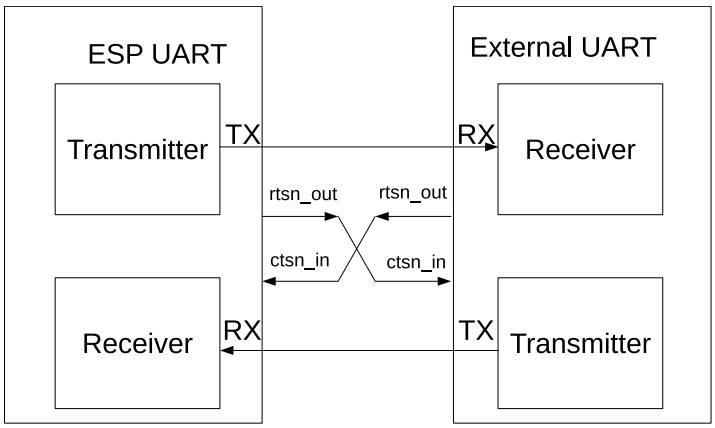

Figure 45.4-9. Connection between Hardware Flow Control Signals

When ctsn_in of IUO is low, IUO is allowed to send data; when ctsn_in is high, IUO is not allowed to send data. When IUO detects an edge change of ctsn_in, a UART_CTS_CHG_INT interrupt is generated.

If dtrn_out of IUO is high, it indicates that IUO is ready to transmit data. dtrn_out is generated by configuring the UART_SW_DTR field. When the IUO transmitter detects an edge change of dsrn_in, a UART_DSR_CHG_INT interrupt is generated. After this interrupt is detected, software can obtain the level of input signal dsrn_in by reading UART_DSRN. If dsrn_in is high, it indicates that EUO is ready to transmit data.

In a two-wire RS485 multidrop network enabled by setting UART_RS485_EN, dtrn_out is generated by hardware and used for transmit/receive turnaround. When data transmission starts, dtrn_out is pulled high and the external driver is enabled; when data transmission completes, dtrn_out is pulled low and the external driver is disabled. Please note that when there is a turnaround delay of one cycle added after the stop bit, dtrn_out is pulled low after the delay.

UART loopback test is enabled by setting UART_LOOPBACK. In the test, UART output signal txd_out is connected to its input signal rxd_in, rtsn_out is connected to ctsn_in, and dtrn_out is connected to dsrn_out. If the data sent matches the data received, it indicates that UART controllers are working properly.

45.4.9.2 Software Flow Control

Instead of CTS/RTS lines, software flow control uses XON/XOFF characters to start or stop data transmission. Such flow control is enabled by setting UART_SW_FLOW_CON_EN to 1.

When using software flow control, hardware automatically detects if there are XON/XOFF characters in the data flow received, and generate a UART_SW_XOFF_INT or a UART_SW_XON_INT interrupt accordingly. If an XOFF character is detected, the transmitter stops data transmission once the current byte has been transmitted; if an XON character is detected, the transmitter starts data transmission. In addition, software can force the transmitter to stop sending data by setting UART_FORCE_XOFF, or to start sending data by setting UART_FORCE_XON.

Software determines whether to insert flow control characters based on the remaining room in RX FIFO. When UART_SEND_XOFF is set, the transmitter sends an XOFF character configured by UART_XOFF_CHAR after the current byte in transmission; when UART_SEND_XON is set, the transmitter sends an XON character configured by UART_XON_CHAR after the current byte in transmission. If the RX FIFO of a UART controller stores more data than UART_XOFF_THRESHOLD, UART_SEND_XOFF is set by hardware. As a result, the transmitter sends an XOFF character configured by UART_XOFF_CHAR after the current byte in transmission. If the RX FIFO of a

UART controller stores less data than UART_XON_THRESHOLD, UART_SEND_XON is set by hardware. As a result, the transmitter sends an XON character configured by UART_XON_CHAR after the current byte in transmission.

In full-duplex mode, when the UART receiver receives an XOFF character, the UART transmitter is not allowed to send any data including XOFF even if the UART receiver receives more data than its threshold. To avoid deadlocks in software flow control or overflow caused thereby, you can set UART_XON_XOFF_STILL_SEND. In this way, the UART transmitter can still send an XOFF character when it is not allowed to send any data.

45.4.10 GDMA Mode

The five UART controllers on ESP32-P4 share one TX/RX GDMA (General Direct Memory Access) channel via UHCI (Universal Host Controller Interface). In GDMA mode, UART controllers support the decoding and encoding of HCI data packets. The UHCI_UART_SEL field determines which UART controller occupies the GDMA TX/RX channel.

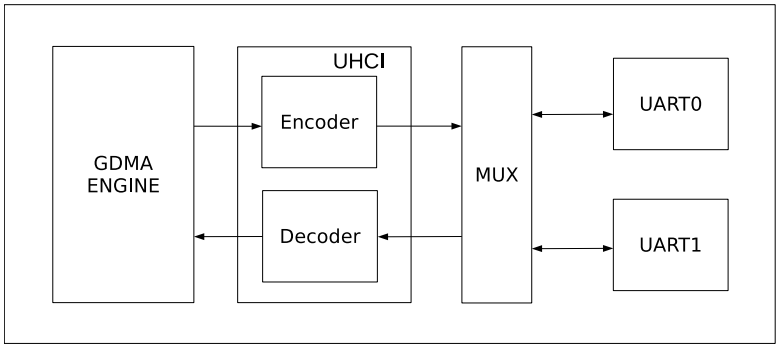

Figure 45.4-10. Data Transfer in GDMA Mode

Figure 45.4-10 shows how data is transferred using GDMA. Before GDMA receives data, software prepares an inlink. GDMA_INLINK_ADDR_CH*n* points to the first receive descriptor in the inlink. After GDMA_INLINK_START_CH*n* is set, UHCI sends data that UART has received to the decoder. The decoded data is then stored into the RAM pointed by the inlink under the control of GDMA.

Before GDMA sends data, software prepares an outlink and data to be sent. GDMA_OUTLINK_ADDR_CH*n* points to the first transmit descriptor in the outlink. After GDMA_OUTLINK_START_CH*n* is set, GDMA reads data from the RAM pointed by outlink. The data is then encoded by the encoder, and sent sequentially by the UART transmitter.

HCI data packets have separators at the beginning and the end, with data bits in the middle (separators + data bits + separators). The encoder inserts separators in front of and after data bits, and replaces data bits identical to separators with special characters. The decoder removes separators in front of and after data bits, and replaces special characters with separators. There can be more than one continuous separator at the beginning and the end of a data packet. The separator is configured by UHCI_SEPER_CHAR, 0xC0 by default. The special character is configured by UHCI_ESC_SEQ0_CHAR0 (0xDB by default) and UHCI_ESC_SEQ0_CHAR1 (0xDD by default). When all data has been sent, a GDMA_OUT_TOTAL_EOF_CH*n*_INT interrupt is generated. When all data has been received, a GDMA_IN_SUC_EOF_CH*n*_INT is generated.

45.4.11 Interrupts

ESP32-P4's UART*n* and UHCI can generate the following interrupt signals that will be sent to the Interrupt Matrix.

- UART*n*_INTR
- UHCI_INTR

There are several internal interrupt sources from UART*n* and UHCI that can generate the above interrupt signals.

UART*n* interrupt sources are listed as follows:

- UART_AT_CMD_CHAR_DET_INT: Triggered when the receiver detects an AT_CMD character.
- UART_RS485_CLASH_INT: Triggered when a collision is detected between the transmitter and the receiver in RS485 mode.
- UART_RS485_FRM_ERR_INT: Triggered when an error is detected in the data frame sent by the transmitter in RS485 mode.
- UART_RS485_PARITY_ERR_INT: Triggered when an error is detected in the parity bit sent by the transmitter in RS485 mode.
- UART_TX_DONE_INT: Triggered when all data in the transmitter's TX FIFO has been sent.
- UART_TX_BRK_IDLE_DONE_INT: Triggered when the transmitter stays idle for the minimum interval (threshold) after sending the last data bit.
- UART_TX_BRK_DONE_INT: Triggered when the transmitter has sent all NULL characters after all data in TX FIFO had been sent.
- UART_GLITCH_DET_INT: Triggered when the receiver detects a glitch in the middle of the start bit.
- UART_SW_XOFF_INT: Triggered when UART_SW_FLOW_CON_EN is set and the receiver receives a XOFF character.
- UART_SW_XON_INT: Triggered when UART_SW_FLOW_CON_EN is set and the receiver receives a XON character.
- UART_RXFIFO_TOUT_INT: Triggered when the receiver has received at least one byte, and the bus remains idle for UART_RX_TOUT_THRHD bit time.
- UART_BRK_DET_INT: Triggered when the receiver detects a NULL character (i.e., logic 0 for one NULL character transmission) after stop bits.
- UART_CTS_CHG_INT: Triggered when the receiver detects an edge change of CTSn signals.
- UART_DSR_CHG_INT: Triggered when the receiver detects an edge change of DSRn signals.
- UART_RXFIFO_OVF_INT: Triggered when the amount of data received by the receiver exceeds the storage capacity of the FIFO.
- UART_FRM_ERR_INT: Triggered when the receiver detects a data frame error.
- UART_PARITY_ERR_INT: Triggered when the receiver detects a parity error.
- UART_TXFIFO_EMPTY_INT: Triggered when TX FIFO stores less data than what UART_TXFIFO_EMPTY_THRHD specifies.

- UART_RXFIFO_FULL_INT: Triggered when the receiver receives more data than what UART_RXFIFO_FULL_THRHD specifies.
- UART_WAKEUP_INT: Triggered when UART is woken up.

UHCI interrupt sources are listed as follows:

- UHCI_APP_CTRL1_INT: Triggered when software sets UHCI_APP_CTRL1_INT_RAW.
- UHCI_APP_CTRL0_INT: Triggered when software sets UHCI_APP_CTRL0_INT_RAW.
- UHCI_OUTLINK_EOF_ERR_INT: Triggered when an EOF error is detected in a transmit descriptor.
- UHCI_SEND_A_REG_Q_INT: Triggered when UHCI has sent a series of short packets using always_send.
- UHCI_SEND_S_REG_Q_INT: Triggered when UHCI has sent a series of short packets using single_send.
- UHCI_TX_HUNG_INT: Triggered when UHCI takes too long to read RAM using a GDMA transmit channel.
- UHCI_RX_HUNG_INT: Triggered when UHCI takes too long to receive data using a GDMA receive channel.
- UHCI_TX_START_INT: Triggered when GDMA detects a separator character.
- UHCI_RX_START_INT: Triggered when a separator character has been sent.

Each interrupt source can be configured by a common set of registers that are described in Section *Interrupt Configuration Registers*. The specific registers can be found in Section 45.6 *Register Summary*.

45.5 Programming Procedures

45.5.1 Register Type

All UART registers are in the APB_CLK domain.

UART configuration registers can be classified into two groups. One group of registers are read in the APB_CLK or AHB_CLK domains, so once such registers are configured no extra operations are required. The other group of registers are read in the UART_SCLK domain, and therefore need to implement the clock domain crossing design. Once these registers are configured, the configured values need to be synchronized to the UART Core's clock domain by writing to UART_REG_UPDATE. Once all values have been synchronized, UART_REG_UPDATE will be automatically cleared by hardware. After configuring registers that need synchronization, it is recommended to check whether UART_REG_UPDATE is 0. This is to ensure that register values configured before have already been synchronized.

To distinguish between these two groups of registers easily, all registers that implement the clock domain crossing design have the _SYNC suffix, and are put together in Section 45.6. Those without the _SYNC suffix in Section 45.6 are configuration registers that require no clock domain crossing.

45.5.2 Detailed Steps

Figure 45.5-1 illustrates the process to program UART controllers, namely initialize UART, configure registers, enable the UART transmitter or receiver, and finish data transmission.

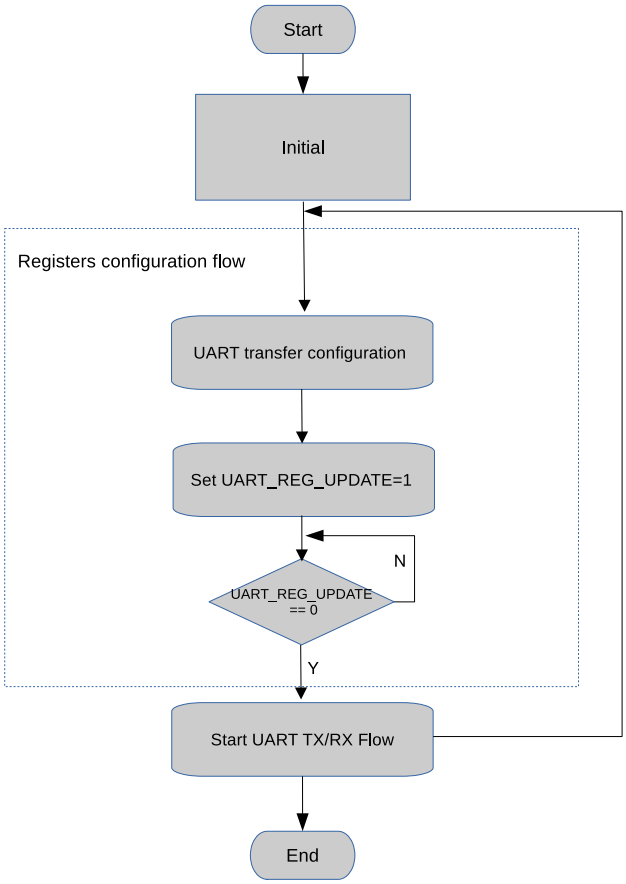

Figure 45.5-1. UART Programming Procedures

45.5.2.1 Initializing UART*n*

To initialize UART*n*:

- Write 1 to HP_SYS_CLKRST_RST_EN_UART*n*_APB.
- Clear HP_SYS_CLKRST_RST_EN_UART*n*_APB to 0.
- Write 1 to HP_SYS_CLKRST_RST_EN_UART*n*_CORE.
- Clear HP_SYS_CLKRST_RST_EN_UART*n*_CORE to 0.

45.5.2.2 Configuring UART*n* Communication

To configure UART*n* communication:

- Wait for UART_REG_UPDATE to become 0, which indicates the completion of the last synchronization.
- Select the clock source via HP_SYS_CLKRST_UART*n*_CLK_SRC_SEL.
- Configure divisor of the divider via HP_SYS_CLKRST_UART*n*_SCLK_DIV_NUM, HP_SYS_CLKRST_UART*n*_SCLK_DIV_DENOMINATOR, and

HP_SYS_CLKRST_UART*n*_SCLK_DIV_NUMERATOR.

- Configure the baud rate for transmission via UART_CLKDIV and UART_CLKDIV_FRAG.
- Configure data length via UART_BIT_NUM.
- Configure odd or even parity check via UART_PARITY_EN and UART_PARITY.
- Optional steps depending on application ...
- Synchronize the configured values to the Core Clock domain by writing 1 to UART_REG_UPDATE.

45.5.2.3 Enabling UART*n*

To enable UART*n* transmitter:

- Configure TX FIFO's empty threshold via UART_TXFIFO_EMPTY_THRHD.
- Disable UART_TXFIFO_EMPTY_INT interrupt by clearing UART_TXFIFO_EMPTY_INT_ENA.
- Write data to be sent to UART_RXFIFO_RD_BYTE.
- Clear UART_TXFIFO_EMPTY_INT interrupt by setting UART_TXFIFO_EMPTY_INT_CLR.
- Enable UART_TXFIFO_EMPTY_INT interrupt by setting UART_TXFIFO_EMPTY_INT_ENA.
- Check UART_TXFIFO_EMPTY_INT_ST and wait for the completion of data transmission.

To enable UART*n* receiver:

- Configure RX FIFO's full threshold via UART_RXFIFO_FULL_THRHD.
- Enable UART_RXFIFO_FULL_INT interrupt by setting UART_RXFIFO_FULL_INT_ENA.
- Check UART_RXFIFO_FULL_INT_ST and wait until the RX FIFO is full.
- Read data from RX FIFO via UART_RXFIFO_RD_BYTE, and obtain the number of bytes received in RX FIFO via UART_RXFIFO_CNT.

45.6 Register Summary

45.6.1 UART Register Summary

The addresses in this section are relative to UART Controller base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
FIFO Configuration			
UART_FIFO_REG	FIFO data register	0x0000	RO
UART_TOUT_CONF_SYNC_REG	UART threshold and allocation configuration	0x0064	R/W
UART Interrupt Register			
UART_INT_RAW_REG	Raw interrupt status	0x0004	R/WTC/SS
UART_INT_ST_REG	Masked interrupt status	0x0008	RO
UART_INT_ENA_REG	Interrupt enable bits	0x000C	R/W
UART_INT_CLR_REG	Interrupt clear bits	0x0010	WT
Configuration Register			
UART_CLKDIV_SYNC_REG	Clock divider configuration	0x0014	R/W
UART_RX_FILT_REG	RX filter configuration	0x0018	R/W
UART_CONF0_SYNC_REG	Configuration register 0	0x0020	R/W
UART_CONF1_REG	Configuration register 1	0x0024	R/W
UART_HWFC_CONF_SYNC_REG	Hardware flow control configuration	0x002C	R/W
UART_SLEEP_CONF0_REG	UART sleep configuration register 0	0x0030	R/W
UART_SLEEP_CONF1_REG	UART sleep configuration register 1	0x0034	R/W
UART_SLEEP_CONF2_REG	UART sleep configuration register 2	0x0038	R/W
UART_SWFC_CONF0_SYNC_REG	Software flow control character configuration	0x003C	varies
UART_SWFC_CONF1_REG	Software flow control character configuration	0x0040	R/W
UART_TXBRK_CONF_SYNC_REG	TX break character configuration	0x0044	R/W
UART_IDLE_CONF_SYNC_REG	Frame end idle time configuration	0x0048	R/W
UART_RS485_CONF_SYNC_REG	RS485 mode configuration	0x004C	R/W
UART_CLK_CONF_REG	UART core clock configuration	0x0088	R/W
UART_REG_UPDATE_REG	UART register configuration update	0x0098	R/W/SC
UART_ID_REG	UART ID register	0x009C	R/W
Status Register			
UART_STATUS_REG	UART status register	0x001C	RO
UART_MEM_TX_STATUS_REG	TX FIFO write and read offset address	0x0068	RO
UART_MEM_RX_STATUS_REG	Rx FIFO write and read offset address	0x006C	RO
UART_FSM_STATUS_REG	UART transmit and receive status	0x0070	RO
UART_AFIFO_STATUS_REG	UART asynchronous FIFO status	0x0090	RO
AT Escape Sequence Selection Configuration			
UART_AT_CMD_PRECNT_SYNC_REG	Pre-sequence timing configuration	0x0050	R/W
UART_AT_CMD_POSTCNT_SYNC_REG	Post-sequence timing configuration	0x0054	R/W
UART_AT_CMD_GAPTOUT_SYNC_REG	Timeout configuration	0x0058	R/W

Name	Description	Address	Access
UART_AT_CMD_CHAR_SYNC_REG	AT escape sequence detection configuration	0x005C	R/W
Autobaud Register			
UART_POSPULSE_REG	Autobaud high pulse register	0x0074	RO
UART_NEGPULSE_REG	Autobaud low pulse register	0x0078	RO
UART_LOWPULSE_REG	Autobaud minimum low pulse duration register	0x007C	RO
UART_HIGHPULSE_REG	Autobaud minimum high pulse duration register	0x0080	RO
UART_RXD_CNT_REG	Autobaud edge change count register	0x0084	RO
Version Register			
UART_DATE_REG	UART version control register	0x008C	R/W

45.6.2 LP UART Register Summary

The addresses in this section are relative to LP UART base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
FIFO Configuration			
LP_UART_FIFO_REG	FIFO data register	0x0000	RO
LP_UART_TOUT_CONF_SYNC_REG	LP UART threshold and allocation configuration	0x0064	R/W
LP UART Interrupt Register			
LP_UART_INT_RAW_REG	Raw interrupt status	0x0004	R/WTC/SS
LP_UART_INT_ST_REG	Masked interrupt status	0x0008	RO
LP_UART_INT_ENA_REG	Interrupt enable bits	0x000C	R/W
LP_UART_INT_CLR_REG	Interrupt clear bits	0x0010	WT
Configuration Register			
LP_UART_CLKDIV_SYNC_REG	Clock divider configuration	0x0014	R/W
LP_UART_RX_FILT_REG	RX filter configuration	0x0018	R/W
LP_UART_CONF0_SYNC_REG	Configuration register 0	0x0020	R/W
LP_UART_CONF1_REG	Configuration register 1	0x0024	R/W
LP_UART_HWFC_CONF_SYNC_REG	Hardware flow control configuration	0x002C	R/W
LP_UART_SLEEP_CONF0_REG	LP UART sleep configuration register 0	0x0030	R/W
LP_UART_SLEEP_CONF1_REG	LP UART sleep configuration register 1	0x0034	R/W
LP_UART_SLEEP_CONF2_REG	LP UART sleep configuration register 2	0x0038	R/W
LP_UART_SWFC_CONF0_SYNC_REG	Software flow control character configuration	0x003C	varies
LP_UART_SWFC_CONF1_REG	Software flow control character configuration	0x0040	R/W
LP_UART_TXBRK_CONF_SYNC_REG	TX break character configuration	0x0044	R/W
LP_UART_IDLE_CONF_SYNC_REG	Frame end idle time configuration	0x0048	R/W
LP_UART_CLK_CONF_REG	LP UART core clock configuration	0x0088	R/W

Name	Description	Address	Access
LP_UART_REG_UPDATE_REG	LP UART register configuration update register	0x0098	R/W/SC
LP_UART_ID_REG	LP UART ID register	0x009C	R/W
Status Register			
LP_UART_STATUS_REG	LP UART status register	0x001C	RO
LP_UART_MEM_TX_STATUS_REG	TX FIFO write and read offset address	0x0068	RO
LP_UART_MEM_RX_STATUS_REG	RX FIFO write and read offset address	0x006C	RO
LP_UART_FSM_STATUS_REG	LP UART transmit and receive status	0x0070	RO
LP_UART_AFIFO_STATUS_REG	LP UART asynchronous FIFO Status	0x0090	RO
AT Escape Sequence Selection Configuration			
LP_UART_AT_CMD_PRECNT_SYNC_REG	Pre-sequence timing configuration	0x0050	R/W
LP_UART_AT_CMD_POSTCNT_SYNC_REG	Post-sequence timing configuration	0x0054	R/W
LP_UART_AT_CMD_GAPTOUT_SYNC_REG	Timeout configuration	0x0058	R/W
LP_UART_AT_CMD_CHAR_SYNC_REG	AT escape sequence detection configuration	0x005C	R/W
Version Register			
LP_UART_DATE_REG	LP UART version register	0x008C	R/W

45.6.3 UHCI Register Summary

The addresses in this section are relative to UHCI base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column **Access** are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
Configuration Register			
UHCI_CONF0_REG	UHCI configuration register	0x0000	R/W
UHCI_CONF1_REG	UHCI configuration register	0x0014	varies
UHCI_ESCAPE_CONF_REG	Escape character configuration	0x0020	R/W
UHCI_HUNG_CONF_REG	Timeout configuration	0x0024	R/W
UHCI_ACK_NUM_REG	UHCI ACK number configuration	0x0028	varies
UHCI_QUICK_SENT_REG	UHCI quick send configuration register	0x0030	varies
UHCI_REG_Q0_WORD0_REG	Q0 WORD0 quick send register	0x0034	R/W
UHCI_REG_Q0_WORD1_REG	Q0 WORD1 quick send register	0x0038	R/W
UHCI_REG_Q1_WORD0_REG	Q1 WORD0 quick send register	0x003C	R/W
UHCI_REG_Q1_WORD1_REG	Q1 WORD1 quick send register	0x0040	R/W
UHCI_REG_Q2_WORD0_REG	Q2 WORD0 quick send register	0x0044	R/W
UHCI_REG_Q2_WORD1_REG	Q2 WORD1 quick send register	0x0048	R/W
UHCI_REG_Q3_WORD0_REG	Q3 WORD0 quick send register	0x004C	R/W
UHCI_REG_Q3_WORD1_REG	Q3 WORD1 quick send register	0x0050	R/W
UHCI_REG_Q4_WORD0_REG	Q4 WORD0 quick send register	0x0054	R/W
UHCI_REG_Q4_WORD1_REG	Q4 WORD1 quick send register	0x0058	R/W
UHCI_REG_Q5_WORD0_REG	Q5 WORD0 quick send register	0x005C	R/W

Name	Description	Address	Access
UHCI_REG_Q5_WORD1_REG	Q5 WORD1 quick send register	0x0060	R/W
UHCI_REG_Q6_WORD0_REG	Q6 WORD0 quick send register	0x0064	R/W
UHCI_REG_Q6_WORD1_REG	Q6 WORD1 quick register	0x0068	R/W
UHCI_ESC_CONF0_REG	Escape sequence configuration register 0	0x006C	R/W
UHCI_ESC_CONF1_REG	Escape sequence configuration register 1	0x0070	R/W
UHCI_ESC_CONF2_REG	Escape sequence configuration register 2	0x0074	R/W
UHCI_ESC_CONF3_REG	Escape sequence configuration register 3	0x0078	R/W
UHCI_PKT_THRES_REG	Configuration register for packet length	0x007C	R/W
UHCI Interrupt Register			
UHCI_INT_RAW_REG	Raw interrupt status	0x0004	varies
UHCI_INT_ST_REG	Masked interrupt status	0x0008	RO
UHCI_INT_ENA_REG	Interrupt enable bits	0x000C	R/W
UHCI_INT_CLR_REG	Interrupt clear bits	0x0010	WT
UHCI Status Register

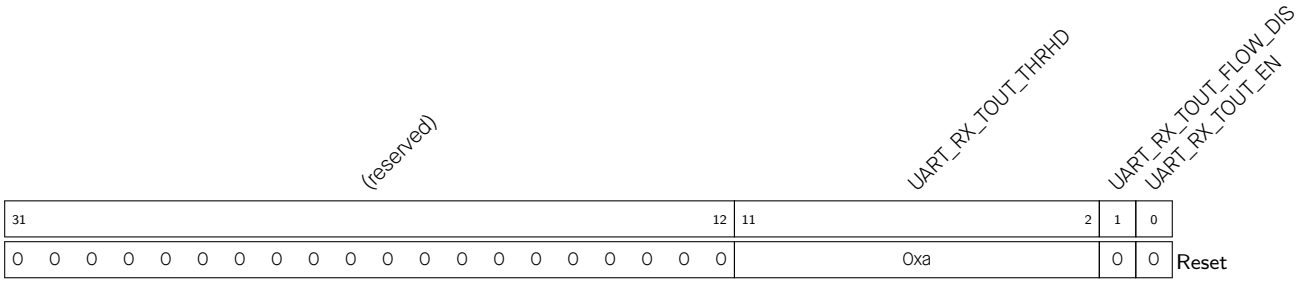
45.7 Registers

45.7.1 UART Registers

The addresses in this section are relative to UART Controller base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

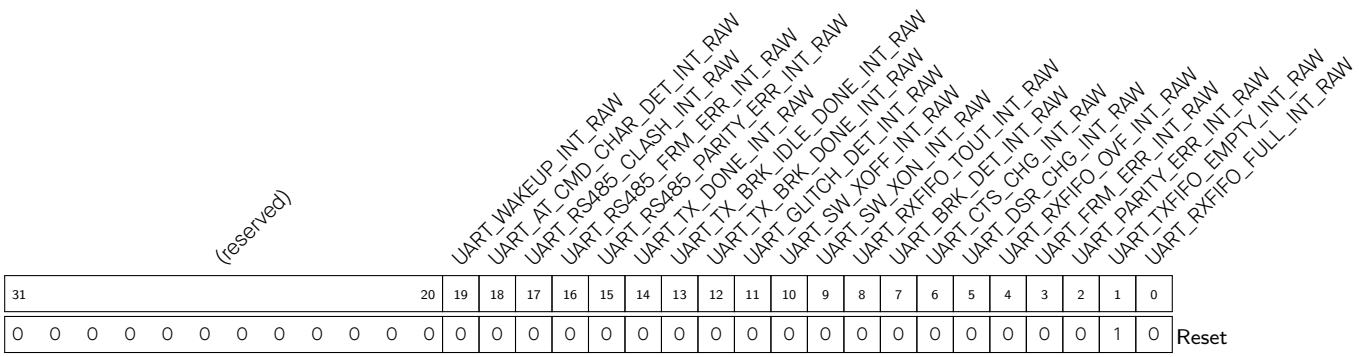


For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 45.1. UART_FIFO_REG (0x0000)

UART_RXFIFO_RD_BYTE Represents the data UART *n* read from FIFO.
Measurement unit: byte. (RO)

Register 45.2. UART_TOUT_CONF_SYNC_REG (0x0064)



UART_RX_TOUT_EN Configures whether or not to enable UART receiver's timeout function.
0: Disable
1: Enable
(R/W)

UART_RX_TOUT_FLOW_DIS Configures whether or not to disable the idle status counter when hardware flow control is enabled.
0: Enable
1: Disable
(R/W)

UART_RX_TOUT_THRHD Configures the amount of time that the bus can remain idle before timeout.
Measurement unit: bit time (the time to transmit 1 bit). (R/W)

Register 45.3. UART_INT_RAW_REG (0x0004)

UART_RXFIFO_FULL_INT_RAW The raw interrupt status of UART_RXFIFO_FULL_INT. (R/WTC/SS)

UART_TXFIFO_EMPTY_INT_RAW The raw interrupt status of UART_TXFIFO_EMPTY_INT. (R/WTC/SS)

UART_PARITY_ERR_INT_RAW The raw interrupt status of UART_PARITY_ERR_INT. (R/WTC/SS)

UART_FRM_ERR_INT_RAW The raw interrupt status of UART_FRM_ERR_INT. (R/WTC/SS)

UART_RXFIFO_OVF_INT_RAW The raw interrupt status of UART_RXFIFO_OVF_INT. (R/WTC/SS)

UART_DSR_CHG_INT_RAW The raw interrupt status of UART_DSR_CHG_INT. (R/WTC/SS)

UART_CTS_CHG_INT_RAW The raw interrupt status of UART_CTS_CHG_INT. (R/WTC/SS)

UART_BRK_DET_INT_RAW The raw interrupt status of UART_BRK_DET_INT. (R/WTC/SS)

UART_RXFIFO_TOUT_INT_RAW The raw interrupt status of UART_RXFIFO_TOUT_INT. (R/WTC/SS)

UART_SW_XON_INT_RAW The raw interrupt status of UART_SW_XON_INT. (R/WTC/SS)

UART_SW_XOFF_INT_RAW UART_SW_XOFF_INT. (R/WTC/SS)

UART_GLITCH_DET_INT_RAW The raw interrupt status of UART_GLITCH_DET_INT. (R/WTC/SS)

UART_TX_BRK_DONE_INT_RAW The raw interrupt status of UART_TX_BRK_DONE_INT. (R/WTC/SS)

UART_TX_BRK_IDLE_DONE_INT_RAW The raw interrupt status of UART_TX_BRK_IDLE_DONE_INT. (R/WTC/SS)

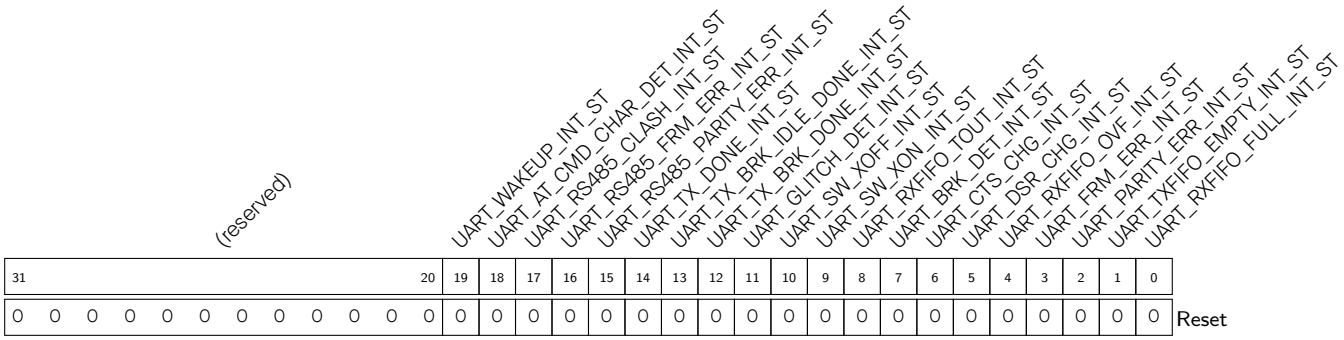
UART_TX_DONE_INT_RAW The raw interrupt status of UART_TX_DONE_INT. (R/WTC/SS)

UART_RS485_PARITY_ERR_INT_RAW The raw interrupt status of UART_RS485_PARITY_ERR_INT. (R/WTC/SS)

UART_RS485_FRM_ERR_INT_RAW The raw interrupt status of UART_RS485_FRM_ERR_INT. (R/WTC/SS)

Continued on the next page...

Register 45.3. UART_INT_RAW_REG (0x0004)



Continued from the previous page...

UART_RS485_CLASH_INT_RAW The raw interrupt status of UART_RS485_CLASH_INT. (R/WTC/SS)

UART_AT_CMD_CHAR_DET_INT_RAW The raw interrupt status of UART_AT_CMD_CHAR_DET_INT. (R/WTC/SS)

UART_WAKEUP_INT_RAW The raw interrupt status of UART_WAKEUP_INT. (R/WTC/SS)

Register 45.4. UART_INT_ST_REG (0x0008)

UART_RXFIFO_FULL_INT_ST The masked interrupt status of UART_RXFIFO_FULL_INT.(RO)

UART_TXFIFO_EMPTY_INT_ST The masked interrupt status of UART_TXFIFO_EMPTY_INT. (RO)

UART_PARITY_ERR_INT_ST The masked interrupt status of UART_PARITY_ERR_INT. (RO)

UART_FRM_ERR_INT_ST The masked interrupt status of UART_FRM_ERR_INT. (RO)

UART_RXFIFO_OVF_INT_ST The masked interrupt status of UART_RXFIFO_OVF_INT. (RO)

UART_DSR_CHG_INT_ST The masked interrupt status of UART_DSR_CHG_INT. (RO)

UART_CTS_CHG_INT_ST The masked interrupt status of UART_CTS_CHG_INT. (RO)

UART_BRK_DET_INT_ST The masked interrupt status of UART_BRK_DET_INT. (RO)

UART_RXFIFO_TOUT_INT_ST The masked interrupt status of UART_RXFIFO_TOUT_INT. (RO)

UART_SW_XON_INT_ST The masked interrupt status of UART_SW_XON_INT. (RO)

UART_SW_XOFF_INT_ST The masked interrupt status of UART_SW_XOFF_INT. (RO)

UART_GLITCH_DET_INT_ST The masked interrupt status of UART_GLITCH_DET_INT. (RO)

UART_TX_BRK_DONE_INT_ST The masked interrupt status of UART_TX_BRK_DONE_INT. (RO)

UART_TX_BRK_IDLE_DONE_INT_ST The masked interrupt status of UART_TX_BRK_IDLE_DONE_INT. (RO)

UART_TX_DONE_INT_ST The masked interrupt status of UART_TX_DONE_INT. (RO)

UART_RS485_PARITY_ERR_INT_ST The masked interrupt status of UART_RS485_PARITY_ERR_INT. (RO)

UART_RS485_FRM_ERR_INT_ST The masked interrupt status of UART_RS485_FRM_ERR_INT. (RO)

UART_RS485_CLASH_INT_ST The masked interrupt status of UART_RS485_CLASH_INT. (RO)

UART_AT_CMD_CHAR_DET_INT_ST The masked interrupt status of UART_AT_CMD_CHAR_DET_INT. (RO)

UART_WAKEUP_INT_ST The masked interrupt status of UART_WAKEUP_INT. (RO)

Register 45.5. UART_INT_ENA_REG (0x000C)

UART_RXFIFO_FULL_INT_ENA Write 1 to enable UART_RXFIFO_FULL_INT. (R/W)

UART_TXFIFO_EMPTY_INT_ENA Write 1 to enable UART_TXFIFO_EMPTY_INT. (R/W)

UART_PARITY_ERR_INT_ENA Write 1 to enable UART_PARITY_ERR_INT. (R/W)

UART_FRM_ERR_INT_ENA Write 1 to enable UART_FRM_ERR_INT. (R/W)

UART_RXFIFO_OVF_INT_ENA Write 1 to enable UART_RXFIFO_OVF_INT. (R/W)

UART_DSR_CHG_INT_ENA Write 1 to enable UART_DSR_CHG_INT. (R/W)

UART_CTS_CHG_INT_ENA Write 1 to enable UART_CTS_CHG_INT. (R/W)

UART_BRK_DET_INT_ENA Write 1 to enable UART_BRK_DET_INT. (R/W)

UART_RXFIFO_TOUT_INT_ENA Write 1 to enable UART_RXFIFO_TOUT_INT. (R/W)

UART_SW_XON_INT_ENA Write 1 to enable UART_SW_XON_INT.(R/W)

UART_SW_XOFF_INT_ENA Write 1 to enable UART_SW_XOFF_INT. (R/W)

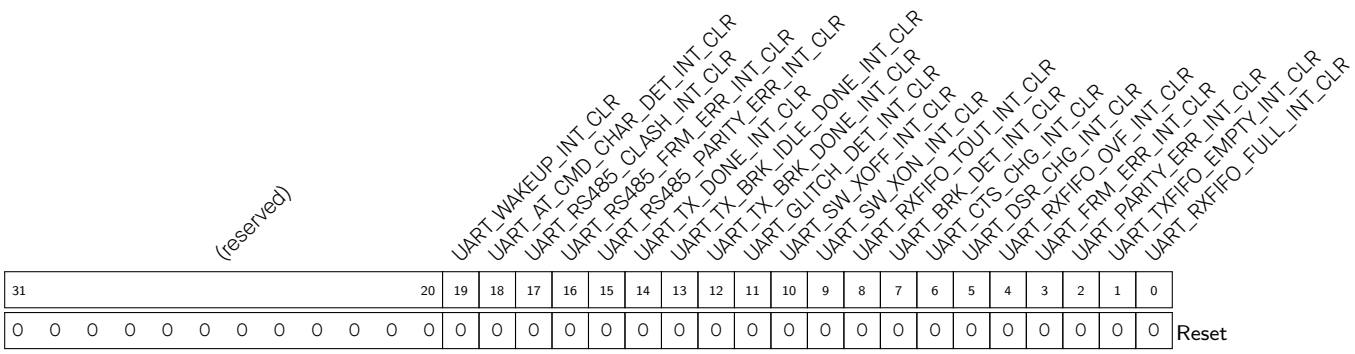
UART_GLITCH_DET_INT_ENA Write 1 to enable UART_GLITCH_DET_INT. (R/W)

UART_TX_BRK_DONE_INT_ENA Write 1 to enable UART_TX_BRK_DONE_INT. (R/W)

UART_TX_BRK_IDLE_DONE_INT_ENA Write 1 to enable UART_TX_BRK_IDLE_DONE_INT. (R/W)

UART_TX_DONE_INT_ENA Write 1 to enable UART_TX_DONE_INT. (R/W)

UART_RS485_PARITY_ERR_INT_ENA Write 1 to enable UART_RS485_PARITY_ERR_INT. (R/W)



UART_RS485_FRM_ERR_INT_ENA Write 1 to enable UART_RS485_FRM_ERR_INT. (R/W)

UART_RS485_CLASH_INT_ENA Write 1 to enable UART_RS485_CLASH_INT. (R/W)

UART_AT_CMD_CHAR_DET_INT_ENA Write 1 to enable UART_AT_CMD_CHAR_DET_INT. (R/W)

UART_WAKEUP_INT_ENA Write 1 to enable UART_WAKEUP_INT. (R/W)

Register 45.6. UART_INT_CLR_REG (0x0010)

UART_RXFIFO_FULL_INT_CLR Write 1 to clear UART_RXFIFO_FULL_INT. (WT)

UART_TXFIFO_EMPTY_INT_CLR Write 1 to clear UART_TXFIFO_EMPTY_INT. (WT)

UART_PARITY_ERR_INT_CLR Write 1 to clear UART_PARITY_ERR_INT. (WT)

UART_FRM_ERR_INT_CLR Write 1 to clear UART_FRM_ERR_INT. (WT)

UART_RXFIFO_OVF_INT_CLR Write 1 to clear UART_RXFIFO_OVF_INT. (WT)

UART_DSR_CHG_INT_CLR Write 1 to clear UART_DSR_CHG_INT. (WT)

UART_CTS_CHG_INT_CLR Write 1 to clear UART_CTS_CHG_INT. (WT)

UART_BRK_DET_INT_CLR Write 1 to clear UART_BRK_DET_INT. (WT)

UART_RXFIFO_TOUT_INT_CLR Write 1 to clear UART_RXFIFO_TOUT_INT. (WT)

UART_SW_XON_INT_CLR Write 1 to clear UART_SW_XON_INT. (WT)

UART_SW_XOFF_INT_CLR Write 1 to clear UART_SW_XOFF_INT. (WT)

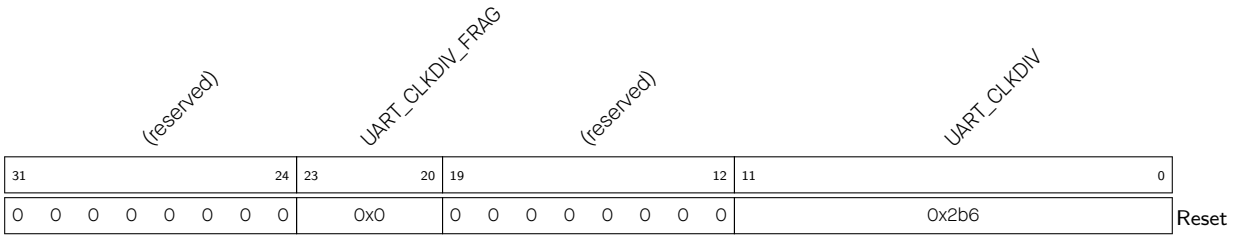
UART_GLITCH_DET_INT_CLR Write 1 to clear UART_GLITCH_DET_INT. (WT)

UART_TX_BRK_DONE_INT_CLR Write 1 to clear UART_TX_BRK_DONE_INT. (WT)

UART_TX_BRK_IDLE_DONE_INT_CLR Write 1 to clear UART_TX_BRK_IDLE_DONE_INT. (WT)

UART_TX_DONE_INT_CLR Write 1 to clear UART_TX_DONE_INT. (WT)

UART_RS485_PARITY_ERR_INT_CLR Write 1 to clear UART_RS485_PARITY_ERR_INT. (WT)

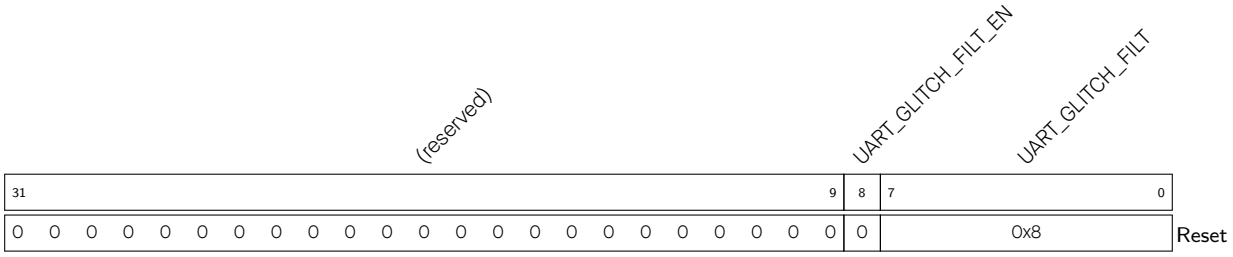


UART_RS485_FRM_ERR_INT_CLR Write 1 to clear UART_RS485_FRM_ERR_INT. (WT)

UART_RS485_CLASH_INT_CLR Write 1 to clear UART_RS485_CLASH_INT. (WT)

UART_AT_CMD_CHAR_DET_INT_CLR Write 1 to clear UART_AT_CMD_CHAR_DET_INT. (WT)

UART_WAKEUP_INT_CLR Write 1 to clear UART_WAKEUP_INT. (WT)



Register 45.7. UART_CLKDIV_SYNC_REG (0x0014)

UART_CLKDIV Configures the integral part of the divisor for baud rate generation. (R/W)

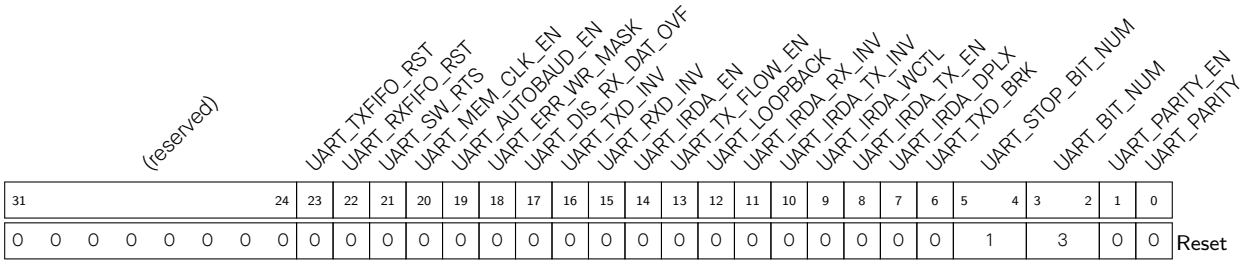
UART_CLKDIV_FRAG Configures the fractional part of the divisor for baud rate generation. (R/W)

Register 45.8. UART_RX_FILT_REG (0x0018)

UART_GLITCH_FILT Configures the width of a pulse to be filtered.

Measurement unit: UART Core's clock cycle.

Pulses whose width is lower than this value will be ignored. (R/W)



UART_GLITCH_FILT_EN Configures whether or not to enable RX signal filter.

0: Disable

1: Enable

(R/W)

Register 45.9. UART_CONF0_SYNC_REG (0x0020)

UART_PARITY Configures the parity check mode.

0: Even parity

1: Odd parity

(R/W)

UART_PARITY_EN Configures whether or not to enable UART parity check.

0: Disable

1: Enable

(R/W)

UART_BIT_NUM Configures the number of data bits.

0: 5 bits

1: 6 bits

2: 7 bits

3: 8 bits

(R/W)

UART_STOP_BIT_NUM Configures the number of stop bits.

0: Invalid. No effect

1: 1 bit

2: 1.5 bits

3: 2 bits

(R/W)

UART_TXD_BRK Configures whether or not to send NULL characters when finishing data transmission.

0: Not send

1: Send

(R/W)

UART_IRDA_DPLX Configures whether or not to enable IrDA loopback test.

0: Disable

1: Enable

(R/W)

UART_IRDA_TX_EN Configures whether or not to enable the IrDA transmitter.

0: Disable

1: Enable

(R/W)

Continued on the next page...

Register 45.9. UART_CONF0_SYNC_REG (0x0020)

Continued from the previous page...

UART_IRDA_WCTL Configures the 11th bit of the IrDA transmitter.

0: This bit is 0.

1: This bit is the same as the 10th bit.

(R/W)

UART_IRDA_TX_INV Configures whether or not to invert the level of the IrDA transmitter.

0: Not invert

1: Invert

(R/W)

UART_IRDA_RX_INV Configures whether or not to invert the level of the IrDA receiver.

0: Not invert

1: Invert

(R/W)

UART_LOOPBACK Configures whether or not to enable UART loopback test.

0: Disable

1: Enable

(R/W)

UART_TX_FLOW_EN Configures whether or not to enable flow control for the transmitter.

0: Disable

1: Enable

(R/W)

UART_IRDA_EN Configures whether or not to enable IrDA protocol.

0: Disable

1: Enable

(R/W)

UART_RXD_INV Configures whether or not to invert the level of UART RXD signal.

0: Not invert

1: Invert

(R/W)

UART_TXD_INV Configures whether or not to invert the level of UART TXD signal.

0: Not invert

1: Invert

(R/W)

UART_DIS_RX_DAT_OVF Configures whether or not to disable data overflow detection for the UART receiver.

0: Enable

1: Disable

(R/W)

Continued on the next page...

Register 45.9. UART_CONF0_SYNC_REG (0x0020)

Continued from the previous page...

UART_ERR_WR_MASK Configures whether or not to store the received data with errors into FIFO.

0: Store

1: Not store

(R/W)

UART_AUTOBAUD_EN Configures whether or not to enable baud rate detection.

0: Disable

1: Enable

(R/W)

UART_MEM_CLK_EN Configures whether or not to enable clock gating for UART memory.

0: Disable

1: Enable

(R/W)

UART_SW_RTS Configures the RTS signal used in software flow control.

0: The UART transmitter is not allowed to send data.

1: The UART transmitted is allowed to send data.

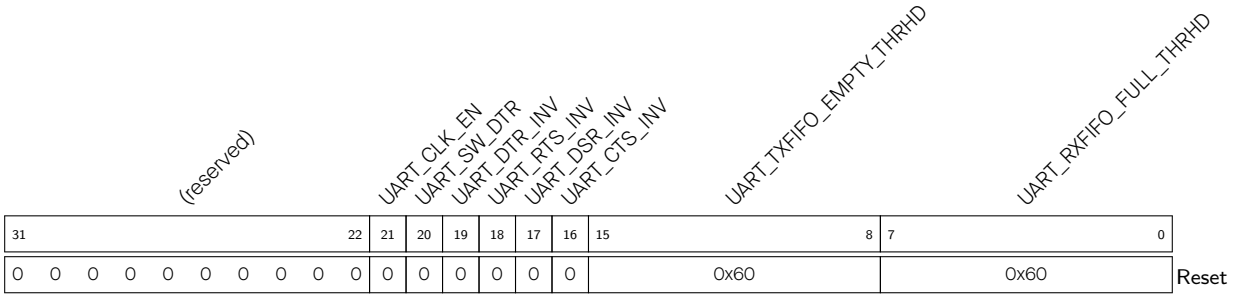
(R/W)

UART_RXFIFO_RST Configures whether or not to reset the UART RX FIFO.

0: Not reset

1: Reset

(R/W)



UART_TXFIFO_RST Configures whether or not to reset the UART TX FIFO.

0: Not reset

1: Reset

(R/W)

Register 45.10. UART_CONF1_REG (0x0024)

UART_RXFIFO_FULL_THRHD Configures the threshold for RX FIFO being full.

Measurement unit: byte. (R/W)

UART_TXFIFO_EMPTY_THRHD Configures the threshold for TX FIFO being empty.

Measurement unit: byte. (R/W)

UART_CTS_INV Configures whether or not to invert the level of UART CTS signal.

0: Not invert

1: Invert

(R/W)

UART_DSR_INV Configures whether or not to invert the level of UART DSR signal.

0: Not invert

1: Invert

(R/W)

UART_RTS_INV Configures whether or not to invert the level of UART RTS signal.

0: Not invert

1: Invert

(R/W)

UART_DTR_INV Configures whether or not to invert the level of UART DTR signal.

0: Not invert

1: Invert

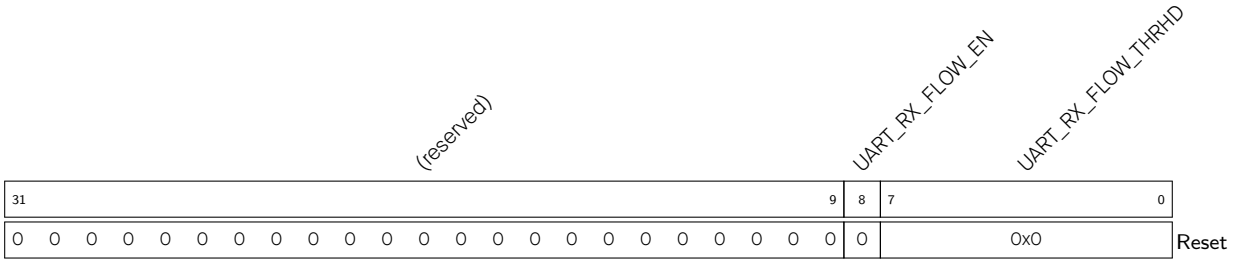
(R/W)

UART_SW_DTR Configures the DTR signal used in software flow control.

0: Data to be transmitted is not ready.

1: Data to be transmitted is ready.

(R/W)



UART_CLK_EN Configures clock gating.

0: Support clock only when the application writes registers.

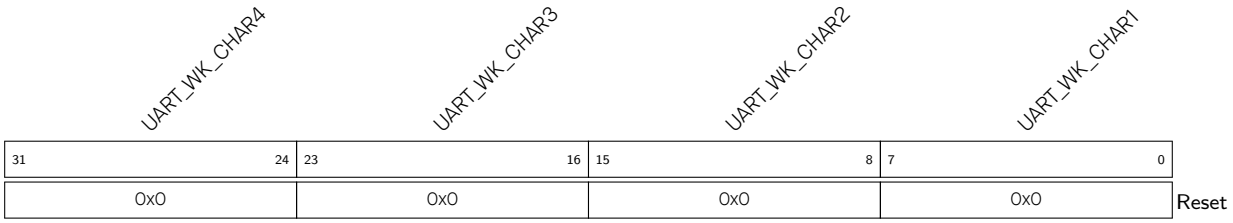
1: Always force the clock on for registers.

(R/W)

Register 45.11. UART_HWFC_CONF_SYNC_REG (0x002C)

UART_RX_FLOW_THRHD Configures the maximum number of data bytes that can be received during hardware flow control.

Measurement unit: byte. (R/W)



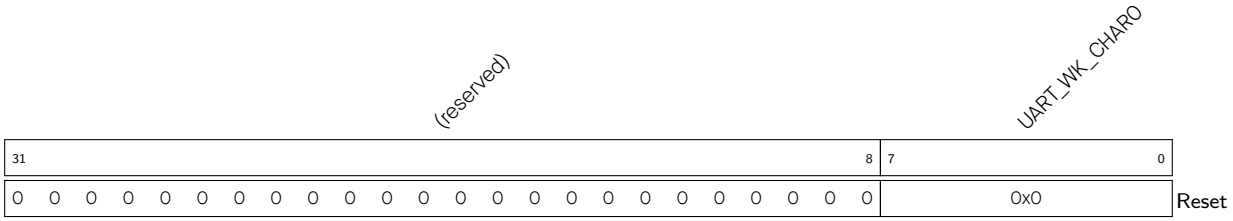
UART_RX_FLOW_EN Configures whether or not to enable the UART receiver.

0: Disable

1: Enable

(R/W)

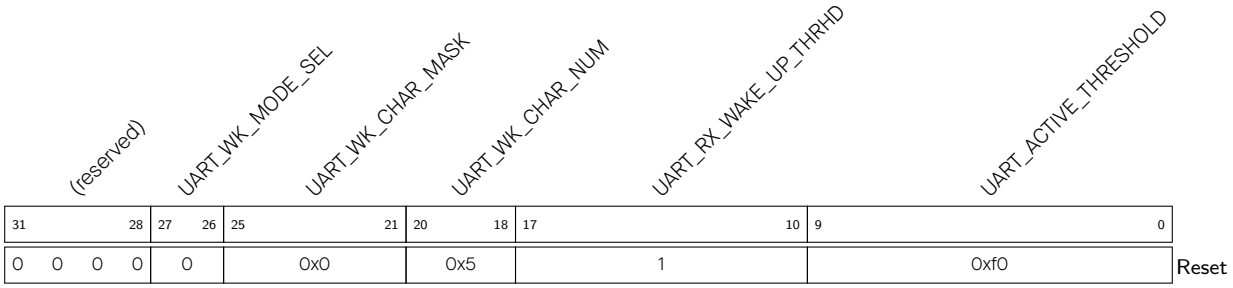
Register 45.12. UART_SLEEP_CONF0_REG (0x0030)



UART_WK_CHAR1 Configures wakeup character 1. (R/W)

UART_WK_CHAR2 Configures wakeup character 2. (R/W)

UART_WK_CHAR3 Configures wakeup character 3. (R/W)



UART_WK_CHAR4 Configures wakeup character 4. (R/W)

Register 45.13. UART_SLEEP_CONF1_REG (0x0034)

UART_WK_CHAR0 Configures wakeup character 0. (R/W)

Register 45.14. UART_SLEEP_CONF2_REG (0x0038)

UART_ACTIVE_THRESHOLD Configures the number of RXD edge changes to wake up the chip in wakeup mode 0. (R/W)

UART_RX_WAKE_UP_THRHD Configures the number of received data bytes to wake up the chip in wakeup mode 1. (R/W)

UART_WK_CHAR_NUM Configures the number of wakeup characters. (R/W)

UART_WK_CHAR_MASK Configures whether or not to mask wakeup characters.

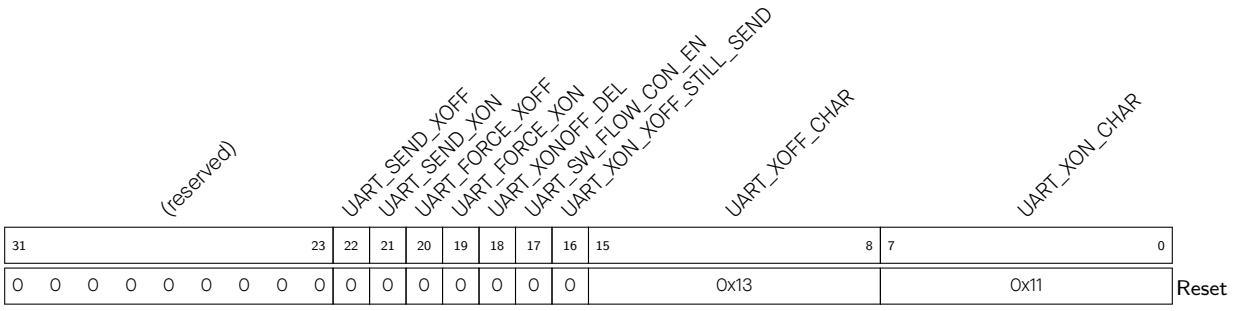
0: Not mask

1: Mask

(R/W)

UART_WK_MODE_SEL Configures which wakeup mode to select. See Section 45.4.8 *Wakeup* for the explanation of each mode.

0: Mode 0



1: Mode 1

2: Mode 2

3: Mode 3

(R/W)

Register 45.15. UART_SWFC_CONF0_SYNC_REG (0x003C)

UART_XON_CHAR Configures the XON character for flow control. (R/W)

UART_XOFF_CHAR Configures the XOFF character for flow control. (R/W)

UART_XON_XOFF_STILL_SEND Configures whether the UART transmitter can send XON or XOFF characters when it is disabled.

0: Cannot send

1: Can send

(R/W)

UART_SW_FLOW_CON_EN Configures whether or not to enable software flow control.

0: Disable

1: Enable

(R/W)

UART_XONOFF_DEL Configures whether or not to remove flow control characters from the received data.

0: Not move

1: Move

(R/W)

UART_FORCE_XON Configures whether the transmitter continues to sending data.

0: Not send

1: Send

(R/W)

UART_FORCE_XOFF Configures whether or not to stop the transmitter from sending data.

0: Not stop

1: Stop

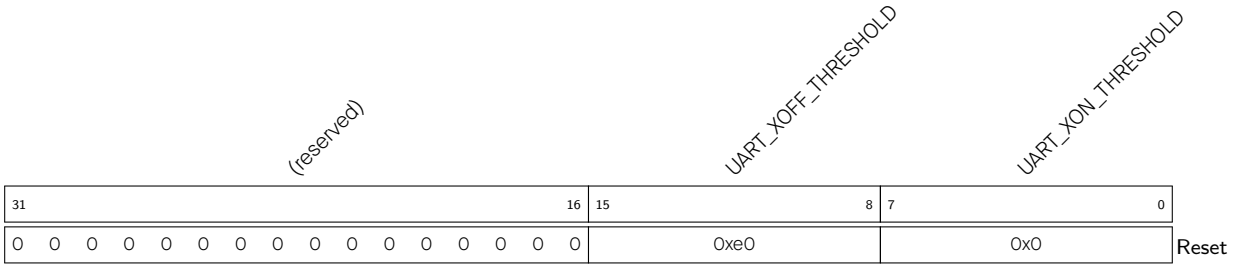
(R/W)

UART_SEND_XON Configures whether or not to send XON characters.

0: Not send

1: Send

(R/W/SS/SC)



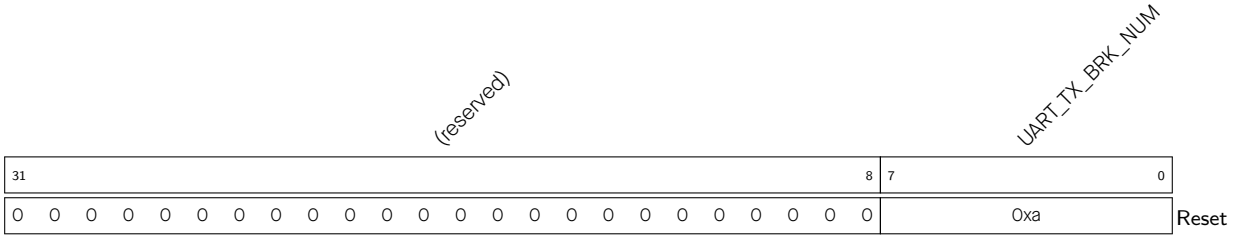
UART_SEND_XOFF Configures whether or not to send XOFF characters.

0: Not send

1: Send

(R/W/SS/SC)

Register 45.16. UART_SWFC_CONF1_REG (0x0040)

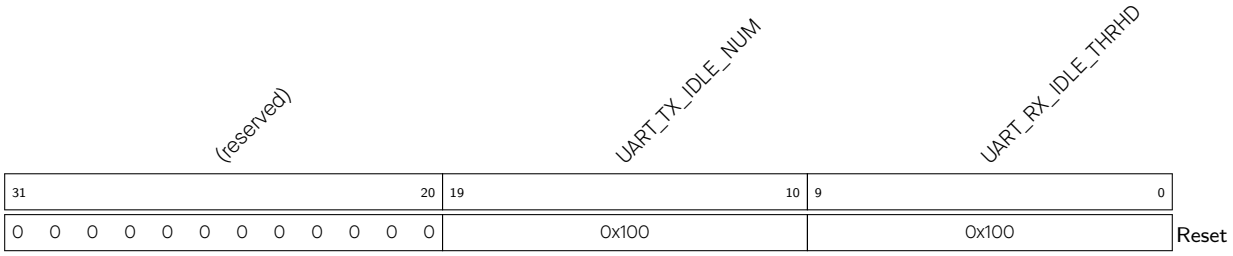


UART_XON_THRESHOLD Configures the threshold for data in RX FIFO to send XON characters in software flow control.

Measurement unit: byte. (R/W)

UART_XOFF_THRESHOLD Configures the threshold for data in RX FIFO to send XOFF characters in software flow control.

Measurement unit: byte. (R/W)

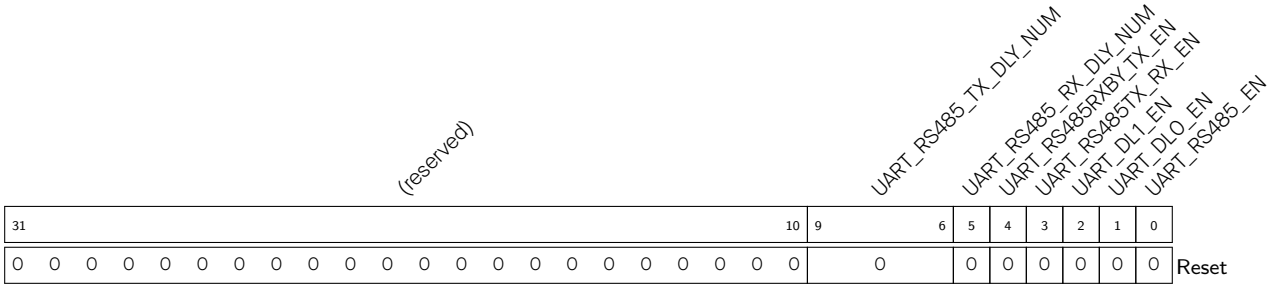


Register 45.17. UART_TXBRK_CONF_SYNC_REG (0x0044)

UART_TX_BRK_NUM Configures the number of NULL characters to be sent after finishing data transmission.

Valid only when UART_TXD_BRK is 1. (R/W)

Register 45.18. UART_IDLE_CONF_SYNC_REG (0x0048)



UART_RX_IDLE_THRHD Configures the threshold to generate a frame end signal when the receiver takes more time to receive one data byte data.

Measurement unit: bit time (the time to transmit 1 bit). (R/W)

UART_TX_IDLE_NUM Configures the interval between two data transfers.

Measurement unit: bit time (the time to transmit 1 bit). (R/W)

Register 45.19. UART_RS485_CONF_SYNC_REG (0x004C)

UART_RS485_EN Configures whether or not to enable RS485 mode.

0: Disable

1: Enable

(R/W)

UART_DL0_EN Configures whether or not to add a turnaround delay of 1 bit before the start bit.

0: Not add

1: Add

(R/W)

UART_DL1_EN Configures whether or not to add a turnaround delay of 1 bit after the stop bit.

0: Not add

1: Add

(R/W)

UART_RS485TX_RX_EN Configures whether or not to enable the receiver for data reception when the transmitter is transmitting data in RS485 mode.

0: Disable

1: Enable

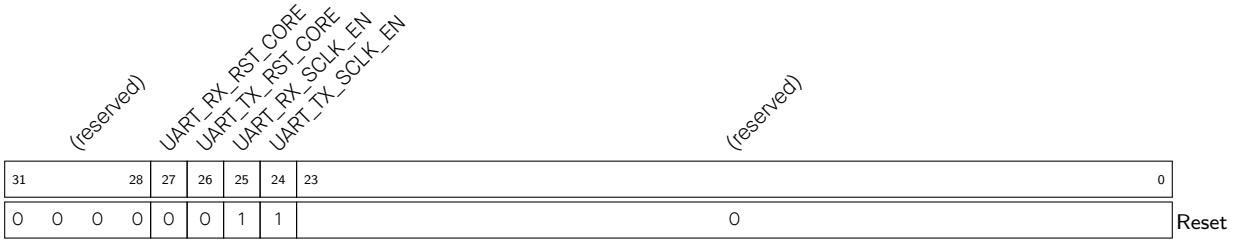
(R/W)

UART_RS485RXBY_TX_EN Configures whether to enable the RS485 transmitter for data transmission when the RS485 receiver is busy.

0: Disable

1: Enable

(R/W)



UART_RS485_RX_DLY_NUM Configures the delay of internal data signals in the receiver.

Measurement unit: bit time (the time to transmit 1 bit).. (R/W)

UART_RS485_TX_DLY_NUM Configures the delay of internal data signals in the transmitter.

Measurement unit: bit time (the time to transmit 1 bit). (R/W)

Register 45.20. UART_CLK_CONF_REG (0x0088)

UART_TX_SCLK_EN Configures whether or not to enable UART TX clock.

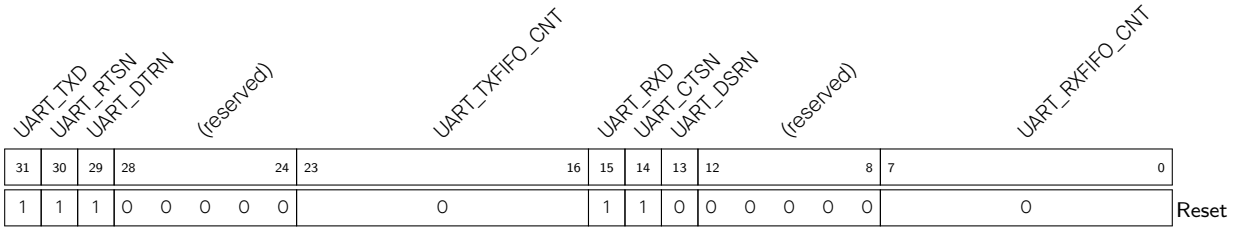
0: Disable

1: Enable

(R/W)

UART_RX_SCLK_EN Configures whether or not to enable UART RX clock.

0: Disable



1: Enable

(R/W)

UART_TX_RST_CORE Write 1 and then write 0 to reset UART TX. (R/W)

UART_RX_RST_CORE Write 1 and then write 0 to reset UART RX. (R/W)

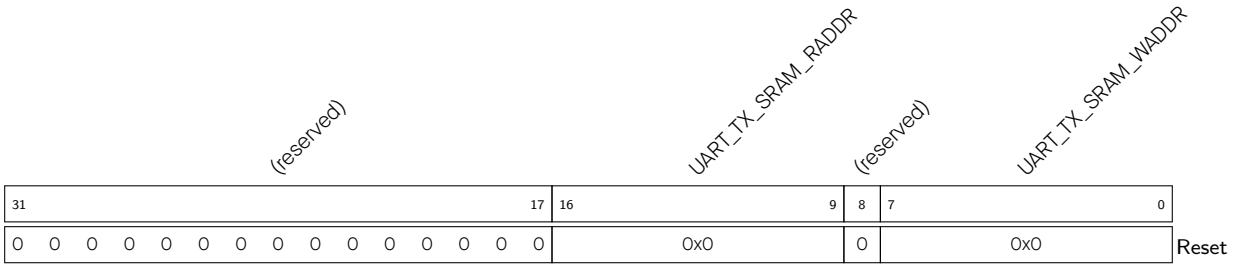
Register 45.21. UART_STATUS_REG (0x001C)

UART_RXFIFO_CNT Represents the number of valid data bytes in RX FIFO. (RO)

UART_DSRN Represents the level of the internal UART DSR signal. (RO)

UART_CTSN Represents the level of the internal UART CTS signal. (RO)

UART_RXD Represents the level of the internal UART RXD signal. (RO)

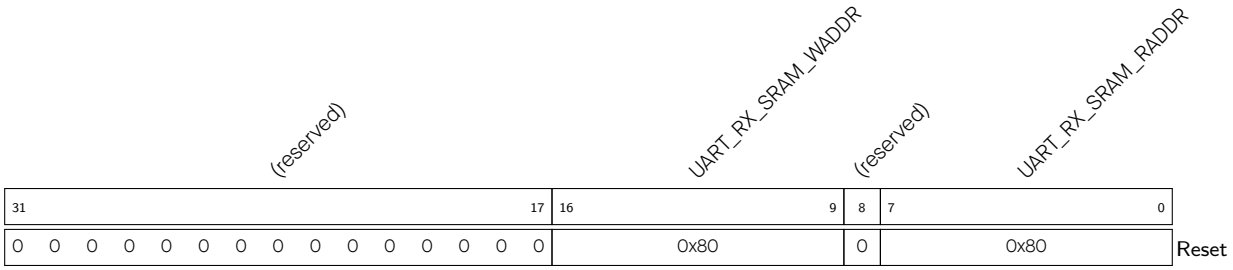


UART_TXFIFO_CNT Represents the number of valid data bytes in RX FIFO. (RO)

UART_DTRN Represents the level of the internal UART DTR signal. (RO)

UART_RTSN Represents the level of the internal UART RTS signal. (RO)

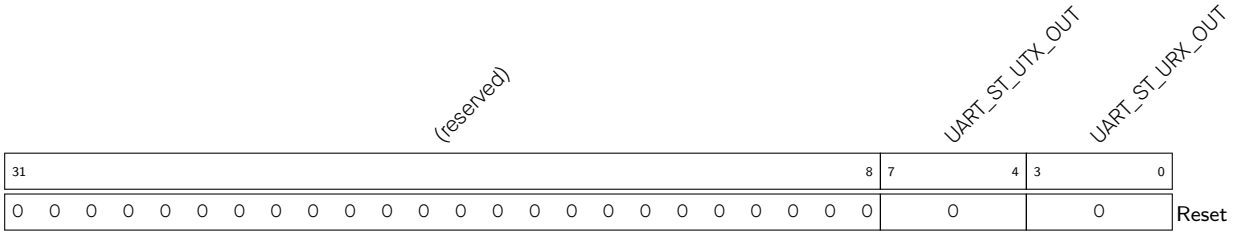
UART_TXD Represents the level of the internal UART TXD signal. (RO)



Register 45.22. UART_MEM_TX_STATUS_REG (0x0068)

UART_TX_SRAM_WADDR Represents the offset address to write TX FIFO. (RO)

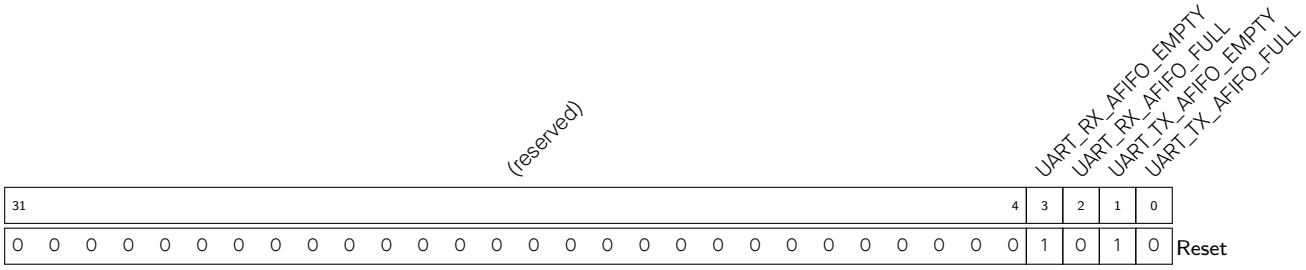
UART_TX_SRAM_RADDR Represents the offset address to read TX FIFO. (RO)



Register 45.23. UART_MEM_RX_STATUS_REG (0x006C)

UART_RX_SRAM_RADDR Represents the offset address to read RX FIFO. (RO)

UART_RX_SRAM_WADDR Represents the offset address to write RX FIFO. (RO)



Register 45.24. UART_FSM_STATUS_REG (0x0070)

UART_ST_URX_OUT Represents the status of the receiver. (RO)

UART_ST_UTX_OUT Represents the status of the transmitter. (RO)

Register 45.25. UART_AFIFO_STATUS_REG (0x0090)

UART_TX_AFIFO_FULL Represents whether or not the APB TX asynchronous FIFO is full.

0: Not full

1: Full

(RO)

UART_TX_AFIFO_EMPTY Represents whether or not the APB TX asynchronous FIFO is empty.

0: Not empty

1: Empty

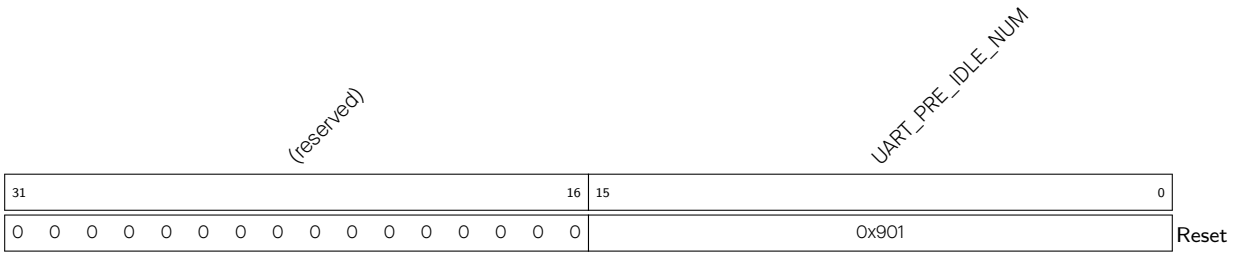
(RO)

UART_RX_AFIFO_FULL Represents whether or not the APB RX asynchronous FIFO is full.

0: Not full

1: Full

(RO)

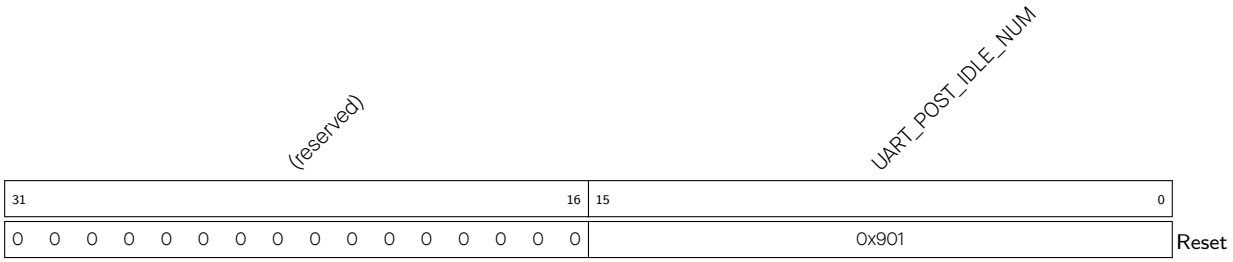


UART_RX_AFIFO_EMPTY Represents whether or not the APB RX asynchronous FIFO is empty.

0: Not empty

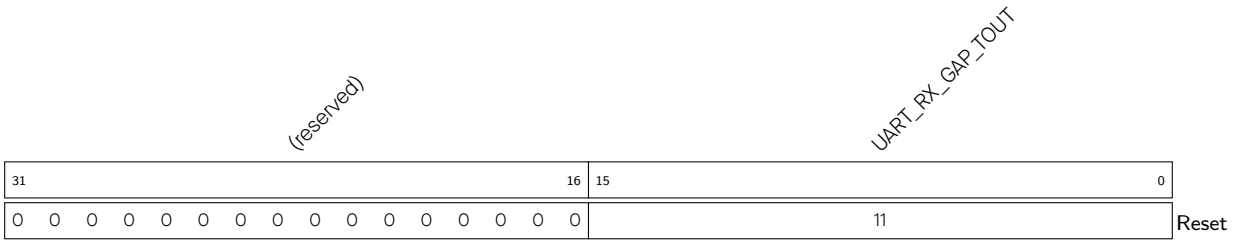
1: Empty

(RO)



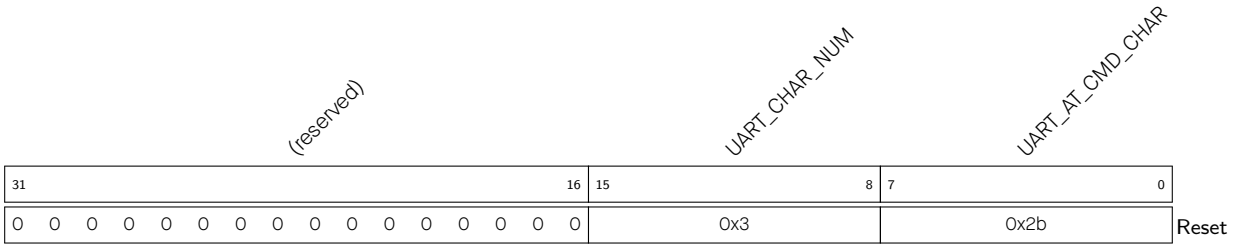
Register 45.26. UART_AT_CMD_PRECNT_SYNC_REG (0x0050)

UART_PRE_IDLE_NUM Configures the idle time before the receiver receives the first AT_CMD.



Measurement unit: bit time (the time to transmit 1 bit). (R/W)

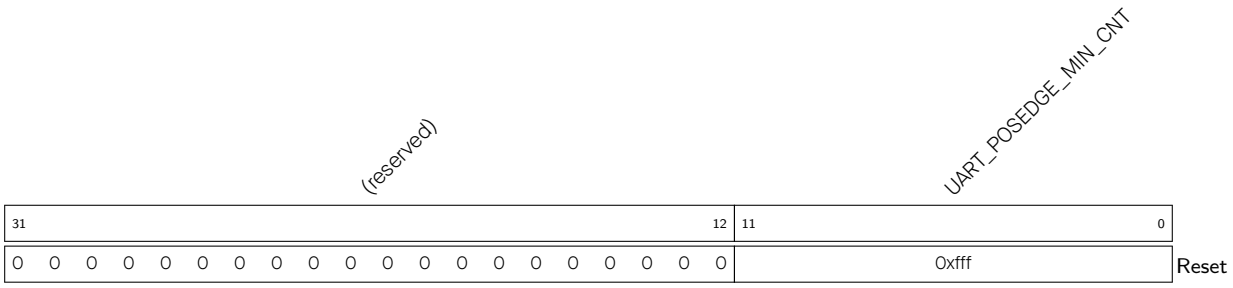
Register 45.27. UART_AT_CMD_POSTCNT_SYNC_REG (0x0054)



UART_POST_IDLE_NUM Configures the interval between the last AT_CMD and subsequent data. Measurement unit: bit time (the time to transmit 1 bit). (R/W)

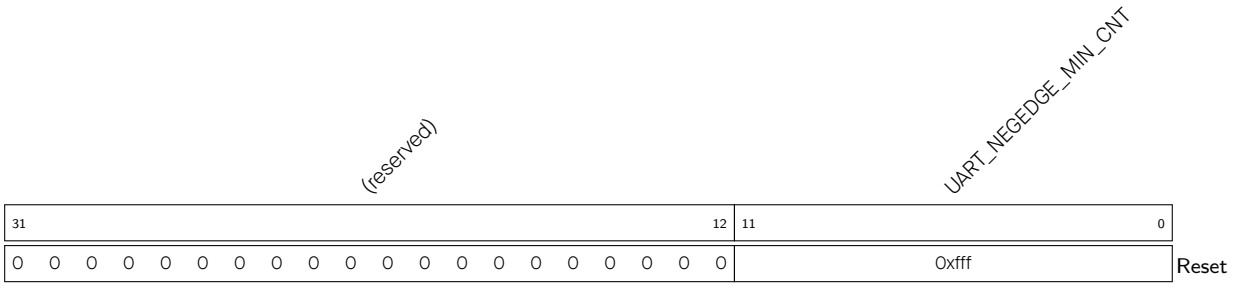
Register 45.28. UART_AT_CMD_GAPTOUT_SYNC_REG (0x0058)

UART_RX_GAP_TOUT Configures the interval between two AT_CMD characters. Measurement unit: bit time (the time to transmit 1 bit). (R/W)



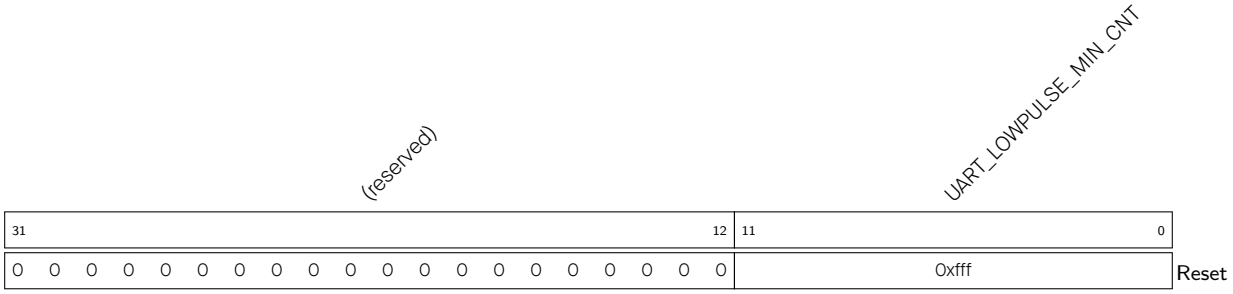
Register 45.29. UART_AT_CMD_CHAR_SYNC_REG (0x005C)

UART_AT_CMD_CHAR Configures the AT_CMD character. (R/W)



UART_CHAR_NUM Configures the number of continuous AT_CMD characters a receiver can receive. (R/W)

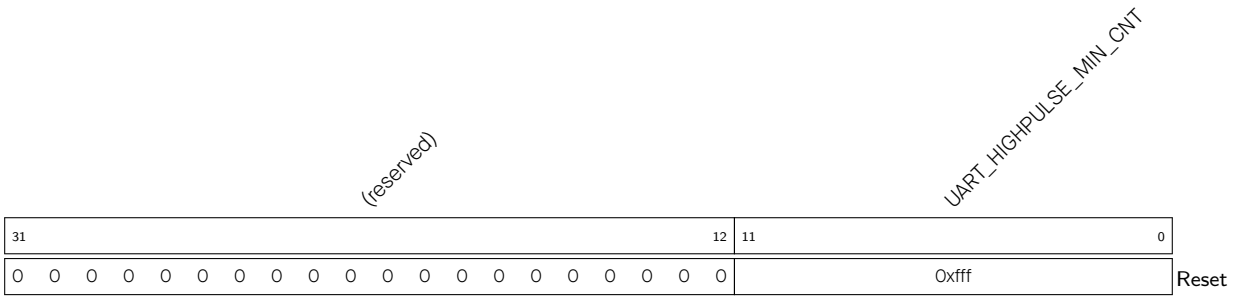
Register 45.30. UART_POSPULSE_REG (0x0074)



UART_POSEDGE_MIN_CNT Represents the minimal input clock counter value between two positive edges. It is used for baud rate detection. (RO)

Register 45.31. UART_NEGPULSE_REG (0x0078)

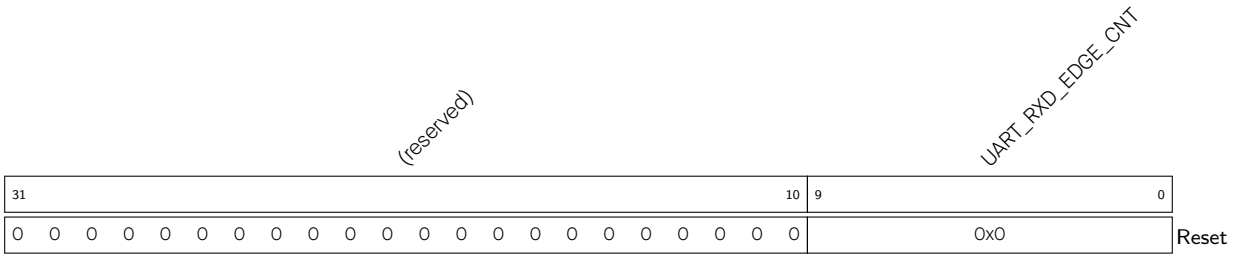
UART_NEGEDGE_MIN_CNT Represents the minimal input clock counter value between two negative edges. It is used for baud rate detection. (RO)



Register 45.32. UART_LOWPULSE_REG (0x007C)

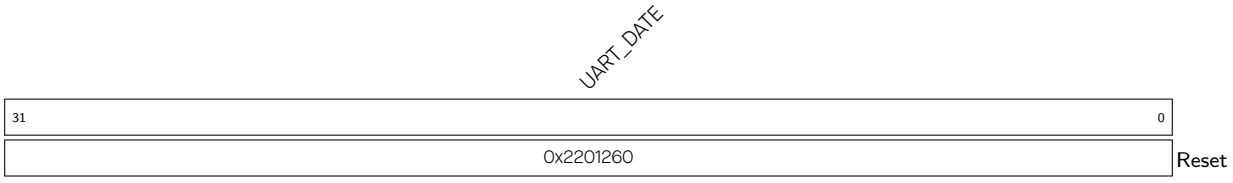
UART_LOWPULSE_MIN_CNT Represents the minimum duration time of a low-level pulse. It is used for baud rate detection.

Measurement unit: APB_CLK clock cycle. (RO)



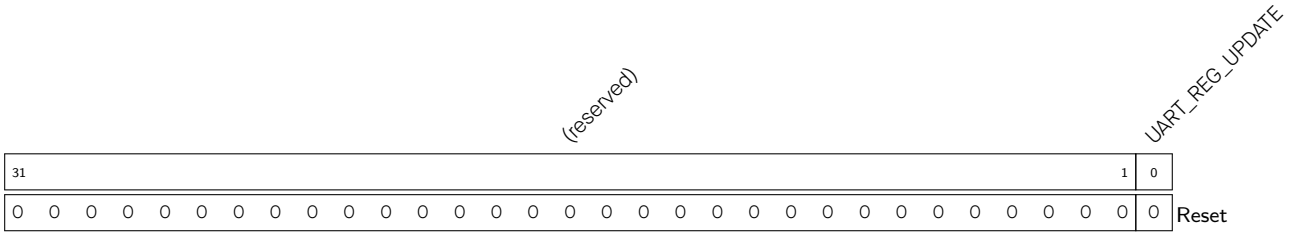
Register 45.33. UART_HIGHPULSE_REG (0x0080)

UART_HIGHPULSE_MIN_CNT Represents the maximum duration time for a high-level pulse. It is used for baud rate detection.



Measurement unit: APB_CLK clock cycle. (RO)

Register 45.34. UART_RXD_CNT_REG (0x0084)

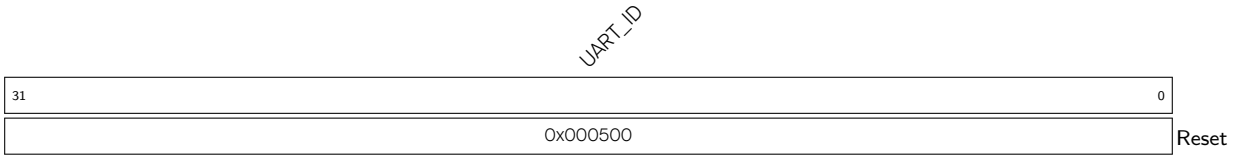


UART_RXD_EDGE_CNT Represents the number of RXD edge changes. It is used for baud rate detection. (RO)

Register 45.35. UART_DATE_REG (0x008C)

UART_DATE Version control register. (R/W)

Register 45.36. UART_REG_UPDATE_REG (0x0098)



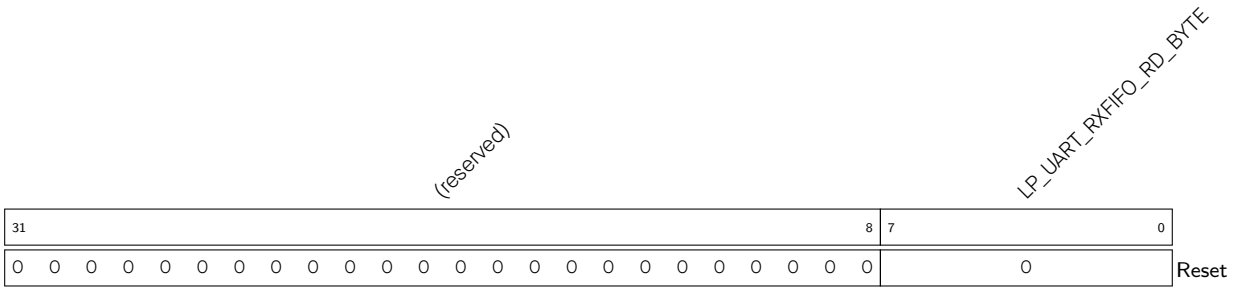
UART_REG_UPDATE Configures whether or not to synchronize registers.

0: Not synchronize

1: Synchronize

(R/W/SC)

Register 45.37. UART_ID_REG (0x009C)

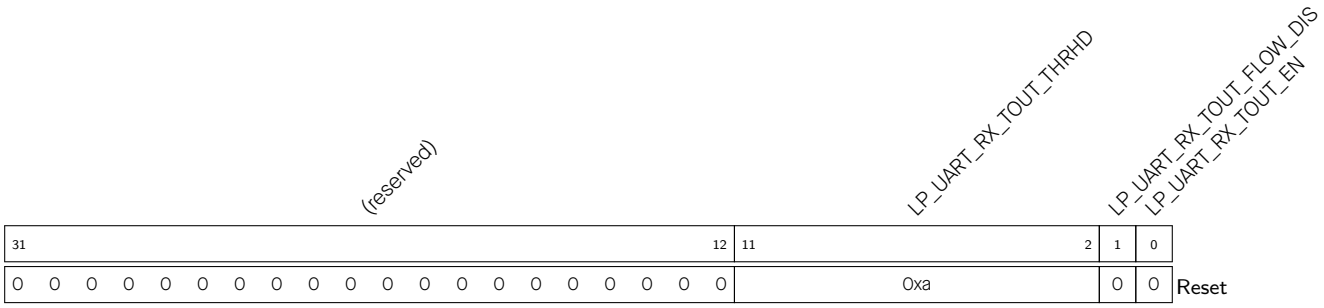


UART_ID Configures the UART ID. (R/W)

45.7.2 LP UART Registers

The addresses in this section are relative to LP UART base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.



Register 45.38. LP_UART_FIFO_REG (0x0000)

LP_UART_RXFIFO_RD_BYTE Represents the data LP UART *n* read from FIFO.

Measurement unit: byte. (RO)

Register 45.39. LP_UART_TOUT_CONF_SYNC_REG (0x0064)

LP_UART_RX_TOUT_EN Configures whether or not to enable LP UART receiver's timeout function.

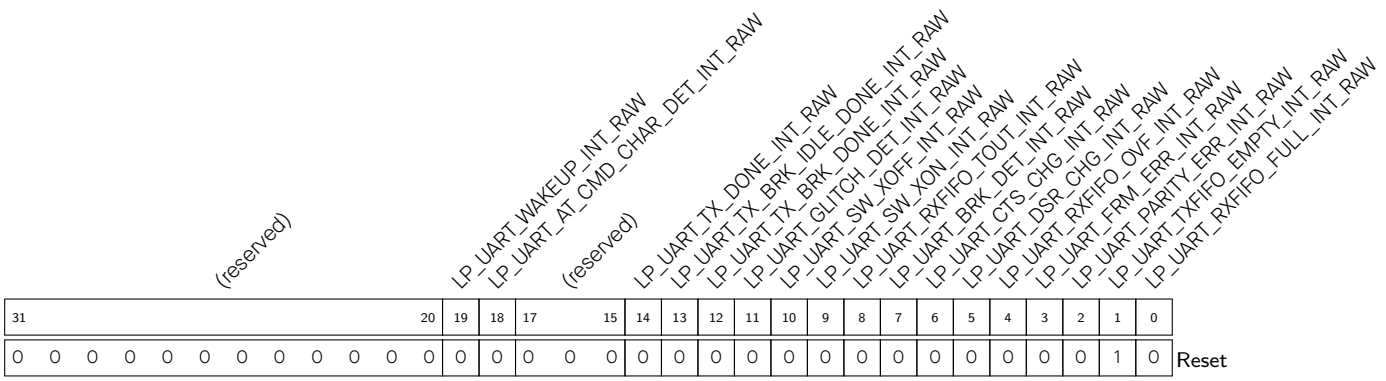
0: Disable

1: Enable

(R/W)

LP_UART_RX_TOUT_FLOW_DIS Configures whether or not to disable the idle status counter when hardware flow control is enabled.

0: Invalid. No effect



1: Disable

(R/W)

LP_UART_RX_TOUT_THRHD Configures the amount of time that the bus can remain idle before time-out.

Measurement unit: bit time (the time to transmit 1 bit). (R/W)

Register 45.40. LP_UART_INT_RAW_REG (0x0004)

LP_UART_RXFIFO_FULL_INT_RAW The raw interrupt status of LP_UART_RXFIFO_FULL_INT. (R/WTC/SS)

LP_UART_TXFIFO_EMPTY_INT_RAW The raw interrupt status of LP_UART_TXFIFO_EMPTY_INT. (R/WTC/SS)

LP_UART_PARITY_ERR_INT_RAW The raw interrupt status of LP_UART_PARITY_ERR_INT. (R/WTC/SS)

LP_UART_FRM_ERR_INT_RAW The raw interrupt status of LP_UART_FRM_ERR_INT. (R/WTC/SS)

LP_UART_RXFIFO_OVF_INT_RAW The raw interrupt status of LP_UART_RXFIFO_OVF_INT. (R/WTC/SS)

LP_UART_DSR_CHG_INT_RAW The raw interrupt status of LP_UART_DSR_CHG_INT. (R/WTC/SS)

LP_UART_CTS_CHG_INT_RAW The raw interrupt status of LP_UART_CTS_CHG_INT. (R/WTC/SS)

LP_UART_BRK_DET_INT_RAW The raw interrupt status of LP_UART_BRK_DET_INT. (R/WTC/SS)

LP_UART_RXFIFO_TOUT_INT_RAW The raw interrupt status of LP_UART_RXFIFO_TOUT_INT. (R/WTC/SS)

LP_UART_SW_XON_INT_RAW The raw interrupt status of LP_UART_SW_XON_INT. (R/WTC/SS)

LP_UART_SW_XOFF_INT_RAW LP_UART_SW_XOFF_INT. (R/WTC/SS)

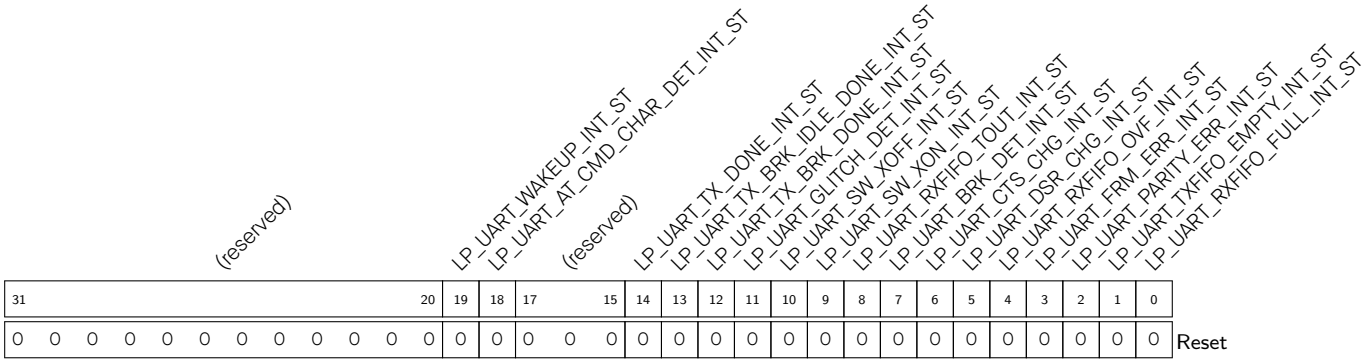
LP_UART_GLITCH_DET_INT_RAW The raw interrupt status of LP_UART_GLITCH_DET_INT. (R/WTC/SS)

LP_UART_TX_BRK_DONE_INT_RAW The raw interrupt status of LP_UART_TX_BRK_DONE_INT. (R/WTC/SS)

LP_UART_TX_BRK_IDLE_DONE_INT_RAW The raw interrupt status of LP_UART_TX_BRK_IDLE_DONE_INT. (R/WTC/SS)

Continued on the next page...

Register 45.40. LP_UART_INT_RAW_REG (0x0004)



Continued from the previous page...

LP_UART_TX_DONE_INT_RAW The raw interrupt status of LP_UART_TX_DONE_INT. (R/WTC/SS)

LP_UART_AT_CMD_CHAR_DET_INT_RAW The raw interrupt status of LP_UART_AT_CMD_CHAR_DET_INT. (R/WTC/SS)

LP_UART_WAKEUP_INT_RAW The raw interrupt status of LP_UART_WAKEUP_INT. (R/WTC/SS)

Register 45.41. LP_UART_INT_ST_REG (0x0008)

LP_UART_RXFIFO_FULL_INT_ST The masked interrupt status of LP_UART_RXFIFO_FULL_INT.(RO)

LP_UART_TXFIFO_EMPTY_INT_ST The masked interrupt status of LP_UART_TXFIFO_EMPTY_INT. (RO)

LP_UART_PARITY_ERR_INT_ST The masked interrupt status of LP_UART_PARITY_ERR_INT. (RO)

LP_UART_FRM_ERR_INT_ST The masked interrupt status of LP_UART_FRM_ERR_INT. (RO)

LP_UART_RXFIFO_OVF_INT_ST The masked interrupt status of LP_UART_RXFIFO_OVF_INT. (RO)

LP_UART_DSR_CHG_INT_ST The masked interrupt status of LP_UART_DSR_CHG_INT. (RO)

LP_UART_CTS_CHG_INT_ST The masked interrupt status of LP_UART_CTS_CHG_INT. (RO)

LP_UART_BRK_DET_INT_ST The masked interrupt status of LP_UART_BRK_DET_INT. (RO)

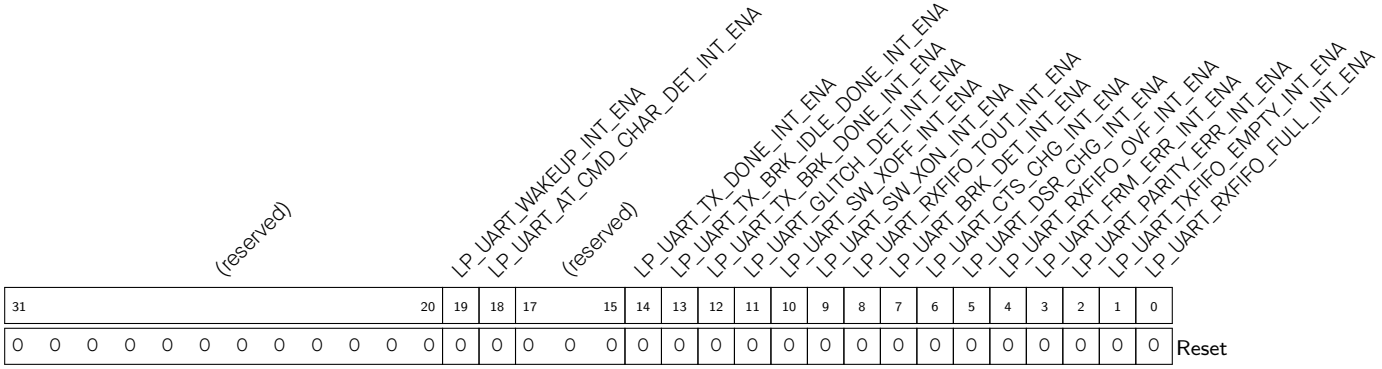
LP_UART_RXFIFO_TOUT_INT_ST The masked interrupt status of LP_UART_RXFIFO_TOUT_INT. (RO)

LP_UART_SW_XON_INT_ST The masked interrupt status of LP_UART_SW_XON_INT. (RO)

LP_UART_SW_XOFF_INT_ST The masked interrupt status of LP_UART_SW_XOFF_INT. (RO)

LP_UART_GLITCH_DET_INT_ST The masked interrupt status of LP_UART_GLITCH_DET_INT. (RO)

LP_UART_TX_BRK_DONE_INT_ST The masked interrupt status of LP_UART_TX_BRK_DONE_INT. (RO)



LP_UART_TX_BRK_IDLE_DONE_INT_ST The masked interrupt status of LP_UART_TX_BRK_IDLE_DONE_INT. (RO)

LP_UART_TX_DONE_INT_ST The masked interrupt status of LP_UART_TX_DONE_INT. (RO)

LP_UART_AT_CMD_CHAR_DET_INT_ST The masked interrupt status of LP_UART_AT_CMD_CHAR_DET_INT. (RO)

LP_UART_WAKEUP_INT_ST The masked interrupt status of LP_UART_WAKEUP_INT. (RO)

Register 45.42. LP_UART_INT_ENA_REG (0x000C)

LP_UART_RXFIFO_FULL_INT_ENA Write 1 to enable LP_UART_RXFIFO_FULL_INT. (R/W)

LP_UART_TXFIFO_EMPTY_INT_ENA Write 1 to enable LP_UART_TXFIFO_EMPTY_INT. (R/W)

LP_UART_PARITY_ERR_INT_ENA Write 1 to enable LP_UART_PARITY_ERR_INT. (R/W)

LP_UART_FRM_ERR_INT_ENA Write 1 to enable LP_UART_FRM_ERR_INT. (R/W)

LP_UART_RXFIFO_OVF_INT_ENA Write 1 to enable LP_UART_RXFIFO_OVF_INT. (R/W)

LP_UART_DSR_CHG_INT_ENA Write 1 to enable LP_UART_DSR_CHG_INT. (R/W)

LP_UART_CTS_CHG_INT_ENA Write 1 to enable LP_UART_CTS_CHG_INT. (R/W)

LP_UART_BRK_DET_INT_ENA Write 1 to enable LP_UART_BRK_DET_INT. (R/W)

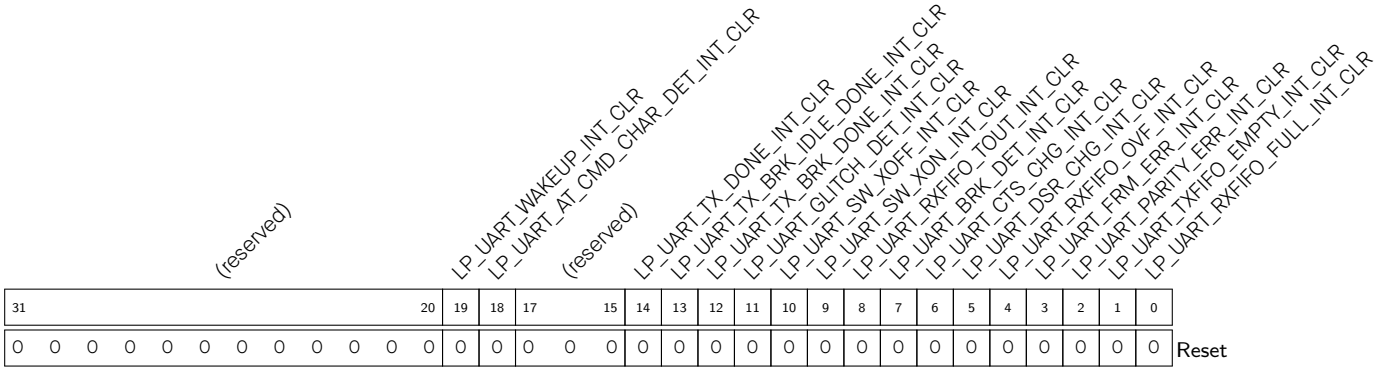
LP_UART_RXFIFO_TOUT_INT_ENA Write 1 to enable LP_UART_RXFIFO_TOUT_INT. (R/W)

LP_UART_SW_XON_INT_ENA Write 1 to enable LP_UART_SW_XON_INT.(R/W)

LP_UART_SW_XOFF_INT_ENA Write 1 to enable LP_UART_SW_XOFF_INT. (R/W)

LP_UART_GLITCH_DET_INT_ENA Write 1 to enable LP_UART_GLITCH_DET_INT. (R/W)

LP_UART_TX_BRK_DONE_INT_ENA Write 1 to enable LP_UART_TX_BRK_DONE_INT. (R/W)



LP_UART_TX_BRK_IDLE_DONE_INT_ENA Write 1 to enable LP_UART_TX_BRK_IDLE_DONE_INT. (R/W)

LP_UART_TX_DONE_INT_ENA Write 1 to enable LP_UART_TX_DONE_INT. (R/W)

LP_UART_AT_CMD_CHAR_DET_INT_ENA Write 1 to enable LP_UART_AT_CMD_CHAR_DET_INT. (R/W)

LP_UART_WAKEUP_INT_ENA Write 1 to enable LP_UART_WAKEUP_INT. (R/W)

Register 45.43. LP_UART_INT_CLR_REG (0x0010)

LP_UART_RXFIFO_FULL_INT_CLR Write 1 to clear LP_UART_RXFIFO_FULL_INT. (WT)

LP_UART_TXFIFO_EMPTY_INT_CLR Write 1 to clear LP_UART_TXFIFO_EMPTY_INT. (WT)

LP_UART_PARITY_ERR_INT_CLR Write 1 to clear LP_UART_PARITY_ERR_INT. (WT)

LP_UART_FRM_ERR_INT_CLR Write 1 to clear LP_UART_FRM_ERR_INT. (WT)

LP_UART_RXFIFO_OVF_INT_CLR Write 1 to clear LP_UART_RXFIFO_OVF_INT. (WT)

LP_UART_DSR_CHG_INT_CLR Write 1 to clear LP_UART_DSR_CHG_INT. (WT)

LP_UART_CTS_CHG_INT_CLR Write 1 to clear LP_UART_CTS_CHG_INT. (WT)

LP_UART_BRK_DET_INT_CLR Write 1 to clear LP_UART_BRK_DET_INT. (WT)

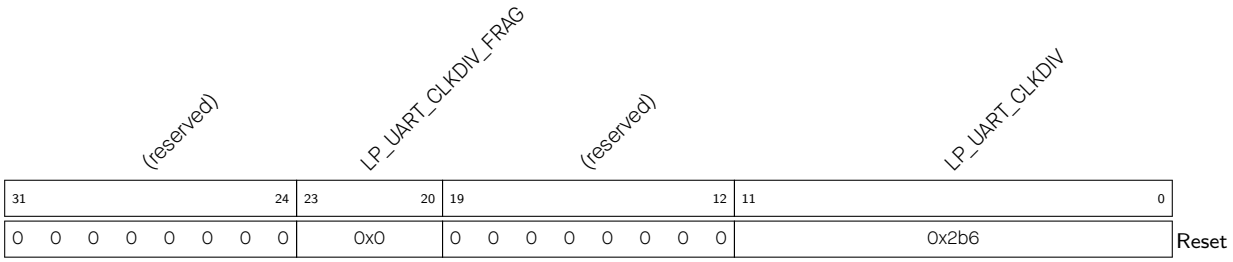
LP_UART_RXFIFO_TOUT_INT_CLR Write 1 to clear LP_UART_RXFIFO_TOUT_INT. (WT)

LP_UART_SW_XON_INT_CLR Write 1 to clear LP_UART_SW_XON_INT. (WT)

LP_UART_SW_XOFF_INT_CLR Write 1 to clear LP_UART_SW_XOFF_INT. (WT)

LP_UART_GLITCH_DET_INT_CLR Write 1 to clear LP_UART_GLITCH_DET_INT. (WT)

LP_UART_TX_BRK_DONE_INT_CLR Write 1 to clear LP_UART_TX_BRK_DONE_INT. (WT)

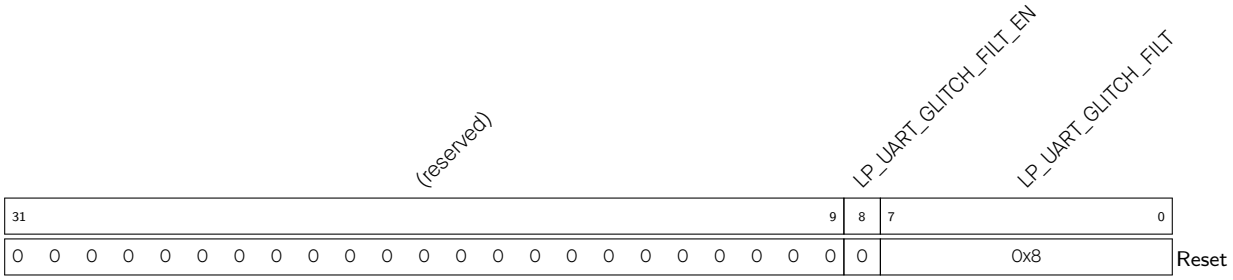


LP_UART_TX_BRK_IDLE_DONE_INT_CLR Write 1 to clear LP_UART_TX_BRK_IDLE_DONE_INT. (WT)

LP_UART_TX_DONE_INT_CLR Write 1 to clear LP_UART_TX_DONE_INT. (WT)

LP_UART_AT_CMD_CHAR_DET_INT_CLR Write 1 to clear LP_UART_AT_CMD_CHAR_DET_INT. (WT)

LP_UART_WAKEUP_INT_CLR Write 1 to clear LP_UART_WAKEUP_INT. (WT)



Register 45.44. LP_UART_CLKDIV_SYNC_REG (0x0014)

LP_UART_CLKDIV Configures the integral part of the divisor for baud rate generation. (R/W)

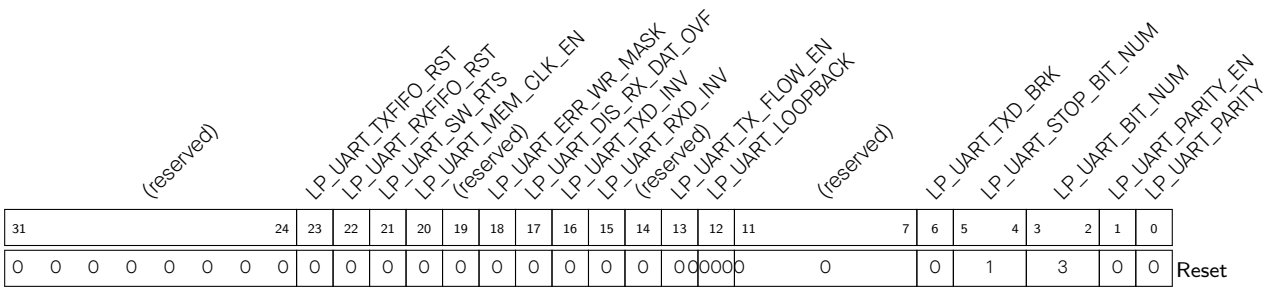
LP_UART_CLKDIV_FRAG Configures the fractional part of the divisor for baud rate generation. (R/W)

Register 45.45. LP_UART_RX_FILT_REG (0x0018)

LP_UART_GLITCH_FILT Configures the width of a pulse to be filtered.

Measurement unit: UART Core's clock cycle.

Pulses whose width is lower than this value will be ignored. (R/W)



LP_UART_GLITCH_FILT_EN Configures whether or not to enable RX signal filter.

0: Disable

1: Enable

(R/W)

Register 45.46. LP_UART_CONF0_SYNC_REG (0x0020)

(reserved)
LP_UART_TXFIFO_RST
LP_UART_RXFIFO_RST
LP_UART_SW_RTS
LP_UART_MEM_CLK_EN

Register 45.46. LP_UART_CONF0_SYNC_REG (0x0020)

Continued from the previous page...

LP_UART_TX_FLOW_EN Configures whether or not to enable flow control for the transmitter.

0: Disable

1: Enable

(R/W)

LP_UART_RXD_INV Configures whether or not to invert the level of LP UART RXD signal.

0: Not invert

1: Invert

(R/W)

LP_UART_TXD_INV Configures whether or not to invert the level of LP UART TXD signal.

0: Not invert

1: Invert

(R/W)

LP_UART_DIS_RX_DAT_OVF Configures whether or not to disable data overflow detection for the LP UART receiver.

0: Enable

1: Disable

(R/W)

LP_UART_ERR_WR_MASK Configures whether or not to store the received data with errors into FIFO.

0: Store

1: Not store

(R/W)

LP_UART_MEM_CLK_EN Configures whether or not to enable clock gating for LP UART memory.

0: Disable

1: Enable

(R/W)

LP_UART_SW_RTS Configures the RTS signal used in software flow control.

0: The LP UART transmitter is not allowed to send data.

1: The LP UART transmitted is allowed to send data.

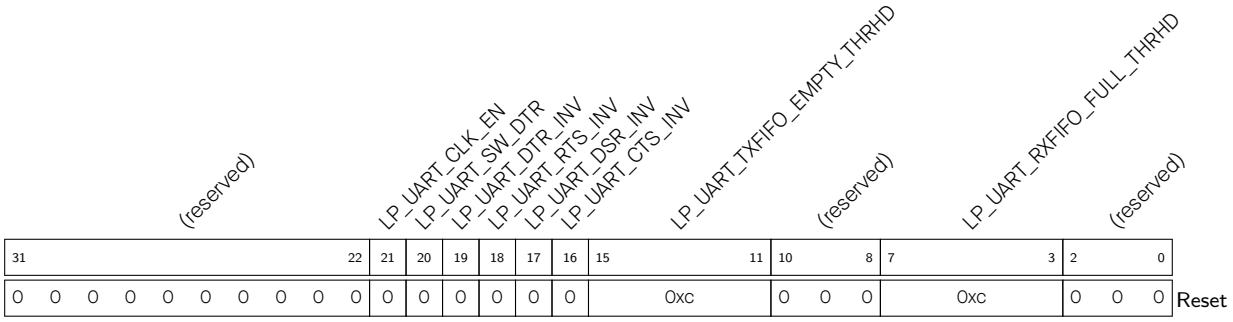
(R/W)

LP_UART_RXFIFO_RST Configures whether or not to reset the LP UART RX FIFO.

0: Not reset

1: Reset

(R/W)



LP_UART_TXFIFO_RST Configures whether or not to reset the LP UART TX FIFO.

0: Not reset

1: Reset

(R/W)

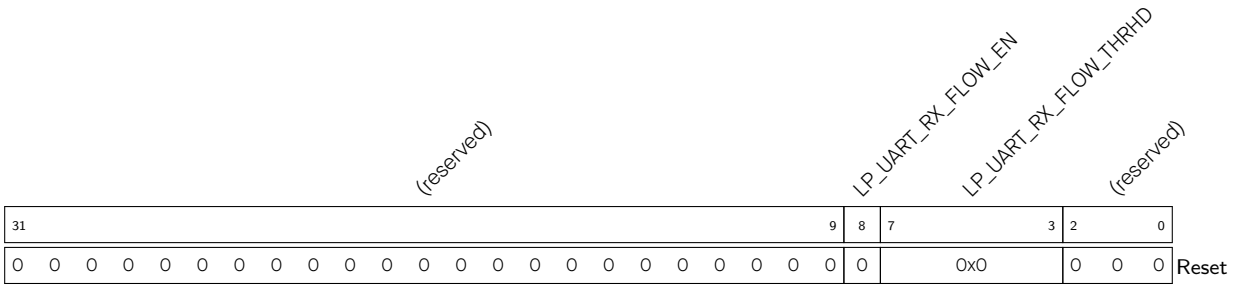
Register 45.47. LP_UART_CONF1_REG (0x0024)

LP_UART_RXFIFO_FULL_THRHD Configures the threshold for RX FIFO being full.
Measurement unit: byte. (R/W)

LP_UART_TXFIFO_EMPTY_THRHD Configures the threshold for TX FIFO being empty.
Measurement unit: byte. (R/W)

LP_UART_CTS_INV Configures whether or not to invert the level of LP UART CTS signal.
0: Not invert
1: Invert
(R/W)

LP_UART_DSR_INV Configures whether or not to invert the level of LP UART DSR signal.
0: Not invert
1: Invert
(R/W)



LP_UART_RTS_INV Configures whether or not to invert the level of LP UART RTS signal.
0: Not invert
1: Invert
(R/W)

LP_UART_DTR_INV Configures whether or not to invert the level of LP UART DTR signal.
0: Not invert
1: Invert
(R/W)

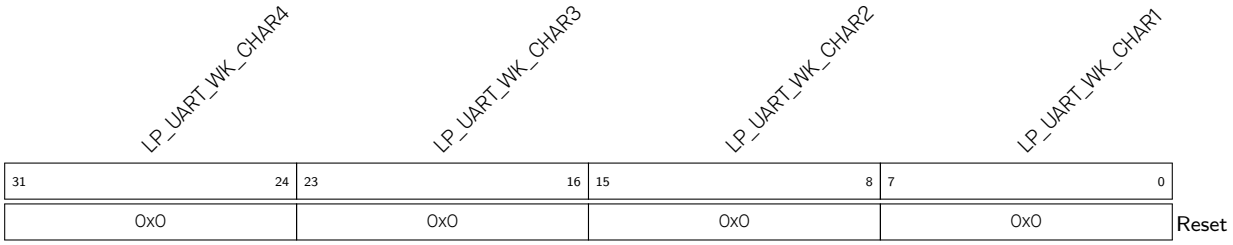
LP_UART_SW_DTR Configures the DTR signal used in software flow control.
0: Data to be transmitted is not ready.
1: Data to be transmitted is ready.
(R/W)

LP_UART_CLK_EN Configures clock gating.
0: Support clock only when the application writes registers.
1: Always force the clock on for registers.
(R/W)

Register 45.48. LP_UART_HWFC_CONF_SYNC_REG (0x002C)

LP_UART_RX_FLOW_THRHD Configures the maximum number of data bytes that can be received during hardware flow control.

Measurement unit: byte. (R/W)



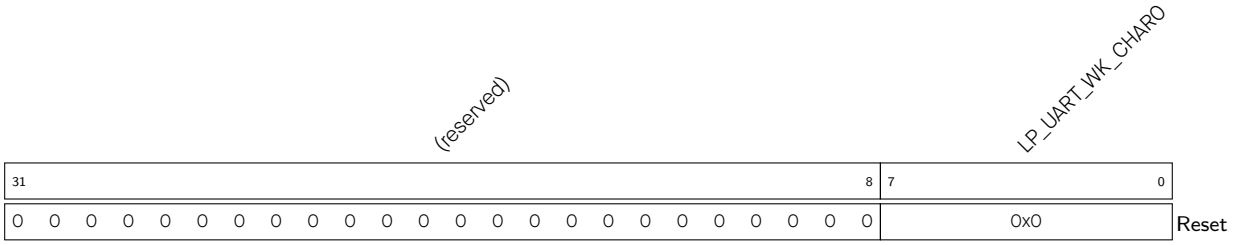
LP_UART_RX_FLOW_EN Configures whether or not to enable the LP UART receiver.

0: Disable

1: Enable

(R/W)

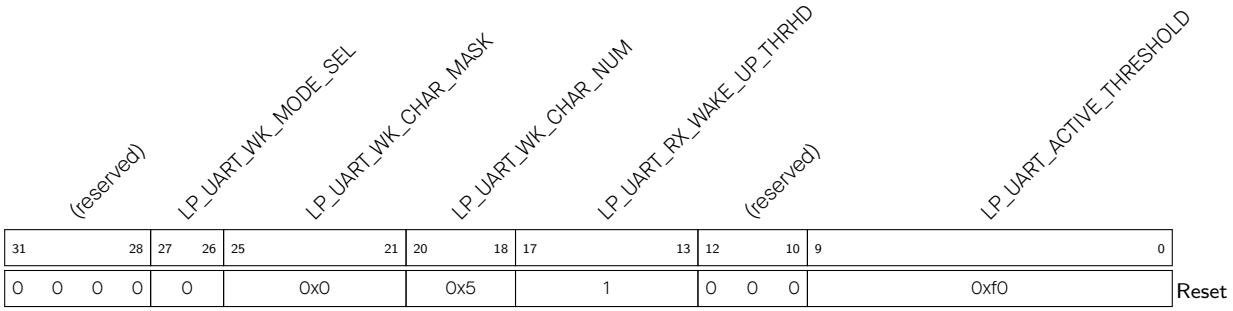
Register 45.49. LP_UART_SLEEP_CONF0_REG (0x0030)



LP_UART_WK_CHAR1 Configures wakeup character 1. (R/W)

LP_UART_WK_CHAR2 Configures wakeup character 2. (R/W)

LP_UART_WK_CHAR3 Configures wakeup character 3. (R/W)



LP_UART_WK_CHAR4 Configures wakeup character 4. (R/W)

Register 45.50. LP_UART_SLEEP_CONF1_REG (0x0034)

LP_UART_WK_CHAR0 Configures wakeup character 0. (R/W)

Register 45.51. LP_UART_SLEEP_CONF2_REG (0x0038)

LP_UART_ACTIVE_THRESHOLD Configures the number of RXD edge changes to wake up the chip in wakeup mode 0. (R/W)

LP_UART_RX_WAKE_UP_THRHD Configures the number of received data bytes to wake up the chip in wakeup mode 1. (R/W)

LP_UART_WK_CHAR_NUM Configures the number of wakeup characters. (R/W)

LP_UART_WK_CHAR_MASK Configures whether or not to mask wakeup characters.

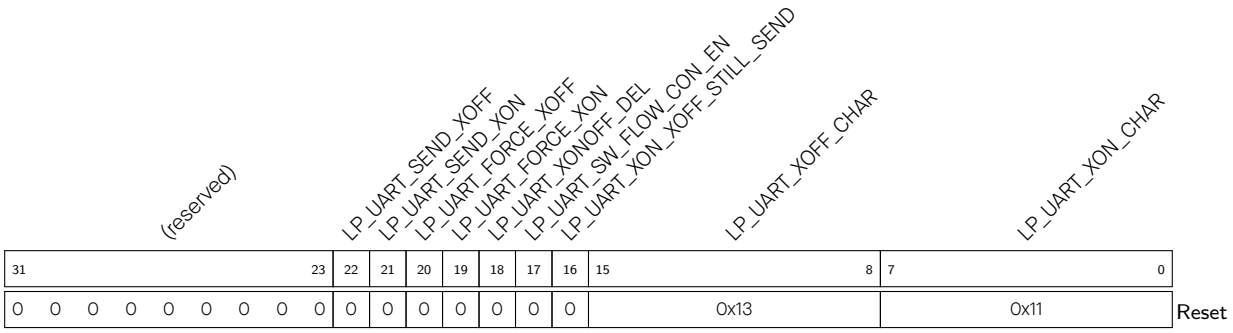
0: Not mask

1: Mask

(R/W)

LP_UART_WK_MODE_SEL Configures which wakeup mode to select.

0: Mode 0



1: Mode 1

2: Mode 2

3: Mode 3

(R/W)

Register 45.52. LP_UART_SWFC_CONF0_SYNC_REG (0x003C)

LP_UART_XON_CHAR Configures the XON character for flow control. (R/W)

LP_UART_XOFF_CHAR Configures the XOFF character for flow control. (R/W)

LP_UART_XON_XOFF_STILL_SEND Configures whether the LP UART transmitter can send XON or XOFF characters when it is disabled.

0: Cannot send

1: Can send

(R/W)

LP_UART_SW_FLOW_CON_EN Configures whether or not to enable software flow control.

0: Disable

1: Enable

(R/W)

LP_UART_XONOFF_DEL Configures whether or not to remove flow control characters from the received data.

0: Not move

1: Move

(R/W)

LP_UART_FORCE_XON Configures whether the transmitter continues to sending data.

0: Not send

1: Send

(R/W)

LP_UART_FORCE_XOFF Configures whether or not to stop the transmitter from sending data.

0: Not stop

1: Stop

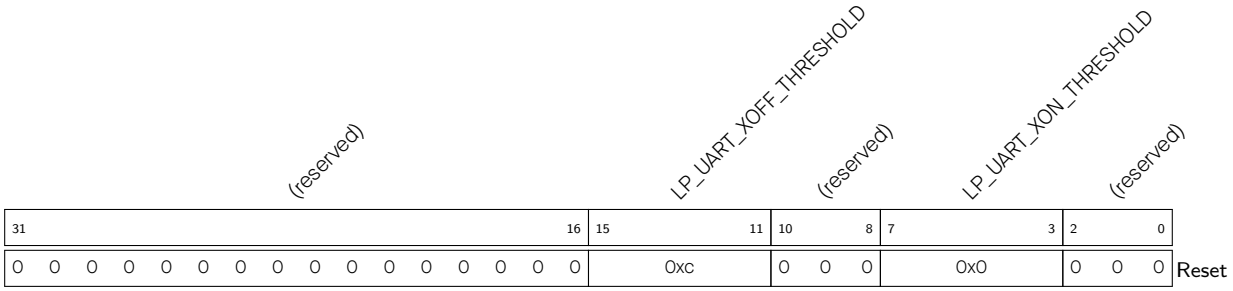
(R/W)

LP_UART_SEND_XON Configures whether or not to send XON characters.

0: Not send

1: Send

(R/W/SS/SC)



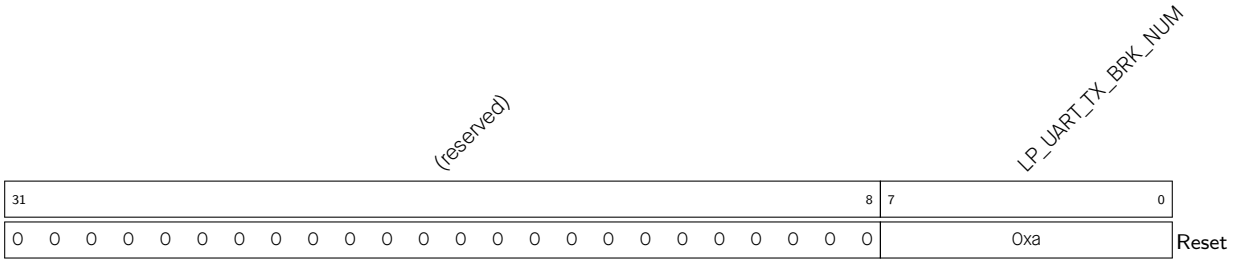
LP_UART_SEND_XOFF Configures whether or not to send XOFF characters.

0: Not send

1: Send

(R/W/SS/SC)

Register 45.53. LP_UART_SWFC_CONF1_REG (0x0040)

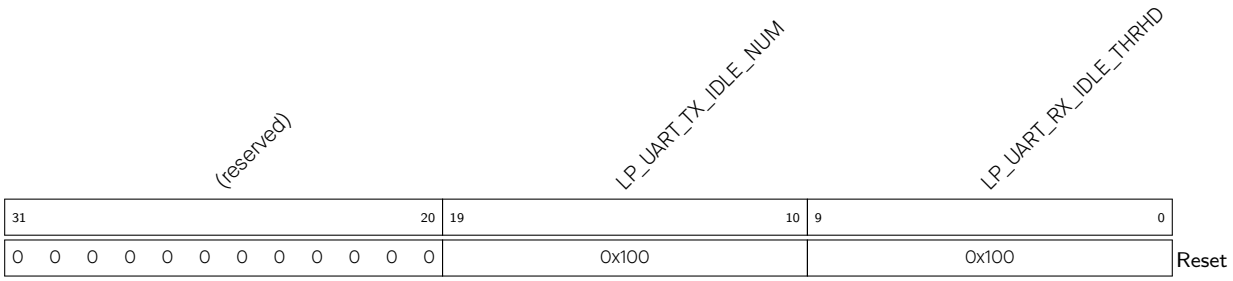


LP_UART_XON_THRESHOLD Configures the threshold for data in RX FIFO to send XON characters in software flow control.

Measurement unit: byte. (R/W)

LP_UART_XOFF_THRESHOLD Configures the threshold for data in RX FIFO to send XOFF characters in software flow control.

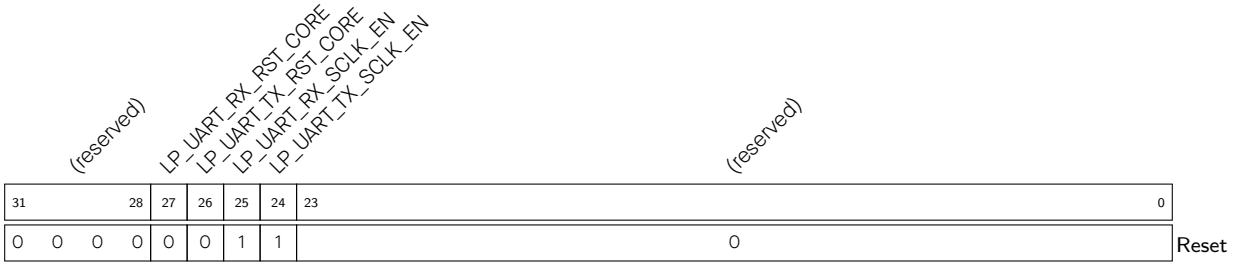
Measurement unit: byte. (R/W)



Register 45.54. LP_UART_TXBRK_CONF_SYNC_REG (0x0044)

LP_UART_TX_BRK_NUM Configures the number of NULL characters to be sent after finishing data transmission.

Valid only when LP_UART_TXD_BRK is 1. (R/W)

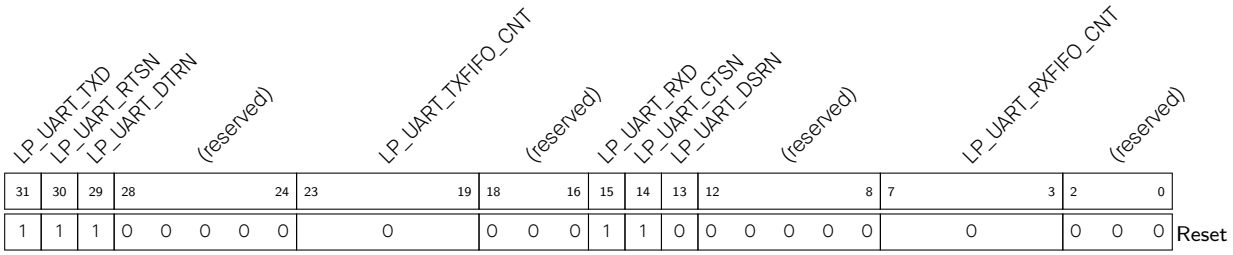


Register 45.55. LP_UART_IDLE_CONF_SYNC_REG (0x0048)

LP_UART_RX_IDLE_THRHD Configures the threshold to generate a frame end signal when the receiver takes more time to receive one data byte data.
Measurement unit: bit time (the time to transmit 1 bit). (R/W)

LP_UART_TX_IDLE_NUM Configures the interval between two data transfers.
Measurement unit: bit time (the time to transmit 1 bit). (R/W)

Register 45.56. LP_UART_CLK_CONF_REG (0x0088)



LP_UART_TX_SCLK_EN Configures whether or not to enable LP UART TX clock.
0: Disable
1: Enable
(R/W)

LP_UART_RX_SCLK_EN Configures whether or not to enable LP UART RX clock.
0: Disable
1: Enable
(R/W)

LP_UART_TX_RST_CORE Write 1 and then write 0 to reset LP UART TX. (R/W)

LP_UART_RX_RST_CORE Write 1 and then write 0 to reset LP UART RX. (R/W)

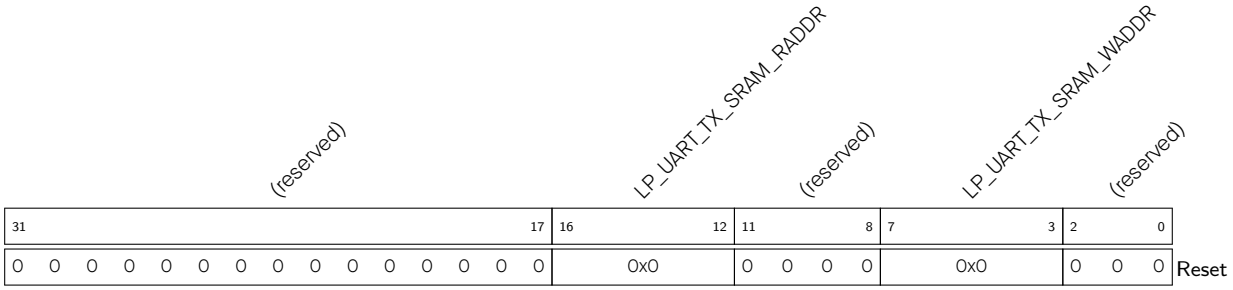
Register 45.57. LP_UART_STATUS_REG (0x001C)

LP_UART_RXFIFO_CNT Represents the number of valid data bytes in RX FIFO. (RO)

LP_UART_DSRN Represents the level of the internal LP UART DSR signal. (RO)

LP_UART_CTSN Represents the level of the internal LP UART CTS signal. (RO)

LP_UART_RXD Represents the level of the internal LP UART RXD signal. (RO)

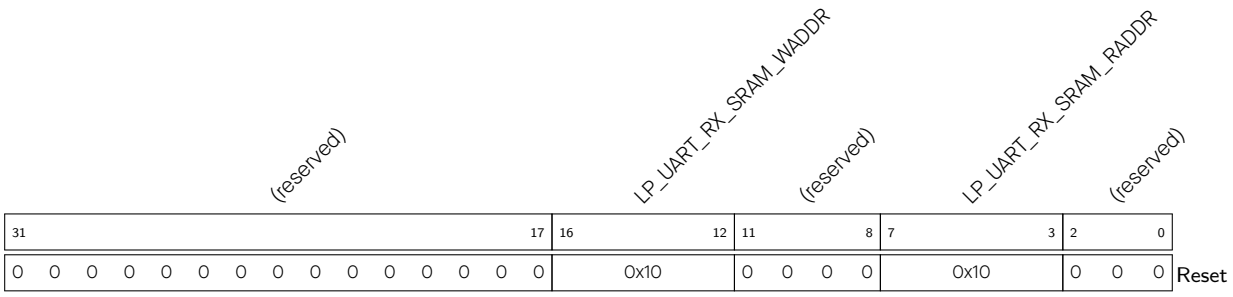


LP_UART_TXFIFO_CNT Represents the number of valid data bytes in RX FIFO. (RO)

LP_UART_DTRN Represents the level of the internal LP UART DTR signal. (RO)

LP_UART_RTSN Represents the level of the internal LP UART RTS signal. (RO)

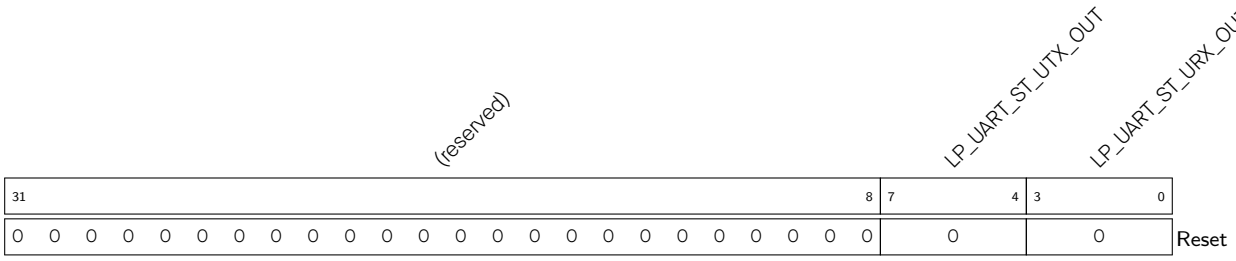
LP_UART_TXD Represents the level of the internal LP UART TXD signal. (RO)



Register 45.58. LP_UART_MEM_TX_STATUS_REG (0x0068)

LP_UART_TX_SRAM_WADDR Represents the offset address to write TX FIFO. (RO)

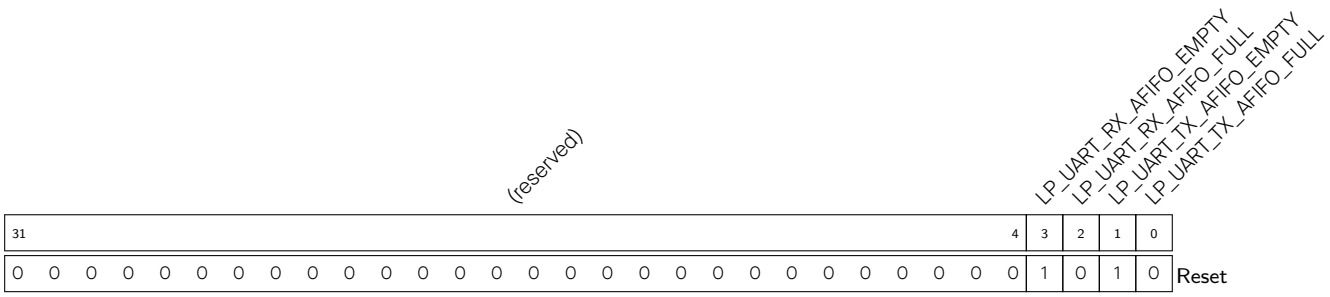
LP_UART_TX_SRAM_RADDR Represents the offset address to read TX FIFO. (RO)



Register 45.59. LP_UART_MEM_RX_STATUS_REG (0x006C)

LP_UART_RX_SRAM_RADDR Represents the offset address to read RX FIFO. (RO)

LP_UART_RX_SRAM_WADDR Represents the offset address to write RX FIFO. (RO)



Register 45.60. LP_UART_FSM_STATUS_REG (0x0070)

LP_UART_ST_URX_OUT Represents the status of the receiver. (RO)

LP_UART_ST_UTX_OUT Represents the status of the transmitter. (RO)

Register 45.61. LP_UART_AFIFO_STATUS_REG (0x0090)

LP_UART_TX_AFIFO_FULL Represents whether or not the APB TX asynchronous FIFO is full.

0: Not full

1: Full

(RO)

LP_UART_TX_AFIFO_EMPTY Represents whether or not the APB TX asynchronous FIFO is empty.

0: Not empty

1: Empty

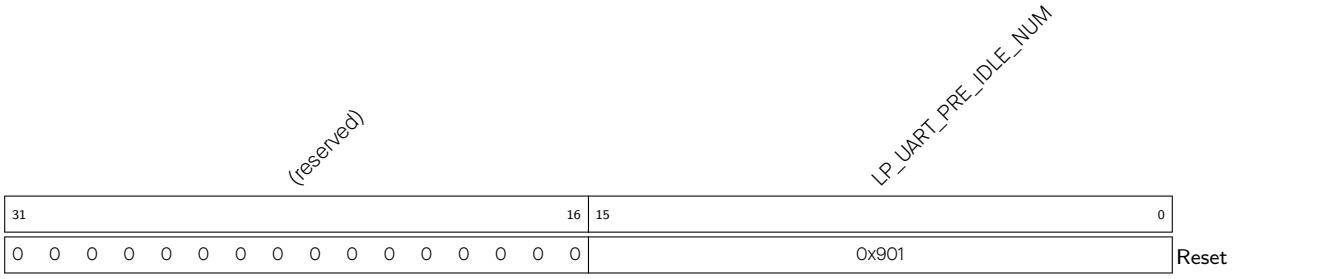
(RO)

LP_UART_RX_AFIFO_FULL Represents whether or not the APB RX asynchronous FIFO is full.

0: Not full

1: Full

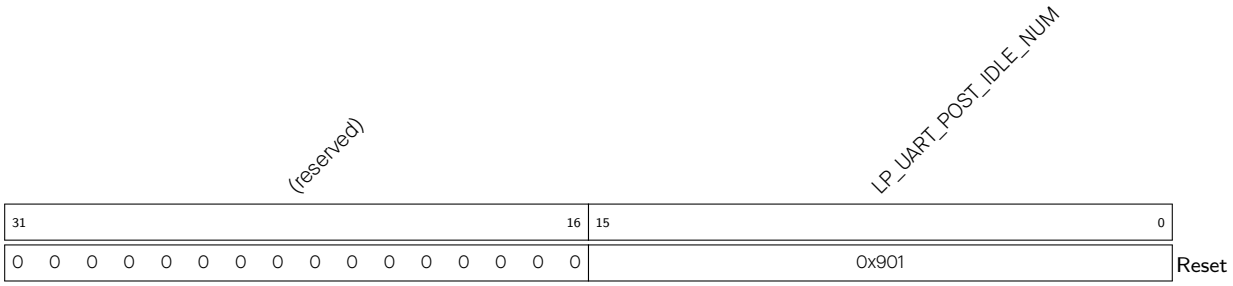
(RO)



LP_UART_RX_AFIFO_EMPTY Represents whether or not the APB RX asynchronous FIFO is empty.

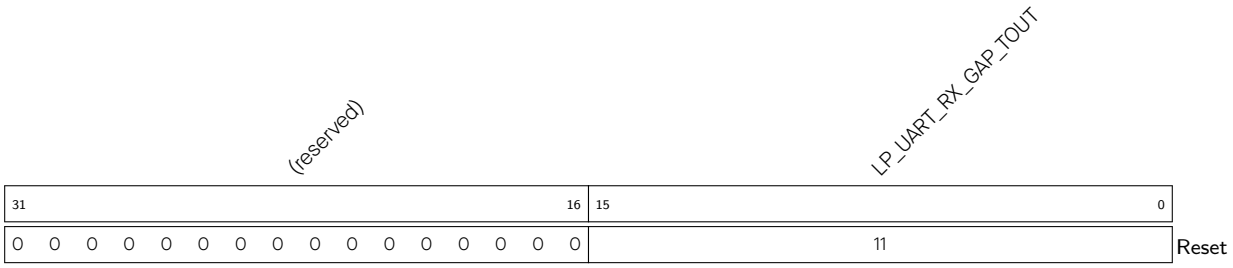
0: Not empty

1: Empty



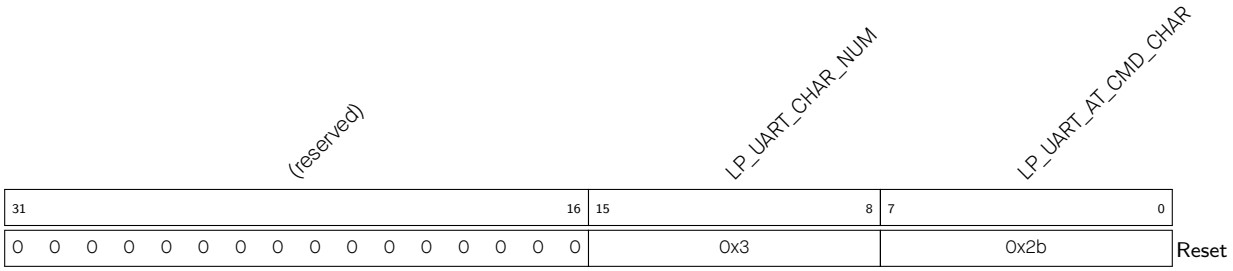
(RO)

Register 45.62. LP_UART_AT_CMD_PRECNT_SYNC_REG (0x0050)



LP_UART_PRE_IDLE_NUM Configures the idle time before the receiver receives the first AT_CMD. Measurement unit: bit time (the time to transmit 1 bit). (R/W)

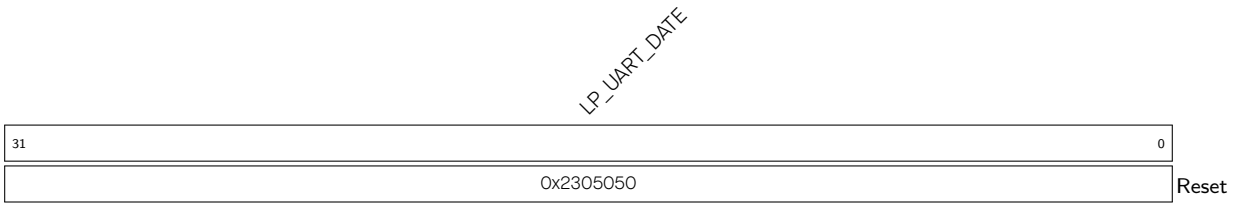
Register 45.63. LP_UART_AT_CMD_POSTCNT_SYNC_REG (0x0054)



LP_UART_POST_IDLE_NUM Configures the interval between the last AT_CMD and subsequent data. Measurement unit: bit time (the time to transmit 1 bit). (R/W)

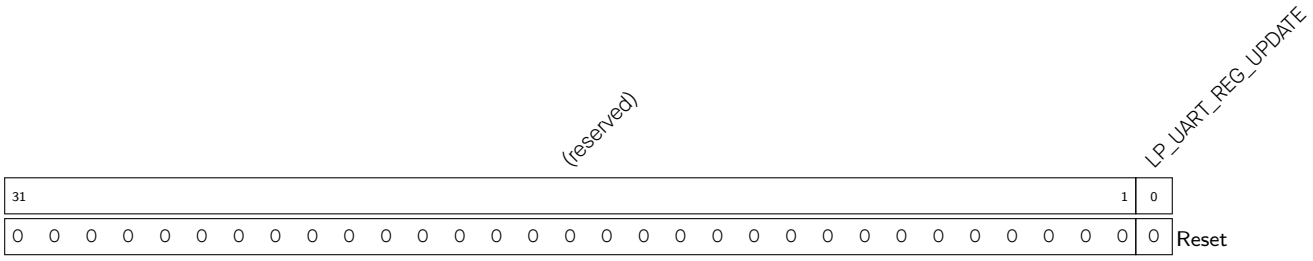
Register 45.64. LP_UART_AT_CMD_GAPTOUT_SYNC_REG (0x0058)

LP_UART_RX_GAP_TOUT Configures the interval between two AT_CMD characters. Measurement unit: bit time (the time to transmit 1 bit). (R/W)



Register 45.65. LP_UART_AT_CMD_CHAR_SYNC_REG (0x005C)

LP_UART_AT_CMD_CHAR Configures the AT_CMD character. (R/W)

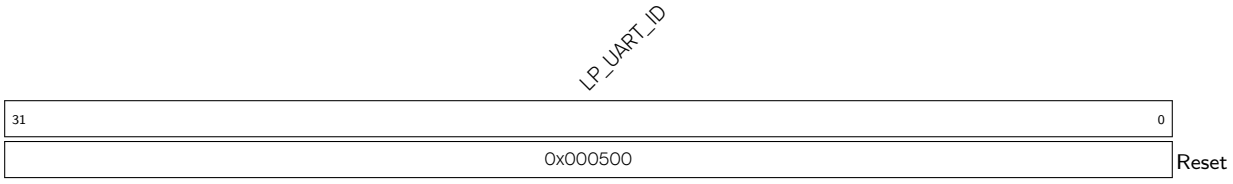


LP_UART_CHAR_NUM Configures the number of continuous AT_CMD characters a receiver can receive. (R/W)

Register 45.66. LP_UART_DATE_REG (0x008C)

LP_UART_DATE Version control register. (R/W)

Register 45.67. LP_UART_REG_UPDATE_REG (0x0098)



LP_UART_REG_UPDATE Configures whether or not to synchronize registers.

0: Not synchronize

1: Synchronize

(R/W/SC)

Register 45.68. LP_UART_ID_REG (0x009C)

LP_UART_ID Configures the LP UART ID. (R/W)

45.7.3 UHCI Registers

The addresses in this section are relative to UHCI base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 45.69. UHCI_CONF0_REG (0x0000)

UHCI_TX_RST Write 1 and then write 0 to reset the decoder state machine. (R/W)

UHCI_RX_RST Write 1 and then write 0 to reset the encoder state machine. (R/W)

UHCI_UART0_CE Select one UART from UART 0 ~ 4 to connect with UHCI.

0: Select UART0
1: Select UART1
2: Select UART2
3: Select UART3
4: Select UART4
5 ~ 7: No effect, as no UART will connect with UHCI
(R/W)

UHCI_UART1_CE Configures whether or not to connect UHCI with UART1.

0: Not connect
1: Connect
(R/W)

UHCI_SEPER_EN Configures whether or not to separate the data frame with a special character.

0: Not separate
1: Separate
(R/W)

UHCI_HEAD_EN Configures whether or not to encode the data packet with a formatting header.

0: Not use formatting header
1: Use formatting header
(R/W)

Continued on the next page...

Register 45.69. UHCI_CONF0_REG (0x0000)

Continued from the previous page...

UHCI_CRC_REC_EN Configures whether or not to enable the reception of the 16-bit CRC.

0: Disable

1: Enable

(R/W)

UHCI_UART_IDLE_EOF_EN Configures whether or not to stop receiving data when UART is idle.

0: Not stop

1: Stop

(R/W)

UHCI_LEN_EOF_EN Configures when the UHCI decoder stops receiving data.

0: Stops after receiving 0xC0

1: Stops when the number of received data bytes reach the specified value. When UHCI_HEAD_EN is 1, the specified value is the data length indicated by the UHCI packet header; when UHCI_HEAD_EN is 0, the specified value is the configured value.

(R/W)

UHCI_ENCODE_CRC_EN Configures whether or not to enable data integrity check by appending a 16 bit CCITT-CRC to the end of the data.

0: Disable

1: Enable

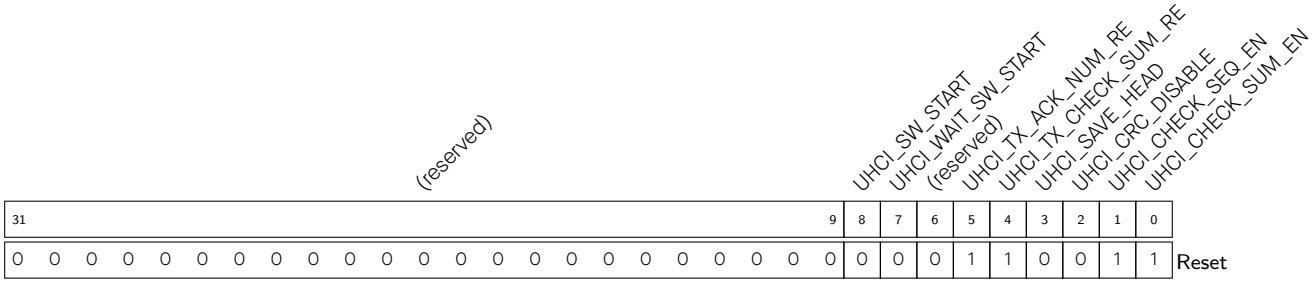
(R/W)

UHCI_CLK_EN Configures clock gating.

0: Support clock only when the application writes registers.

1: Always force the clock on for registers.

(R/W)



UHCI_UART_RX_BRK_EOF_EN Configures whether or not to stop UHCI from receiving data after UART has received a NULL frame.

0: Not stop

1: Stop

(R/W)

Register 45.70. UHCI_CONF1_REG (0x0014)

UHCI_CHECK_SUM_EN Configures whether or not to enable header checksum validation when UHCI receives a data packet.

0: Disable

1: Enable

(R/W)

UHCI_CHECK_SEQ_EN Configures whether or not to enable the sequence number check when UHCI receives a data packet.

0: Disable

1: Enable

(R/W)

UHCI_CRC_DISABLE Configures whether or not to enable CRC calculation.

0: Disable

1: Enable

Valid only when the Data Integrity Check Present bit in UHCI packet is 1.

(R/W)

UHCI_SAVE_HEAD Configures whether or not to save the packet header when UHCI receives a data packet.

0: Not save

1: Save

(R/W)

UHCI_TX_CHECK_SUM_RE Configures whether or not to encode the data packet with a checksum.

0: Not use checksum

1: Use checksum

(R/W)

UHCI_TX_ACK_NUM_RE Configures whether or not to encode the data packet with an acknowledgment when a reliable packet is to be transmitted.

0: Not use acknowledgement

1: Use acknowledgement

(R/W)

Continued on the next page...

Register 45.70. UHCI_CONF1_REG (0x0014)

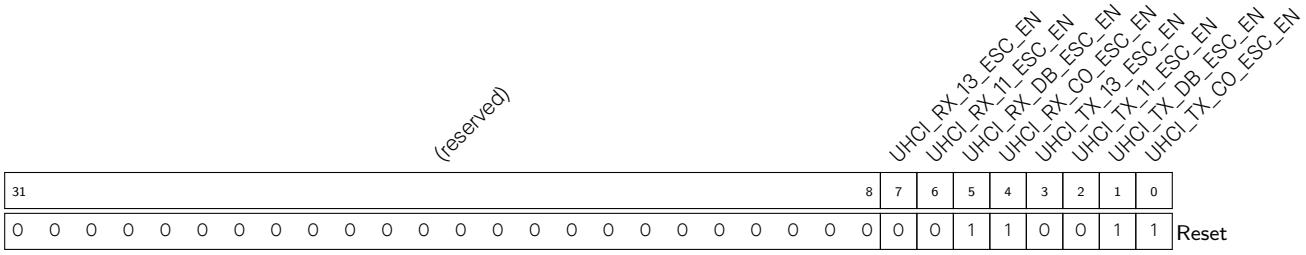
Continued from the previous page...

UHCI_WAIT_SW_START Configures whether or not to put the UHCI encoder state machine to ST_SW_WAIT state.

0: No

1: Yes

(R/W)



UHCI_SW_START Configures whether or not to send data packets when the encoder state machine is in ST_SW_WAIT state.

0: Not send

1: Send

(R/W/SC)

Register 45.71. UHCI_ESCAPE_CONF_REG (0x0020)

UHCI_TX_C0_ESC_EN Configures whether or not to decode character 0xC0 when DMA receives data.

0: Not decode

1: Decode

(R/W)

UHCI_TX_DB_ESC_EN Configures whether or not to decode character 0xDB when DMA receives data.

0: Not decode

1: Decode

(R/W)

UHCI_TX_11_ESC_EN Configures whether or not to decode flow control character 0x11 when DMA receives data.

0: Not decode

1: Decode

(R/W)

UHCI_TX_13_ESC_EN Configures whether or not to decode flow control character 0x13 when DMA receives data.

0: Not decode

1: Decode

(R/W)

UHCI_RX_C0_ESC_EN Configures whether or not to replace 0xC0 by special characters when DMA sends data.

0: Not replace

1: Replace

(R/W)

UHCI_RX_DB_ESC_EN Configures whether or not to replace 0xDB by special characters when DMA sends data.

0: Not replace

1: Replace

(R/W)

Continued on the next page...

Register 45.71. UHCI_ESCAPE_CONF_REG (0x0020)

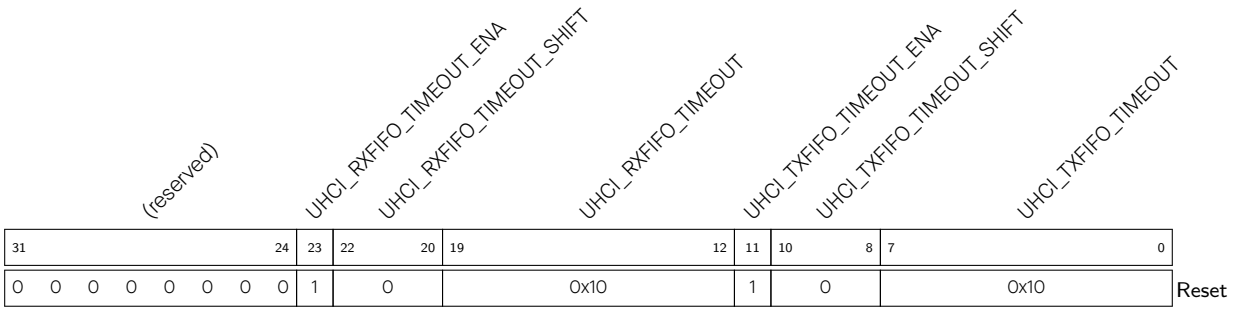
Continued from the previous page...

UHCI_RX_11_ESC_EN Configures whether or not to replace flow control character 0x11 by special characters when DMA sends data.

0: Not replace

1: Replace

(R/W)



UHCI_RX_13_ESC_EN Configures whether or not to replace flow control character 0x13 by special characters when DMA sends data.

0: Not replace

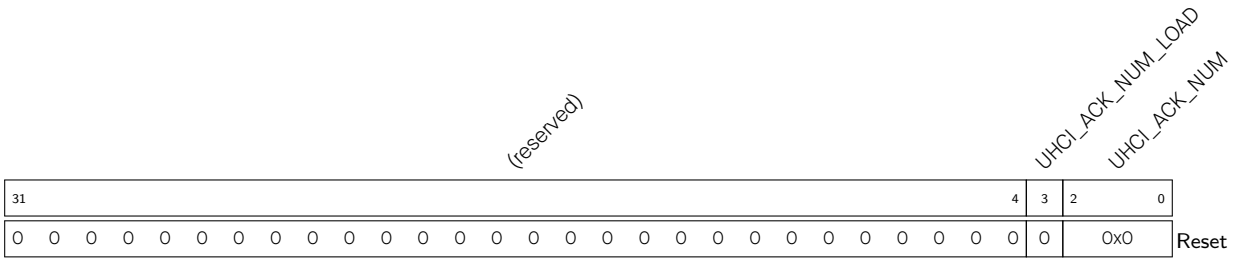
1: Replace

(R/W)

Register 45.72. UHCI_HUNG_CONF_REG (0x0024)

UHCI_TXFIFO_TIMEOUT Configures the timeout value for DMA data reception.
Measurement unit: ms. (R/W)

UHCI_TXFIFO_TIMEOUT_SHIFT Configures the upper limit of the timeout counter for TX FIFO. (R/W)



UHCI_TXFIFO_TIMEOUT_ENA Configures whether or not to enable the data reception timeout for TX FIFO.
0: Disable
1: Enable
(R/W)

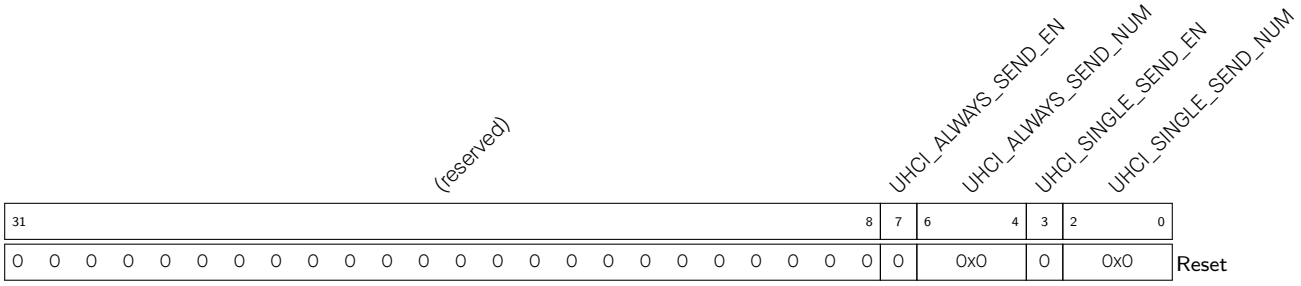
UHCI_RXFIFO_TIMEOUT Configures the timeout value for DMA to read data from RAM.
Measurement unit: ms. (R/W)

UHCI_RXFIFO_TIMEOUT_SHIFT Configures the upper limit of the timeout counter for RX FIFO. (R/W)

UHCI_RXFIFO_TIMEOUT_ENA Configures whether or not to enable the DMA data transmission timeout.
0: Disable
1: Enable
(R/W)

Register 45.73. UHCI_ACK_NUM_REG (0x0028)

UHCI_ACK_NUM Configures the number of acknowledgements used in software flow control. (R/W)



UHCI_ACK_NUM_LOAD Configures whether or not load acknowledgements.

0: Not load

1: Load

(WT)

Register 45.74. UHCI_QUICK_SENT_REG (0x0030)

UHCI_SINGLE_SEND_NUM Configures the source of data to be transmitted in single_send mode.

0: Q0 register

3: Q3 register

4: Q4 register

5: Q5 register

6: Q6 register

7: Invalid. No effect

(R/W)

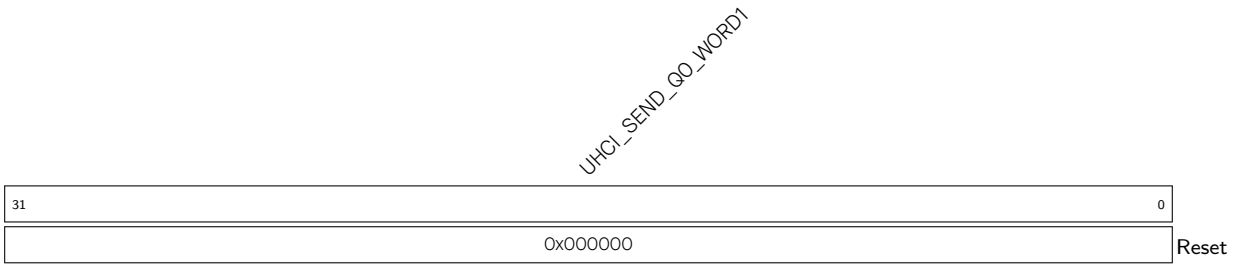
UHCI_ALWAYS_SEND_EN Configures whether or not to enable always_send mode.

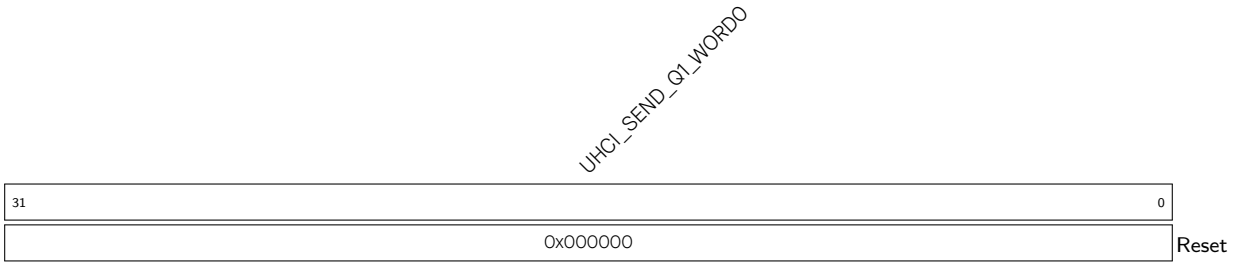
0: Disable

1: Enable



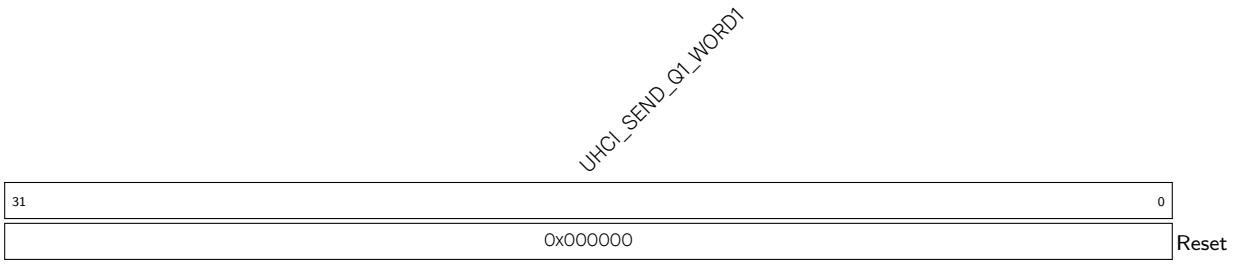
(R/W)

Register 45.75. UHCI_REG_Q0_WORD0_REG (0x0034)



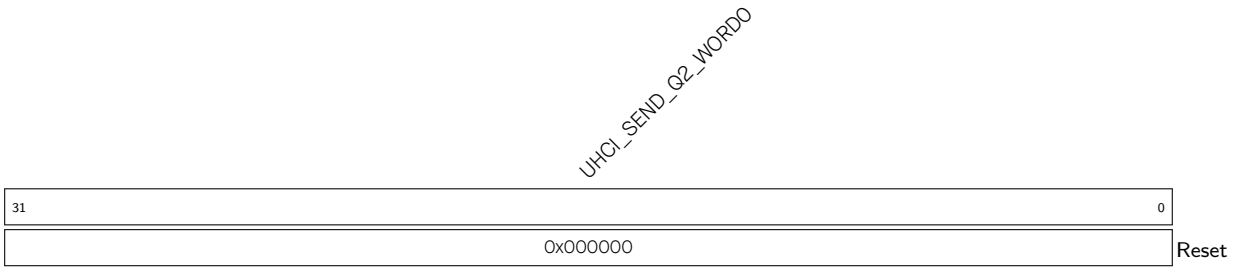
UHCI_SEND_Q0_WORD0 Data to be transmitted in Q0 register. (R/W)

Register 45.76. UHCI_REG_Q0_WORD1_REG (0x0038)



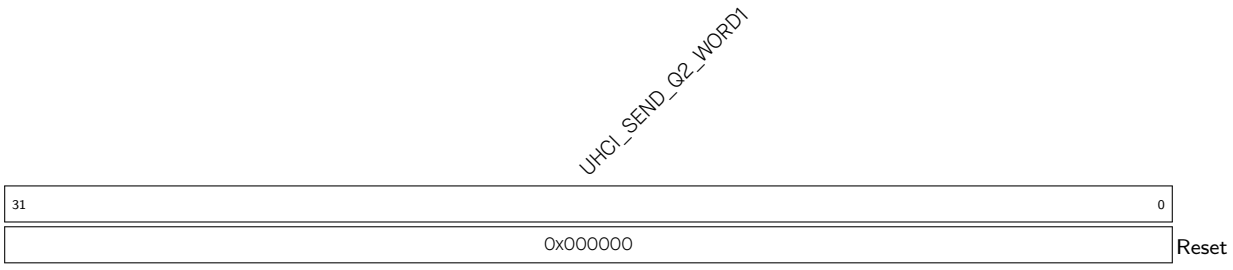
UHCI_SEND_Q0_WORD1 Data to be transmitted in Q0 register. (R/W)

Register 45.77. UHCI_REG_Q1_WORD0_REG (0x003C)



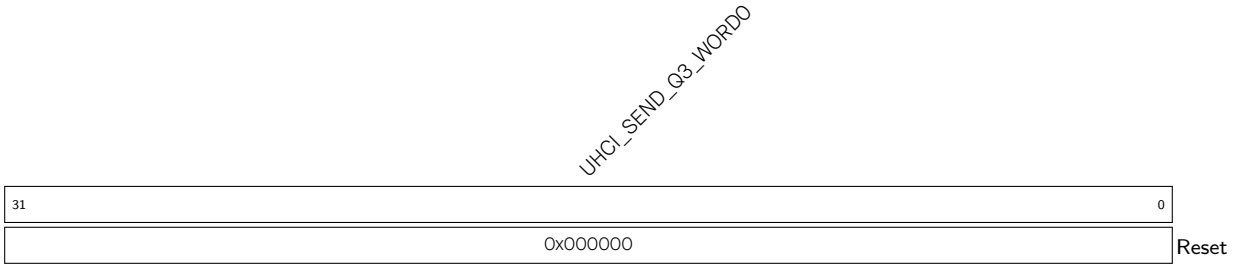
UHCI_SEND_Q1_WORD0 Data to be transmitted in Q1 register. (R/W)

Register 45.78. UHCI_REG_Q1_WORD1_REG (0x0040)



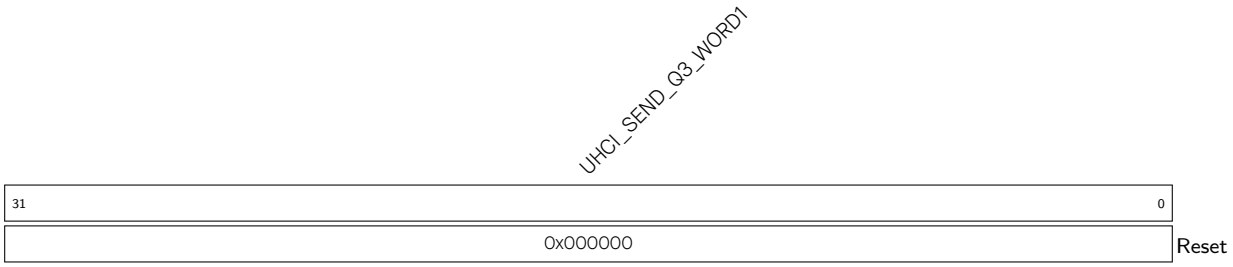
UHCI_SEND_Q1_WORD1 Data to be transmitted in Q1 register. (R/W)

Register 45.79. UHCI_REG_Q2_WORD0_REG (0x0044)



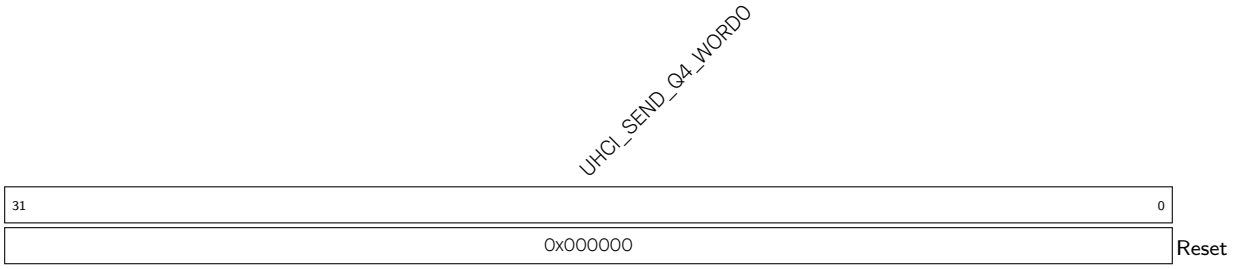
UHCI_SEND_Q2_WORD0 Data to be transmitted in Q2 register. (R/W)

Register 45.80. UHCI_REG_Q2_WORD1_REG (0x0048)



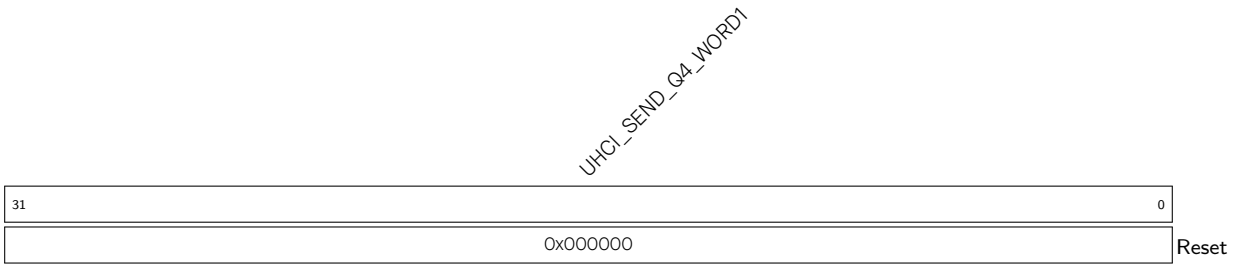
UHCI_SEND_Q2_WORD1 Data to be transmitted in Q2 register. (R/W)

Register 45.81. UHCI_REG_Q3_WORD0_REG (0x004C)



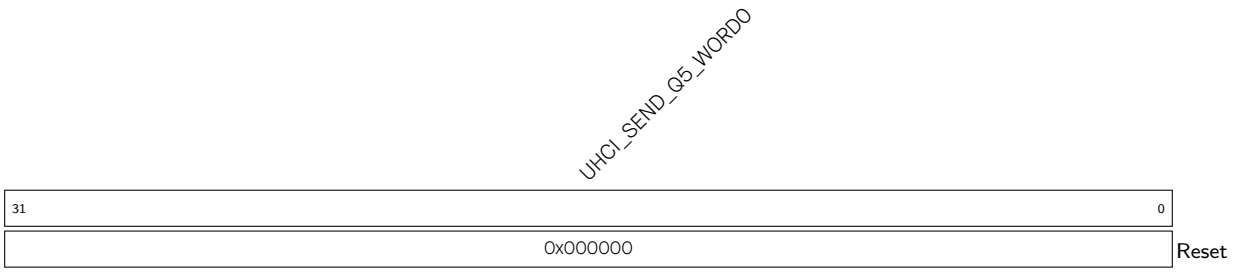
UHCI_SEND_Q3_WORD0 Data to be transmitted in Q3 register. (R/W)

Register 45.82. UHCI_REG_Q3_WORD1_REG (0x0050)



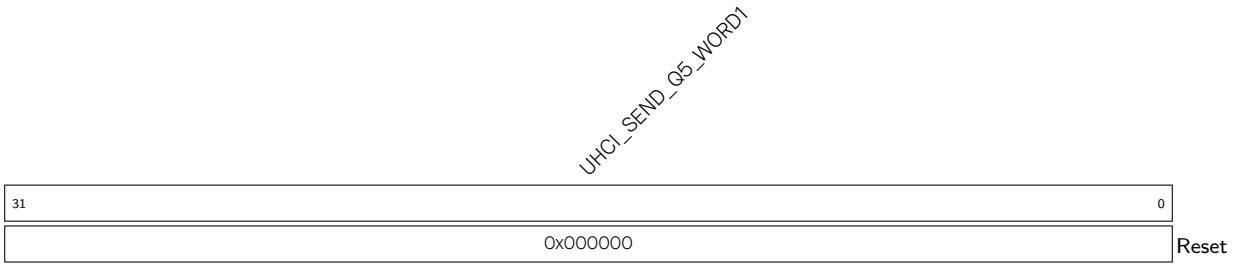
UHCI_SEND_Q3_WORD1 Data to be transmitted in Q3 register. (R/W)

Register 45.83. UHCI_REG_Q4_WORD0_REG (0x0054)



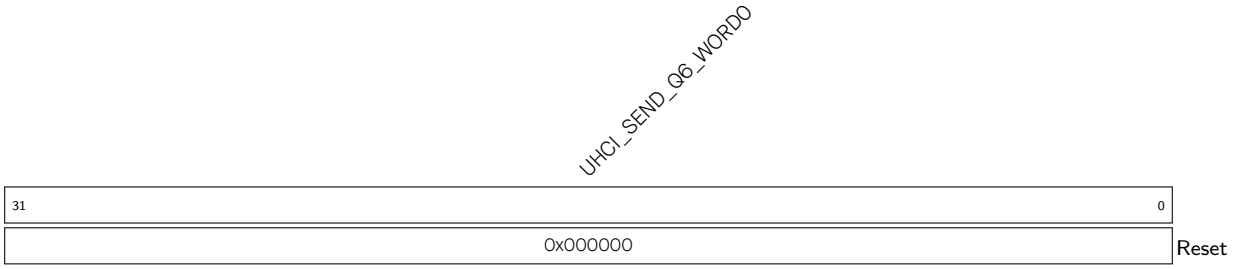
UHCI_SEND_Q4_WORD0 Data to be transmitted in Q4 register. (R/W)

Register 45.84. UHCI_REG_Q4_WORD1_REG (0x0058)



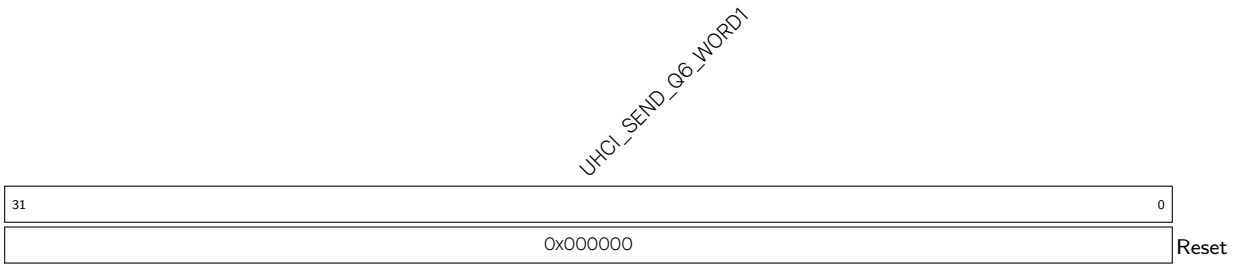
UHCI_SEND_Q4_WORD1 Data to be transmitted in Q4 register. (R/W)

Register 45.85. UHCI_REG_Q5_WORD0_REG (0x005C)



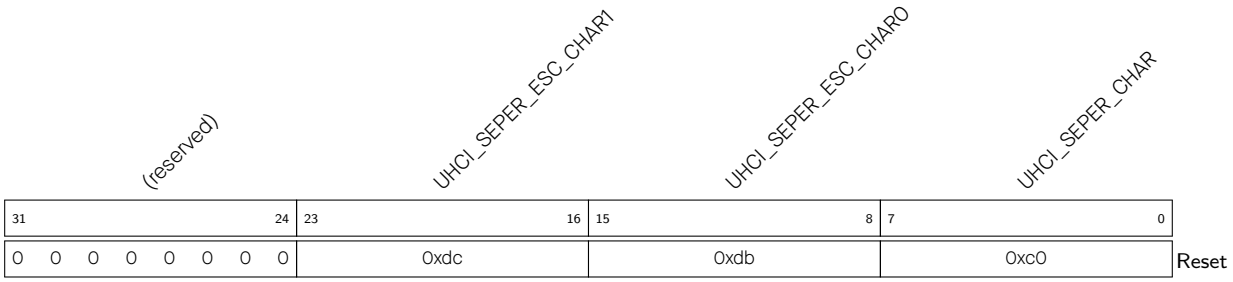
UHCI_SEND_Q5_WORD0 Data to be transmitted in Q5 register. (R/W)

Register 45.86. UHCI_REG_Q5_WORD1_REG (0x0060)



UHCI_SEND_Q5_WORD1 Data to be transmitted in Q5 register. (R/W)

Register 45.87. UHCI_REG_Q6_WORD0_REG (0x0064)

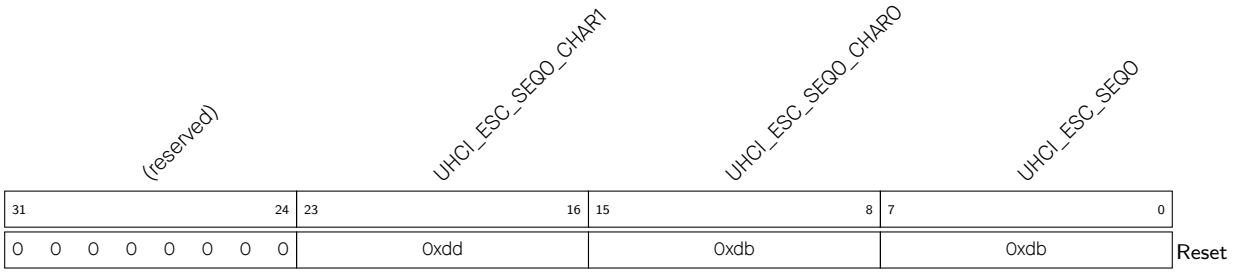


UHCI_SEND_Q6_WORD0 Data to be transmitted in Q6 register. (R/W)

Register 45.88. UHCI_REG_Q6_WORD1_REG (0x0068)

UHCI_SEND_Q6_WORD1 Data to be transmitted in Q6 register. (R/W)

Register 45.89. UHCI_ESC_CONF0_REG (0x006C)

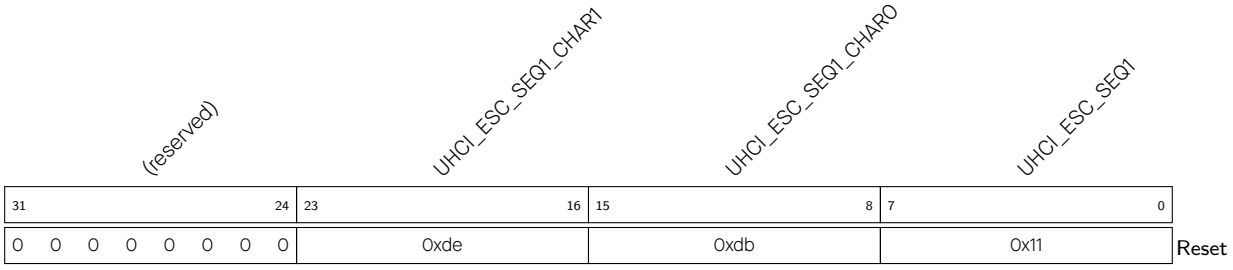


UHCI_SEPER_CHAR Configures separators to encode data packets. The default value is 0xC0. (R/W)

UHCI_SEPER_ESC_CHAR0 Configures the first character of SLIP escape sequence. The default value is 0xDB. (R/W)

UHCI_SEPER_ESC_CHAR1 Configures the second character of SLIP escape sequence. The default value is 0xDC. (R/W)

Register 45.90. UHCI_ESC_CONF1_REG (0x0070)

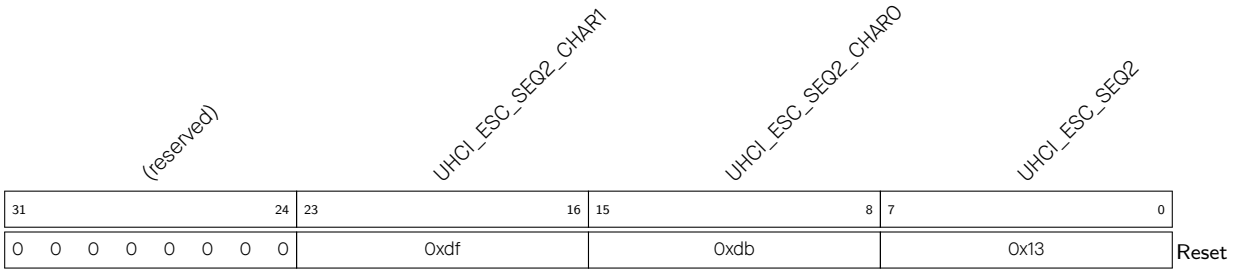


UHCI_ESC_SEQ0 Configures the character that needs to be encoded. The default value is 0xDB used as the first character of SLIP escape sequence. (R/W)

UHCI_ESC_SEQ0_CHAR0 Configures the first character of SLIP escape sequence. The default value is 0xDB. (R/W)

UHCI_ESC_SEQ0_CHAR1 Configures the second character of SLIP escape sequence. The default value is 0xDD. (R/W)

Register 45.91. UHCI_ESC_CONF2_REG (0x0074)

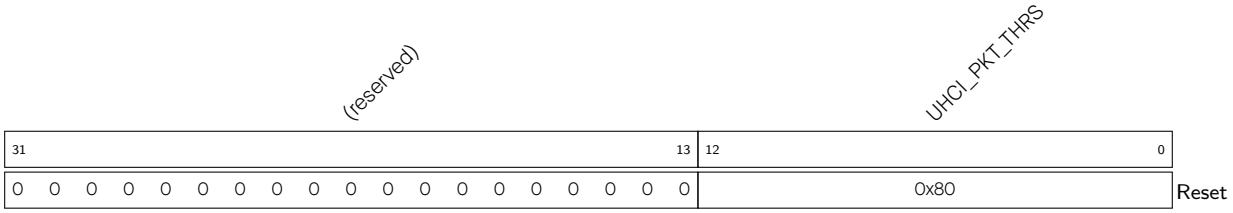


UHCI_ESC_SEQ1 Configures a character that need to be encoded. The default value is 0x11 used as a flow control character. (R/W)

UHCI_ESC_SEQ1_CHAR0 Configures the first character of SLIP escape sequence. The default value is 0xDB. (R/W)

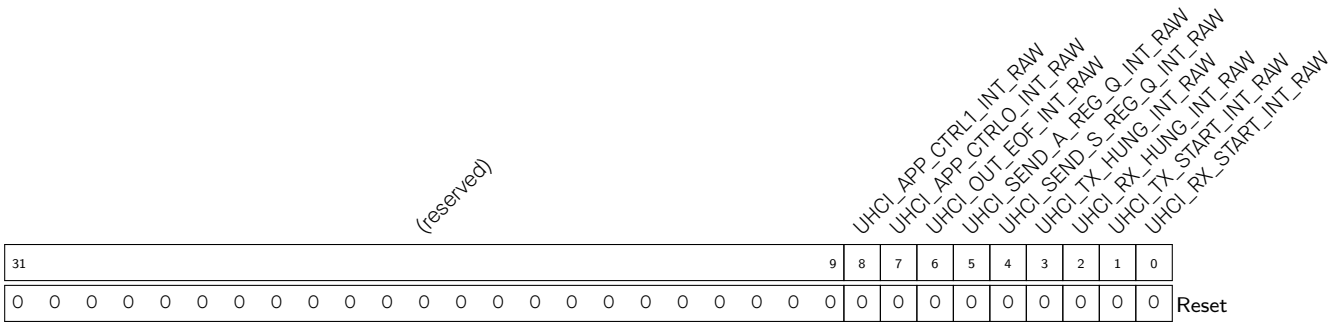
UHCI_ESC_SEQ1_CHAR1 Configures the second character of SLIP escape sequence. The default value is 0xDE. (R/W)

Register 45.92. UHCI_ESC_CONF3_REG (0x0078)



UHCI_ESC_SEQ2 Configures the character that needs to be decoded. The default value is 0x13 used as a flow control character. (R/W)

UHCI_ESC_SEQ2_CHAR0 Configures the first character of SLIP escape sequence. The default value is 0xDB. (R/W)



UHCI_ESC_SEQ2_CHAR1 Configures the second character of SLIP escape sequence. The default value is 0xDF. (R/W)

Register 45.93. UHCI_PKT_THRES_REG (0x007C)

UHCI_PKT_THRS Configures the maximum value of the packet length.
Measurement unit: byte.
Valid only when UHCI_HEAD_EN is 0. (R/W)

Register 45.94. UHCI_INT_RAW_REG (0x0004)

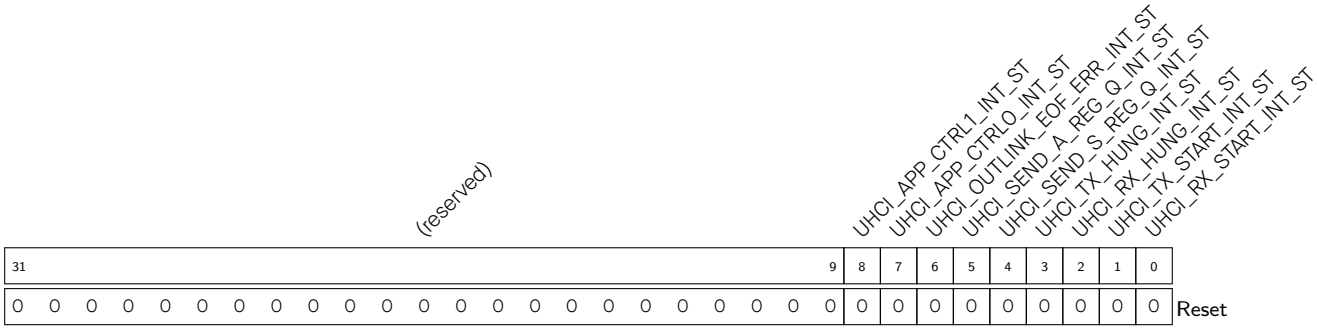
UHCI_RX_START_INT_RAW The raw interrupt status of UHCI_RX_START_INT. (R/WTC/SS)

UHCI_TX_START_INT_RAW The raw interrupt status of UHCI_TX_START_INT. (R/WTC/SS)

UHCI_RX_HUNG_INT_RAW The raw interrupt status of UHCI_RX_HUNG_INT. (R/WTC/SS)

UHCI_TX_HUNG_INT_RAW The raw interrupt status of UHCI_TX_HUNG_INT. (R/WTC/SS)

UHCI_SEND_S_REG_Q_INT_RAW The raw interrupt status of UHCI_SEND_S_REG_Q_INT. (R/WTC/SS)



UHCI_SEND_A_REG_Q_INT_RAW The raw interrupt status of UHCI_SEND_A_REG_Q_INT. (R/WTC/SS)

UHCI_OUT_EOF_INT_RAW The raw interrupt status of UHCI_OUT_EOF_INT. (R/WTC/SS)

UHCI_APP_CTRL0_INT_RAW The raw interrupt status of UHCI_APP_CTRL0_INT. (R/W)

UHCI_APP_CTRL1_INT_RAW The raw interrupt status of UHCI_APP_CTRL1_INT. (R/W)

Register 45.95. UHCI_INT_ST_REG (0x0008)

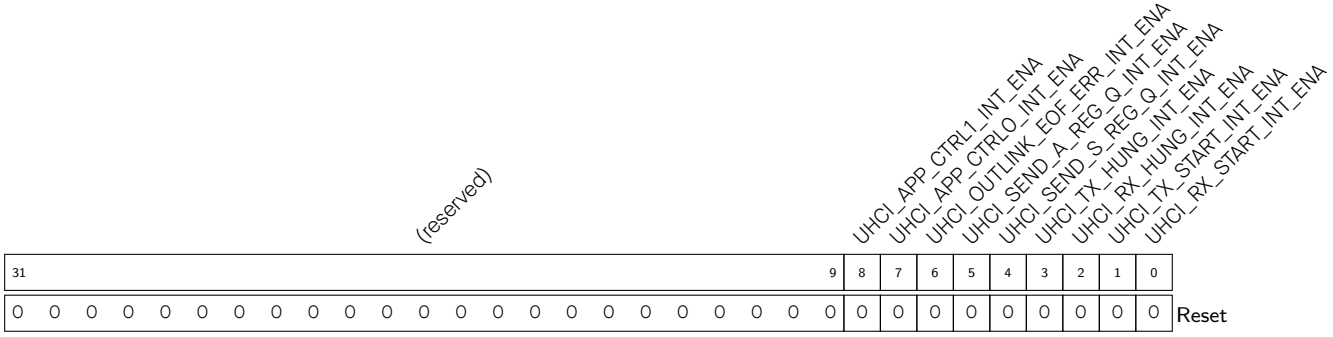
UHCI_RX_START_INT_ST The masked interrupt status of UHCI_RX_START_INT. (RO)

UHCI_TX_START_INT_ST The masked interrupt status of UHCI_TX_START_INT. (RO)

UHCI_RX_HUNG_INT_ST The masked interrupt status of UHCI_RX_HUNG_INT. (RO)

UHCI_TX_HUNG_INT_ST The masked interrupt status of UHCI_TX_HUNG_INT. (RO)

UHCI_SEND_S_REG_Q_INT_ST The masked interrupt status of UHCI_SEND_S_REG_Q_INT. (RO)



UHCI_SEND_A_REG_Q_INT_ST The masked interrupt status of UHCI_SEND_A_REG_Q_INT. (RO)

UHCI_OUTLINK_EOF_ERR_INT_ST The masked interrupt status of UHCI_OUTLINK_EOF_ERR_INT. (RO)

UHCI_APP_CTRL0_INT_ST The masked interrupt status of UHCI_APP_CTRL0_INT. (RO)

UHCI_APP_CTRL1_INT_ST The masked interrupt status of UHCI_APP_CTRL1_INT. (RO)

Register 45.96. UHCI_INT_ENA_REG (0x000C)

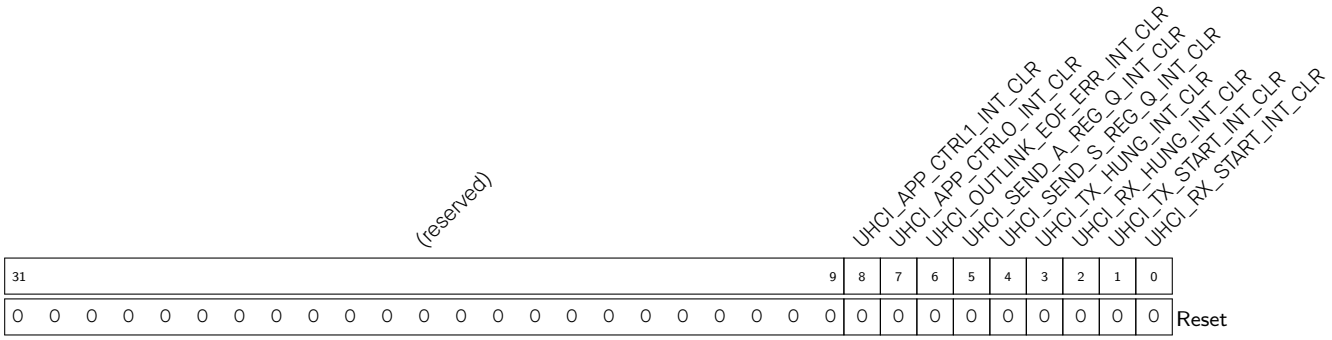
UHCI_RX_START_INT_ENA Write 1 to enable UHCI_RX_START_INT. (R/W)

UHCI_TX_START_INT_ENA Write 1 to enable UHCI_TX_START_INT. (R/W)

UHCI_RX_HUNG_INT_ENA Write 1 to enable UHCI_RX_HUNG_INT. (R/W)

UHCI_TX_HUNG_INT_ENA Write 1 to enable UHCI_TX_HUNG_INT. (R/W)

UHCI_SEND_S_REG_Q_INT_ENA Write 1 to enable UHCI_SEND_S_REG_Q_INT. (R/W)



UHCI_SEND_A_REG_Q_INT_ENA Write 1 to enable UHCI_SEND_A_REG_Q_INT. (R/W)

UHCI_OUTLINK_EOF_ERR_INT_ENA Write 1 to enable UHCI_OUTLINK_EOF_ERR_INT. (R/W)

UHCI_APP_CTRL0_INT_ENA Write 1 to enable UHCI_APP_CTRL0_INT. (R/W)

UHCI_APP_CTRL1_INT_ENA Write 1 to enable UHCI_APP_CTRL1_INT. (R/W)

Register 45.97. UHCI_INT_CLR_REG (0x0010)

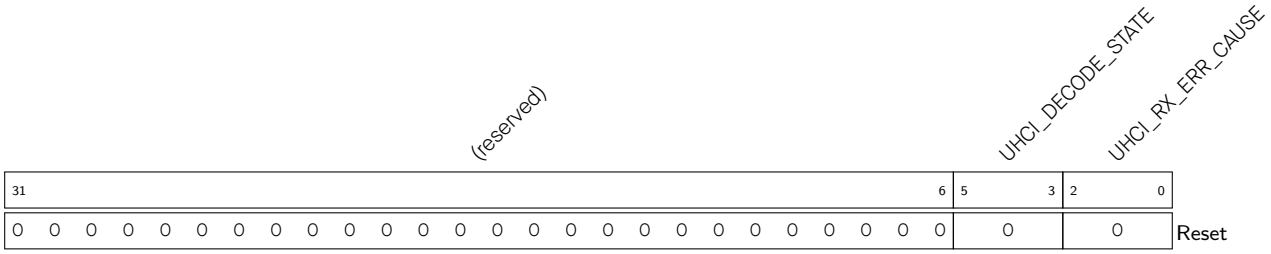
UHCI_RX_START_INT_CLR Write 1 to clear UHCI_RX_START_INT. (WT)

UHCI_TX_START_INT_CLR Write 1 to clear UHCI_TX_START_INT. (WT)

UHCI_RX_HUNG_INT_CLR Write 1 to clear UHCI_RX_HUNG_INT. (WT)

UHCI_TX_HUNG_INT_CLR Write 1 to clear UHCI_TX_HUNG_INT. (WT)

UHCI_SEND_S_REG_Q_INT_CLR Write 1 to clear UHCI_SEND_S_REG_Q_INT. (WT)



UHCI_SEND_A_REG_Q_INT_CLR Write 1 to clear UHCI_SEND_A_REG_Q_INT. (WT)

UHCI_OUTLINK_EOF_ERR_INT_CLR Write 1 to clear UHCI_OUTLINK_EOF_ERR_INT. (WT)

UHCI_APP_CTRL0_INT_CLR Write 1 to clear UHCI_APP_CTRL0_INT. (WT)

UHCI_APP_CTRL1_INT_CLR Write 1 to clear UHCI_APP_CTRL1_INT. (WT)

Register 45.98. UHCI_STATE0_REG (0x0018)

UHCI_RX_ERR_CAUSE Represents the error type when DMA has received a packet with error.

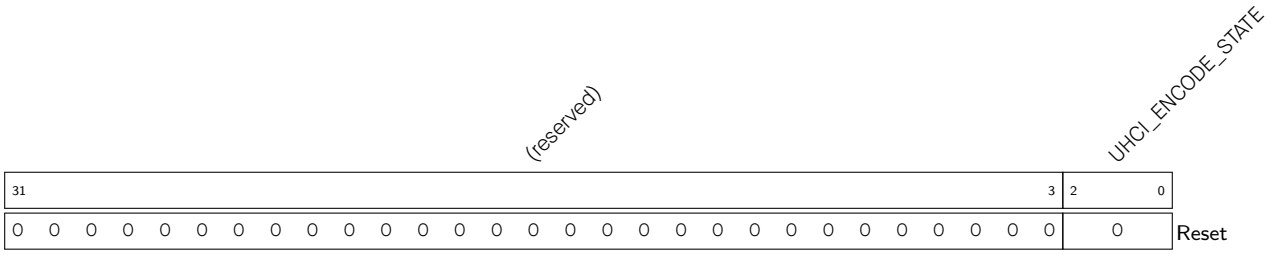
0: Invalid. No effect

1: Checksum error in the HCI packet

2: Sequence number error in the HCI packet

3: CRC bit error in the HCI packet

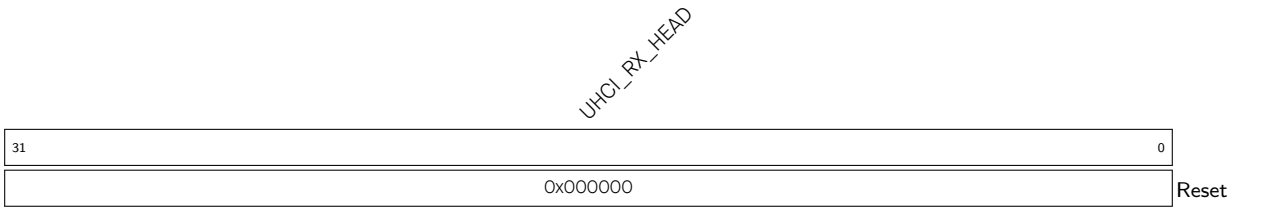
4: 0xC0 is found but the received HCI packet is not complete 5: 0xC0 is not found when the HCI packet has been received



6: CRC check error

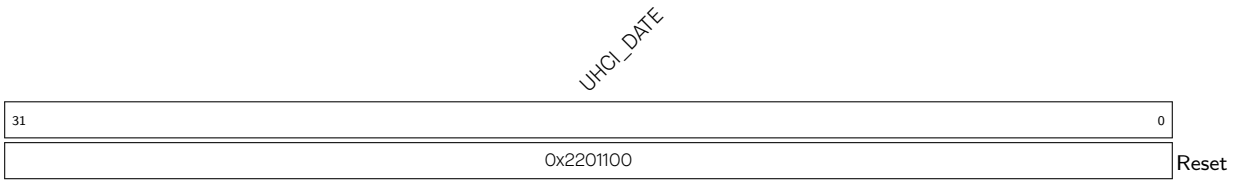
7: Invalid. No effect

(RO)



UHCI_DECODE_STATE Represents the UHCI decoder status. (RO)

Register 45.99. UHCI_STATE1_REG (0x001C)



UHCI_ENCODE_STATE Represents the UHCI encoder status. (RO)

Register 45.100. UHCI_RX_HEAD_REG (0x002C)

UHCI_RX_HEAD Represents the header of the current received packet. (RO)

Register 45.101. UHCI_DATE_REG (0x0080)

UHCI_DATE Version control register. (R/W)

Chapter 46

SPI Controller (SPI)

Note:
This chapter applies only to ESP32-P4 chip revision v1.3. Content for the latest chip revision is still under development and will be published in a future TRM version.

46.1 Overview

The Serial Peripheral Interface (SPI) is a synchronous serial interface useful for communication with external peripherals. The ESP32-P4 chip integrates four SPI controllers:

- MSPI controller, including two sub-controllers
  - FLASH MSPI controller
    - FLASH MSPI SPI0
    - FLASH MSPI SPI1
  - PSRAM MSPI controller
    - PSRAM MSPI SPI0
    - PSRAM MSPI SPI1
- General Purpose SPI2 (GP-SPI2)
- General Purpose SPI3 (GP-SPI3)
- Low-Power SPI (LP-SPI)

MSPI controller is primarily reserved for internal use to communicate with external flash and PSRAM memory. This chapter mainly focuses on the GP-SPI and LP-SPI. **In this chapter unless otherwise stated, GP-SPI refers to both GP-SPI2 and GP-SPI3.**

46.2 Glossary

To better illustrate the functions of GP-SPI and LP-SPI, the following terms are used in this chapter.

Master Mode	GP-SPI or LP-SPI acts as an SPI master and initiates SPI transactions.
Slave Mode	GP-SPI or LP-SPI acts as an SPI slave and exchanges data with its master when its CS is asserted.
MISO	Master in, slave out, data transmission from a slave to a master.
MOSI	Master out, slave in, data transmission from a master to a slave.

Transaction One instance of a master asserting a CS line, transferring data to and from a slave, and de-asserting the CS line. Transactions are atomic, which means they can never be interrupted by another transaction.

SPI Transfer The whole process of an SPI master exchanging data with a slave. One SPI transfer consists of one or more SPI transactions.

Single Transfer An SPI transfer that consists of only one transaction.

CPU-Controlled Transfer A data transfer that happens between CPU configured buffer SPI_W0_REG~SPI_W15_REG (LP_SPI_W0_REG~LP_SPI_W15_REG) and SPI peripherals.

DMA-Controlled Transfer A data transfer that happens between DMA and SPI peripherals, controlled by the DMA engine.

Configurable Segmented Transfer A data transfer controlled by DMA when GP-SPI2 works as a master. Such transfer consists of multiple transactions (segments), and each of transaction can be configured independently.

Slave Segmented Transfer A data transfer controlled by DMA when GP-SPI works as a slave. Such transfer consists of multiple transactions (segments).

Full-duplex The sending line and receiving line between the master and the slave are independent. Sending data and receiving data happen at the same time.

Half-duplex Only one side, the master or the slave, sends data first, and the other side receives data. Sending data and receiving data can not happen at the same time.

4-line full-duplex 4-line here means: clock line, CS line, and two data lines. The two data lines can be used to send or receive data simultaneously.

4-line half-duplex 4-line here means: clock line, CS line, and two data lines. The two data lines can not be used simultaneously.

3-line half-duplex 3-line here means: clock line, CS line, and one data line. The data line is used to transmit or receive data.

1-bit SPI In one clock cycle, one bit can be transferred.

(2-bit) Dual SPI In one clock cycle, two bits can be transferred.

Dual Output Read A data mode of Dual SPI. In one clock cycle, one bit of a command, or one bit of an address, or two bits of data can be transferred.

Dual I/O Read Another data mode of Dual SPI. In one clock cycle, one bit of a command, or two bits of an address, or two bits of data can be transferred.

(4-bit) Quad SPI In one clock cycle, four bits can be transferred.

Quad Output Read A data mode of Quad SPI. In one clock cycle, one bit of a command, or one bit of an address, or four bits of data can be transferred.

Quad I/O Read Another data mode of Quad SPI. In one clock cycle, one bit of a command, or four bits of an address, or four bits of data can be transferred.

QPI In one clock cycle, four bits of a command, or four bits of an address, or four bits of data can be transferred.

(8-bit) Octal SPI In one clock cycle, eight bits can be transferred.

Octal Output Read A data mode of Octal SPI. In one clock cycle, one bit of a command, or one bit of an address, or eight bits of data can be transferred.

Octal I/O Read Another data mode of Octal SPI. In one clock cycle, one bit of a command, or eight bits of an address, or eight bits of data can be transferred.

OPI In one clock cycle, eight bits of a command, or eight bits of an address, or eight bits of data can be transferred.

SPI2 The prefix of the signals for GP-SPI2. SPI2 bus signals are routed to GPIO pins via HP GPIO matrix or HP IO MUX.

SPI3 The prefix of the signals for GP-SPI3. SPI3 bus signals are routed to GPIO pins via HP GPIO matrix only.

LP_SPI The prefix of the signals for LP-SPI. LP_SPI bus signals are routed to GPIO pins via LP GPIO matrix only.

46.3 Features

GP-SPI has the following features:

- Works as master or as slave
- Half- and full-duplex communications
- CPU- and DMA-controlled transfers
- Various data modes
  - **GP-SPI2**
    * 1-bit SPI mode
    * 2-bit Dual SPI mode
    * 4-bit Quad SPI mode
    * QPI mode
    * 8-bit Octal SPI mode (available only when GP-SPI2 works as a master)
    * OPI mode (available only when GP-SPI2 works as a master)
  - **GP-SPI3**
    * 1-bit SPI mode
    * 2-bit Dual SPI mode
    * 4-bit Quad SPI mode
    * QPI mode
- Configurable module clock frequency
  - Master: up to 80 MHz
  - Slave: up to 60 MHz

- Configurable data length
  - CPU-controlled transfer as master or as slave: 1∼64 bytes
  - DMA-controlled single transfer as master: 1∼32 KB
  - DMA-controlled configurable segmented transfer as master: data length is unlimited
  - DMA-controlled single transfer or segmented transfer as slave: data length is unlimited
- Configurable bit read/write order
- Independent interrupts for CPU-controlled transfer and DMA-controlled transfer
- Configurable clock polarity and phase
- Four SPI clock modes: mode 0∼mode 3
- Multiple CS lines as master
  - **GP-SPI2**: CS0∼CS5
  - **GP-SPI3**: CS0∼CS2
- Able to communicate with SPI devices, such as a sensor, a screen controller, as well as a flash or RAM chip

LP-SPI is a simplified version of GP-SPI and has a subset of GP-SPI's features:

- Works as a master or as a slave
- Half- and full-duplex communications
- CPU-controlled transfer
- 1-bit SPI data mode
- Configurable module clock frequency:
  - Master: up to 40 MHz
  - Slave: up to 40 MHz
- Configurable data length:
  - CPU-controlled transfer as master or as slave: 1∼64 bytes
- Configurable bit read/write order
- Interrupts for CPU-controlled transfer
- Configurable clock polarity and phase
- Four SPI clock modes: mode 0∼mode 3
- One CS line as master: CS0
- Wake-up feature as slave (the only new feature compared with GP-SPI)

46.4 Architectural Overview

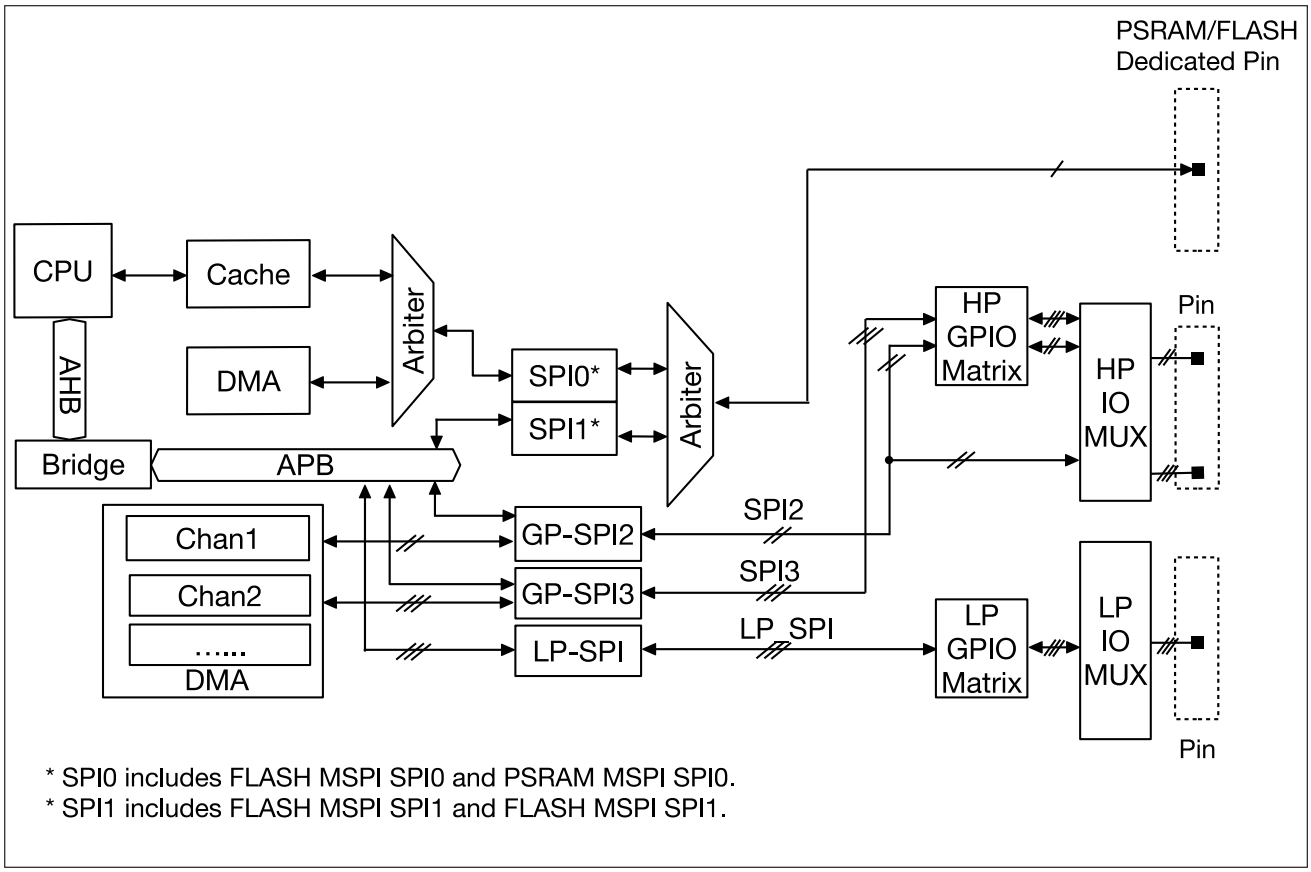


Figure 46.4-1. SPI Module Overview

Figure 46.4-1 shows an overview of this SPI module. GP-SPI2, GP-SPI3, and LP-SPI exchange data with SPI devices by the following ways:

- CPU-controlled transfer:
  - CPU ↔ LP-SPI ↔ SPI devices
  - CPU ↔ GP-SPI2 (GP-SPI3) ↔ SPI devices
- DMA-controlled transfer: DMA ↔ GP-SPI2 (GP-SPI3) ↔ SPI devices

In this chip, "SPI2", "SPI3", and "LP_SPI" are used as prefixes of GP-SPI2, GP-SPI3, and LP-SPI input and output signal buses to illustrate the SPI bus functions.

SPI2 bus signals are routed to GPIO pins via either the HP GPIO matrix or the HP IO MUX, while SPI3 bus signals are routed to GPIO pins via the HP GPIO matrix only. LP_SPI bus signals are routed via the LP GPIO matrix only. For more information, see Chapter 10 *GPIO Matrix and IO MUX*.

The functionalities of GP-SPI3 are nearly the same as those of GP-SPI2. The functionalities of LP-SPI are a subset of the GP-SPI functionalities. GP-SPI2's functionalities are described in Section 46.5. The differences among GP-SPI2, GP-SPI3, and LP-SPI are described in Section 46.5.1 and Section 46.10.

46.5 Functional Description

46.5.1 Data Modes

GP-SPI and LP-SPI can be configured as either a master or a slave to communicate with other SPI devices in the following data modes, see Table 46.5-1. For more information about the data modes used when GP-SPI or LP-SPI works as a master, see Section 46.5.9, and Section 46.5.10 for GP-SPI working as a slave.

Table 46.5-1. Data Modes Supported by GP-SPI and LP-SPI

Data Mode		CMD State	Address State	Data State	GP-SPI2	GP-SPI3	LP-SPI
1-bit SPI		1-bit	1-bit	1-bit	Y	Y	Y
Dual SPI	Dual Output Read	1-bit	1-bit	2-bit	Y	Y	—
	Dual I/O Read	1-bit	2-bit	2-bit	Y	Y	—
Quad SPI	Quad Output Read	1-bit	1-bit	4-bit	Y	Y	—
	Quad I/O Read	1-bit	4-bit	4-bit	Y	Y	—
Octal SPI	Octal Output Read	1-bit	1-bit	8-bit	Y	—	—
	Octal I/O Read	1-bit	8-bit	8-bit	Y	—	—
QPI		4-bit	4-bit	4-bit	Y	Y	—
OPI		8-bit	8-bit	8-bit	Y	—	—

46.5.2 Introduction to Bus Signals

The functional description of SPI2/SPI3 and LP_SPI bus signals is shown in Table 46.5-2. Tables 46.5-3, 46.5-4, and 46.5-5 list the signals used in various SPI modes.

Table 46.5-2. Functional Description of SPI2/SPI3 and LP_SPI Bus Signals

SPI2 Bus Signal	SPI3 Bus Signal	LP-SPI Bus Signal	Function
SPI2CLK	SPI3_CLK	LP_SPI_CLK	Input and output clock as master/slave
SPI2CS0	SPI3_CS0	LP_SPI_CS	Input and output CS signal as master/slave
SPI2CS1 ~5	SPI3_CS1~2	—	Output CS signal as master
SPI2D	SPI3_D	LP_SPI_D	MOSI/SIO0 (serial data input and output, bit0)
SPI2Q	SPI3_Q	LP_SPI_Q	MISO/SIO1 (serial data input and output, bit1)
SPI2WP	SPI3_WP	—	SIO2 (serial data input and output, bit2)
SPI2HD	SPI3_HD	—	SIO3 (serial data input and output, bit3)
SPI2D4~7	—	—	SIO4~7 (serial data input and output, bit4~7)
SPI2DQS	—	—	Output data mask signal as master

Table 46.5-3. SPI2 Bus Signals Used in Various SPI Modes

SPI2 Bus Signal	Master								Slave					
	1-bit SPI			Dual SPI	Quad SPI	QPI	Octal SPI	OPI	1-bit SPI			Dual SPI	Quad SPI	QPI
	FD[1]	3-line HD[2]	4-line HD						FD	3-line HD	4-line HD			
SPI2CLK	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
SPI2CS0	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
SPI2CS1	Y	Y	Y	Y	Y	Y	Y	Y						
SPI2CS2	Y	Y	Y	Y	Y	Y	Y	Y						
SPI2CS3	Y	Y	Y	Y	Y	Y	Y	Y						
SPI2CS4	Y	Y	Y	Y	Y	Y	Y	Y						
SPI2CS5	Y	Y	Y	Y	Y	Y	Y	Y						
SPI2D	Y	Y	(Y)[3]	Y[4]	Y[5]	Y	Y	Y	Y	Y	(Y)[6]	Y[7]	Y[8]	Y
SPI2Q	Y		(Y)[3]	Y[4]	Y[5]	Y	Y	Y	Y		(Y)[6]	Y[7]	Y[8]	Y
SPI2WP					Y[5]	Y	Y	Y					Y[8]	Y
SPI2HD					Y[5]	Y	Y	Y					Y[8]	Y
SPI2D4~7							Y	Y						
SPI2DQS							Y	Y						

[1] FD: full-duplex

[2] HD: half-duplex

[3] Only one of the two signals is used at a time.

[4] The two signals are used in parallel.

[5] The four signals are used in parallel.

[6] Only one of the two signals is used at a time.

[7] The two signals are used in parallel.

[8] The four signals are used in parallel.

Table 46.5-4. SPI3 Bus Signals Used in Various SPI Modes

SPI3 Bus Signal	Master						Slave					
	1-bit SPI			Dual SPI	Quad SPI	QPI	1-bit SPI			Dual SPI	Quad SPI	QPI
	FD[1]	3-line HD[2]	4-line HD				FD	3-line HD	4-line HD			
SPI3_CLK	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
SPI3_CS0	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
SPI3_CS1	Y	Y	Y	Y	Y	Y						
SPI3_CS2	Y	Y	Y	Y	Y	Y						
SPI3_D	Y	Y	(Y)[3]	Y[4]	Y[5]	Y	Y	Y	(Y)[6]	Y[7]	Y[8]	Y
SPI3_Q	Y		(Y)[3]	Y[4]	Y[5]	Y	Y		(Y)[6]	Y[7]	Y[8]	Y
SPI3_WP					Y[5]	Y					Y[8]	Y
SPI3_HD					Y[5]	Y					Y[8]	Y

[1] FD: full-duplex

[2] HD: half-duplex

[3] Only one of the two signals is used at a time.

[4] The two signals are used in parallel.

[5] The four signals are used in parallel.

[6] Only one of the two signals is used at a time.

[7] The two signals are used in parallel.

[8] The four signals are used in parallel.

Table 46.5-5. LP-SPI Bus Signals Used in Various SPI Modes

LP_SPI Bus Signal	Master (1-bit SPI)			Slave (1-bit SPI)		
	FD[1]	3-line HD[2]	4-line HD	FD	3-line HD	4-line HD
LP_SPI_CLK	Y	Y	Y	Y	Y	Y
LP_SPI_CS	Y	Y	Y	Y	Y	Y
LP_SPI_D	Y	Y	(Y)[3]	Y	Y	(Y)[3]
LP_SPI_Q	Y		(Y)[3]	Y		(Y)[3]

[1] FD: full-duplex

[2] HD: half-duplex

[3] Only one of the two signals is used at a time.

46.5.3 Bit Read/Write Order Control

- GP-SPI
  - When operating as a master:
    * The bit order of the command, address and data sent by the GP-SPI master is controlled by SPI_WR_BIT_ORDER.
    * The bit order of the data received by the master is controlled by SPI_RD_BIT_ORDER.
  - When operating as a slave:
    * The bit order of the data sent by the GP-SPI slave is controlled by SPI_WR_BIT_ORDER.
    * The bit order of the command, address and data received by the slave is controlled by SPI_RD_BIT_ORDER.
- LP-SPI
  - When operating as a master:
    * The bit order of the command, address and data sent by the LP-SPI master is controlled by LP_SPI_WR_BIT_ORDER.
    * The bit order of the data received by the master is controlled by LP_SPI_RD_BIT_ORDER.
  - When operating as a slave:
    * The bit order of the data sent by the LP-SPI slave is controlled by LP_SPI_WR_BIT_ORDER.
    * The bit order of the command, address and data received by the slave is controlled by LP_SPI_RD_BIT_ORDER.

Tables 46.5-6 and 46.5-7 show the functions of SPI_RD/WR_BIT_ORDER and LP_SPI_RD/WR_BIT_ORDER.

GoBack

Table 46.5-6. Bit Order Control in GP-SPI (Take GP-SPI2 as an Example)

Bit Mode	SPI2 Bus Data	SPI_RD/WR_BIT_ORDER = 0 (MSB)	SPI_RD/WR_BIT_ORDER = 2 (MSB)	SPI_RD/WR_BIT_ORDER = 1 (LSB)	SPI_RD/WR_BIT_ORDER = 3 (LSB)

Table 46.5-7. Bit Order Control in LP-SPI

Bit Mode	LP_SPI Bus Signal	LP_SPI_RD/WR_BIT_ORDER = 0 (MSB)	LP_SPI_RD/WR_BIT_ORDER = 1 (LSB)
1-bit mode	LP_SPI_D or LP_SPI_Q	B7→B6→B5→B4→B3→B2→B1→B0	B0→B1→B2→B3→B4→B5→B6→B7

46.5.4 Unaligned Byte Transfer

- When operating as a master, GP-SPI sends and receives data in bits. The bit length is equal to SPI_MS_DATA_BITLEN + 1, a multiple of 1/2/4/8 in 1/2/4/8-bit mode.
  - When sending data whose length is not an integer multiple of 8 bits, the software needs to fill the last part of the data less than 8 bits into a full 1-byte data.
  - When receiving data whose length is not an integer multiple of 8 bits, the part less than 1 byte is still received as 1 byte.
- When operating as slave, GP-SPI sends and receives data in bits. The bit length is a multiple of 1/2/4/8 in 1/2/4/8-bit mode.
  - When sending data whose length is not an integer multiple of 8 bits, the software needs to fill the last part of the data less than 8 bits into a full 1-byte data.
  - When receiving data whose length is not an integer multiple of 8 bits, the part less than 1 byte is still received as 1 byte. The total bit length received can be read from SPI_SLV_DATA_BITLEN. The valid bits in the last 1 byte is indicated by SPI_SLV_LAST_BYTE_STRB.

Note:

- No matter working as master or slave, GP-SPI sends and receives the data parts less than 1 byte following the same bit order as the other data bits as configured.
- LP-SPI does not support this unaligned byte transfer.

46.5.5 Transfer Types

The transfer types supported by GP-SPI working as a master or a slave are shown in Table 46.5-8.

Table 46.5-8. Supported Transfer Types as Master or Slave

Mode		CPU-Controlled Single Transfer [1]	DMA-Controlled Single Transfer	DMA-Controlled Configurable Segmented Transfer [2]	DMA-Controlled Slave Segmented Transfer
Master	Full-Duplex	Y	Y	Y	—
	Half-Duplex	Y	Y	Y	—
Slave	Full-Duplex	Y	Y	—	Y
	Half-Duplex	Y	Y	—	Y

[1] LP-SPI supports only the CPU-controlled single transfer.

[2] GP-SPI3 does not support DMA-controlled configurable segmented transfer.

The following sections provide detailed information about the transfer types listed in the table above.

46.5.6 CPU-Controlled Data Transfer

Note:
Both GP-SPI and LP-SPI provide 16 x 32-bit data buffers:

- GP-SPI: SPI_W0_REG~SPI_W15_REG
- LP-SPI: LP_SPI_W0_REG~LP_SPI_W15_REG

The following section illustrates the buffer's structure using GP-SPI data buffer as an example.

Figure 46.5-1 shows the buffer's structure. CPU-controlled transfer indicates the transfer, in which the data to send is from GP-SPI data buffer and the received data is stored to GP-SPI data buffer. In such transfer, every single transaction needs to be triggered by the CPU, after its related registers are configured. For such reason, the CPU-controlled transfer is always single transfer (consisting of only one transaction). CPU-controlled transfer supports full-duplex communication and half-duplex communication.

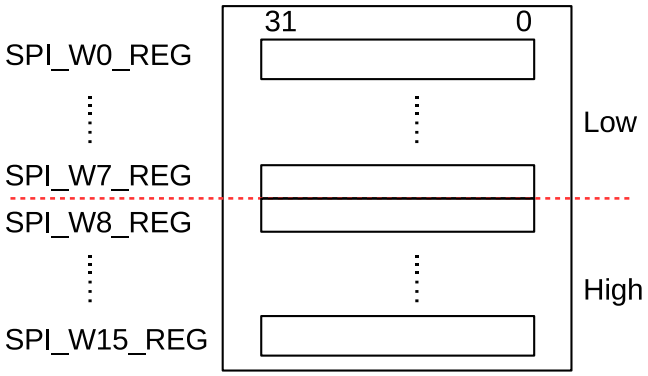

Figure 46.5-1. Data Buffer Used in CPU-Controlled Transfer

46.5.6.1 CPU-Controlled Master Transfer

In a CPU-controlled master full-duplex or half-duplex transfer, the RX or TX data is saved to or sent from SPI_W0_REG~SPI_W15_REG. The bits SPI_USR_MOSI_HIGHPART and SPI_USR_MISO_HIGHPART control which buffers are used. See the description below.

- **TX data**
  - When SPI_USR_MOSI_HIGHPART is cleared, i.e., high part mode is disabled, TX data is read from SPI_W0_REG~SPI_W15_REG and the data address is incremented by 1 on each byte transferred. **If the data byte length is larger than 64, the data in SPI_W0_REG~SPI_W15_REG may be sent more than once.**
    Take each 256 bytes as a cycle:
    * The first 64 bytes (*Byte 0~Byte 63*) are read from SPI_W0_REG~SPI_W15_REG, sequentially.
    * *Byte 64~Byte 255* are read from SPI_W15_REG[31:24] repeatedly.
    * *Byte 256~Byte 319* (the first 64 bytes in another 256 bytes) are read from SPI_W0_REG~SPI_W15_REG again, sequentially, same as the behaviors described above.

    For instance: to send 258 bytes (*Byte 0~Byte 257*), the data is read from the registers as follows:
    * The first 64 bytes (*Byte 0~Byte 63*) are read from SPI_W0_REG~SPI_W15_REG, sequentially.
    * *Byte 64~Byte 255* are read from SPI_W15_REG[31:24] repeatedly.

* The other bytes (*Byte 256* and *Byte 257*) are read from SPI_W0_REG[7:0] and SPI_W0_REG[15:8] again, sequentially. The logic is:
  - The address to read data for *Byte 256* is the result of (256 % 64 = 0), i.e., SPI_W0_REG[7:0].
  - The address to read data for *Byte 257* is the result of (257 % 64 = 1), i.e., SPI_W0_REG[15:8].

– When SPI_USR_MOSI_HIGHPART is set, i.e., high part mode is enabled, TX data is read from SPI_W8_REG~SPI_W15_REG and the data address is incremented by 1 on each byte transferred. **If the data byte length is larger than 32, the data in SPI_W8_REG~SPI_W15_REG may be sent more than once.**
Take each 256 bytes as a cycle:

* The first 32 bytes (*Byte 0~Byte 31*) are read from SPI_W8_REG~SPI_W15_REG, sequentially.
* *Byte 32~Byte 255* are read from SPI_W15_REG[31:24] repeatedly.
* *Byte 256~Byte 287* (the first 32 bytes in the another 256 bytes) are read from SPI_W8_REG~SPI_W15_REG again, sequentially, same as the behaviors described above.

For instance: to send 258 bytes (*Byte 0~Byte 257*), the data is read from the registers as follows:

* The first 32 bytes (*Byte 0~Byte 31*) are read from SPI_W8_REG~SPI_W15_REG, sequentially.
* *Byte 32~Byte 255* are read from SPI_W15_REG[31:24] repeatedly.
* The other bytes (*Byte 256* and *Byte 257*) are read from SPI_W8_REG[7:0] and SPI_W8_REG[15:8] again, sequentially. The logic is:
  - The address to read data for *Byte 256* is the result of (256 % 32 = 0), i.e., SPI_W8_REG[7:0].
  - The address to read data for *Byte 257* is the result of (257 % 32 = 1), i.e., SPI_W8_REG[15:8].

- **RX data**

– When SPI_USR_MISO_HIGHPART is cleared, i.e., high part mode is disabled, RX data is saved to SPI_W0_REG~SPI_W15_REG, and the data address is incremented by 1 on each byte transferred. **If the data byte length is larger than 64, the data in SPI_W0_REG~SPI_W15_REG may be overwritten.**
Take each 256 bytes as a cycle:

* The first 64 bytes (*Byte 0~Byte 63*) are saved to SPI_W0_REG~SPI_W15_REG, sequentially.
* *Byte 64~Byte 255* are saved to SPI_W15_REG[31:24] repeatedly.
* *Byte 255~Byte 319* (the first 64 bytes in the another 256 bytes) are saved to SPI_W0_REG~SPI_W15_REG again, sequentially, same as the behaviors described above.

For instance: to receive 258 bytes (*Byte 0~Byte 257*), the data is saved to the registers as follows:

* The first 64 bytes (*Byte 0~Byte 63*) are saved to SPI_W0_REG~SPI_W15_REG, sequentially.
* *Byte 64~Byte 255* are saved to SPI_W15_REG[31:24] repeatedly.

* The other bytes (*Byte 256* and *Byte 257*) are saved to SPI_W0_REG[7:0] and SPI_W0_REG[15:8] again, sequentially. The logic is:
  - The address to save *Byte 256* is the result of (256 % 64 = 0), i.e., SPI_W0_REG[7:0].
  - The address to save *Byte 257* is the result of (257 % 64 = 1), i.e., SPI_W0_REG[15:8].

– When SPI_USR_MISO_HIGHPART is set, i.e., high part mode is enabled, the RX data is saved to SPI_W8_REG~SPI_W15_REG, and the data address is incremented by 1 on each byte transferred. **If the data byte length is larger than 32, the content of SPI_W8_REG~SPI_W15_REG may be overwritten.**
Take each 256 bytes as a cycle:

* *Byte 0~Byte 31* are saved to SPI_W8_REG~SPI_W15_REG, sequentially.
* *Byte 32~Byte 255* are saved to SPI_W15_REG[31:24] repeatedly.
* *Byte 256~Byte 287* (the first 32 bytes in the another 256 bytes) are saved to SPI_W8_REG~SPI_W15_REG again, sequentially.

For instance: to receive 258 bytes (*Byte 0~Byte 257*), the data is saved to the registers as follows:

* The first 32 bytes (*Byte 0~Byte 31*) are saved to SPI_W8_REG~SPI_W15_REG, sequentially.
* *Byte 32~Byte 255* are saved to SPI_W15_REG[31:24] repeatedly.
* The other bytes (*Byte 256* and *Byte 257*) are saved to SPI_W8_REG[7:0] and SPI_W8_REG[15:8] again, sequentially. The logic is:
  - The address to save *Byte 256* is the result of (256 % 32 = 0), i.e., SPI_W8_REG[7:0].
  - The address to save *Byte 257* is the result of (257 % 32 = 1), i.e., SPI_W8_REG[15:8].

Note:

- TX/RX data address mentioned above both are byte-addressable.
  - If high part mode is disabled, Address 0 stands for SPI_W0_REG[7:0], and Address 1 for SPI_W0_REG[15:8], and so on.
  - If high part mode is enabled, Address 0 stands for SPI_W8_REG[7:0], and Address 1 for SPI_W8_REG[15:8], and so on.

  The largest address points to SPI_W15_REG[31:24].
- To avoid any possible error in TX/RX data, such as TX data being sent more than once or RX data being overwritten, please make sure the registers are configured correctly.
- LP-SPI functions similarly, but uses LP-SPI registers and LP-SPI data buffers, as shown in Section 46.12.3.

46.5.6.2 CPU-Controlled Slave Transfer

In a CPU-controlled slave full-duplex or half-duplex transfer, the RX or TX data is saved to or sent from SPI_W0_REG~SPI_W15_REG, which are byte-addressable.

- In full-duplex communication, the address of SPI_W0_REG~SPI_W15_REG starts from 0 and is incremented by 1 on each byte transferred. If the data address is larger than 63, the data in SPI_W0_REG~SPI_W15_REG will be overwritten, same as the behaviors described in the master transfer when high part mode is disabled.

- In half-duplex communication, the *ADDR* value in transmission format is the start address of the RX or TX data, corresponding to the registers SPI_W0_REG~SPI_W15_REG. The RX or TX address is incremented by 1 on each byte transferred. If the address is larger than 63 (the highest byte address, i.e., SPI_W15_REG[31:24]), the data in SPI_W8_REG~SPI_W15_REG will be overwritten, same as the behaviors described in the master transfer when high part mode is enabled.

According to your applications, the registers SPI_W0_REG~SPI_W15_REG can be used as:

- data buffers only
- data buffers and status buffers
- status buffers only

46.5.7 DMA-Controlled Data Transfer

Note:
LP-SPI does not support this transfer. The description below is for GP-SPI only.

DMA-controlled transfer refers to the transfer in which the DMA RX module receives data and the DMA TX module sends data. This transfer is supported both as master and as slave.

A DMA-controlled transfer can be:

- a single transfer, consisting of only one transaction. GP-SPI supports this transfer both as master and as slave.
- a configurable segmented transfer, consisting of several transactions (segments). Only GP-SPI2 supports this transfer when working as a master. For more information, see Section 46.5.9.5.
- a slave segmented transfer, consisting of several transactions (segments). GP-SPI supports this transfer only when working as a slave. For more information, see Section 46.5.10.3.

A DMA-controlled transfer only needs to be triggered once by CPU. When such a transfer is triggered, data is transferred by the DMA engine from or to the DMA-linked memory, without CPU operation.

DMA-controlled transfer supports full-duplex communication, half-duplex communication and functions described in Section 46.5.9 and Section 46.5.10. Meanwhile, the DMA RX module is independent from the DMA TX module, which means that there are four kinds of full-duplex communications:

- Data is received in DMA-controlled mode and sent in DMA-controlled mode.
- Data is received in DMA-controlled mode but sent in CPU-controlled mode.
- Data is received in CPU-controlled mode but sent in DMA-controlled mode.
- Data is received in CPU-controlled mode and sent in CPU-controlled mode.

46.5.7.1 DMA Configuration

- Select a DMA channel *n* and configure DMA TX/RX descriptor. See Chapter 6 *GDMA Controller (GDMA-AHB, GDMA-AXI)*.

- Set AXI_DMA_INLINK_START_CH*n* or AXI_DMA_OUTLINK_START_CH*n* to start DMA RX or TX engine, respectively.
- Before all the DMA TX buffer is used or the DMA TX engine is reset, if AXI_DMA_OUTLINK_RESTART_CH*n* is set, a new TX buffer will be added to the end of the last TX buffer in use.
- DMA RX buffer is linked in the same way as the DMA TX buffer, by setting AXI_DMA_INLINK_START_CH*n* or AXI_DMA_INLINK_RESTART_CH*n*.
- The TX and RX data lengths are determined by the configured DMA TX and RX buffer respectively, both of which are 0~32 KB.
- Initialize DMA inlink and outlink before DMA starts. The bits SPI_DMA_RX_ENA and SPI_DMA_TX_ENA in register SPI_DMA_CONF_REG should be set, otherwise the read/write data will be stored to/sent from the registers SPI_W0_REG~SPI_W15_REG.

When GP-SPI operating as master, if AXI_DMA_IN_SUC_EOF_CH*n*_INT_ENA is set, then the interrupt AXI_DMA_IN_SUC_EOF_CH*n*_INT will be triggered when one single transfer or one configurable segmented transfer is finished.

When GP-SPI operating as slave, if AXI_DMA_IN_SUC_EOF_CH*n*_INT_ENA is set, then the interrupt AXI_DMA_IN_SUC_EOF_CH*n*_INT will be triggered when one of the following conditions are met.

Table 46.5-9. Interrupt Trigger Condition on GP-SPI Data Transfer as Slave

Transfer Type	Control Bit [1]	Control Bit [2]	Condition
Slave Single Transfer	0	0	A single transfer is done.
	1	0	A single transfer is done. Or the length of the received data is equal to (SPI_MS_DATA_BITLEN + 1).
Slave Segmented Transfer	0	1	CMD7 or End_SEG_TRANS is received correctly.
	1	1	CMD7 or End_SEG_TRANS is received correctly. Or the length of the received data is equal to (SPI_MS_DATA_BITLEN + 1).

[1] SPI_RX_EOF_EN
[2] SPI_DMA_SLV_SEG_TRANS_EN

46.5.7.2 DMA TX/RX Buffer Length Control

It is recommended that the length of the configured DMA TX/RX buffer is equal to the length of actual data transferred.

- If the length of the configured DMA TX buffer is shorter than that of the actual data transferred, the extra data will be the same as the last transferred data. SPI_OUTFIFO_EMPTY_ERR_INT and AXI_DMA_OUT_EOF_CH*n*_INT are triggered.
- If the length of the configured DMA TX buffer is longer than that of actual data transferred, the TX buffer is not fully used, and the remaining buffer will be used for the following transaction even if a new TX buffer is linked later. Please keep it in mind. Or save the unused data and reset the DMA.
- If the length of the configured DMA RX buffer is shorter than that of the actual data transferred, the extra data will be lost. SPI_INFIFO_FULL_ERR_INT and SPI_TRANS_DONE_INT are triggered. But AXI_DMA_IN_SUC_EOF_CH*n*_INT is not triggered.

- If the length of the configured DMA RX buffer is longer than that of the actual data transferred, the RX buffer is not fully used, and the remaining buffer is discarded. In the following transaction, a new linked buffer will be used directly.

46.5.8 Data Flow Control (Take GP-SPI as an Example)

CPU-controlled and DMA-controlled transfers are supported in GP-SPI both as master and as slave. CPU-controlled transfer means that data is transferred between registers SPI_W0_REG~SPI_W15_REG and the SPI device. DMA-controlled transfer means that data is transferred between the configured DMA TX/RX buffer and the SPI device. To select between the two transfer types, configure SPI_DMA_RX_ENA and SPI_DMA_TX_ENA before the transfer starts.

46.5.8.1 GP-SPI Functional Blocks

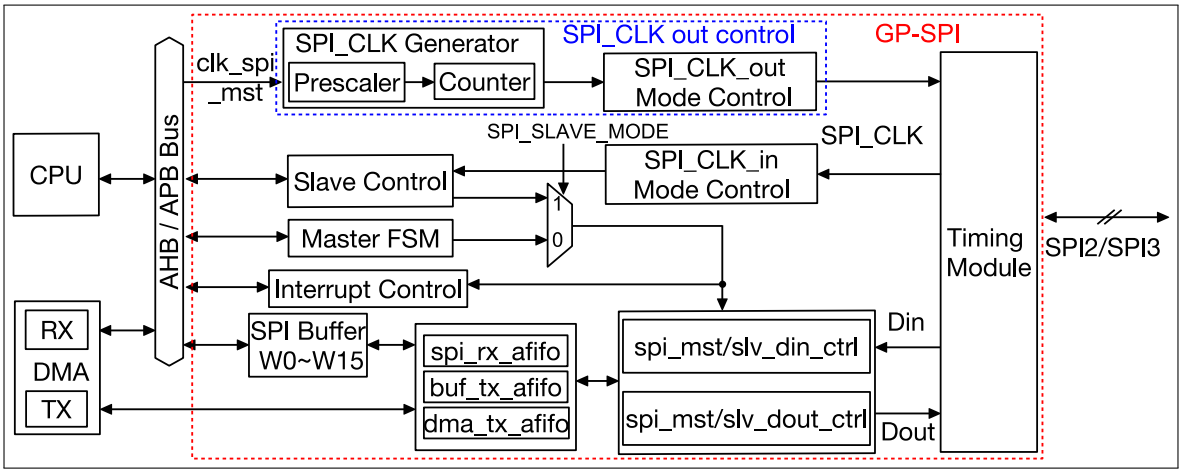

Figure 46.5-2. GP-SPI Functional Blocks

Figure 46.5-2 shows the main functional blocks in GP-SPI, including:

- Master FSM: all the features supported in GP-SPI as master are controlled by this state machine together with register configuration.
- SPI Buffer: SPI_W0_REG~SPI_W15_REG. See Figure 46.5-1. The data in CPU-controlled transfer is prepared in this buffer.
- Timing Module: captures data on SPI2/SPI3 bus.
- spi_mst/slv_din_ctrl and spi_mst/slv_dout_ctrl: converts the TX/RX data into bytes.
- spi_rx_afifo: stores the received data.
- buf_tx_afifo: stores the data to send.
- dma_tx_afifo: stores the data from DMA.
- clk_spi_mst: this clock is the module clock of GP-SPI and is used in GP-SPI as master to generate SPI_CLK signal for data transfer and for slaves.
- SPI_CLK Generator: generates SPI_CLK by dividing clk_spi_mst. The divider is determined by SPI_CLKCNT_N and SPI_CLKDIV_PRE.

- SPI_CLK_out Mode Control: outputs the SPI_CLK signal for data transfer and for slaves.
- SPI_CLK_in Mode Control: captures the SPI_CLK signal from SPI master when GP-SPI works as a slave.

46.5.8.2 Data Flow Control as Master

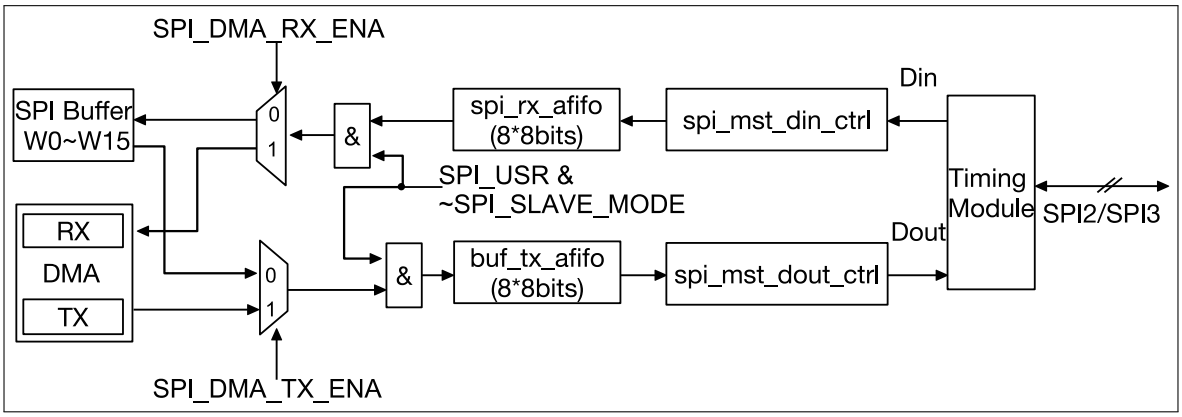

Figure 46.5-3. Data Flow Control in GP-SPI as Master

Figure 46.5-3 shows the data flow of GP-SPI as master. Its control logic is as follows:

- RX data: data bits in SPI2/SPI3 bus is captured by *Timing Module*, converted into bytes by *spi_mst_din_ctrl* module, then buffered in *spi_rx_afifo*, and finally stored in corresponding addresses according to the transfer types.
  - CPU-controlled transfer: the data is stored to registers SPI_W0_REG ~SPI_W15_REG.
  - DMA-controlled transfer: the data is stored to DMA RX buffer.
- TX data: the TX data is from corresponding addresses according to transfer modes and is saved to *buf_tx_afifo*.
  - CPU-controlled transfer: TX data is from SPI_W0_REG~SPI_W15_REG.
  - DMA-controlled transfer: TX data is from DMA TX buffer.

The data in *buf_tx_afifo* is sent out to Timing Module in 1/2/4/(8)-bit modes, controlled by GP-SPI state machine. The Timing Module can be used for timing compensation. For more information, see Section 46.8.

46.5.8.3 Data Flow Control as Slave

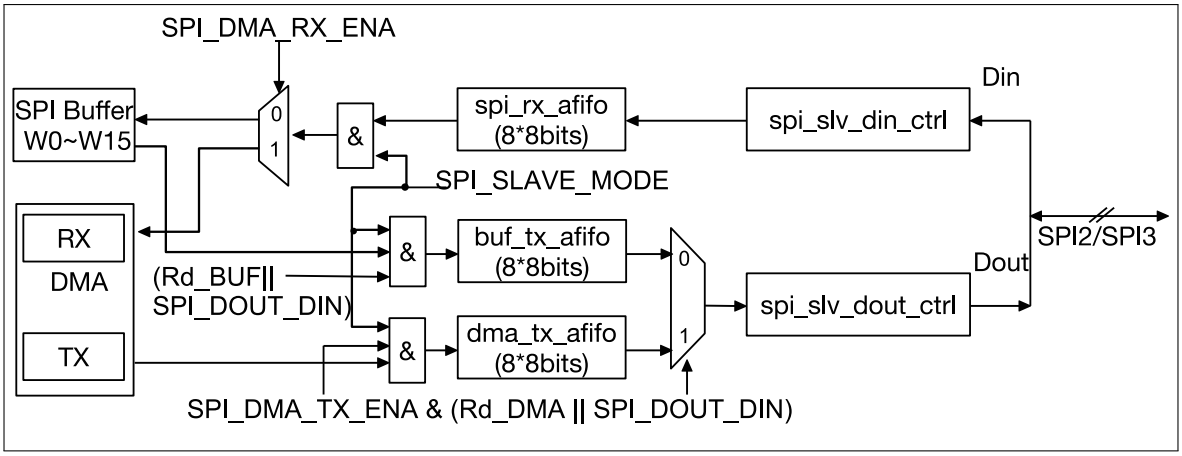

Figure 46.5-4. Data Flow Control in GP-SPI as Slave

Figure 46.5-4 shows the data flow of GP-SPI as slave. Its control logic is as follows:

- In CPU/DMA-controlled full-/half-duplex transfer, when an external SPI master starts the SPI transfer, data on the SPI2/SPI3 bus is captured, converted into bytes by the *spi_slv_din_ctrl* module, and then is stored in *spi_rx_afifo*.
  - In CPU-controlled full-duplex transfer, the received data in *spi_rx_afifo* will be later stored into registers SPI_W0_REG~SPI_W15_REG, successively.
  - In half-duplex Wr_BUF transfer, when the value of address (SLV_ADDR[7:0]) is received, the received data in *spi_rx_afifo* will be stored in the related address of registers SPI_W0_REG ~SPI_W15_REG.
  - In DMA-controlled full-duplex transfer or in half-duplex Wr_DMA transfer, the received data in spi_rx_afifo will be stored in the configured DMA RX buffer.
- In CPU-controlled full-/half-duplex transfer, the data to send is stored in *buf_tx_afifo*. In DMA-controlled full-/half-duplex transfer, the data to send is stored in *dma_tx_afifo*. Therefore, Rd_BUF transaction controlled by CPU and Rd_DMA transaction controlled by DMA can be done in one slave segmented transfer.
  - In CPU-controlled full-duplex transfer, when SPI_SLAVE_MODE and SPI_DOUTDIN are set and SPI_DMA_TX_ENA is cleared, the data in SPI_W0_REG~SPI_W15_REG will be stored into *buf_tx_afifo*.
  - In CPU-controlled half-duplex transfer, when SPI_SLAVE_MODE is set, SPI_DOUTDIN is cleared, Rd_BUF command and SLV_ADDR[7:0] are received, the data started from the related address of SPI_W0_REG~SPI_W15_REG will be stored into *buf_tx_afifo*.
  - In DMA-controlled full-duplex transfer, when SPI_SLAVE_MODE, SPI_DOUTDIN, and SPI_DMA_TX_ENA are set, the data in the configured DMA TX buffer will be stored into *dma_tx_afifo*.
  - In DMA-controlled half-duplex transfer, when SPI_SLAVE_MODE is set, SPI_DOUTDIN is cleared, and Rd_DMA command is received, the data in the configured DMA TX buffer will be stored into *dma_tx_afifo*.

The data in *buf_tx_afifo* or *dma_tx_afifo* is sent out by *spi_slv_dout_ctrl* module in 1/2/4(8)-bit modes.

46.5.9 GP-SPI as a Master

GP-SPI can be configured as a SPI master by clearing the bit SPI_SLAVE_MODE in SPI_SLAVE_REG. In this operation mode, GP-SPI provides clock signal (the divided clock from GP-SPI module clock) and CS signal.

46.5.9.1 State Machine

When GP-SPI works as a master, the state machine controls GP-SPI's various states during data transfer, including configuration (CONF), preparation (PREP), command (CMD), address (ADDR), dummy (DUMMY), data out (DOUT), and data in (DIN) states. GP-SPI is mainly used to access 1/2/4/8-bit SPI devices, such as flash and external RAM, thus the naming of GP-SPI states keeps consistent with the sequence naming of flash and external RAM. The meaning of each state is described as follows and Figure 46.5-5 shows the workflow of GP-SPI state machine.

1. IDLE: GP-SPI is not active or is operating as a slave.
2. CONF (valid for GP-SPI2 only): only used in DMA-controlled configurable segmented transfer. Set SPI_USR and SPI_USR_CONF to enable this state. If this state is not enabled, it means the current transfer is a single transfer.
3. PREP: prepare an SPI transaction and control SPI CS setup time. Set SPI_USR and SPI_CS_SETUP to enable this state.
4. CMD: send command sequence. Set SPI_USR and SPI_USR_COMMAND to enable this state.
5. ADDR: send address sequence. Set SPI_USR and SPI_USR_ADDR to enable this state.
6. DUMMY (wait cycle): send dummy sequence. set SPI_USR and SPI_USR_DUMMY to enable this state.
7. DATA: transfer data.
   - DOUT: send data sequence. Set SPI_USR and SPI_USR_MOSI to enable this state.
   - DIN: receive data sequence. Set SPI_USR and SPI_USR_MISO to enable this state.
8. DONE: control SPI CS hold time. Set SPI_USR to enable this state.

Note:

To start this state machine, set SPI_USR first. SPI_MST_FD_WAIT_DMA_TX_DATA controls when SPI_USR takes effect:

- 0: the configured state takes effect immediately after SPI_USR and other control registers are configured.
- 1: if DOUT state is configured, the SPI_USR and other control registers will take effect, and the state machine will start, only when the data is ready in *buf_tx_afifo*.

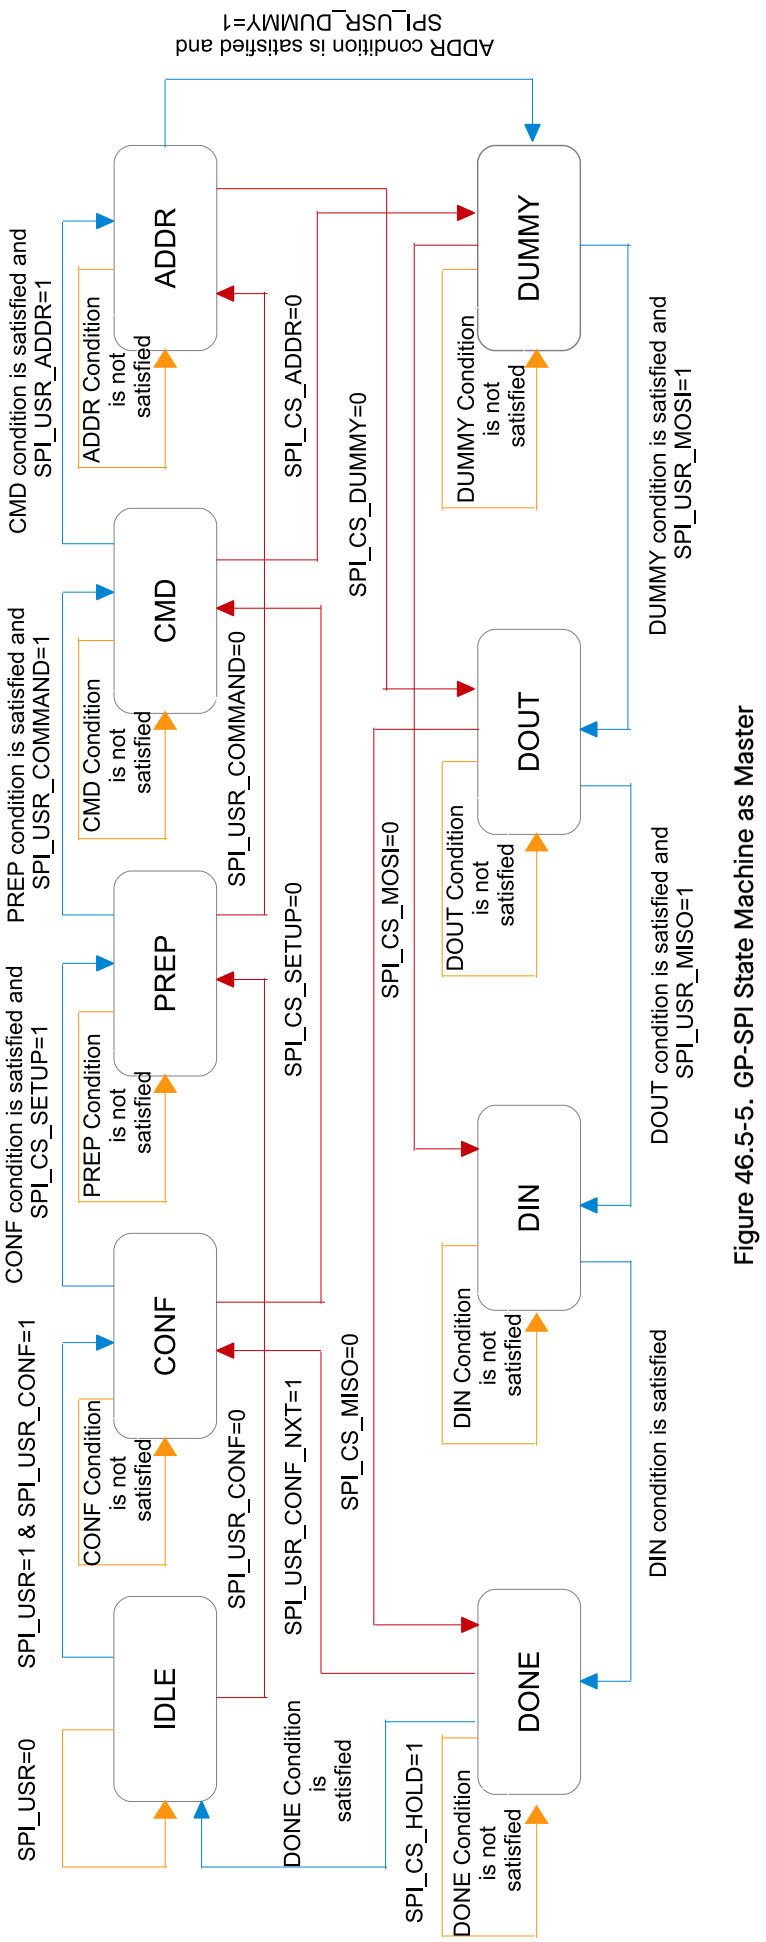

Figure 46.5-5. GP-SPI State Machine as Master

Legend to state flow:

- —: indicates corresponding state condition is not satisfied; repeats current state.
- —: corresponding registers are set and conditions are satisfied; goes to next state.
- —: state registers are not set; skips one or more following states, depending on the registers of the following states are set or not.

Explanation to the conditions listed in the figure above:

- CONF condition: gpc[17:0] >= SPI_CONF_BITLEN[17:0]
- PREP condition: gpc[4:0] >= SPI_CS_SETUP_TIME[4:0]
- CMD condition: gpc[3:0] >= SPI_USR_COMMAND_BITLEN[3:0]
- ADDR condition: gpc[4:0] >= SPI_USR_ADDR_BITLEN[4:0]
- DUMMY condition: gpc[7:0] >= SPI_USR_DUMMY_CYCLELEN[7:0]
- DOUT condition: gpc[17:0] >= SPI_MS_DATA_BITLEN[17:0]
- DIN condition: gpc[17:0] >= SPI_MS_DATA_BITLEN[17:0]
- DONE condition: (gpc[4:0] >= SPI_CS_HOLD_TIME[4:0] || SPI_CS_HOLD == 1'b0)

A counter (gpc[17:0]) is used in the state machine to control the cycle length of each state. The states CONF, PREP, CMD, ADDR, DUMMY, DOUT, and DIN can be enabled or disabled independently. The cycle length of each state can also be configured independently.

46.5.9.2 Register Configuration for State and Bit Mode Control

Introduction

The registers, related to GP-SPI state control, are listed in Table 46.5-10. Users can enable QPI mode for GP-SPI by setting the bit SPI_QPI_MODE in register SPI_USER_REG.

Table 46.5-10. Registers Used for State Control in 1/2/4/8-bit Modes

State	Control Registers for 1-bit Mode SPI2/SPI3 Bus	Control Registers for 2-bit Mode SPI2/SPI3 Bus	Control Registers for 4-bit Mode SPI2/SPI3 Bus	Control Registers for 8-bit Mode SPI2 Bus
CMD	SPI_USR_COMMAND_VALUE SPI_USR_COMMAND_BITLEN SPI_USR_COMMAND	SPI_USR_COMMAND_VALUE SPI_USR_COMMAND_BITLEN SPI_FCMD_DUAL SPI_USR_COMMAND	SPI_USR_COMMAND_VALUE SPI_USR_COMMAND_BITLEN SPI_FCMD_QUAD SPI_USR_COMMAND	SPI_USR_COMMAND_VALUE SPI_USR_COMMAND_BITLEN SPI_FCMD_OCT SPI_USR_COMMAND
ADDR	SPI_USR_ADDR_VALUE SPI_USR_ADDR_BITLEN SPI_USR_ADDR	SPI_USR_ADDR_VALUE SPI_USR_ADDR_BITLEN SPI_USR_ADDR SPI_FADDR_DUAL	SPI_USR_ADDR_VALUE SPI_USR_ADDR_BITLEN SPI_USR_ADDR SPI_FADDR_QUAD	SPI_USR_ADDR_VALUE SPI_USR_ADDR_BITLEN SPI_USR_ADDR SPI_FADDR_OCT
DUMMY	SPI_USR_DUMMY_CYCLELEN SPI_USR_DUMMY	SPI_USR_DUMMY_CYCLELEN SPI_USR_DUMMY	SPI_USR_DUMMY_CYCLELEN SPI_USR_DUMMY	SPI_USR_DUMMY_CYCLELEN SPI_USR_DUMMY
DIN	SPI_USR_MISO SPI_MS_DATA_BITLEN	SPI_USR_MISO SPI_MS_DATA_BITLEN SPI_FREAD_DUAL	SPI_USR_MISO SPI_MS_DATA_BITLEN SPI_FREAD_QUAD	SPI_USR_MISO SPI_MS_DATA_BITLEN SPI_FREAD_OCT
DOUT	SPI_USR_MOSI SPI_MS_DATA_BITLEN	SPI_USR_MOSI SPI_MS_DATA_BITLEN SPI_FWRITE_DUAL	SPI_USR_MOSI SPI_MS_DATA_BITLEN SPI_FWRITE_QUAD	SPI_USR_MOSI SPI_MS_DATA_BITLEN SPI_FWRITE_OCT

As shown in Table 46.5-10, the registers in each cell should be configured to set the SPI2/SPI3 bus to corresponding bit mode, i.e., the mode shown in the table header, at a specific state (corresponding to the first column).

Configuration

For instance, when GP-SPI2 reads data, and

- CMD is in 1-bit mode
- ADDR is in 2-bit mode
- DUMMY lasts for 8 clock cycles
- DIN is in 4-bit mode

The register configuration can be as follows:

1. Configure CMD state related registers.
   - Configure the required command value in SPI_USR_COMMAND_VALUE.
   - Configure command bit length in SPI_USR_COMMAND_BITLEN. SPI_USR_COMMAND_BITLEN = expected bit length - 1.
   - Set SPI_USR_COMMAND.
   - Clear SPI_FCMD_DUAL, SPI_FCMD_QUAD, and SPI_FCMD_OCT.
2. Configure ADDR state related registers.
   - Configure the required address value in SPI_USR_ADDR_VALUE.
   - Configure address bit length in SPI_USR_ADDR_BITLEN. SPI_USR_ADDR_BITLEN = expected bit length - 1.
   - Set SPI_USR_ADDR and SPI_FADDR_DUAL.
   - Clear SPI_FADDR_QUAD and SPI_FCMD_OCT.
3. Configure DUMMY state related registers.
   - Configure DUMMY cycles in SPI_USR_DUMMY_CYCLELEN. SPI_USR_DUMMY_CYCLELEN = expected clock cycles - 1.
   - Set SPI_USR_DUMMY.
4. Configure DIN state related registers.
   - Configure read data bit length in SPI_MS_DATA_BITLEN. SPI_MS_DATA_BITLEN = expected bit length - 1.
   - Set SPI_FREAD_QUAD and SPI_USR_MISO.
   - Clear SPI_FREAD_DUAL and SPI_FCMD_OCT.
   - Configure DMA for DMA-controlled transfer. For CPU controlled transfer, no action is needed.
5. Clear SPI_USR_MOSI.
6. Set SPI_DMA_AFIFO_RST, SPI_BUF_AFIFO_RST, and SPI_RX_AFIFO_RST to reset these buffers.
7. Set SPI_USR to start GP-SPI2 transfer.

Note:
Updating the configuration when the GP-SPI works as master described in this and subsequent sections requires to set SPI_UPDATE accordingly to synchronize the configuration from AHB_CLK domain to clk_spi_mst domain. For more detailed configuration, see the sections above. No operation is required when the GP-SPI works as slave.

When writing data (DOUT state), SPI_USR_MOSI should be configured instead, while SPI_USR_MISO should be cleared. The output data bit length is the value of SPI_MS_DATA_BITLEN + 1. Output data should be configured in GP-SPI2 data buffer (SPI_W0_REG~SPI_W15_REG) for CPU-controlled transfer, or DMA TX buffer for DMA-controlled transfer.

Pay special attention to the command value in SPI_USR_COMMAND_VALUE and to address value in SPI_USR_ADDR_VALUE.

The configuration of command value is as follows:

Table 46.5-11. Sending Sequence of Command Value

COMMAND_BITLEN[1]	COMMAND_VALUE[2]	BIT_ORDER[3]	Sending Sequence of Command Value
0~7	[7:0]	1	COMMAND_VALUE[COMMAND_BITLEN:0] is sent first.
		0	COMMAND_VALUE[7:7−COMMAND_BITLEN] is sent first.
8~15	[15:0]	1	COMMAND_VALUE[7:0] is sent first, and then COMMAND_VALUE[COMMAND_BITLEN:8].
		0	COMMAND_VALUE[7:0] is sent first, and then COMMAND_VALUE[15:15−COMMAND_BITLEN].

[1] SPI_USR_COMMAND_BITLEN: this field is used to configure the bit length of the command.
[2] SPI_USR_COMMAND_VALUE: command value is written into this field. For which part of this field is used, see the table above.
[3] SPI_WR_BIT_ORDER: 0: LSB first; 1: MSB first.

The configuration of address value is as follows:

Table 46.5-12. Sending Sequence of Address Value

ADDR_BITLEN[1]	ADDR_VALUE[2]	BIT_ORDER[3]	Sending Sequence of Address Value
0~7	[31:24]	1	COMMAND_VALUE[ADDR_BITLEN + 24:24] is sent first.
		0	ADDR_VALUE[31:31−ADDR_BITLEN] is sent first.
8~15	[31:16]	1	ADDR_VALUE[31:24] is sent first, and then ADDR_VALUE[ADDR_BITLEN + 8:16].
		0	ADDR_VALUE[31:24] is sent first, and then ADDR_VALUE[23:31−ADDR_BITLEN].
16~23	[31:8]	1	ADDR_VALUE[31:16] is sent first, and then ADDR_VALUE[ADDR_BITLEN−8:8].

		0	ADDR_VALUE[31:16] is sent first, and then ADDR_VALUE[15:31−ADDR_BITLEN].
24∼31	[31:0]	1	ADDR_VALUE[31:8] is sent first, and then ADDR_VALUE[ADDR_BITLEN−24:0].
		0	ADDR_VALUE[31:8] is sent first, and then ADDR_VALUE[7:31−ADDR_BITLEN].

[1] SPI_USR_ADDR_BITLEN: this field is used to configure the bit length of the address.
[2] SPI_USR_ADDR_VALUE: address value is written into this field. For which part of this field is used, see the table above.
[3] SPI_WR_BIT_ORDER: 0: LSB first; 1: MSB first.

46.5.9.3 Full-Duplex Communication (1-bit Mode Only)

Introduction

GP-SPI supports SPI full-duplex communication. In this mode, SPI master provides CLK and CS signals, exchanging data with SPI slave in 1-bit mode via MOSI (SPI2D/SPI3_D, sending) and MISO (SPI2Q/SPI3_Q, receiving) at the same time. To enable this communication mode, set the bit SPI_DOUTDIN in register SPI_USER_REG. Figure 46.5-6 illustrates the connection of GP-SPI2 with its slave in full-duplex communication.

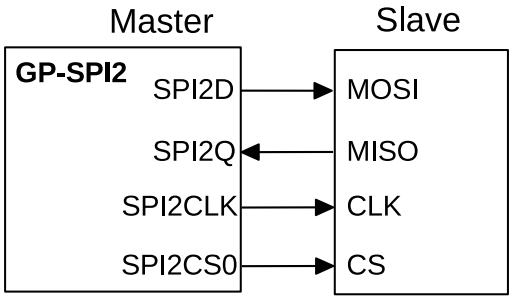

Figure 46.5-6. Full-Duplex Communication Between GP-SPI2 Master and a Slave

In full-duplex communication, the behavior of states CMD, ADDR, DUMMY, DOUT and DIN are configurable. Usually, the states CMD, ADDR and DUMMY are not used in this communication. The bit length of transferred data is configured in SPI_MS_DATA_BITLEN. The actual bit length used in communication equals to (SPI_MS_DATA_BITLEN + 1).

Configuration (Take GP-SPI2 as an example)

To start a data transfer, follow the steps below:

- Configure the IO path via IO MUX or GPIO matrix between GP-SPI2 and an external SPI device.
- Configure AHB clock (AHB_CLK, see Chapter 11 *Reset and Clock*) and module clock (clk_spi_mst) for the GP-SPI2 module.
- Set SPI_DOUTDIN and clear SPI_SLAVE_MODE, to enable master full-duplex communication.
- Configure GP-SPI2 registers listed in Table 46.5-10.
- Configure SPI CS setup time and hold time according to Section 46.6.

- Set the property of SPI2CLK according to Section 46.7.
- Prepare data according to the selected transfer type:
  - In CPU-controlled MOSI transfer, prepare data in registers SPI_W0_REG~SPI_W15_REG.
  - In DMA-controlled transfer,
    * configure SPI_DMA_TX_ENA/SPI_DMA_RX_ENA,
    * configure DMA TX/RX link,
    * and start DMA TX/RX engine, as described in Section 46.5.7 and Section 46.5.8.
- Configure interrupts and wait for SPI slave to get ready for transfer.
- Set SPI_DMA_AFIFO_RST, SPI_BUF_AFIFO_RST, and SPI_RX_AFIFO_RST to reset these buffers.
- Set SPI_USR in register SPI_CMD_REG to start the transfer and wait for the configured interrupts.

46.5.9.4 Half-Duplex Communication (1/2/4/(8)-bit Mode)

Introduction

In this mode, GP-SPI provides CLK and CS signals. Only one side (SPI master or slave) can send data at a time, while the other side receives the data. To enable this communication mode, clear the bit SPI_DOUTDIN in register SPI_USER_REG. The standard format of SPI half-duplex communication is CMD + [ADDR +] [DUMMY +] [DOUT or DIN]. The states ADDR, DUMMY, DOUT, and DIN are optional, and can be disabled or enabled independently.

As described in Section 46.5.9.2, the properties of GP-SPI states: CMD, ADDR, DUMMY, DOUT and DIN, such as cycle length, value, and parallel bus bit mode, can be set independently. For the register configuration, see Table 46.5-10.

The detailed properties of half-duplex GP-SPI are as follows:

1. CMD: 0~16 bits, master output, slave input.
2. ADDR: 0~32 bits, master output, slave input.
3. DUMMY: 0~256 SPI2CLK/SPI3_CLK cycles, master output, slave input.
4. DOUT: 0~512 bits (64 bytes) in CPU-controlled transfer, 0~256 Kbits (32 KB) in DMA-controlled single transfer, and unlimited length in DMA-controlled configurable segmented transfer, master output, slave input.
5. DIN: 0~512 bits (64 bytes) in CPU-controlled transfer, 0~256 Kbits (32 KB) in DMA-controlled single transfer, and unlimited length in DMA-controlled configurable segmented transfer, slave output, master input.

GP-SPI2 also supports Double Transfer Rate (DTR) in 1/2/4/8-bit modes, in which data is sent and received at the rising and the falling edges of SPI clock:

- If SPI_CMD_DTR_EN is set, the CMD value will be sent in DTR mode; otherwise CMD phase will be in Single Transfer Rate (STR) mode.
- If SPI_ADDR_DTR_EN is set, the ADDR value will be sent in DTR mode; otherwise ADDR phase will be in STR mode.

- If SPI_DATA_DTR_EN is set, the input data in state DIN or output data in state DOUT will be sent in DTR mode; otherwise the data will be in STR mode.

The control bits SPI_CMD_DTR_EN, SPI_ADDR_DTR_EN, and SPI_DATA_DTR_EN can be configured independently, which means CMD in STR mode, ADDR and DOUT or DIN in DTR mode are supported.

GP-SPI2 can only output SPI2DQS signal, but can not receive the signal. Therefore, only flash or external RAM working in fixed dummy mode (dummy cycles in a read sequence is fixed) are supported.

Configuration (Take GP-SPI2 as an example)

The register configuration can be as follows:

1. Configure the IO path via HP IO MUX or HP GPIO matrix between GP-SPI2 and an external SPI device.
2. Configure AHB clock (AHB_CLK) and module clock (clk_spi_mst) for the GP-SPI2 module.
3. Clear SPI_DOUTDIN and SPI_SLAVE_MODE, to enable master half-duplex communication.
4. Configure GP-SPI2 registers listed in Table 46.5-10.
5. Configure SPI CS setup time and hold time according to Section 46.6.
6. Set the property of SPI2CLK according to Section 46.7.
7. Prepare data according to the selected transfer type:
   - In CPU-controlled MOSI transfer, prepare data in registers SPI_W0_REG~SPI_W15_REG.
   - In DMA-controlled transfer,
     - configure SPI_DMA_TX_ENA/SPI_DMA_RX_ENA,
     - configure DMA TX/RX link,
     - and start DMA TX/RX engine, as described in Section 46.5.7 and Section 46.5.8.
8. Configure interrupts and wait for SPI slave to get ready for transfer.
9. Set SPI_DMA_AFIFO_RST, SPI_BUF_AFIFO_RST, and SPI_RX_AFIFO_RST to reset these buffers.
10. Set SPI_USR in register SPI_CMD_REG to start the transfer and wait for the configured interrupts.

Application Example (Take GP-SPI2 as an example)

The following example shows how GP-SPI2 accesses flash and external RAM in master half-duplex communication.

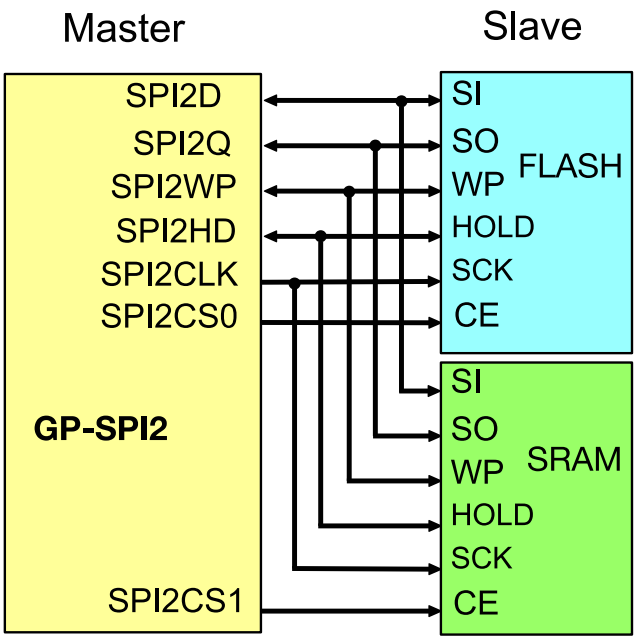

Figure 46.5-7. Connection of GP-SPI2 to Flash and External RAM in 4-bit Mode

Figure 46.5-8 indicates GP-SPI2 Quad I/O Read sequence according to standard flash specification. Other GP-SPI2 command sequences are implemented in accordance with the requirements of SPI slaves.

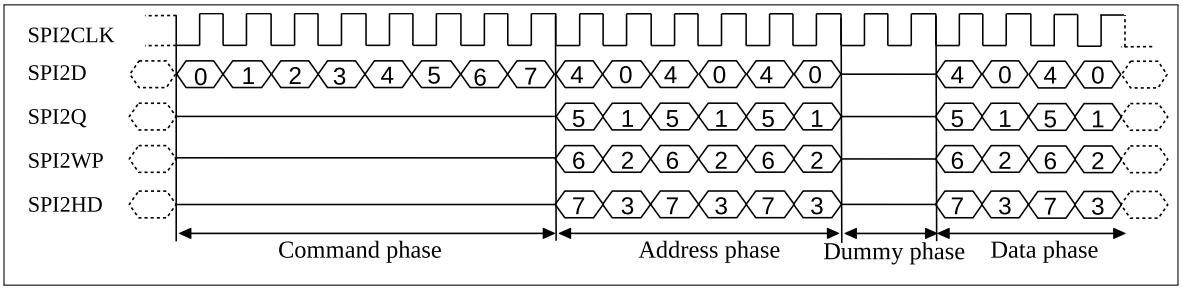

Figure 46.5-8. SPI Quad I/O Read Command Sequence Sent by GP-SPI2 to Flash

46.5.9.5 DMA-Controlled Configurable Segmented Transfer

Note:

- LP-SPI and GP-SPI3 do not support DMA-controlled configurable segmented transfer.
- Note that there is no separate section on how to configure a single transfer as master, since the CONF state of a configurable segmented transfer can be skipped to implement a single transfer.

Introduction

When GP-SPI2 works as a master, it provides a feature named configurable segmented transfer controlled by DMA.

A DMA-controlled transfer as master can be:

- a single transfer, consisting of only one transaction;
- or a configurable segmented transfer, consisting of several transactions (segments).

In a configurable segmented transfer, the registers of each single transaction (segment) are configurable. This feature enables GP-SPI2 to do as many transactions (segments) as configured after such transfer is triggered once by the CPU. Figure 46.5-9 shows how this feature works.

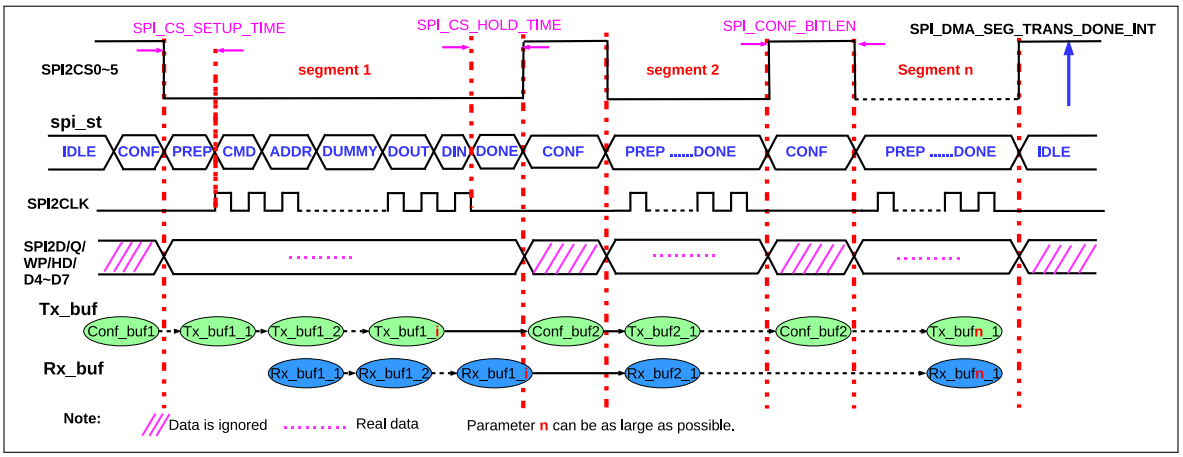

Figure 46.5-9. Configurable Segmented Transfer as Master

As shown in Figure 46.5-9, the registers for one transaction (segment *n*) can be reconfigured by GP-SPI2 hardware according to the content in its Conf_buf*n* during the CONF state, before this segment starts.

It is recommended to provide separate DMA CONF links and CONF buffers (Conf_buf*i* in Figure 46.5-9) for each CONF state. A DMA TX link is used to connect all the CONF buffers and TX data buffers (Tx_buf*i* in Figure 46.5-9) into a chain. Hence, the behavior of the SPI2 bus in each segment can be controlled independently.

For example, in a configurable segmented transfer, its segment *i*, segment *j*, and segment *k* can be configured to full-duplex, half-duplex MISO, and half-duplex MOSI, respectively. *i*, *j*, and *k* represent different segment numbers.

Meanwhile, the state of GP-SPI2, the data length and cycle length of the SPI2 bus, and the behavior of the DMA, can be configured independently for each segment. When this whole DMA-controlled transfer (consisting of several segments) has finished, a GP-SPI2 interrupt, SPI_DMA_SEG_TRANS_DONE_INT, is triggered.

Configuration

1. Configure the IO path via HP IO MUX or HP GPIO matrix between GP-SPI2 and an external SPI device.
2. Configure AHB clock (AHB_CLK) and module clock (clk_spi_mst) for the GP-SPI2 module.
3. Clear SPI_DOUTDIN and SPI_SLAVE_MODE, to enable master half-duplex communication.
4. Configure GP-SPI2 registers listed in Table 46.5-10.
5. Configure SPI CS setup time and hold time according to Section 46.6.
6. Set the property of SPI2CLK according to Section 46.7.
7. Prepare descriptors for DMA CONF buffer and TX data (optional) for each segment. Chain the descriptors of CONF buffer and TX buffers of several segments into one linked list.
8. Similarly, prepare descriptors for RX buffers for each segment and chain them into one linked list.

9. Configure all the needed CONF buffers, TX buffers and RX buffers, respectively for each segment before this DMA-controlled transfer begins.
10. Point AXI_DMA_OUTLINK_ADDR_CH*n* to the head address of the CONF and TX buffer descriptor linked list, and then set AXI_DMA_OUTLINK_START_CH*n* to start the TX DMA.
11. Clear the bit SPI_RX_EOF_EN in register SPI_DMA_CONF_REG. Point AXI_DMA_INLINK_ADDR_CH*n* to the head address of the CONF and RX buffer descriptor linked list, and then set AXI_DMA_INLINK_START_CH*n* to start the RX DMA.
12. Set SPI_USR_CONF to enable CONF state.
13. Set SPI_DMA_SEG_TRANS_DONE_INT_ENA to enable the SPI_DMA_SEG_TRANS_DONE_INT interrupt. Configure other interrupts if needed according to Section 46.11.
14. Wait for all the slaves to get ready for transfer.
15. Set SPI_DMA_AFIFO_RST, SPI_BUF_AFIFO_RST, and SPI_RX_AFIFO_RST to reset these buffers.
16. Set SPI_USR to start this DMA-controlled transfer.
17. Wait for SPI_DMA_SEG_TRANS_DONE_INT interrupt, which means this transfer has finished and the data has been stored into corresponding memory.

Note:

Prepare the data to send for each segment in its PREP state. Shall ensure that:

$$(SPI_CS_SETUP_TIME + 1) \times T_{SPI_CLK} >= 4 \times (T_{AHB_CLK} + Tclk_spi_mst)$$

Configuration of CONF Buffer and Magic Value

In a configurable segmented transfer, only registers which change from the last transaction (segment) need to be re-configured to new values in CONF state. The configuration of other registers can be skipped (i.e., kept the same) to save time and chip resources.

The first word in DMA CONF buffer*i*, called SPI_BIT_MAP_WORD, defines whether given GP-SPI2 register is to be updated or not in segment *i*. The relation of SPI_BIT_MAP_WORD and GP-SPI2 registers to update can be seen in Table 46.5-13 Bitmap (BM) Table. If a bit in the BM table is set to 1, its corresponding register value will be updated in this segment. Otherwise, if some registers should be kept from being changed, the related bits should be set to 0.

Table 46.5-13. BM Table for CONF State

BM Bit	Register	BM Bit	Register
0	SPI_ADDR_REG	7	SPI_MISC_REG
1	SPI_CTRL_REG	8	SPI_DIN_MODE_REG
2	SPI_CLOCK_REG	9	SPI_DIN_NUM_REG
3	SPI_USER_REG	10	SPI_DOUT_MODE_REG
4	SPI_USER1_REG	11	SPI_DMA_CONF_REG
5	SPI_USER2_REG	12	SPI_DMA_INT_ENA_REG
6	SPI_MS_DLEN_REG	13	SPI_DMA_INT_CLR_REG

Then new values of all the registers to be modified should be placed right after SPI_BIT_MAP_WORD, in consecutive words in the CONF buffer.

To ensure the correctness of the content in each CONF buffer, the value in SPI_BIT_MAP_WORD[31:28] is used as a "magic value", and will be compared with SPI_DMA_SEG_MAGIC_VALUE in register SPI_SLAVE_REG. The value of SPI_DMA_SEG_MAGIC_VALUE should be configured before this DMA-controlled transfer starts, and can not be changed during these segments.

- If SPI_BIT_MAP_WORD[31:28] == SPI_DMA_SEG_MAGIC_VALUE, this DMA-controlled transfer continues normally. SPI_DMA_SEG_TRANS_DONE_INT is triggered at the end of this DMA-controlled transfer.
- If SPI_BIT_MAP_WORD[31:28] != SPI_DMA_SEG_MAGIC_VALUE, GP-SPI2 state (spi_st) goes back to IDLE and the transfer is ended immediately. The interrupt SPI_DMA_SEG_TRANS_DONE_INT is still triggered, with SPI_SEG_MAGIC_ERR_INT_RAW bit set to 1.

CONF Buffer Configuration Example

Table 46.5-14 and Table 46.5-15 provide an example to show how to configure a CONF buffer for a transaction (segment*i*) in which SPI_ADDR_REG, SPI_CTRL_REG, SPI_CLOCK_REG, SPI_USER_REG, and SPI_USER1_REG need to be updated.

Table 46.5-14. An Example of CONF buffer*i* in Segment *i*

CONF buffer*i*	Note
SPI_BIT_MAP_WORD	The first word in this buffer. Its value is 0xA000001F in this example when the SPI_DMA_SEG_MAGIC_VALUE is set to 0xA. As shown in Table 46.5-15, bits 0, 1, 2, 3, and 4 are set, indicating the following registers will be updated.
SPI_ADDR_REG	The second word, stores the new value to SPI_ADDR_REG.
SPI_CTRL_REG	The third word, stores the new value to SPI_CTRL_REG.
SPI_CLOCK_REG	The fourth word, stores the new value to SPI_CLOCK_REG.
SPI_USER_REG	The fifth word, stores the new value to SPI_USER_REG.
SPI_USER1_REG	The sixth word, stores the new value to SPI_USER1_REG.

Table 46.5-15. BM Bit Value and Register to Be Updated in This Example

BM Bit	Value	Register	BM Bit	Value	Register
0	1	SPI_ADDR_REG	7	0	SPI_MISC_REG
1	1	SPI_CTRL_REG	8	0	SPI_DIN_MODE_REG
2	1	SPI_CLOCK_REG	9	0	SPI_DIN_NUM_REG
3	1	SPI_USER_REG	10	0	SPI_DOUT_MODE_REG
4	1	SPI_USER1_REG	11	0	SPI_DMA_CONF_REG
5	0	SPI_USER2_REG	12	0	SPI_DMA_INT_ENA_REG
6	0	SPI_MS_DLEN_REG	13	0	SPI_DMA_INT_CLR_REG

Notes

In a DMA-controlled configurable segmented transfer, please pay special attention to the following bits:

- SPI_USR_CONF: set SPI_USR_CONF before SPI_USR is set, to enable this transfer.
- SPI_USR_CONF_NXT: if segment *i* is not the final transaction of this whole DMA-controlled transfer, its SPI_USR_CONF_NXT bit should be set to 1.
- SPI_CONF_BITLEN: GP-SPI2 CS setup time and hold time are programmable independently in each segment, see Section 46.6 for detailed configuration. The CS high time in each segment is about:

$$(SPI_CONF_BITLEN + 5) \times T_{AHB_CLK}$$

  The CS high time in CONF state can be set from 62.5 ns~3.2768 ms when $f_{\text{AHB_CLK}}$ is 80 MHz. (SPI_CONF_BITLEN + 5) will overflow from (0x40000 - SPI_CONF_BITLEN - 5) if SPI_CONF_BITLEN is larger than 0x3FFFA.

46.5.10 GP-SPI Works as a Slave

GP-SPI can be used as a slave to communicate with an SPI master. As a slave, GP-SPI supports 1-bit SPI, 2-bit dual SPI, 4-bit quad SPI, and QPI modes, with specific communication formats. To enable this mode, set SPI_SLAVE_MODE in register SPI_SLAVE_REG.

The CS signal must be held low during the transfer, and its falling/rising edges indicate the start/end of a single or segmented transfer. Take CS low-level effective as an example, when GP-SPI is used as a slave, the CS invalid duration (high-level) between each SPI transfer should not be less than 8 T_{AHB_CLK} to ensure that each transfer can end normally.

46.5.10.1 Configurable Communication Formats

When GP-SPI works as a slave, SPI full-duplex and half-duplex communications are available. To select from the two communications, configure SPI_DOUTDIN in register SPI_USER_REG.

Full-duplex communication means that input data and output data are transmitted simultaneously throughout the entire transaction. All bits are treated as input or output data, which means no command, address or dummy states are expected. The interrupt SPI_TRANS_DONE_INT is triggered once the transaction ends.

In half-duplex communication, the format is CMD+ADDR+DUMMY+DATA (DIN or DOUT).

- "DIN" means that an SPI master reads data from GP-SPI.
- "DOUT" means that an SPI master writes data to GP-SPI.

The detailed properties of each state are as follows:

1. CMD:
   - Indicate the function of SPI slave.
   - One byte from master to slave.
   - Only the values in Table 46.5-16 and Table 46.5-17 are valid.
   - Can be sent in 1-bit SPI mode or 4-bit QPI mode.
2. ADDR:
   - The address for Wr_BUF and Rd_BUF commands in CPU-controlled transfer, or placeholder bits in other transfers and can be defined by application.

- One byte from master to slave.
- Can be sent in 1-bit, 2-bit or 4-bit modes according to the command.

3. DUMMY:
   - Its value is meaningless. SPI slave prepares data in this state.
   - Bit mode of SPI2 bus is also meaningless here.
   - Last for eight SPI_CLK cycles.
4. DIN or DOUT:
   - Data length can be 0~64 bytes in CPU-controlled transfer and unlimited in DMA-controlled transfer.
   - Can be sent in 1-bit, 2-bit or 4-bit modes according to the CMD value.

Note:
The states of ADDR and DUMMY can never be skipped in any half-duplex communications.

When a half-duplex transaction is complete, the transferred CMD and ADDR values are latched into SPI_SLV_LAST_COMMAND and SPI_SLV_LAST_ADDR, respectively. SPI_SLV_CMD_ERR_INT_RAW will be set if the transferred CMD value is not supported by GP-SPI as slave. SPI_SLV_CMD_ERR_INT_RAW can only be cleared by software.

46.5.10.2 CMD Values Supported in Half-Duplex Communication

In half-duplex communication, the defined values of CMD determine the transfer types. Unsupported CMD values are disregarded, meanwhile the related transfer is ignored and SPI_SLV_CMD_ERR_INT_RAW is set. The transfer format is CMD (8 bits) + ADDR (8 bits) + DUMMY (8 SPI_CLK cycles) + DATA (unit in bytes). The detailed description of CMD[3:0] is as follows:

- 0x1 (Wr_BUF): CPU-controlled write operation. Master sends data and GP-SPI receives data. The data is stored in the related address of SPI_W0_REG~SPI_W15_REG.
- 0x2 (Rd_BUF): CPU-controlled read operation. Master receives the data sent by GP-SPI. The data comes from the related address of SPI_W0_REG~SPI_W15_REG.
- 0x3 (Wr_DMA): DMA-controlled write operation. Master sends data and GP-SPI receives data. The data is stored in GP-SPI DMA RX buffer.
- 0x4 (Rd_DMA): DMA-controlled read operation. Master receives the data sent by GP-SPI. The data comes from GP-SPI DMA TX buffer.
- 0x7 (CMD7): used to generate an SPI_SLV_CMD7_INT interrupt. It can also generate a AXI_DMA_IN_SUC_EOF_CH*n*_INT interrupt in a slave segmented transfer when DMA RX link is used. But it will not end GP-SPI's slave segmented transfer.
- 0x8 (CMD8): only used to generate an SPI_SLV_CMD8_INT interrupt, which will not end GP-SPI's slave segmented transfer.
- 0x9 (CMD9): only used to generate an SPI_SLV_CMD9_INT interrupt, which will not end GP-SPI's slave segmented transfer.

- 0xA (CMDA): only used to generate an SPI_SLV_CMDA_INT interrupt, which will not end GP-SPI's slave segmented transfer.

CMD7, CMD8, CMD9, and CMDA commands are reserved for user definition. These commands can be used as handshake signals, as passwords of some specific functions, as trigger signals of some user defined actions, and so on.

1/2/4-bit modes in states of CMD, ADDR, DATA are supported, which are determined by value of CMD[7:4]. The DUMMY state is always in 1-bit mode and lasts for eight SPI_CLK cycles. The definition of CMD[7:4] is as follows:

- 0x0: CMD, ADDR, and DATA states all are in 1-bit mode.
- 0x1: CMD and ADDR are in 1-bit mode. DATA is in 2-bit mode.
- 0x2: CMD and ADDR are in 1-bit mode. DATA is in 4-bit mode.
- 0x5: CMD is in 1-bit mode. ADDR and DATA are in 2-bit mode.
- 0xA: CMD is in 1-bit mode, ADDR and DATA are in 4-bit mode or in QPI mode.

In addition, if the value of CMD[7:0] is 0x05, 0xA5, 0x06, or 0xDD, DUMMY and DATA states are skipped. The definition of CMD[7:0] is as follows:

- 0x05 (End_SEG_TRANS): master sends this command to end slave segmented transfer in SPI mode.
- 0xA5 (End_SEG_TRANS): master sends this command to end slave segmented transfer in QPI mode.
- 0x06 (En_QPI): GP-SPI enters QPI mode when receiving this command and the bit SPI_QPI_MODE in register SPI_USER_REG is set.
- 0xDD (Ex_QPI): GP-SPI exits QPI mode when receiving this command and the bit SPI_QPI_MODE is cleared.

All the CMD values supported by GP-SPI are listed in Table 46.5-16 and Table 46.5-17. Note that the DUMMY state is always in 1-bit mode and lasts for eight SPI_CLK cycles.

Table 46.5-16. CMD Values Supported in SPI Mode

Transfer Type	CMD[7:0]	CMD State	ADDR State	DATA State
Wr_BUF	0x01	1-bit mode	1-bit mode	1-bit mode
	0x11	1-bit mode	1-bit mode	2-bit mode

CMDA	0xAA	4-bit mode	4-bit mode	-
End_SEG_TRANS	0xA5	4-bit mode	4-bit mode	-
Ex_QPI	0xDD	4-bit mode	4-bit mode	-

Master sends 0x06 CMD (En_QPI) to set GP-SPI slave to QPI mode and all the states of supported transfer will be in 4-bit mode afterwards. If 0xDD CMD (Ex_QPI) is received, GP-SPI slave will be back to SPI mode.

Other transfer types than these described in Table 46.5-16 and Table 46.5-17 are ignored. But if the CS low-level duration is longer than two APB_CLK cycles, SPI_TRANS_DONE_INT will be triggered. For more information on interrupts triggered at the end of transmissions, please refer to Section 46.11.

46.5.10.3 Slave Single Transfer and Slave Segmented Transfer

When GP-SPI works as a slave, it supports full-duplex and half-duplex communications controlled by DMA and by CPU. DMA-controlled transfer can be a single transfer, or a slave segmented transfer consisting of several transactions (segments). The CPU-controlled transfer can only be one single transfer, since each CPU-controlled transaction needs to be triggered by CPU.

In a slave segmented transfer, all transfer types listed in Table 46.5-16 and Table 46.5-17 are supported in a single transaction (segment). It means that CPU-controlled transaction and DMA-controlled transaction can be mixed in one slave segmented transfer.

It is recommended that in a slave segmented transfer:

- CPU-controlled transaction is used for handshake communication and short data transfers.
- DMA-controlled transaction is used for large data transfers.

46.5.10.4 Configuration of Slave Single Transfer

When operating as slave, GP-SPI supports CPU/DMA-controlled full-duplex/half-duplex single transfers.

The register configuration procedure is as follows (take GP-SPI2 as an example):

1. Configure the IO path via HP IO MUX or HP GPIO matrix between GP-SPI2 and an external SPI device.
2. Configure AHB clock (AHB_CLK).
3. Set SPI_SLAVE_MODE to enable slave mode.
4. Configure SPI_DOUTDIN:
    - 1: enable full-duplex communication.
    - 0: enable half-duplex communication.
5. Prepare data:
    - if CPU-controlled transfer is selected and GP-SPI2 is used to send data, then prepare data in registers SPI_W0_REG~SPI_W15_REG.
    - if DMA-controlled transfer is selected,
        - configure SPI_DMA_TX_ENA/SPI_DMA_RX_ENA and SPI_RX_EOF_EN.
        - configure DMA TX/RX link,
        - and start DMA TX/RX engine, as described in Section 46.5.7 and Section 46.5.8.
6. Set SPI_DMA_AFIFO_RST, SPI_BUF_AFIFO_RST, and SPI_RX_AFIFO_RST to reset these buffers.

7. Clear SPI_DMA_SLV_SEG_TRANS_EN in register SPI_DMA_CONF_REG to enable slave single transfer.
8. Set SPI_TRANS_DONE_INT_ENA in register SPI_DMA_INT_ENA_REG and wait for the interrupt SPI_TRANS_DONE_INT. In DMA-controlled mode, it is recommended to wait for the interrupt AXI_DMA_IN_SUC_EOF_CH*n*_INT when DMA RX buffer is used, which means that data has been stored in the related memory. Other interrupts described in Section 46.11 are optional.

46.5.10.5 Configuration of Slave Segmented Transfer in Half-Duplex

DMA must be used in this mode. The register configuration procedure is as follows (take GP-SPI2 as an example):

1. Configure the IO path via HP IO MUX or HP GPIO matrix between GP-SPI2 and an external SPI device.
2. Configure APB clock (APB_CLK).
3. Set SPI_SLAVE_MODE to enable slave mode.
4. Clear SPI_DOUTDIN to enable half-duplex communication.
5. Prepare data in registers SPI_W0_REG~SPI_W15_REG, if needed.
6. Set SPI_DMA_AFIFO_RST, SPI_BUF_AFIFO_RST, and SPI_RX_AFIFO_RST to reset these buffers.
7. Set bits SPI_DMA_RX_ENA and SPI_DMA_TX_ENA. Clear the bit SPI_RX_EOF_EN. Configure DMA TX/RX link and start DMA TX/RX engine, as shown in Section 46.5.7 and Section 46.5.8.
8. Set SPI_DMA_SLV_SEG_TRANS_EN in register SPI_DMA_CONF_REG to enable slave segmented transfer.
9. Set SPI_DMA_SEG_TRANS_DONE_INT_ENA in register SPI_DMA_INT_ENA_REG and wait for the interrupt SPI_DMA_SEG_TRANS_DONE_INT, which means that the segmented transfer has finished and data has been put into the related memory. Other interrupts described in Section 46.11 are optional.

When End_SEG_TRANS (0x05 in SPI mode, 0xA5 in QPI mode) is received by GP-SPI, this slave segmented transfer is ended and the interrupt SPI_DMA_SEG_TRANS_DONE_INT is triggered.

46.5.10.6 Configuration of Slave Segmented Transfer in Full-Duplex

DMA must be used in this mode. In such transfer, the data is transferred from and to the DMA buffer. The interrupt AXI_DMA_IN_SUC_EOF_CH*n*_INT is triggered when the transfer ends.

The register configuration procedure is as follows (take GP-SPI2 as an example):

1. Configure the IO path via HP IO MUX or HP GPIO matrix between GP-SPI2 and an external SPI device.
2. Configure APB clock (APB_CLK).
3. Set SPI_SLAVE_MODE and SPI_DOUTDIN, to enable slave full-duplex communication.
4. Set SPI_DMA_AFIFO_RST, SPI_BUF_AFIFO_RST, and SPI_RX_AFIFO_RST to reset these buffers.
5. Set SPI_DMA_TX_ENA/SPI_DMA_RX_ENA. Configure DMA TX/RX link and start DMA TX/RX engine, as shown in Section 46.5.7 and Section 46.5.8.
6. Set SPI_RX_EOF_EN in register SPI_DMA_CONF_REG. Configure SPI_MS_DATA_BITLEN[17:0] in register SPI_MS_DLEN_REG to the bit length of the received DMA data.
7. Set SPI_DMA_SLV_SEG_TRANS_EN in register SPI_DMA_CONF_REG to enable slave segmented transfer.

8. Set AXI_DMA_IN_SUC_EOF_CH*n*_INT_ENA and wait for the interrupt AXI_DMA_IN_SUC_EOF_CH*n*_INT.

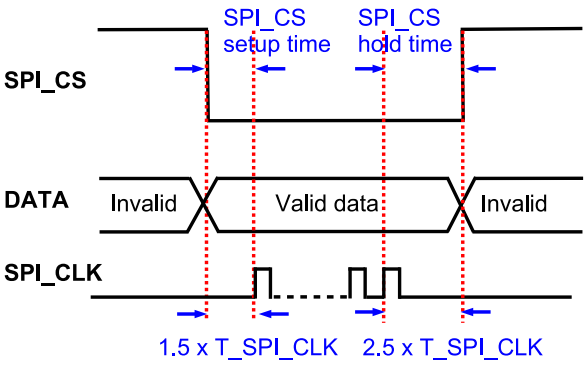
46.6 CS Setup Time and Hold Time Control

SPI bus CS (SPI_CS) setup time and hold time are very important to meet the timing requirements of various SPI devices (e.g., flash or PSRAM).

CS setup time is the time between the CS falling edge and the first latch edge of SPI bus CLK (SPI_CLK). The first latch edge for mode 0 and mode 3 is rising edge, and falling edge for mode 1 and mode 2.

CS hold time is the time between the last latch edge of SPI_CLK and the CS rising edge.

When operating as slave, the CS setup time and hold time should be longer than 0.5 x T_SPI_CLK, otherwise the SPI transfer may be incorrect. T_SPI_CLK is one cycle of SPI_CLK.



When operating as master, set the CS setup time by specifying SPI_CS_SETUP in register SPI_USER_REG and SPI_CS_SETUP_TIME in register SPI_USER1_REG.

- If SPI_CS_SETUP is cleared, the SPI CS setup time is 0.5 x T_SPI_CLK.
- If SPI_CS_SETUP is set, the SPI CS setup time is (SPI_CS_SETUP_TIME + 1.5) x T_SPI_CLK.

Set the CS hold time by specifying SPI_CS_HOLD in register SPI_USER_REG and SPI_CS_HOLD_TIME in register SPI_USER1_REG.

- If SPI_CS_HOLD is cleared, the SPI CS hold time is 0.5 x T_SPI_CLK.
- If SPI_CS_HOLD is set, the SPI CS hold time is (SPI_CS_HOLD_TIME + 1.5) x T_SPI_CLK.

Figure 46.6-1 and Figure 46.6-2 show the recommended CS timing and register configuration to access external RAM and flash.

Register Configurations:

SPI_CS_SETUP = 1; SPI_CS_SETUP_TIME = 0;
SPI_CS_HOLD = 1; SPI_CS_HOLD_TIME = 1.

Figure 46.6-1. Recommended CS Timing and Settings When Accessing External RAM

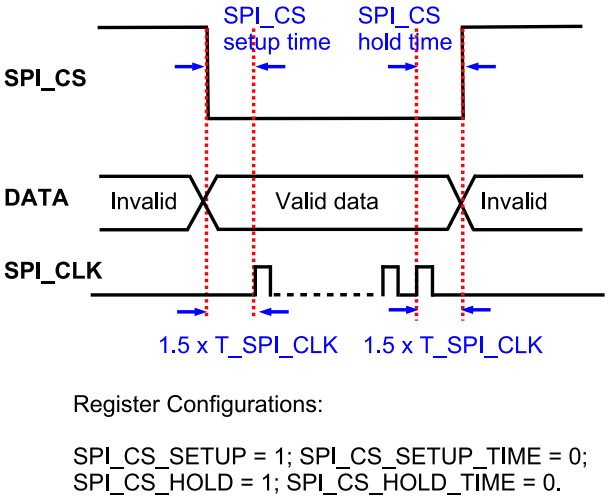


Figure 46.6-2. Recommended CS Timing and Settings When Accessing Flash

46.7 Clock Control

46.7.1 GP-SPI Clock Control

GP-SPI has the following clocks:

- clk_spi_mst: module clock of GP-SPI, derived from the following clock sources, depending on the configuration of HP_SYS_CLKRST_GPSPI2/3_CLK_SRC_SEL:
  - 0: XTAL_CLK
  - 1: RC_FAST_CLK
  - 2: SDIO_PLLO_CLK
  - 3: APLL_CLK
  - 4: SPLL_CLK (480 MHz)

  The divider value is equal to HP_SYS_CLKRST_GPSPI2/3_MST_CLK_DIV_NUM + 1. HP_SYS_CLKRST_GPSPI2/3_SYS_CLK_EN is used to enable the selected clock source. clk_spi_mst is used in GP-SPI as master to generate SPI_CLK signal for data transfer and for slaves.
- clk_hclk: module timing compensation clock of GP-SPI, which is a frequency-doubled clock derived from the same source as clk_spi_mst. Its clock source is also determined by HP_SYS_CLKRST_GPSPI2/3_CLK_SRC_SEL. To use this clock, HP_SYS_CLKRST_GPSPI2/3_HS_CLK_EN must be set, and the divider value is equal to HP_SYS_CLKRST_GPSPI2/3_HS_CLK_DIV_NUM + 1.
- SPI_CLK: this is the output clock when the GP-SPI works as master, or IO input clock when the GP-SPI works as slave.
- AHB_CLK: clock for register configuration.

When operating as master, the maximum output clock frequency of GP-SPI is $f_{clk_spi_mst}$. To have slower frequencies, the output clock frequency can be divided as follows:

$$f_{SPI_CLK} = \frac{f_{clk_spi_mst}}{(SPI_CLKCNT_N + 1)(SPI_CLKDIV_PRE + 1)}$$

The divider is configured by SPI_CLKCNT_N and SPI_CLKDIV_PRE in register SPI_CLOCK_REG. When the bit SPI_CLK_EQU_SYSCLK in register SPI_CLOCK_REG is set, the output clock frequency of GP-SPI will be $f_{clk_spi_mst}$. For other integral clock divisions, SPI_CLK_EQU_SYSCLK should be cleared.

When operating as slave, the supported input clock frequency (f_{SPI_CLK}) of GP-SPI is:

- If f_{AHB_CLK} >= 60 MHz, f_{SPI_CLK} <= 60 MHz.
- If f_{AHB_CLK} < 60 MHz, f_{SPI_CLK} <= f_{AHB_CLK}.

46.7.2 LP-SPI Clock Control

LP-SPI has the following clocks:

- lp_spi_pclk: LP-SPI module clock and clock for register configuration. lp_spi_pclk is used to generate LP_SPI_CLK for data transfer and for slaves when LP-SPI works as master. LPPERI_CK_EN_LP_SPI is used to enable this lp_spi_pclk.
- LP_SPI_CLK: output clock as master.

46.7.3 Clock Phase and Polarity

SPI protocol has four clock modes, i.e., modes 0~3. See Figure 46.7-1 and Figure 46.7-2 (excerpted from SPI protocol):

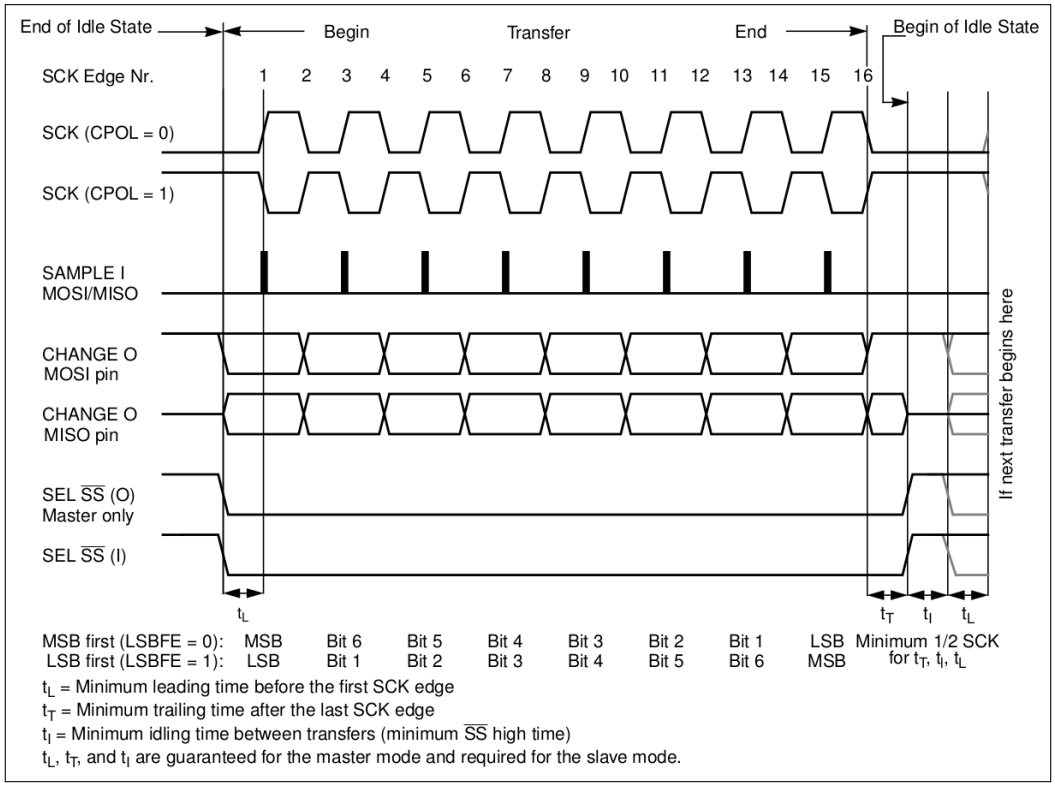

Figure 46.7-1. SPI Clock Mode 0 or 2

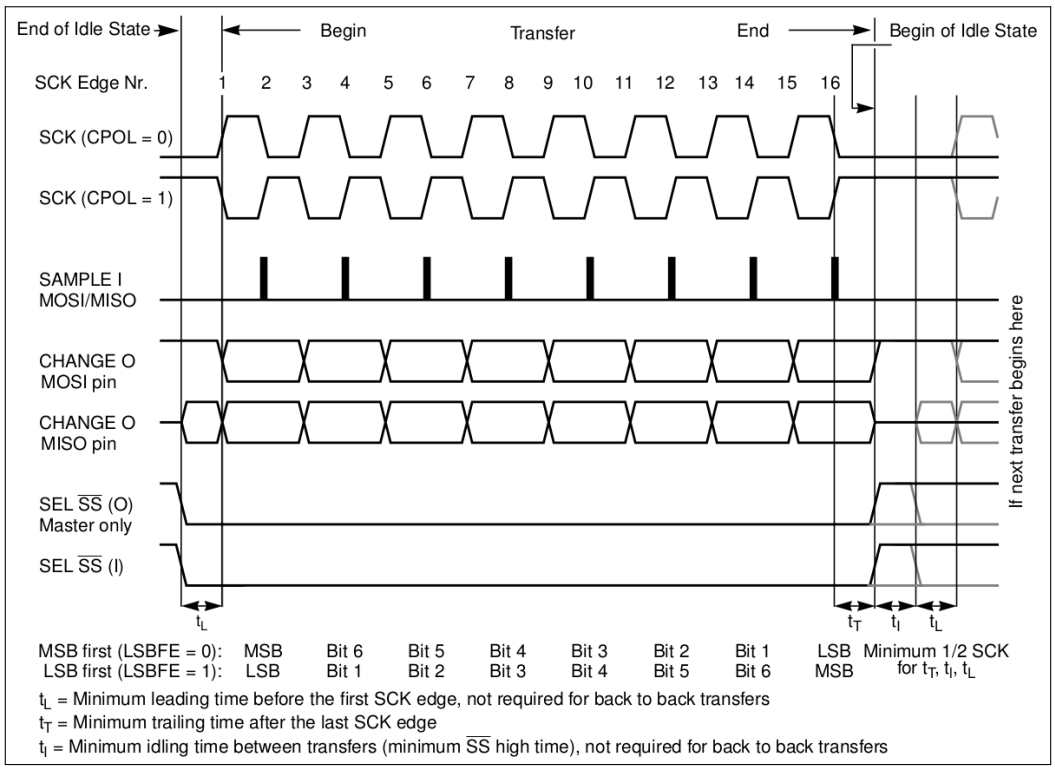

Figure 46.7-2. SPI Clock Mode 1 or 3

1. Mode 0: CPOL = 0, CPHA = 0; SCK is 0 when the SPI is in idle state; data is changed on the falling edge of SCK and sampled on the rising edge. The first data is shifted out before the first falling edge of SCK.
2. Mode 1: CPOL = 0, CPHA = 1; SCK is 0 when the SPI is in idle state; data is changed on the rising edge of SCK and sampled on the falling edge.
3. Mode 2: CPOL = 1, CPHA = 0; SCK is 1 when the SPI is in idle state; data is changed on the rising edge of SCK and sampled on the falling edge. The first data is shifted out before the first rising edge of SCK.
4. Mode 3: CPOL = 1, CPHA = 1; SCK is 1 when the SPI is in idle state; data is changed on the falling edge of SCK and sampled on the rising edge.

46.7.4 Clock Control as Master

The four clock modes 0~3 are supported in GP-SPI as master. The polarity and phase of GP-SPI clock are controlled by the bit SPI_CK_IDLE_EDGE in register SPI_MISC_REG and the bit SPI_CK_OUT_EDGE in register SPI_USER_REG. The register configuration for SPI clock modes 0~3 is provided in Table 46.7-1, and can be changed according to the path delay in the application.

Table 46.7-1. Clock Phase and Polarity Configuration as Master

Control Bit	Mode 0	Mode 1	Mode 2	Mode 3
SPI_CK_IDLE_EDGE	0	0	1	1
SPI_CK_OUT_EDGE	0	1	1	0

SPI_CLK_MODE is used to select the number of rising edges of SPI_CLK when SPI_CS raises high to be 0, 1, 2 or SPI_CLK always on.

Note:
When SPI_CLK_MODE is configured to 1 or 2, the bit SPI_CS_HOLD must be set and the value of SPI_CS_HOLD_TIME should be larger than 1.

46.7.5 Clock Control as Slave

GP-SPI as slave also supports clock modes 0~3. The polarity and phase are configured by the bits SPI_TSCK_I_EDGE and SPI_RSCK_I_EDGE in register SPI_USER_REG. The output edge of data is controlled by SPI_CLK_MODE_13 in register SPI_SLAVE_REG. The detailed register configuration is shown in Table 46.7-2:

Table 46.7-2. Clock Phase and Polarity Configuration as Slave

Control Bit	Mode 0	Mode 1	Mode 2	Mode 3
SPI_TSCK_I_EDGE	0	1	1	0
SPI_RSCK_I_EDGE	0	1	1	0
SPI_CLK_MODE_13	0	1	0	1

46.8 GP-SPI Timing Compensation

Introduction

The I/O lines are mapped via GPIO matrix or IO MUX. But there is no timing adjustment in IO MUX. The input data and output data can be delayed for 1 or 2 IO MUX operating clock cycles at the rising or falling edge in GPIO matrix. For detailed register configuration, see Chapter 10 *GPIO Matrix and IO MUX*. Timing compensation is supported only by GP-SPI.

Figure 46.8-1 shows the timing compensation control for GP-SPI as master, including the following paths:

- "CLK": the output path of GP-SPI bus clock. The clock is sent out by SPI_CLK out control module, passes through GPIO matrix or IO MUX and then goes to an external SPI device.
- "IN": data input path of GP-SPI (see line 3 path in color purple in Figure 46.8-1). The input data from an external SPI device passes through GPIO matrix or IO MUX, then is adjusted by the Timing Module (see Figure 46.5-2) and finally is stored into spi_rx_afifo.
- "OUT": data output path of GP-SPI (see line 2 path in color rose-red in Figure 46.8-1). The output data is sent out to the Timing Module, passes through GPIO matrix or IO MUX and is then captured by an external SPI device.

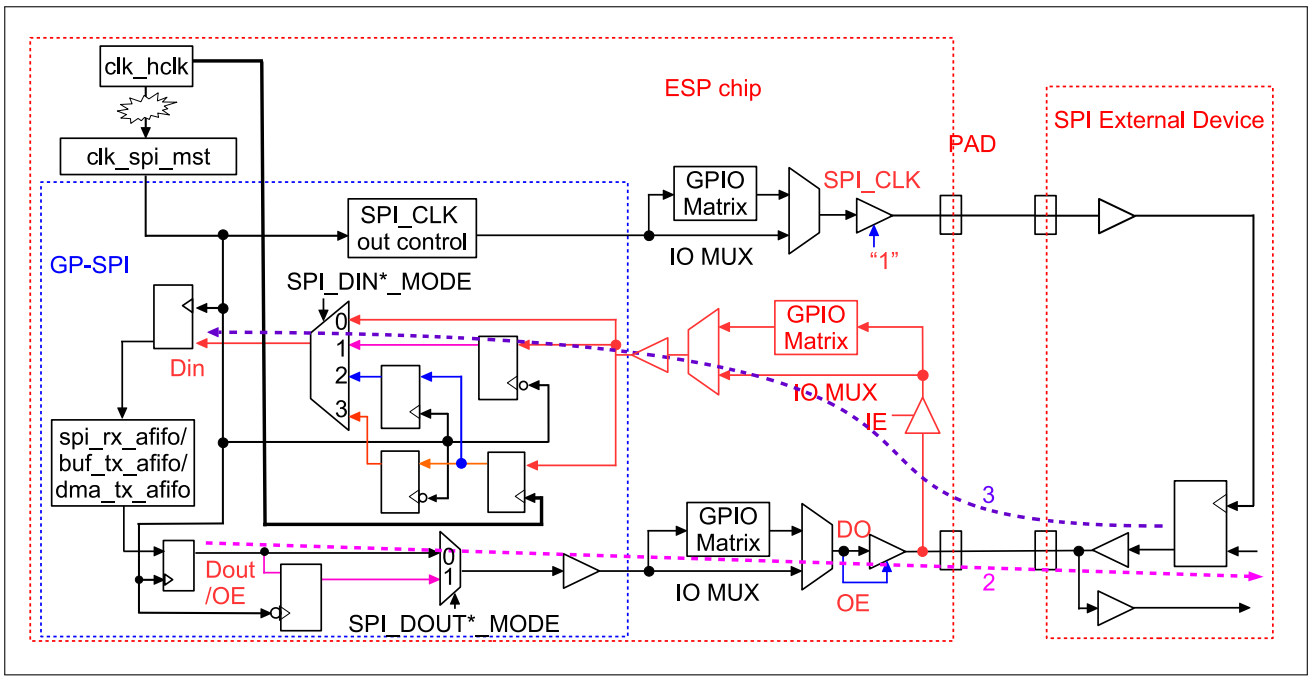

Figure 46.8-1. Timing Compensation Control Diagram in GP-SPI as Master

Every input and output data is passing through the Timing Module and the module can be used to apply delay in units of $T_{clk_spi_mst}$ (one cycle of clk_spi_mst) on rising or falling edge.

Key Registers

- SPI_DIN_MODE_REG: select the latch edge of input data
- SPI_DIN_NUM_REG: select the delay cycles of input data
- SPI_DOUT_MODE_REG: select the latch edge of output data

Timing Compensation Example

Figure 46.8-2 shows a timing compensation example in GP-SPI2 as master. Note that DUMMY cycle length is configurable to compensate the delay in I/O lines, so as to enhance the performance of GP-SPI2.

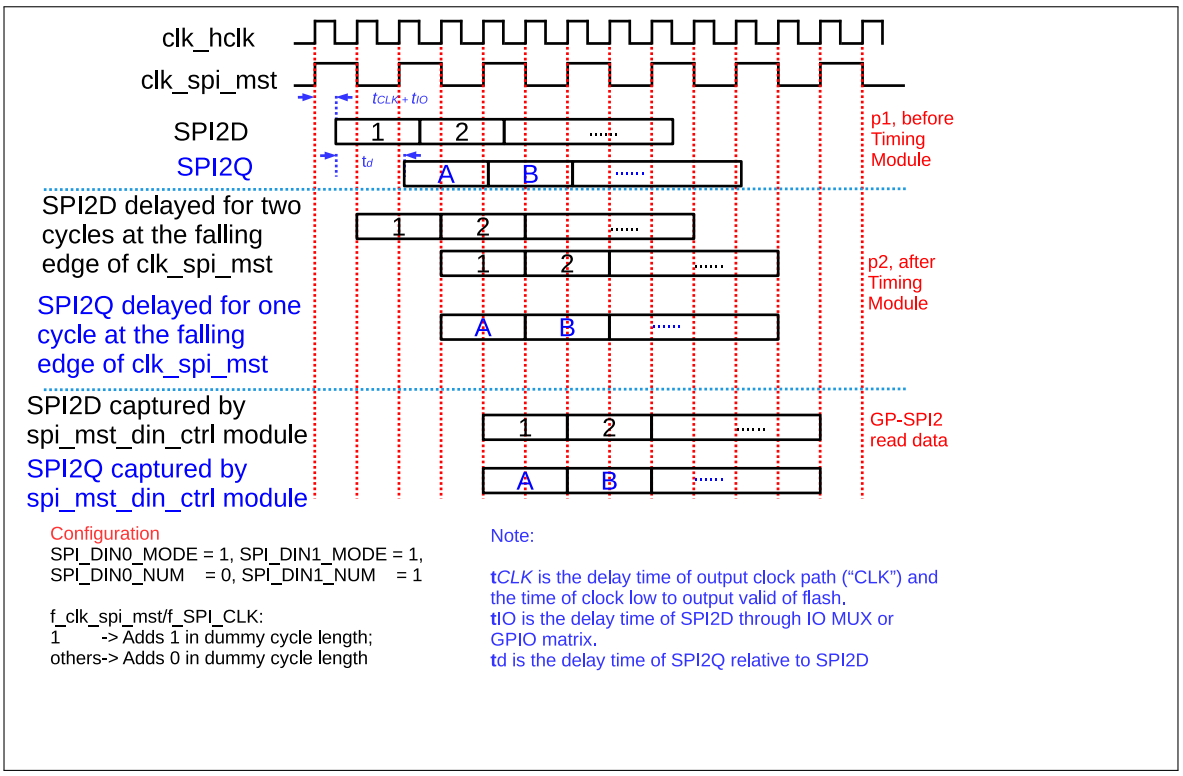

Figure 46.8-2. Timing Compensation Example in GP-SPI2 as Master

In Figure 46.8-2, "p1" is the point of input data of Timing Module, "p2" is the point of output data of Timing Module. Since the input data SPI2Q is unaligned to SPI2D, the read data of GP-SPI2 will be wrong without the timing compensation.

To get the correct read data, follow the settings below. Assuming $f_{clk_spi_mst}$ equals to f_{SPI_CLK}:

- Delay SPI2D for two cycles at the falling edge of clk_spi_mst.
- Delay SPI2Q for one cycle at the falling edge of clk_spi_mst.
- Add one extra dummy cycle.

When GP-SPI works as slave, if the bit SPI_RSCK_DATA_OUT in register SPI_SLAVE_REG is set to 1, the output data is sent at latch edge, which is half an SPI clock cycle earlier. This can be used for slave mode timing compensation.

46.9 LP-SPI Wake-Up

LP-SPI supports wake-up feature when working as a slave. When LP-SPI is in a sleep state (set LP_SPI_SLEEP_EN to 1), it can generate a wake_up signal and trigger PMU to wake up the chip by configuring LP_SPI_SLV_WK_MODE_SEL to select the wake up mode. For the detailed wake-up flow, see Chapter 15 *Low-Power Management*.

- When LP_SPI_SLV_WK_MODE_SEL = 0, LP-SPI wakes up the chip after detecting the start bit.
- When LP_SPI_SLV_WK_MODE_SEL = 1, LP-SPI wakes up the chip after receiving a specific character sequence.

- LP_SPI_SLEEP_WK_DATA_SEL selects to monitor the specific character starting from the CMD state or DIN state.
- LP_SPI_SLEEP_DIS_RXFIFO_WR_EN selects whether to save data before waking up.
- LP_SPI_SLV_WK_CHAR0~LP_SPI_SLV_WK_CHAR4 define wake up characters. LP-SPI wakes up the chip once it detects the character sequence consisting of CHAR0/CHAR1/CHAR2/CHAR3/CHAR4.
- LP_SPI_SLV_WK_CHAR_NUM and LP_SPI_SLV_WK_CHAR_MASK configure various character sequences, see Table 46.9-1. LP-SPI also supports fuzzy detection. For example, LP_SPI_WK_SLV_CHAR_NUM = 5 and LP_SPI_SLV_WK_MASK = 0x15 (binary 10101), then the character sequence will be */CHAR1/*/CHAR3/*.

Table 46.9-1. LP-SPI Wake-Up Configuration When Working as a Slave

LP_SPI_WK_SLV_CHAR_NUM	LP_SPI_SLV_WK_MASK	Character Sequence
1	0xF	CHAR4
2	0x7	CHAR3/CHAR4
3	0x3	CHAR2/CHAR3/CHAR4
4	0x1	CHAR1/CHAR2/CHAR3/CHAR4
5	0x0	CHAR0/CHAR1/CHAR2/CHAR3/CHAR4

46.10 Differences Among LP-SPI, GP-SPI2, and GP-SPI3

46.10.1 Feature Differences

Table 46.10-1 lists the differences among GP-SPI2, GP-SPI3, and LP-SPI on their supported features.

Table 46.10-1. Feature Differences Among GP-SPI2, GP-SPI3, and LP-SPI

Feature	GP-SPI2	GP-SPI3	LP-SPI
Data modes supported in CMD/ADDR/DOUT/DIN states when working as a master	1/2/4/8-bit	1/2/4-bit	1-bit
Data modes supported in CMD/ADDR/DOUT/DIN states when working as a slave	1/2/4-bit	1/2/4-bit	1-bit
DMA-controlled transfers	Support all DMA-controlled transfers	Not support DMA-controlled configurable segmented transfer	Not support any DMA related transfers

46.11 Interrupt

46.11.1 Interrupt Description

ESP32-P4 LP-SPI and GP-SPI can generate the following external interrupt signals:

- LP-SPI: LP_SPI_INTR
- GP-SPI2: SPI_INTR_2
- GP-SPI3: SPI_INTR_3

LP_SPI_INTR is directly mapped to LP CPU (see *Low-Power CPU*), and SPI_INTR_2/SPI_INTR_3 can be mapped to HP CPU0/1 through the Interrupt Matrix. These interrupt signals are generated by internal interrupt sources of LP-SPI and GP-SPI. Table 46.11-1 lists the internal interrupt sources, interrupt trigger conditions, and generated interrupt signals of LP-SPI and GP-SPI.

Table 46.11-1. Internal Interrupt Sources of LP-SPI and GP-SPI

Internal Interrupt Source	Trigger Condition	Interrupt Signal
SPI_DMA_INFIFO_FULL_ERR_INT	The length of DMA RX FIFO is shorter than that of actual data transferred	SPI_INTR_2/SPI_INTR_3
SPI_DMA_OUTFIFO_EMPTY_ERR_INT	The length of DMA TX FIFO is shorter than that of actual data transferred	SPI_INTR_2/SPI_INTR_3
SPI_SLV_EX_QPI_INT	Ex_QPI is received correctly in GP-SPI2 as slave and the SPI transfer ends	SPI_INTR_2/SPI_INTR_3
SPI_SLV_EN_QPI_INT	En_QPI is received correctly in GP-SPI2 as slave and the SPI transfer ends	SPI_INTR_2/SPI_INTR_3

Cont'd on next page

Table 46.11-1 – cont'd from previous page

Internal Interrupt Source	Trigger Condition	Interrupt Signal
SPI_SLV_CMD7_INT	CMD7 is received correctly in GP-SPI2 as slave and the SPI transfer ends	SPI_INTR_2/SPI_INTR_3
SPI_SLV_CMD8_INT	CMD8 is received correctly in GP-SPI2 as slave and the SPI transfer ends	SPI_INTR_2/SPI_INTR_3
SPI_SLV_CMD9_INT	CMD9 is received correctly in GP-SPI2 as slave and the SPI transfer ends	SPI_INTR_2/SPI_INTR_3
SPI_SLV_CMDA_INT	CMDA is received correctly in GP-SPI2 as slave and the SPI transfer ends	SPI_INTR_2/SPI_INTR_3
SPI_SLV_RD_DMA_DONE_INT	At the end of Rd_DMA transfer as slave	SPI_INTR_2/SPI_INTR_3
SPI_SLV_WR_DMA_DONE_INT	At the end of Wr_DMA transfer as slave	SPI_INTR_2/SPI_INTR_3
SPI_SLV_RD_BUF_DONE_INT	At the end of Rd_BUF transfer as slave	LP_SPI_INTR/SPI_INTR_2/ SPI_INTR_3
SPI_SLV_WR_BUF_DONE_INT	At the end of Wr_BUF transfer as slave	LP_SPI_INTR/SPI_INTR_2/ SPI_INTR_3
SPI_TRANS_DONE_INT	At the end of SPI bus transfer in both as master and as slave.	LP_SPI_INTR/SPI_INTR_2/ SPI_INTR_3
SPI_DMA_SEG_TRANS_DONE _INT	At the end of End_SEG_TRANS transfer in GP-SPI slave segmented transfer mode or at the end of configurable segmented transfer as master	SPI_INTR_2/SPI_INTR_3
SPI_SEG_MAGIC_ERR_INT	A Magic error occurs in CONF buffer during configurable segmented transfer as master	SPI_INTR_2
SPI_MST_RX_AFIFO_WFULL _ERR_INT	RX AFIFO write-full error in GP-SPI as master	LP_SPI_INTR/SPI_INTR_2/ SPI_INTR_3
SPI_MST_TX_AFIFO_REMPTY _ERR_INT	TX AFIFO read-empty error in GP-SPI as master	LP_SPI_INTR/SPI_INTR_2/ SPI_INTR_3
SPI_SLV_CMD_ERR_INT	A received command value is not supported in GP-SPI as slave	LP_SPI_INTR/SPI_INTR_2/ SPI_INTR_3
SPI_APP2_INT	Set SPI_APP2_INT_SET (Only used for user defined function)	LP_SPI_INTR/SPI_INTR_2/ SPI_INTR_3
SPI_APP1_INT	Set SPI_APP1_INT_SET (Only used for user defined function)	LP_SPI_INTR/SPI_INTR_2/ SPI_INTR_3

Cont'd on next page

Table 46.11-1 – cont'd from previous page

Internal Interrupt Source	Trigger Condition	Interrupt Signal
LP_SPI_WAKEUP_INT	Pre-defined chars are received and wake_up signal is generated	LP_SPI_INTR

LP-SPI is a simplified version of GP-SPI, which contains only some GP-SPI interrupt sources. Each interrupt source has a common set of configuration registers, see the *Interrupt Registers* in Section *Register Summary*.

46.11.2 Interrupts Used in Master and in Slave (Take GP-SPI as an Example)

Table 46.11-2 and Table 46.11-3 show the interrupts used in GP-SPI master and slave modes. Set the interrupt enable bit SPI_*_INT_ENA in SPI_DMA_INT_ENA_REG and wait for the interrupt. When the transfer ends, the related interrupt is triggered and should be cleared by software before the next transfer.

Table 46.11-2. GP-SPI Master Mode Interrupts

Transfer Type	Communication Mode	Controlled by	Interrupt
Single Transfer	Full-duplex	DMA	AXI_DMA_IN_SUC_EOF_CH*n*_INT [1]
		CPU	SPI_TRANS_DONE_INT [2]
	Half-duplex MOSI Mode	DMA	SPI_TRANS_DONE_INT
		CPU	SPI_TRANS_DONE_INT
	Half-duplex MISO Mode	DMA	AXI_DMA_IN_SUC_EOF_CH*n*_INT
		CPU	SPI_TRANS_DONE_INT
Configurable Segmented Transfer	Full-duplex	DMA	SPI_DMA_SEG_TRANS_DONE_INT [3]
		CPU	Not supported
	Half-duplex MOSI Mode	DMA	SPI_DMA_SEG_TRANS_DONE_INT
		CPU	Not supported
	Half-duplex MISO	DMA	SPI_DMA_SEG_TRANS_DONE_INT
		CPU	Not supported

[1] If AXI_DMA_IN_SUC_EOF_CH*n*_INT is triggered, it means all the RX data of GP-SPI has been stored in the RX buffer, and the TX data has been transferred to the slave.

[2] SPI_TRANS_DONE_INT is triggered when CS is high, which indicates that master has completed the data exchange in SPI_W0_REG~SPI_W15_REG with slave in this mode.

[3] If SPI_DMA_SEG_TRANS_DONE_INT is triggered, it means that the whole configurable segmented transfer (consisting of several segments) has finished, i.e., the RX data has been stored in the RX buffer completely and all the TX data has been sent out.

Table 46.11-3. GP-SPI Slave Mode Interrupts

Transfer Type	Communication Mode	Controlled by	Interrupt
Single Transfer	Full-duplex	DMA	AXI_DMA_IN_SUC_EOF_CH*n*_INT [1]
		CPU	SPI_TRANS_DONE_INT [2]
	Half-duplex MOSI Mode	DMA (Wr_DMA)	AXI_DMA_IN_SUC_EOF_CH*n*_INT [3]
		CPU (Wr_BUF)	SPI_TRANS_DONE_INT [4]
	Half-duplex MISO Mode	DMA (Rd_DMA)	SPI_TRANS_DONE_INT [5]
		CPU (Rd_BUF)	SPI_TRANS_DONE_INT [6]
Slave Segmented Transfer	Full-duplex	DMA	AXI_DMA_IN_SUC_EOF_CH*n*_INT [7]
		CPU	Not supported [8]
	Half-duplex MOSI Mode	DMA (Wr_DMA)	SPI_DMA_SEG_TRANS_DONE_INT [9]
		CPU (Wr_BUF)	Not supported [10]
	Half-duplex MISO Mode	DMA (Rd_DMA)	SPI_DMA_SEG_TRANS_DONE_INT [11]
		CPU (Rd_BUF)	Not supported [12]

[1] If AXI_DMA_IN_SUC_EOF_CH*n*_INT is triggered, it means all the RX data has been stored in the RX buffer, and the TX data has been sent to the slave.

[2] SPI_TRANS_DONE_INT is triggered when CS is high, which indicates that master has completed the data exchange in SPI_W0_REG~SPI_W15_REG with slave in this mode.

[3] SPI_SLV_WR_DMA_DONE_INT just means that the transmission on the SPI bus is done, but can not ensure that all the push data has been stored in the RX buffer. For this reason, AXI_DMA_IN_SUC_EOF_CH*n*_INT is recommended.

[4] Or wait for SPI_SLV_WR_BUF_DONE_INT.

[5] Or wait for SPI_SLV_RD_DMA_DONE_INT.

[6] Or wait for SPI_SLV_RD_BUF_DONE_INT.

[7] Slave should set the total read data byte length in SPI_MS_DATA_BITLEN before the transfer begins. Set SPI_RX_EOF_EN to 1 before the end of the interrupt program.

[8] Master and slave should define a method to end the segmented transfer, such as via GPIO interrupt.

[9] Master sends End_SEG_TRAN to end the segmented transfer or slave sets the total read data byte length in SPI_MS_DATA_BITLEN and waits for AXI_DMA_IN_SUC_EOF_CH*n*_INT.

[10] Half-duplex Wr_BUF single transfer can be used in a slave segmented transfer.

[11] Master sends End_SEG_TRAN to end the segmented transfer.

[12] Half-duplex Rd_BUF single transfer can be used in a slave segmented transfer.

46.12 Register Summary

46.12.1 GP-SPI2 Register Summary

The addresses in this section are relative to GP-SPI2 base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column Access are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
User-defined control registers			

Name	Description	Address	Access
SPI_CMD_REG	Command control register	0x0000	varies
SPI_ADDR_REG	Address value register	0x0004	R/W
SPI_USER_REG	SPI USER control register	0x0010	varies
SPI_USER1_REG	SPI USER control register 1	0x0014	R/W
SPI_USER2_REG	SPI USER control register 2	0x0018	R/W
Control and configuration registers

46.12.3 LP-SPI Register Summary

The addresses in this section are relative to LP-SPI base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

The abbreviations given in Column Access are explained in Section *Access Types for Registers*.

Name	Description	Address	Access
User-defined control registers			
LP_SPI_CMD_REG	Command control register	0x0000	varies
LP_SPI_ADDR_REG	Address value register	0x0004	R/W
LP_SPI_USER_REG	LP-SPI USER control register	0x0010	R/W
LP_SPI_USER1_REG	LP-SPI USER control register 1	0x0014	R/W
LP_SPI_USER2_REG	LP-SPI USER control register 2	0x0018	R/W
Control and configuration registers			
LP_SPI_CTRL_REG	LP-SPI control register	0x0008	R/W
LP_SPI_MS_DLEN_REG	LP-SPI data bit length control register	0x001C	R/W
LP_SPI_MISC_REG	LP-SPI misc register	0x0020	R/W
LP_SPI_DMA_CONF_REG	LP-SPI DMA control register	0x0030	WT
LP_SPI_SLEEP_CONF0_REG	LP-SPI sleep configure register 0	0x0044	R/W
LP_SPI_SLEEP_CONF1_REG	LP-SPI sleep configure register 1	0x0048	R/W
LP_SPI_SLAVE_REG	LP-SPI slave control register	0x00E0	varies
LP_SPI_SLAVE1_REG	LP-SPI slave control register 1	0x00E4	R/W/SS
Clock control registers			
LP_SPI_CLOCK_REG	LP-SPI clock control register	0x000C	R/W
LP_SPI_CLK_GATE_REG	LP-SPI module clock and register clock control	0x00E8	R/W
Timing registers			
LP_SPI_DIN_MODE_REG	LP-SPI input delay mode configuration	0x0024	R/W
LP_SPI_DIN_NUM_REG	LP-SPI input delay number configuration	0x0028	R/W
LP_SPI_DOUT_MODE_REG	LP-SPI output delay mode configuration	0x002C	R/W
Interrupt registers			
LP_SPI_DMA_INT_ENA_REG	LP-SPI interrupt enable register	0x0034	R/W

Name	Description	Address	Access
LP_SPI_DMA_INT_CLR_REG	LP-SPI interrupt clear register	0x0038	WT
LP_SPI_DMA_INT_RAW_REG	LP-SPI interrupt raw register	0x003C	R/WTC/SS
LP_SPI_DMA_INT_ST_REG	LP-SPI interrupt status register	0x0040	RO
LP_SPI_DMA_INT_SET_REG	LP-SPI interrupt software set register	0x004C	WT
CPU-controlled data buffer			
LP_SPI_W0_REG	LP-SPI CPU-controlled buffer 0	0x0098	R/W/SS
LP_SPI_W1_REG	LP-SPI CPU-controlled buffer 1	0x009C	R/W/SS
LP_SPI_W2_REG	LP-SPI CPU-controlled buffer 2	0x00A0	R/W/SS
LP_SPI_W3_REG	LP-SPI CPU-controlled buffer 3	0x00A4	R/W/SS
LP_SPI_W4_REG	LP-SPI CPU-controlled buffer 4	0x00A8	R/W/SS
LP_SPI_W5_REG	LP-SPI CPU-controlled buffer 5	0x00AC	R/W/SS
LP_SPI_W6_REG	LP-SPI CPU-controlled buffer 6	0x00B0	R/W/SS
LP_SPI_W7_REG	LP-SPI CPU-controlled buffer 7	0x00B4	R/W/SS
LP_SPI_W8_REG	LP-SPI CPU-controlled buffer 8	0x00B8	R/W/SS
LP_SPI_W9_REG	LP-SPI CPU-controlled buffer 9	0x00BC	R/W/SS
LP_SPI_W10_REG	LP-SPI CPU-controlled buffer 10	0x00C0	R/W/SS
LP_SPI_W11_REG	LP-SPI CPU-controlled buffer 11	0x00C4	R/W/SS
LP_SPI_W12_REG	LP-SPI CPU-controlled buffer 12	0x00C8	R/W/SS
LP_SPI_W13_REG	LP-SPI CPU-controlled buffer 13	0x00CC	R/W/SS
LP_SPI_W14_REG	LP-SPI CPU-controlled buffer 14	0x00D0	R/W/SS

46.13 Register

46.13.1 GP-SPI2 Register

The addresses in this section are relative to GP-SPI2 base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 46.1. SPI_CMD_REG (0x0000)

SPI_CONF_BITLEN Configures the SPI_CLK cycles of SPI CONF state.

Measurement unit: SPI_CLK clock cycle.

Can be configured in CONF state.

(R/W)

SPI_UPDATE Configures whether or not to synchronize SPI registers from APB clock domain into SPI module clock domain.

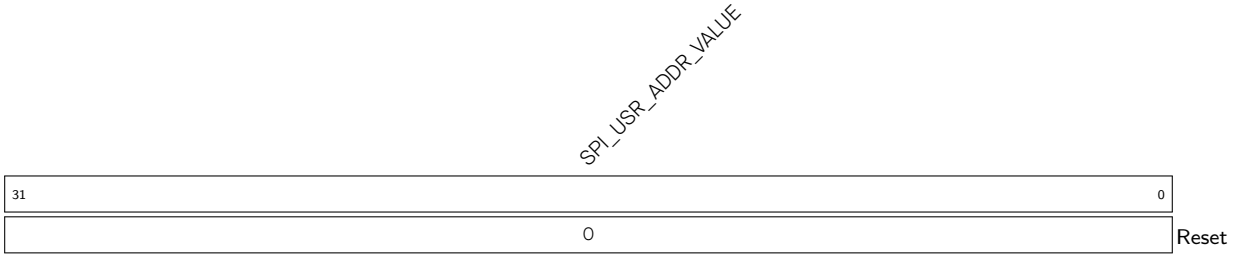
0: Not synchronize

1: Synchronize

This bit is only used in SPI master transfer.

(WT)

SPI_USR Configures whether or not to enable user-defined command.

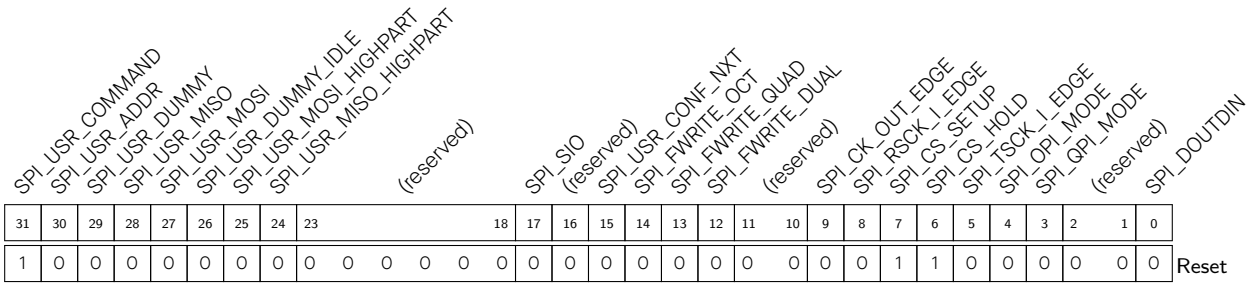


0: Not enable

1: Enable

An SPI operation will be triggered when the bit is set. This bit will be cleared once the operation is done. Can not be changed by CONF_buf.

(R/W/SC)



Register 46.2. SPI_ADDR_REG (0x0004)

SPI_USR_ADDR_VALUE Configures the address to slave. Can be configured in CONF state.

(R/W)

Register 46.3. SPI_USER_REG (0x0010)

SPI_DOUTDIN Configures whether or not to enable full-duplex communication.

0: Disable

1: Enable

Can be configured in CONF state.

(R/W)

SPI_QPI_MODE Configures whether or not to enable QPI mode.

0: Disable

1: Enable

This configuration is applicable when the SPI controller works as master or slave. Can be configured in CONF state.

(R/W/SS/SC)

SPI_OPI_MODE Configures whether or not to enable OPI mode.

0: Disable. SPI controller works in other modes.

1: Enable. SPI controller works in OPI mode, all phases of which are in 8-bit mode.

This configuration is only applicable when the SPI controller works as master. Can be configured in CONF state.

(R/W)

SPI_TSCK_I_EDGE Configures whether or not to change the polarity of TSCK in slave transfer.

0: TSCK = SPI_CK_I

1: TSCK = !SPI_CK_I

(R/W)

SPI_CS_HOLD Configures whether or not to keep SPI CS low when SPI is in DONE state.

0: Not keep low

1: Keep low

Can be configured in CONF state.

(R/W)

SPI_CS_SETUP Configures whether or not to enable SPI CS when SPI is in prepare (PREP) state.

0: Disable

1: Enable

Can be configured in CONF state.

(R/W)

Continued on the next page...

Register 46.3. SPI_USER_REG (0x0010)

Continued from the previous page...

SPI_RSCK_I_EDGE Configures whether or not to change the polarity of RSCK in slave transfer.
0: RSCK = !SPI_CK_I
1: RSCK = SPI_CK_I
(R/W)

SPI_CK_OUT_EDGE Configures SPI clock mode together with SPI_CK_IDLE_EDGE. Can be configured in CONF state. For more information, see Section 46.7.4.
(R/W)

SPI_FWRITE_DUAL Configures whether or not to enable the 2-bit mode of read-data phase in write operations.
0: Not enable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_FWRITE_QUAD Configures whether or not to enable the 4-bit mode of read-data phase in write operations.
0: Not enable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_FWRITE_OCT Configures whether or not to enable the 8-bit mode of read-data phase in write operations.
0: Not enable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_USR_CONF_NXT Configures whether or not to enable the CONF state for the next transaction (segment) in a configurable segmented transfer.
0: This transfer will end after the current transaction (segment) is finished. Or this is not a configurable segmented transfer.
1: This configurable segmented transfer will continue its next transaction (segment).
Can be configured in CONF state.
(R/W)

SPI_SIO Configures whether or not to enable 3-line half-duplex communication, where MOSI and MISO signals share the same pin.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

Continued on the next page...

Register 46.3. SPI_USER_REG (0x0010)

Continued from the previous page...

SPI_USR_MISO_HIGHPART Configures whether or not to enable High-Part mode in read-data phase, i.e., only access to high-part of the buffers: SPI_W8_REG ~ SPI_W15_REG.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_USR_MOSI_HIGHPART Configures whether or not to enable High-Part mode in write-data phase, i.e., only access to high-part of the buffers: SPI_W8_REG ~ SPI_W15_REG.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_USR_DUMMY_IDLE Configures whether or not to disable SPI clock in DUMMY state.
0: Not disable
1: Disable
Can be configured in CONF state.
(R/W)

SPI_USR_MOSI Configures whether or not to enable the write-data (DOUT) state of an operation.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_USR_MISO Configures whether or not to enable the read-data (DIN) state of an operation.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_USR_DUMMY Configures whether or not to enable the DUMMY state of an operation.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

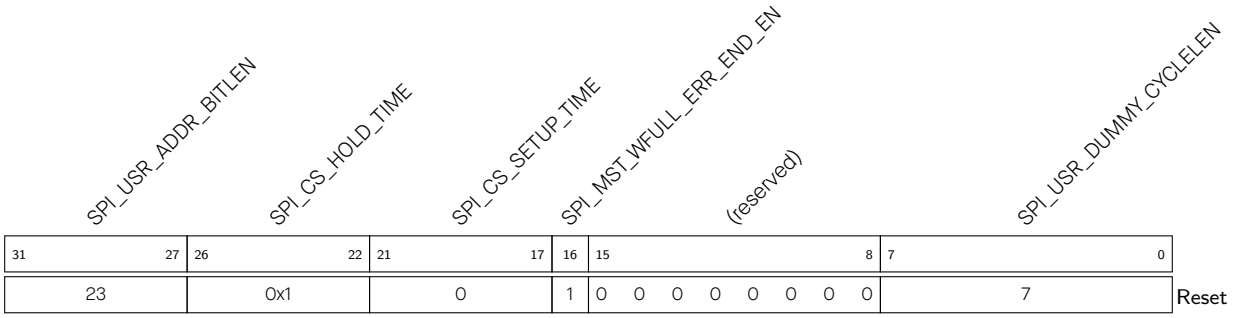
SPI_USR_ADDR Configures whether or not to enable the address (ADDR) state of an operation.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

Continued on the next page...

Register 46.3. SPI_USER_REG (0x0010)

Continued from the previous page...

SPI_USR_COMMAND Configures whether or not to enable the command (CMD) state of an operation.



0: Disable

1: Enable

Can be configured in CONF state.

(R/W)

Register 46.4. SPI_USER1_REG (0x0014)

SPI_USR_DUMMY_CYCLELEN Configures the length of DUMMY state.

Measurement unit: SPI_CLK clock cycles.

This value is (the expected cycle number - 1).

Can be configured in CONF state.

(R/W)

SPI_MST_WFULL_ERR_END_EN Configures whether or not to end the SPI transfer when SPI RX AFIFO wfull error occurs in master full-/half-duplex transfers.

0: Not end

1: End

(R/W)

SPI_CS_SETUP_TIME Configures the length of prepare (PREP) state.

Measurement unit: SPI_CLK clock cycles.

This value is equal to the expected cycles - 1. This field is used together with SPI_CS_SETUP.

Can be configured in CONF state.

(R/W)

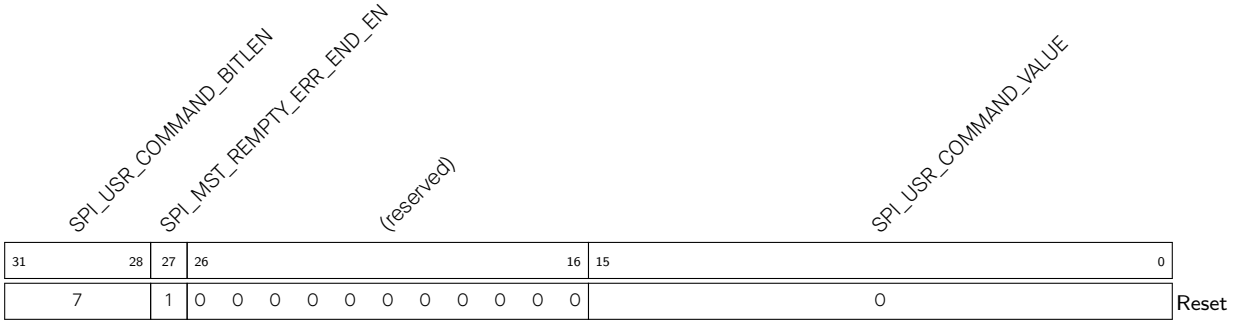
SPI_CS_HOLD_TIME Configures the delay cycles of CS pin.

Measurement unit: SPI_CLK clock cycles.

This field is used together with SPI_CS_HOLD.

Can be configured in CONF state.

(R/W)



SPI_USR_ADDR_BITLEN Configures the bit length in address state.

This value is (expected bit number - 1).

Can be configured in CONF state.

(R/W)

Register 46.5. SPI_USER2_REG (0x0018)

SPI_USR_COMMAND_VALUE Configures the command value.

Can be configured in CONF state.

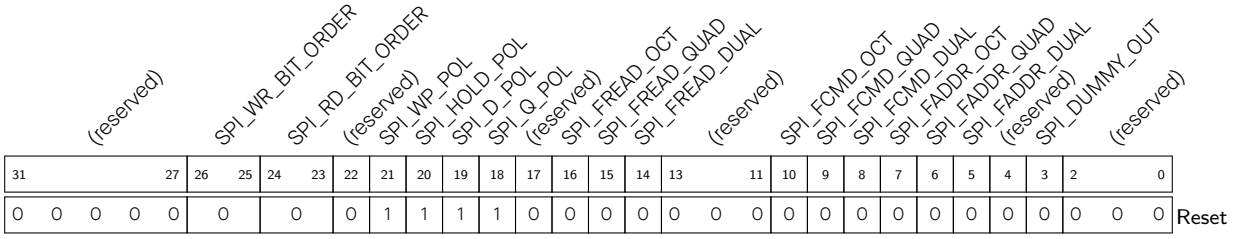
(R/W)

SPI_MST_REMPTY_ERR_END_EN Configures whether or not to end the SPI transfer when SPI TX AFIFO read empty error occurs in master full-/half-duplex transfers.

0: Not end

1: End

(R/W)



SPI_USR_COMMAND_BITLEN Configures the bit length of command state.

This value is (expected bit number - 1).

Can be configured in CONF state.

(R/W)

Register 46.6. SPI_CTRL_REG (0x0008)

SPI_DUMMY_OUT Configures whether or not to output the SPI2 bus signals in DUMMY state.

0: Not output

1: Output

Can be configured in CONF state.

(R/W)

SPI_FADDR_DUAL Configures whether or not to enable 2-bit mode during address (ADDR) state.

0: Disable

1: Enable

Can be configured in CONF state.

(R/W)

SPI_FADDR_QUAD Configures whether or not to enable 4-bit mode during address (ADDR) state.

0: Disable

1: Enable

Can be configured in CONF state.

(R/W)

SPI_FADDR_OCT Configures whether or not to enable 8-bit mode during address (ADDR) state.

0: Disable

1: Enable

Can be configured in CONF state.

(R/W)

SPI_FCMD_DUAL Configures whether or not to enable 2-bit mode during command (CMD) state.

0: Disable

1: Enable

Can be configured in CONF state.

(R/W)

SPI_FCMD_QUAD Configures whether or not to enable 4-bit mode during command (CMD) state.

0: Disable

1: Enable

Can be configured in CONF state.

(R/W)

Continued on the next page...

Register 46.6. SPI_CTRL_REG (0x0008)

Continued from the previous page...

SPI_FCMD_OCT Configures whether or not to enable 8-bit mode during command (CMD) state.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_FREAD_DUAL Configures whether or not to enable the 2-bit mode of read-data (DIN) state in read operations.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_FREAD_QUAD Configures whether or not to enable the 4-bit mode of read-data (DIN) state in read operations.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_FREAD_OCT Configures whether or not to enable the 8-bit mode of read-data (DIN) state in read operations.
0: Disable
1: Enable
Can be configured in CONF state. (R/W)

SPI_Q_POL Configures MISO line polarity.
0: Low
1: High
Can be configured in CONF state.
(R/W)

SPI_D_POL Configures MOSI line polarity.
0: Low
1: High
Can be configured in CONF state.
(R/W)

SPI_HOLD_POL Configures SPI_HOLD output value when SPI is in idle.
0: Output low
1: Output high
Can be configured in CONF state.
(R/W)

Continued on the next page...

Register 46.6. SPI_CTRL_REG (0x0008)

Continued from the previous page...

SPI_WP_POL Configures the output value of write-protect signal when SPI is in idle.

0: Output low

1: Output high

Can be configured in CONF state.

(R/W)

SPI_RD_BIT_ORDER Configures the bit order in read-data (MISO) state.

0: MSB first

1: LSB first

2: MSB first

3: LSB first

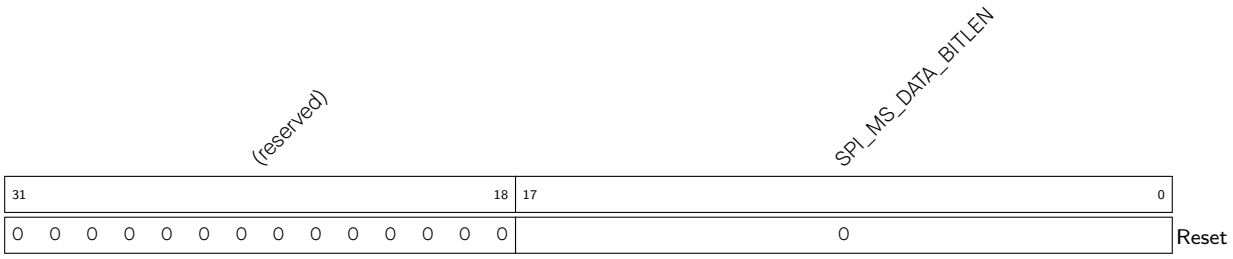
Can be configured in CONF state. For more information, see Table 46.5-6.

(R/W)

SPI_WR_BIT_ORDER Configures the bit order in command (CMD), address (ADDR), and write-data (MOSI) states.

0: MSB first

1: LSB first



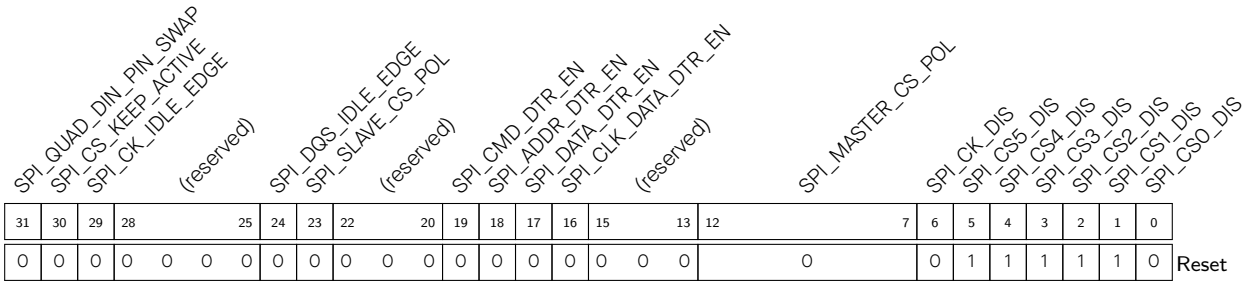
2: MSB first

3: LSB first

Can be configured in CONF state. For more information, see Table 46.5-6.

(R/W)

Register 46.7. SPI_MS_DLEN_REG (0x001C)



SPI_MS_DATA_BITLEN Configures the data bit length of SPI transfer in DMA-controlled master transfer or in CPU-controlled master transfer. Or configures the bit length of SPI RX transfer in DMA-controlled slave transfer.

This value shall be (expected bit_num - 1).

Can be configured in CONF state.

(R/W)

Register 46.8. SPI_MISC_REG (0x0020)

SPI_CS0_DIS Configures whether or not to disable SPI_CS0 pin.

0: SPI_CS0 signal is from/to SPI_CS0 pin.

1: Disable SPI_CS0 pin.

Can be configured in CONF state.

(R/W)

SPI_CS1_DIS Configures whether or not to disable SPI_CS1 pin.

0: SPI_CS1 signal is from/to SPI_CS1 pin.

1: Disable SPI_CS1 pin.

Can be configured in CONF state.

(R/W)

SPI_CS2_DIS Configures whether or not to disable SPI_CS2 pin.

0: SPI_CS2 signal is from/to SPI_CS2 pin.

1: Disable SPI_CS2 pin.

Can be configured in CONF state.

(R/W)

SPI_CS3_DIS Configures whether or not to disable SPI_CS3 pin.

0: SPI_CS3 signal is from/to SPI_CS3 pin.

1: Disable SPI_CS3 pin.

Can be configured in CONF state.

(R/W)

SPI_CS4_DIS Configures whether or not to disable SPI_CS4 pin.

0: SPI_CS4 signal is from/to SPI_CS4 pin.

1: Disable SPI_CS4 pin.

Can be configured in CONF state.

(R/W)

SPI_CS5_DIS Configures whether or not to disable SPI_CS5 pin.

0: SPI_CS5 signal is from/to SPI_CS5 pin.

1: Disable SPI_CS5 pin.

Can be configured in CONF state.

(R/W)

Continued on the next page...

Register 46.8. SPI_MISC_REG (0x0020)

Continued from the previous page...

SPI_CK_DIS Configures whether or not to disable SPI_CLK output.

0: Enable

1: Disable

Can be configured in CONF state.

(R/W)

SPI_MASTER_CS_POL Configures the polarity of SPI_CS*n* (*n* = 0∼5) line in master transfer.

0: SPI_CS*n* is low active.

1: SPI_CS*n* is high active.

Can be configured in CONF state.

(R/W)

SPI_CLK_DATA_DTR_EN Configures whether or not to enable DTR mode for SPI_CLK, DATA, and SPI_DQS when the SPI works as master.

0: Enable DTR mode only for SPI_DQS

1: Enable DTR mode for SPI_CLK, DATA, and SPI_DQS.

This bit should be used with SPI_DATA_DTR_EN, SPI_ADDR_DTR_EN, and SPI_CMD_DTR_EN.

(R/W)

SPI_DATA_DTR_EN Configures whether or not to enable DTR mode for SPI_CLK and DATA in DOUT and DIN states when the SPI works as master in 1/2/4/8-bit mode.

0: Not enable

1: Enable

Can be configured in CONF state.

(R/W)

SPI_ADDR_DTR_EN Configures whether or not to enable DTR mode for SPI_CLK and DATA in ADDR state when the SPI works as master in 1/2/4/8-bit mode.

0: Not enable

1: Enable

Can be configured in CONF state.

(R/W)

SPI_CMD_DTR_EN Configures whether or not to enable DTR mode for SPI_CLK and DATA in CMD state when the SPI works as master in 1/2/4/8-bit mode.

0: Not enable

1: Enable

Can be configured in CONF state.

(R/W)

SPI_SLAVE_CS_POL Configures whether or not to invert SPI slave input CS polarity.

0: Not change

1: Invert

Can be configured in CONF state.

(R/W)

Continued on the next page...

Register 46.8. SPI_MISC_REG (0x0020)

Continued from the previous page...

SPI_DQS_IDLE_EDGE Configured the default value of SPI_DQS.

0: Low

1: High

Can be configured in CONF state.

(R/W)

SPI_CK_IDLE_EDGE Configures the level of SPI_CLK line when GP-SPI2 is in idle.

0: Low

1: High

Can be configured in CONF state.

(R/W)

SPI_CS_KEEP_ACTIVE Configures whether or not to keep the SPI_CS line low.

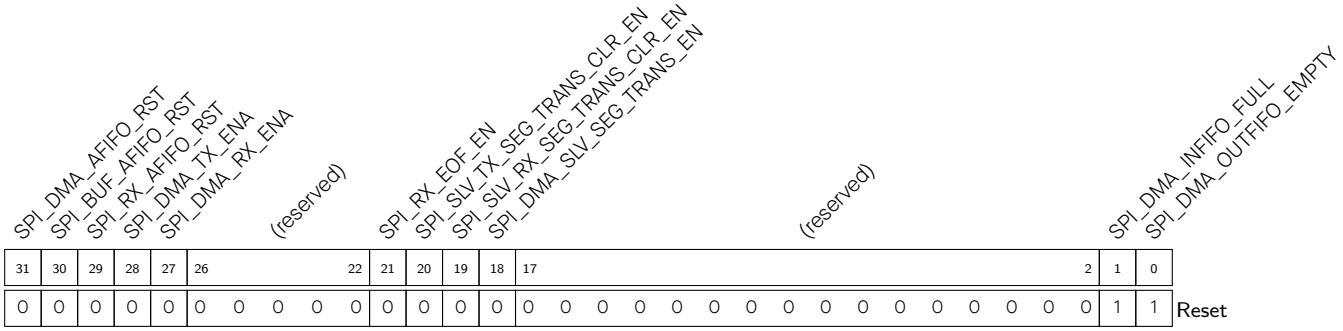
0: Not keep low

1: Keep low

Can be configured in CONF state.

(R/W)

SPI_QUAD_DIN_PIN_SWAP Configures whether or not to swap SPI Quad input pins.



0: Not swap

1: Swap SPI2D with SPI2Q, and SPI2WP with SPI2HD

Can be configured in CONF state.

(R/W)

Register 46.9. SPI_DMA_CONF_REG (0x0030)

SPI_DMA_OUTFIFO_EMPTY Represents whether or not the DMA TX FIFO is ready for sending data.

0: Ready

1: Not ready

(RO)

SPI_DMA_INFIFO_FULL Represents whether or not the DMA RX FIFO is ready for receiving data.

0: Ready

1: Not ready

(RO)

SPI_DMA_SLV_SEG_TRANS_EN Configures whether or not to enable DMA-controlled segmented transfer in slave half-duplex communication.

0: Disable

1: Enable

(R/W)

SPI_SLV_RX_SEG_TRANS_CLR_EN In slave segmented transfer, if the size of the DMA RX buffer is smaller than the size of the received data,

1: the data in all the following Wr_DMA transactions will not be received.

0: the data in this Wr_DMA transaction will not be received, but in the following transactions,

- if the size of DMA RX buffer is not 0, the data in following Wr_DMA transactions will be received.
- if the size of DMA RX buffer is 0, the data in following Wr_DMA transactions will not be received.

(R/W)

SPI_SLV_TX_SEG_TRANS_CLR_EN In slave segmented transfer, if the size of the DMA TX buffer is smaller than the size of the transmitted data,

1: the data in the following transactions will not be updated, i.e. the old data is transmitted repeatedly.

0: the data in this transaction will not be updated. But in the following transactions,

- if new data is filled in DMA TX FIFO, new data will be transmitted.
- if no new data is filled in DMA TX FIFO, no new data will be transmitted.

(R/W)

Continued on the next page...

Register 46.9. SPI_DMA_CONF_REG (0x0030)

Continued from the previous page...

SPI_RX_EOF_EN Configures the trigger source of GDMA_IN_SUC_EOF_CH*n*_INT_RAW.

0: GDMA_IN_SUC_EOF_CH*n*_INT_RAW is set by SPI_TRANS_DONE_INT event in a single transfer, or by an SPI_DMA_SEG_TRANS_DONE_INT event in a segmented transfer.

1: In a DAM-controlled transfer, if the bit number of transferred data is equal to (SPI_MS_DATA_BITLEN + 1), then GDMA_IN_SUC_EOF_CH*n*_INT_RAW will be set by hardware. (R/W)

SPI_DMA_RX_ENA Configures whether or not to enable DMA-controlled receive data transfer.

0: Disable

1: Enable

(R/W)

SPI_DMA_TX_ENA Configures whether or not to enable DMA-controlled send data transfer.

0: Disable

1: Enable

(R/W)

SPI_RX_AFIFO_RST Configures whether or not to reset RX AFIFO (i.e., spi_rx_afifo in Figure 46.5-3 and Figure 46.5-4), which is used to receive data in SPI master and slave transfer.

0: Not reset

1: Reset

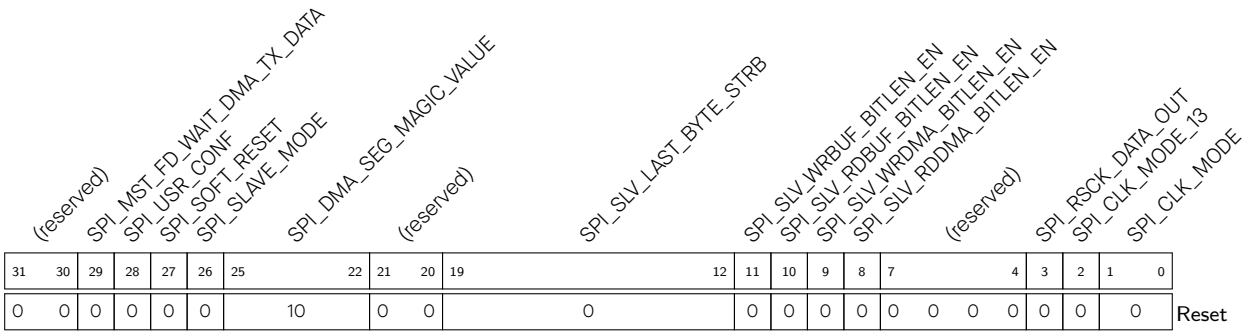
(WT)

SPI_BUF_AFIFO_RST Configures whether or not to reset BUF TX AFIFO (i.e., buf_tx_afifo in Figure 46.5-3 and Figure 46.5-4), which is used to send data out in SPI slave CPU-controlled transfer and master transfer.

0: Not reset

1: Reset

(WT)



SPI_DMA_AFIFO_RST Configures whether or not to reset DMA TX AFIFO (i.e., dma_tx_afifo in Figure 46.5-3 and Figure 46.5-4), which is used to send data out in SPI slave DMA-controlled transfer.

0: Not reset

1: Reset

(WT)

Register 46.10. SPI_SLAVE_REG (0x00E0)

SPI_CLK_MODE Configures SPI clock mode.

0: SPI clock is off when CS becomes inactive.

1: SPI clock is delayed one cycle after CS becomes inactive.

2: SPI clock is delayed two cycles after CS becomes inactive.

3: SPI clock is always on.

Can be configured in CONF state.

(R/W)

SPI_CLK_MODE_13 Configures clock mode.

0: SPI clock mode 1 and mode 3. See Table 46.7-2.

1: SPI clock mode 0 and mode 2. See Table 46.7-2.

(R/W)

SPI_RSCK_DATA_OUT Configures the edge of output data.

0: Output data at TSCK rising edge.

1: Output data at RSCK rising edge.

(R/W)

SPI_SLV_RDDMA_BITLEN_EN Configures whether or not to use SPI_SLV_DATA_BITLEN to store the data bit length of Rd_DMA transfer.

0: Not use

1: Use

(R/W)

SPI_SLV_WRDMA_BITLEN_EN Configures whether or not to use SPI_SLV_DATA_BITLEN to store the data bit length of Wr_DMA transfer.

0: Not use

1: Use

(R/W)

SPI_SLV_RDBUF_BITLEN_EN Configures whether or not to use SPI_SLV_DATA_BITLEN to store the data bit length of Rd_BUF transfer.

0: Not use

1: Use

(R/W)

Continued on the next page...

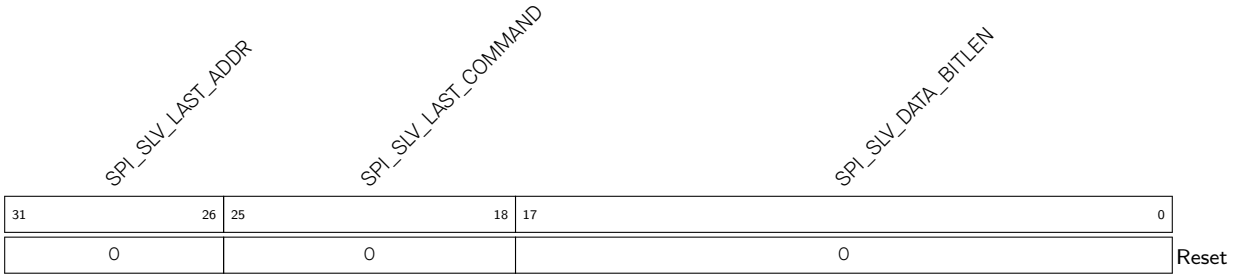
Register 46.10. SPI_SLAVE_REG (0x00E0)

Continued from the previous page...

SPI_SLV_WRBUF_BITLEN_EN Configures whether or not to use SPI_SLV_DATA_BITLEN to store the data bit length of Wr_BUF transfer.
0: Not use
1: Use
(R/W)

SPI_SLV_LAST_BYTE_STRB Represents the valid bits of the last received data byte in SPI slave full-duplex and half-duplex transfer.
(R/SS)

SPI_DMA_SEG_MAGIC_VALUE Configures the magic value of BM table in DMA-controlled configurable segmented transfer.
(R/W)



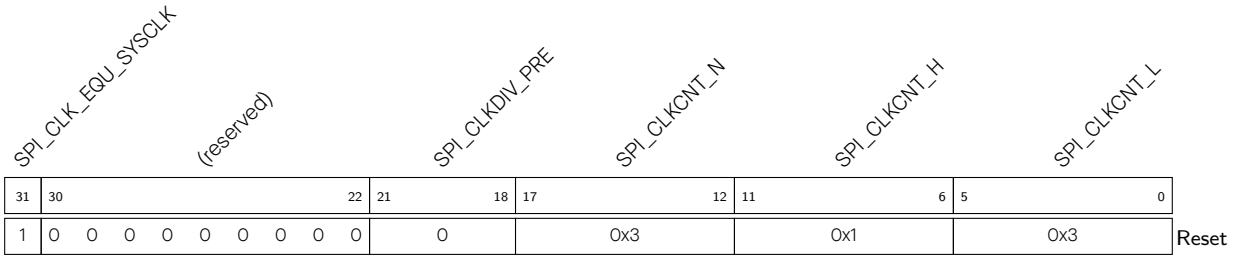
SPI_SLAVE_MODE Configures SPI work mode.
0: Master
1: Slave
(R/W)

SPI_SOFT_RESET Configures whether or not to reset the SPI clock line, CS line, and data line via software.
0: Not reset
1: Reset
Can be configured in CONF state.
(WT)

SPI_USR_CONF Configures whether or not to enable the CONF state of current DMA-controlled configurable segmented transfer.
0: No effect, which means the current transfer is not a configurable segmented transfer.
1: Enable, which means a configurable segmented transfer is started.
(R/W)

SPI_MST_FD_WAIT_DMA_TX_DATA Configures whether or not to wait DMA TX data gets ready before starting SPI transfer in master full-duplex transfer.
0: Not wait
1: Wait
(R/W)

Register 46.11. SPI_SLAVE1_REG (0x00E4)



SPI_SLV_DATA_BITLEN Configures the transferred data bit length in SPI slave full-/half-duplex modes.
(R/W/SS)

SPI_SLV_LAST_COMMAND Configures the command value in slave mode.
(R/W/SS)

SPI_SLV_LAST_ADDR Configures the address value in slave mode.
(R/W/SS)

Register 46.12. SPI_CLOCK_REG (0x000C)

SPI_CLKCNT_L Configures clock duty cycles, together with SPI_CLKCNT_H and SPI_CLKCNT_N.

In master transfer, this field must be equal to SPI_CLKCNT_N.

In slave mode, it must be 0.

Can be configured in CONF state.

(R/W)

SPI_CLKCNT_H Configures the duty cycle of SPI_CLK (high level) in master transfer.

It's recommended to configure this value to floor((SPI_CLKCNT_N + 1)/2 - 1). floor() here is to round a number down, e.g., floor(2.2) = 2.

In slave mode, it must be 0.

Can be configured in CONF state.

(R/W)

SPI_CLKCNT_N Configures the divider of SPI_CLK in master transfer.

SPI_CLK frequency is $f_{clk_spi_mst}$/(SPI_CLKDIV_PRE + 1)/(SPI_CLKCNT_N + 1).

Can be configured in CONF state.

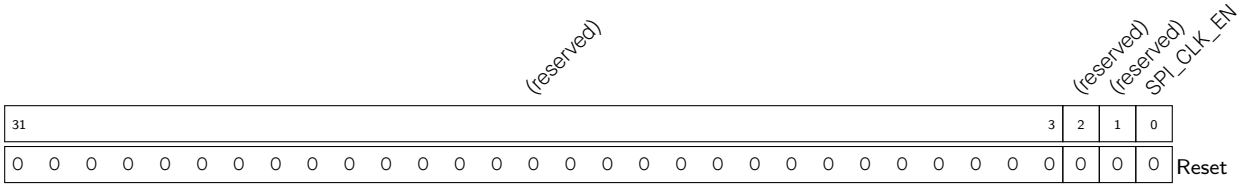
(R/W)

SPI_CLKDIV_PRE Configures the pre-divider of SPI_CLK in master transfer.

Can be configured in CONF state.

(R/W)

SPI_CLK_EQU_SYSCLK Configures whether or not the SPI_CLK is equal to clk_spi_mst in master transfer.



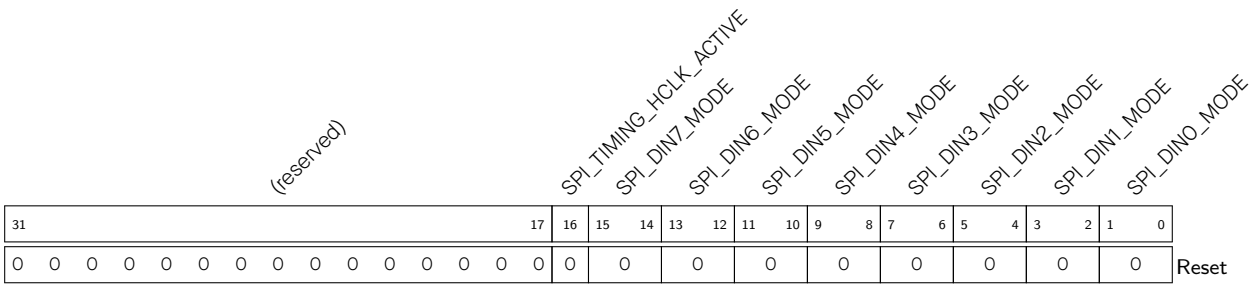
0: SPI_CLK is divided from clk_spi_mst.

1: SPI_CLK is equal to clk_spi_mst.

Can be configured in CONF state.

(R/W)

Register 46.13. SPI_CLK_GATE_REG (0x00E8)



SPI_CLK_EN Configures whether or not to enable clock gate.

0: Disable

1: Enable

(R/W)

Register 46.14. SPI_DIN_MODE_REG (0x0024)

SPI_DIN0_MODE Configures the input mode for SPI2D signal.

0: Input without delay

1: Input at the (SPI_DIN0_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN0_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN0_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

Can be configured in CONF state.

(R/W)

SPI_DIN1_MODE Configures the input mode for SPI2Q signal.

0: Input without delay

1: Input at the (SPI_DIN1_NUM+1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN1_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN1_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

Can be configured in CONF state.

(R/W)

SPI_DIN2_MODE Configures the input mode for SPI2WP signal.

0: Input without delay

1: Input at the (SPI_DIN2_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN2_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN2_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

Can be configured in CONF state.

(R/W)

Continued on the next page...

Register 46.14. SPI_DIN_MODE_REG (0x0024)

Continued from the previous page...

SPI_DIN3_MODE Configures the input mode for SPI2HD signal.

0: Input without delay

1: Input at the (SPI_DIN3_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN3_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN3_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

Can be configured in CONF state.

(R/W)

SPI_DIN4_MODE Configures the input mode for SPI2D4 signal.

0: Input without delay

1: Input at the (SPI_DIN4_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN4_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN4_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

Can be configured in CONF state.

(R/W)

SPI_DIN5_MODE Configures the input mode for SPI2D5 signal.

0: Input without delay

1: Input at the (SPI_DIN5_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN5_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN5_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

Can be configured in CONF state.

(R/W)

SPI_DIN6_MODE Configures the input mode for SPI2D6 signal.

0: Input without delay

1: Input at the (SPI_DIN6_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN6_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN6_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

Can be configured in CONF state.

(R/W)

Continued on the next page...

Register 46.14. SPI_DIN_MODE_REG (0x0024)

Continued from the previous page...

SPI_DIN7_MODE Configures the input mode for SPI2D7 signal.

0: Input without delay

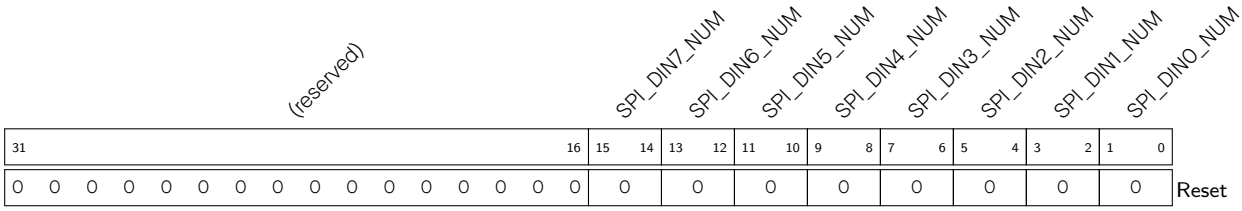
1: Input at the (SPI_DIN7_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN7_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN7_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

Can be configured in CONF state.

(R/W)



SPI_TIMING_HCLK_ACTIVE Configures whether or not to enable HCLK (high-frequency clock) in SPI input timing module.

0: Disable

1: Enable

Can be configured in CONF state. (R/W)

Register 46.15. SPI_DIN_NUM_REG (0x0028)

SPI_DIN0_NUM Configures the delays to input signal SPI2D based on the setting of SPI_DIN0_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
Can be configured in CONF state.
(R/W)

SPI_DIN1_NUM Configures the delays to input signal SPI2Q based on the setting of SPI_DIN1_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
Can be configured in CONF state.
(R/W)

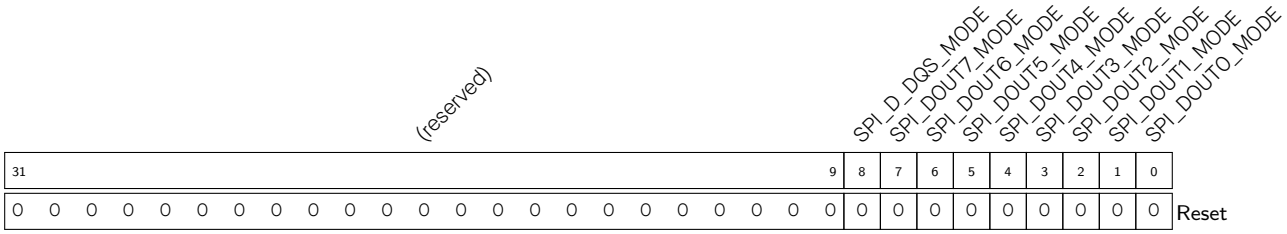
SPI_DIN2_NUM Configures the delays to input signal SPI2WP based on the setting of SPI_DIN2_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
Can be configured in CONF state.
(R/W)

SPI_DIN3_NUM Configures the delays to input signal SPI2HD based on the setting of SPI_DIN3_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
Can be configured in CONF state.
(R/W)

Continued on the next page...

Register 46.15. SPI_DIN_NUM_REG (0x0028)

Continued from the previous page...



SPI_DIN4_NUM Configures the delays to input signal SPI2D4 based on the setting of SPI_DIN4_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
Can be configured in CONF state.
(R/W)

SPI_DIN5_NUM Configures the delays to input signal SPI2D5 based on the setting of SPI_DIN5_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
Can be configured in CONF state.
(R/W)

SPI_DIN6_NUM Configures the delays to input signal SPI2D6 based on the setting of SPI_DIN6_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
Can be configured in CONF state.
(R/W)

SPI_DIN7_NUM Configures the delays to input signal SPI2D7 based on the setting of SPI_DIN7_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
Can be configured in CONF state.
(R/W)

Register 46.16. SPI_DOUT_MODE_REG (0x002C)

SPI_DOUT0_MODE Configures the output mode for SPI2D signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

Can be configured in CONF state.

(R/W)

SPI_DOUT1_MODE Configures the output mode for SPI2Q signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

Can be configured in CONF state.

(R/W)

SPI_DOUT2_MODE Configures the output mode for SPI2WP signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

Can be configured in CONF state.

(R/W)

SPI_DOUT3_MODE Configures the output mode for SPI2HD signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

Can be configured in CONF state.

(R/W)

SPI_DOUT4_MODE Configures the output mode for SPI2D4 signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

Can be configured in CONF state.

(R/W)

SPI_DOUT5_MODE Configures the output mode for SPI2D5 signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

Can be configured in CONF state.

(R/W)

SPI_DOUT6_MODE Configures the output mode for SPI2D6 signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

Can be configured in CONF state.

(R/W)

Continued on the next page...

Register 46.16. SPI_DOUT_MODE_REG (0x002C)

Continued from the previous page...

SPI_DOUT7_MODE Configures the output mode for SPI2D7 signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

Can be configured in CONF state.

(R/W)

SPI_D_DQS_MODE Configures the output mode for output SPI_DQS signal.

0: Output without delay

1: Output is delayed for a SPI clock cycle at its falling edge.

Can be configured in CONF state.

(R/W)

Register 46.17. SPI_DMA_INT_ENA_REG (0x0034)

SPI_DMA_INFIFO_FULL_ERR_INT_ENA Write 1 to enable SPI_DMA_INFIFO_FULL_ERR_INT interrupt.
(R/W)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_ENA Write 1 to enable SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt.
(R/W)

SPI_SLV_EX_QPI_INT_ENA Write 1 to enable SPI_SLV_EX_QPI_INT interrupt.
(R/W)

SPI_SLV_EN_QPI_INT_ENA Write 1 to enable SPI_SLV_EN_QPI_INT interrupt.
(R/W)

SPI_SLV_CMD7_INT_ENA Write 1 to enable SPI_SLV_CMD7_INT interrupt.
(R/W)

SPI_SLV_CMD8_INT_ENA Write 1 to enable SPI_SLV_CMD8_INT interrupt.
(R/W)

SPI_SLV_CMD9_INT_ENA Write 1 to enable SPI_SLV_CMD9_INT interrupt.
(R/W)

SPI_SLV_CMDA_INT_ENA Write 1 to enable SPI_SLV_CMDA_INT interrupt.
(R/W)

SPI_SLV_RD_DMA_DONE_INT_ENA Write 1 to enable SPI_SLV_RD_DMA_DONE_INT interrupt.
(R/W)

SPI_SLV_WR_DMA_DONE_INT_ENA Write 1 to enable SPI_SLV_WR_DMA_DONE_INT interrupt.
(R/W)

SPI_SLV_RD_BUF_DONE_INT_ENA Write 1 to enable SPI_SLV_RD_BUF_DONE_INT interrupt.
(R/W)

SPI_SLV_WR_BUF_DONE_INT_ENA Write 1 to enable SPI_SLV_WR_BUF_DONE_INT interrupt.
(R/W)

SPI_TRANS_DONE_INT_ENA Write 1 to enable SPI_TRANS_DONE_INT interrupt.
(R/W)

Continued on the next page...

Register 46.17. SPI_DMA_INT_ENA_REG (0x0034)

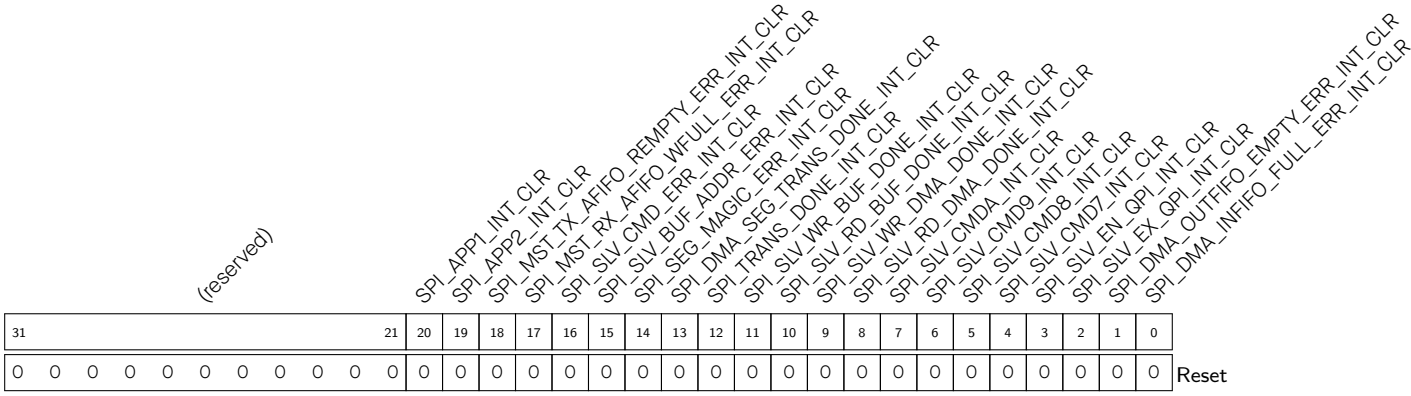
Continued from the previous page...

SPI_DMA_SEG_TRANS_DONE_INT_ENA Write 1 to enable SPI_DMA_SEG_TRANS_DONE_INT interrupt.
(R/W)

SPI_SEG_MAGIC_ERR_INT_ENA Write 1 to enable SPI_SEG_MAGIC_ERR_INT interrupt.
(R/W)

SPI_SLV_BUF_ADDR_ERR_INT_ENA Write 1 to enable SPI_SLV_BUF_ADDR_ERR_INT interrupt.
(R/W)

SPI_SLV_CMD_ERR_INT_ENA Write 1 to enable SPI_SLV_CMD_ERR_INT interrupt.
(R/W)



SPI_MST_RX_AFIFO_WFULL_ERR_INT_ENA Write 1 to enable SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt.
(R/W)

SPI_MST_TX_AFIFO_REMPTY_ERR_INT_ENA Write 1 to enable SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt.
(R/W)

SPI_APP2_INT_ENA Write 1 to enable SPI_APP2_INT interrupt.
(R/W)

SPI_APP1_INT_ENA Write 1 to enable SPI_APP1_INT interrupt.
(R/W)

Register 46.18. SPI_DMA_INT_CLR_REG (0x0038)

SPI_DMA_INFIFO_FULL_ERR_INT_CLR Write 1 to clear SPI_DMA_INFIFO_FULL_ERR_INT interrupt. (WT)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_CLR Write 1 to clear SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt. (WT)

SPI_SLV_EX_QPI_INT_CLR Write 1 to clear SPI_SLV_EX_QPI_INT interrupt. (WT)

SPI_SLV_EN_QPI_INT_CLR Write 1 to clear SPI_SLV_EN_QPI_INT interrupt. (WT)

SPI_SLV_CMD7_INT_CLR Write 1 to clear SPI_SLV_CMD7_INT interrupt. (WT)

SPI_SLV_CMD8_INT_CLR Write 1 to clear SPI_SLV_CMD8_INT interrupt. (WT)

SPI_SLV_CMD9_INT_CLR Write 1 to clear SPI_SLV_CMD9_INT interrupt. (WT)

SPI_SLV_CMDA_INT_CLR Write 1 to clear SPI_SLV_CMDA_INT interrupt. (WT)

SPI_SLV_RD_DMA_DONE_INT_CLR Write 1 to clear SPI_SLV_RD_DMA_DONE_INT interrupt. (WT)

SPI_SLV_WR_DMA_DONE_INT_CLR Write 1 to clear SPI_SLV_WR_DMA_DONE_INT interrupt. (WT)

SPI_SLV_RD_BUF_DONE_INT_CLR Write 1 to clear SPI_SLV_RD_BUF_DONE_INT interrupt. (WT)

SPI_SLV_WR_BUF_DONE_INT_CLR Write 1 to clear SPI_SLV_WR_BUF_DONE_INT interrupt. (WT)

SPI_TRANS_DONE_INT_CLR Write 1 to clear SPI_TRANS_DONE_INT interrupt. (WT)

Continued on the next page...

Register 46.18. SPI_DMA_INT_CLR_REG (0x0038)

Continued from the previous page...

SPI_DMA_SEG_TRANS_DONE_INT_CLR Write 1 to clear SPI_DMA_SEG_TRANS_DONE_INT interrupt.
(WT)

SPI_SEG_MAGIC_ERR_INT_CLR Write 1 to clear SPI_SEG_MAGIC_ERR_INT interrupt.
(WT)

SPI_SLV_BUF_ADDR_ERR_INT_CLR Write 1 to clear SPI_SLV_BUF_ADDR_ERR_INT interrupt.
(WT)

SPI_SLV_CMD_ERR_INT_CLR Write 1 to clear SPI_SLV_CMD_ERR_INT interrupt.
(WT)

SPI_MST_RX_AFIFO_WFULL_ERR_INT_CLR Write 1 to clear SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt.
(WT)

SPI_MST_TX_AFIFO_REMPTY_ERR_INT_CLR Write 1 to clear SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt.
(WT)

SPI_APP2_INT_CLR Write 1 to clear SPI_APP2_INT interrupt.
(WT)

SPI_APP1_INT_CLR Write 1 to clear SPI_APP1_INT interrupt.
(WT)

Register 46.19. SPI_DMA_INT_RAW_REG (0x003C)

SPI_DMA_INFIFO_FULL_ERR_INT_RAW The raw interrupt status of SPI_DMA_INFIFO_FULL_ERR_INT interrupt.
(R/WTC/SS)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_RAW The raw interrupt status of SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt.
(R/WTC/SS)

SPI_SLV_EX_QPI_INT_RAW The raw interrupt status of SPI_SLV_EX_QPI_INT interrupt.
(R/WTC/SS)

SPI_SLV_EN_QPI_INT_RAW The raw interrupt status of SPI_SLV_EN_QPI_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMD7_INT_RAW The raw interrupt status of SPI_SLV_CMD7_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMD8_INT_RAW The raw interrupt status of SPI_SLV_CMD8_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMD9_INT_RAW The raw interrupt status of SPI_SLV_CMD9_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMDA_INT_RAW The raw interrupt status of SPI_SLV_CMDA_INT interrupt.
(R/WTC/SS)

SPI_SLV_RD_DMA_DONE_INT_RAW The raw interrupt status of SPI_SLV_RD_DMA_DONE_INT interrupt.
(R/WTC/SS)

SPI_SLV_WR_DMA_DONE_INT_RAW The raw interrupt status of SPI_SLV_WR_DMA_DONE_INT interrupt.
(R/WTC/SS)

SPI_SLV_RD_BUF_DONE_INT_RAW The raw interrupt status of SPI_SLV_RD_BUF_DONE_INT interrupt.
(R/WTC/SS)

Continued on the next page...

Register 46.19. SPI_DMA_INT_RAW_REG (0x003C)

Continued from the previous page...

SPI_SLV_WR_BUF_DONE_INT_RAW The raw interrupt status of SPI_SLV_WR_BUF_DONE_INT interrupt.
(R/WTC/SS)

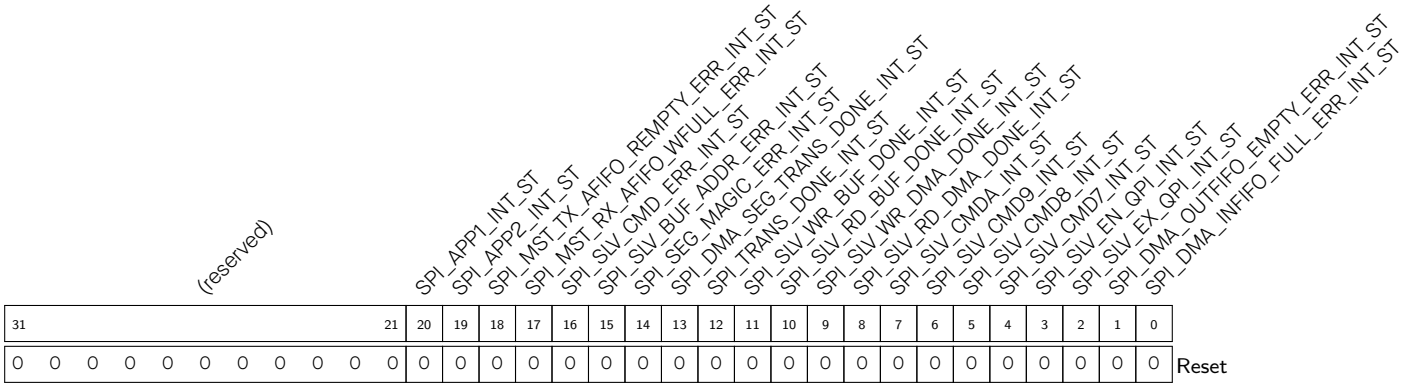
SPI_TRANS_DONE_INT_RAW The raw interrupt status of SPI_TRANS_DONE_INT interrupt.
(R/WTC/SS)

SPI_DMA_SEG_TRANS_DONE_INT_RAW The raw interrupt status of SPI_DMA_SEG_TRANS_DONE_INT interrupt.
(R/WTC/SS)

SPI_SEG_MAGIC_ERR_INT_RAW The raw interrupt status of SPI_SEG_MAGIC_ERR_INT interrupt.
(R/WTC/SS)

SPI_SLV_BUF_ADDR_ERR_INT_RAW The raw interrupt status of SPI_SLV_BUF_ADDR_ERR_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMD_ERR_INT_RAW The raw interrupt status of SPI_SLV_CMD_ERR_INT interrupt.
(R/WTC/SS)



SPI_MST_RX_AFIFO_WFULL_ERR_INT_RAW The raw interrupt status of SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt.
(R/WTC/SS)

SPI_MST_TX_AFIFO_REMPTY_ERR_INT_RAW The raw interrupt status of SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt.
(R/WTC/SS)

SPI_APP2_INT_RAW The raw interrupt status of SPI_APP2_INT interrupt. The value is only controlled by the application.
(R/WTC/SS)

SPI_APP1_INT_RAW The raw interrupt status of SPI_APP1_INT interrupt. The value is only controlled by the application.
(R/WTC/SS)

Register 46.20. SPI_DMA_INT_ST_REG (0x0040)

SPI_DMA_INFIFO_FULL_ERR_INT_ST The interrupt status of SPI_DMA_INFIFO_FULL_ERR_INT interrupt.
(RO)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_ST The interrupt status of SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt.
(RO)

SPI_SLV_EX_QPI_INT_ST The interrupt status of SPI_SLV_EX_QPI_INT interrupt.
(RO)

SPI_SLV_EN_QPI_INT_ST The interrupt status of SPI_SLV_EN_QPI_INT interrupt.
(RO)

SPI_SLV_CMD7_INT_ST The interrupt status of SPI_SLV_CMD7_INT interrupt.
(RO)

SPI_SLV_CMD8_INT_ST The interrupt status of SPI_SLV_CMD8_INT interrupt.
(RO)

SPI_SLV_CMD9_INT_ST The interrupt status of SPI_SLV_CMD9_INT interrupt.
(RO)

SPI_SLV_CMDA_INT_ST The interrupt status of SPI_SLV_CMDA_INT interrupt.
(RO)

SPI_SLV_RD_DMA_DONE_INT_ST The interrupt status of SPI_SLV_RD_DMA_DONE_INT interrupt.
(RO)

SPI_SLV_WR_DMA_DONE_INT_ST The interrupt status of SPI_SLV_WR_DMA_DONE_INT interrupt.
(RO)

SPI_SLV_RD_BUF_DONE_INT_ST The interrupt status of SPI_SLV_RD_BUF_DONE_INT interrupt.
(RO)

SPI_SLV_WR_BUF_DONE_INT_ST The interrupt status of SPI_SLV_WR_BUF_DONE_INT interrupt.
(RO)

Continued on the next page...

Register 46.20. SPI_DMA_INT_ST_REG (0x0040)

Continued from the previous page...

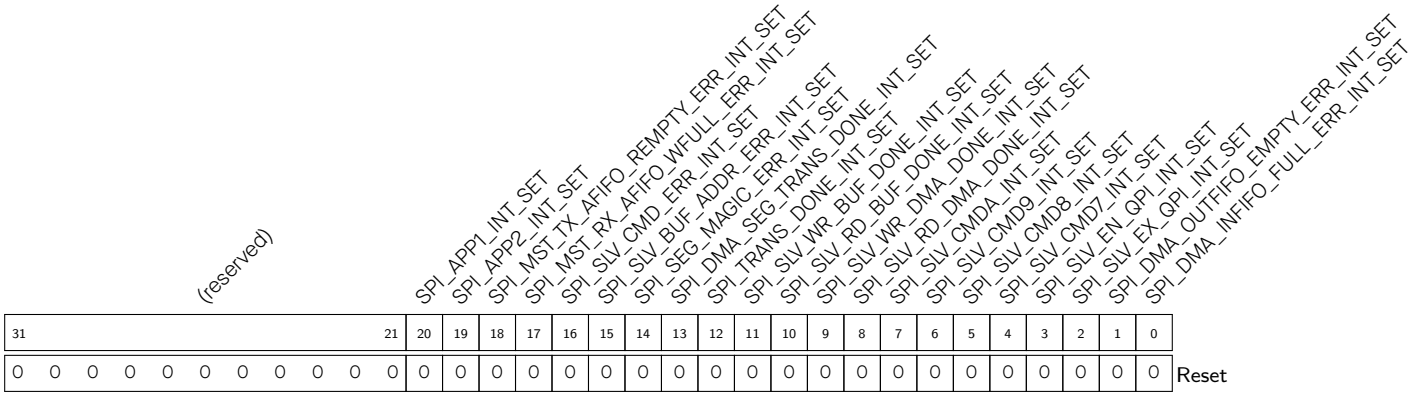
SPI_TRANS_DONE_INT_ST The interrupt status of SPI_TRANS_DONE_INT interrupt.
(RO)

SPI_DMA_SEG_TRANS_DONE_INT_ST The interrupt status of SPI_DMA_SEG_TRANS_DONE_INT interrupt.
(RO)

SPI_SEG_MAGIC_ERR_INT_ST The interrupt status of SPI_SEG_MAGIC_ERR_INT interrupt.
(RO)

SPI_SLV_BUF_ADDR_ERR_INT_ST The status bit for SPI_SLV_BUF_ADDR_ERR_INT interrupt.
(RO)

SPI_SLV_CMD_ERR_INT_ST The interrupt status of SPI_SLV_CMD_ERR_INT interrupt.
(RO)



SPI_MST_RX_AFIFO_WFULL_ERR_INT_ST The interrupt status of SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt.
(RO)

SPI_MST_TX_AFIFO_REMPTY_ERR_INT_ST The interrupt status of SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt.
(RO)

SPI_APP2_INT_ST The interrupt status of SPI_APP2_INT interrupt.
(RO)

SPI_APP1_INT_ST The interrupt status of SPI_APP1_INT interrupt.
(RO)

Register 46.21. SPI_DMA_INT_SET_REG (0x0044)

SPI_DMA_INFIFO_FULL_ERR_INT_SET Write 1 to set SPI_DMA_INFIFO_FULL_ERR_INT interrupt. (WT)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_SET Write 1 to set SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt. (WT)

SPI_SLV_EX_QPI_INT_SET Write 1 to set SPI_SLV_EX_QPI_INT interrupt. (WT)

SPI_SLV_EN_QPI_INT_SET Write 1 to set SPI_SLV_EN_QPI_INT interrupt. (WT)

SPI_SLV_CMD7_INT_SET Write 1 to set SPI_SLV_CMD7_INT interrupt. (WT)

SPI_SLV_CMD8_INT_SET Write 1 to set SPI_SLV_CMD8_INT interrupt. (WT)

SPI_SLV_CMD9_INT_SET Write 1 to set SPI_SLV_CMD9_INT interrupt. (WT)

SPI_SLV_CMDA_INT_SET Write 1 to set SPI_SLV_CMDA_INT interrupt. (WT)

SPI_SLV_RD_DMA_DONE_INT_SET Write 1 to set SPI_SLV_RD_DMA_DONE_INT interrupt. (WT)

SPI_SLV_WR_DMA_DONE_INT_SET Write 1 to set SPI_SLV_WR_DMA_DONE_INT interrupt. (WT)

SPI_SLV_RD_BUF_DONE_INT_SET Write 1 to set SPI_SLV_RD_BUF_DONE_INT interrupt. (WT)

SPI_SLV_WR_BUF_DONE_INT_SET Write 1 to set SPI_SLV_WR_BUF_DONE_INT interrupt. (WT)

SPI_TRANS_DONE_INT_SET Write 1 to set SPI_TRANS_DONE_INT interrupt. (WT)

Continued on the next page...

Register 46.21. SPI_DMA_INT_SET_REG (0x0044)

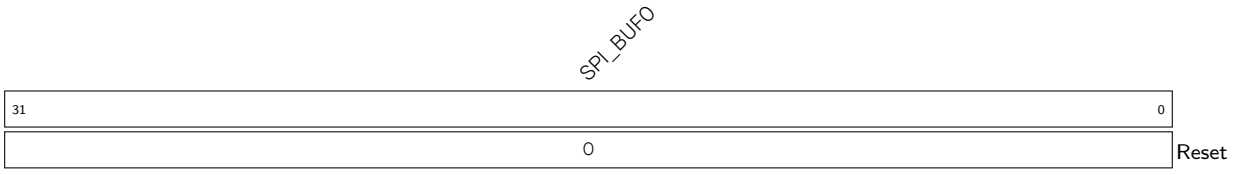
Continued from the previous page...

SPI_DMA_SEG_TRANS_DONE_INT_SET Write 1 to set SPI_DMA_SEG_TRANS_DONE_INT interrupt. (WT)

SPI_SEG_MAGIC_ERR_INT_SET Write 1 to set SPI_SEG_MAGIC_ERR_INT interrupt. (WT)

SPI_SLV_BUF_ADDR_ERR_INT_SET Write 1 to set SPI_SLV_BUF_ADDR_ERR_INT interrupt. (WT)

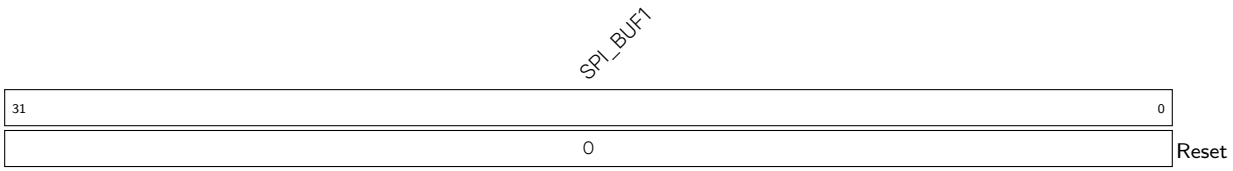
SPI_SLV_CMD_ERR_INT_SET Write 1 to set SPI_SLV_CMD_ERR_INT interrupt. (WT)



SPI_MST_RX_AFIFO_WFULL_ERR_INT_SET Write 1 to set SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt. (WT)

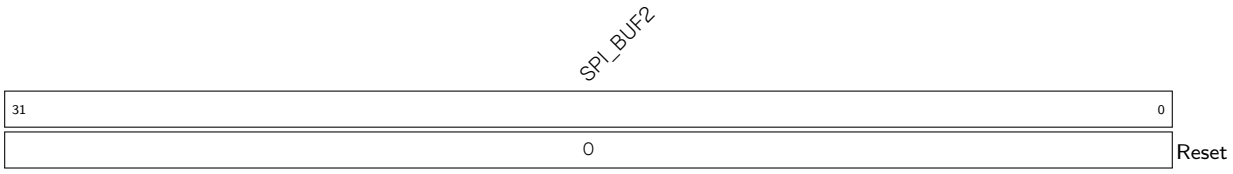
SPI_MST_TX_AFIFO_REMPTY_ERR_INT_SET Write 1 to set SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt. (WT)

SPI_APP2_INT_SET Write 1 to set SPI_APP2_INT interrupt. (WT)



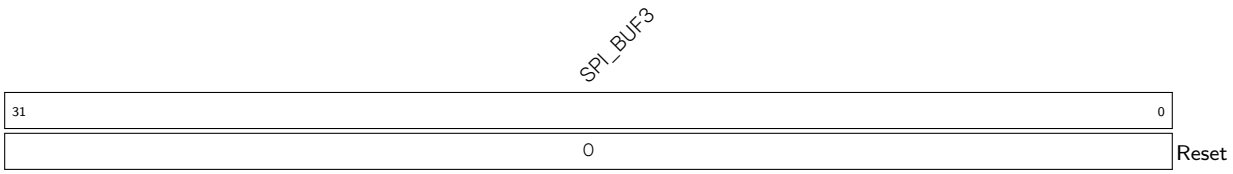
SPI_APP1_INT_SET Write 1 to set SPI_APP1_INT interrupt. (WT)

Register 46.22. SPI_W0_REG (0x0098)



SPI_BUF0 32-bit data buffer 0. (R/W/SS)

Register 46.23. SPI_W1_REG (0x009C)



SPI_BUF1 32-bit data buffer 1.
(R/W/SS)

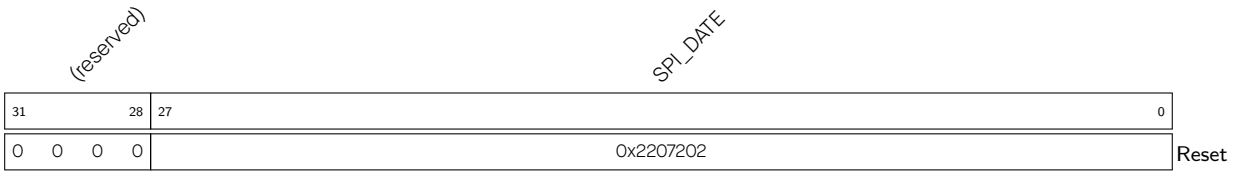
SPI_BUF14 32-bit data buffer 14.

(R/W/SS)



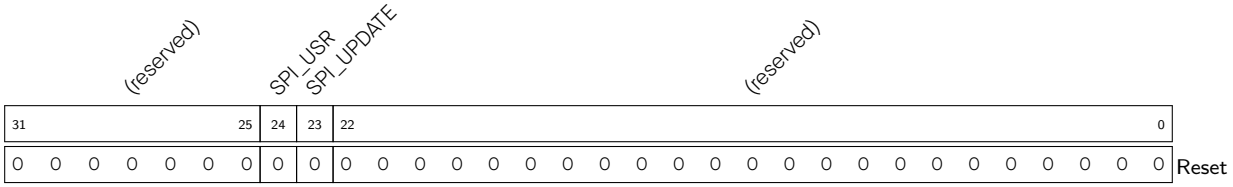
Register 46.37. SPI_W15_REG (0x00D4)

SPI_BUF15 32-bit data buffer 15.

(R/W/SS)

Register 46.38. SPI_DATE_REG (0x00F0)

SPI_DATE Version control register.



(R/W)

46.13.2 GP-SPI3 Register

The addresses in this section are relative to GP-SPI3 base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 46.39. SPI_CMD_REG (0x0000)

SPI_UPDATE Configures whether or not to synchronize SPI registers from APB clock domain into SPI module clock domain.

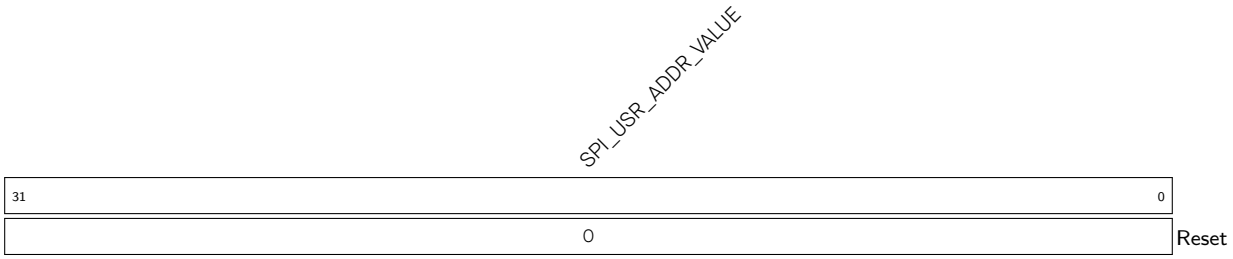
0: Not synchronize

1: Synchronize

This bit is only used in SPI master transfer.

(WT)

SPI_USR Configures whether or not to enable user-defined command.

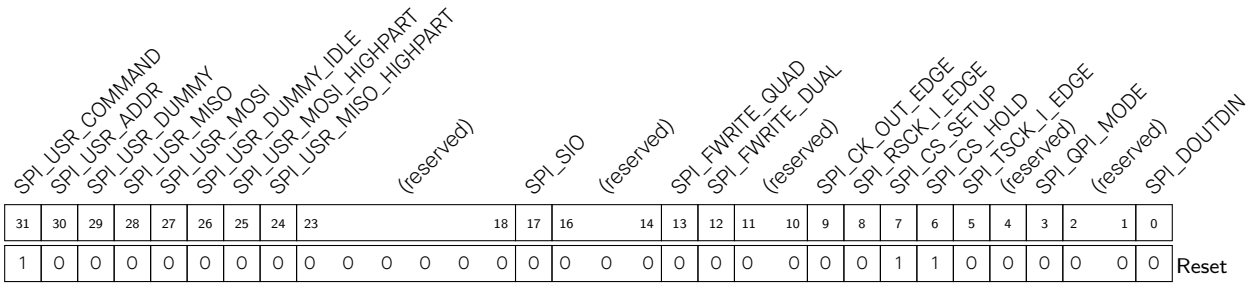


0: Not enable

1: Enable

An SPI operation will be triggered when the bit is set. This bit will be cleared once the operation is done.

(R/W/SC)



Register 46.40. SPI_ADDR_REG (0x0004)

SPI_USR_ADDR_VALUE Configures the address to slave.

(R/W)

Register 46.41. SPI_USER_REG (0x0010)

SPI_DOUTDIN Configures whether or not to enable full-duplex communication.

0: Disable

1: Enable

(R/W)

SPI_QPI_MODE Configures whether or not to enable QPI mode.

0: Disable

1: Enable

This configuration is applicable when the SPI controller works as master or slave.

(R/W/SS/SC)

SPI_TSCK_I_EDGE Configures whether or not to change the polarity of TSCK in slave transfer.

0: TSCK = SPI_CK_I

1: TSCK = !SPI_CK_I

(R/W)

SPI_CS_HOLD Configures whether or not to keep SPI CS low when SPI is in DONE state.

0: Not keep low

1: Keep low

(R/W)

SPI_CS_SETUP Configures whether or not to enable SPI CS when SPI is in prepare (PREP) state.

0: Disable

1: Enable

(R/W)

SPI_RSCK_I_EDGE Configures whether or not to change the polarity of RSCK in slave transfer.

0: RSCK = !SPI_CK_I

1: RSCK = SPI_CK_I

(R/W)

SPI_CK_OUT_EDGE Configures SPI clock mode together with SPI_CK_IDLE_EDGE. For more information, see Section 46.7.4.

(R/W)

Continued on the next page...

Register 46.41. SPI_USER_REG (0x0010)

Continued from the previous page...

SPI_FWRITE_DUAL Configures whether or not to enable the 2-bit mode of read-data phase in write operations.
0: Not enable
1: Enable
(R/W)

SPI_FWRITE_QUAD Configures whether or not to enable the 4-bit mode of read-data phase in write operations.
0: Not enable
1: Enable
(R/W)

SPI_SIO Configures whether or not to enable 3-line half-duplex communication, where MOSI and MISO signals share the same pin.
0: Disable
1: Enable
(R/W)

SPI_USR_MISO_HIGHPART Configures whether or not to enable High-Part mode in read-data phase, i.e., only access to high-part of the buffers: SPI_W8_REG ~ SPI_W15_REG.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_USR_MOSI_HIGHPART Configures whether or not to enable High-Part mode in write-data phase, i.e., only access to high-part of the buffers: SPI_W8_REG ~ SPI_W15_REG.
0: Disable
1: Enable
Can be configured in CONF state.
(R/W)

SPI_USR_DUMMY_IDLE Configures whether or not to disable SPI clock in DUMMY state.
0: Not disable
1: Disable
(R/W)

SPI_USR_MOSI Configures whether or not to enable the write-data (DOUT) state of an operation.
0: Disable
1: Enable
(R/W)

Continued on the next page...

Register 46.41. SPI_USER_REG (0x0010)

Continued from the previous page...

SPI_USR_MISO Configures whether or not to enable the read-data (DIN) state of an operation.

0: Disable

1: Enable

(R/W)

SPI_USR_DUMMY Configures whether or not to enable the DUMMY state of an operation.

0: Disable

1: Enable

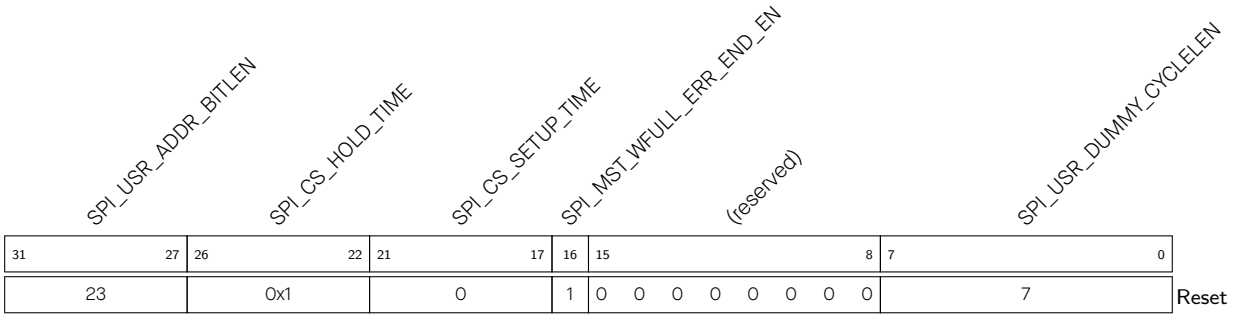
(R/W)

SPI_USR_ADDR Configures whether or not to enable the address (ADDR) state of an operation.

0: Disable

1: Enable

(R/W)



SPI_USR_COMMAND Configures whether or not to enable the command (CMD) state of an operation.

0: Disable

1: Enable

(R/W)

Register 46.42. SPI_USER1_REG (0x0014)

SPI_USR_DUMMY_CYCLELEN Configures the length of DUMMY state.

Measurement unit: SPI_CLK clock cycles.

This value is (the expected cycle number - 1).

(R/W)

SPI_MST_WFULL_ERR_END_EN Configures whether or not to end the SPI transfer when SPI RX AFIFO wfull error occurs in master full-/half-duplex transfers.

0: Not end

1: End

(R/W)

SPI_CS_SETUP_TIME Configures the length of prepare (PREP) state.

Measurement unit: SPI_CLK clock cycles.

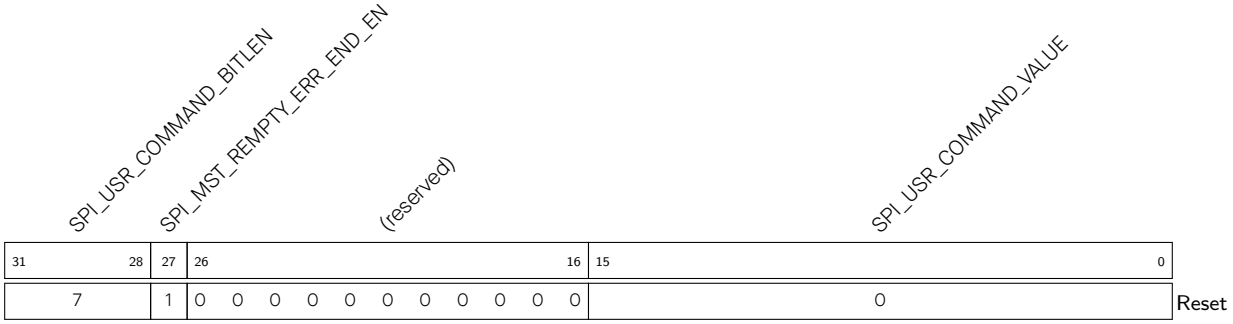
This value is equal to the expected cycles - 1. This field is used together with SPI_CS_SETUP.

(R/W)

SPI_CS_HOLD_TIME Configures the delay cycles of CS pin.

Measurement unit: SPI_CLK clock cycles.

This field is used together with SPI_CS_HOLD.



(R/W)

SPI_USR_ADDR_BITLEN Configures the bit length in address state.

This value is (expected bit number - 1).

(R/W)

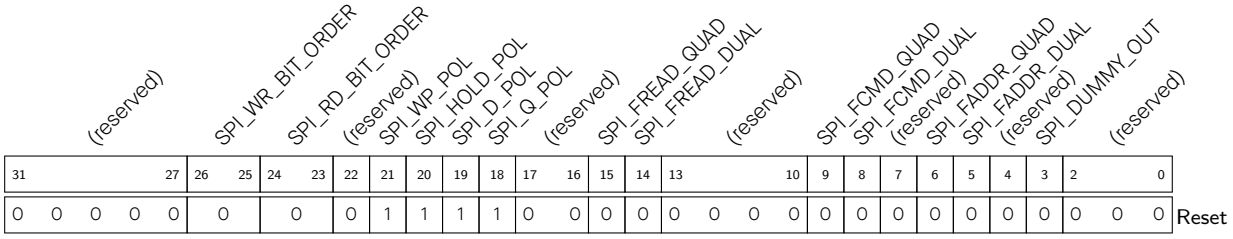
Register 46.43. SPI_USER2_REG (0x0018)

SPI_USR_COMMAND_VALUE Configures the command value.

(R/W)

SPI_MST_REMPTY_ERR_END_EN Configures whether or not to end the SPI transfer when SPI TX AFIFO read empty error occurs in master full-/half-duplex transfers.

0: Not end



1: End

(R/W)

SPI_USR_COMMAND_BITLEN Configures the bit length of command state. This value is (expected bit number - 1).

(R/W)

Register 46.44. SPI_CTRL_REG (0x0008)

SPI_DUMMY_OUT Configures whether or not to output the SPI3 bus signals in DUMMY state.

0: Not output

1: Output

(R/W)

SPI_FADDR_DUAL Configures whether or not to enable 2-bit mode during address (ADDR) state.

0: Disable

1: Enable

(R/W)

SPI_FADDR_QUAD Configures whether or not to enable 4-bit mode during address (ADDR) state.

0: Disable

1: Enable

(R/W)

SPI_FCMD_DUAL Configures whether or not to enable 2-bit mode during command (CMD) state.

0: Disable

1: Enable

(R/W)

SPI_FCMD_QUAD Configures whether or not to enable 4-bit mode during command (CMD) state.

0: Disable

1: Enable

(R/W)

SPI_FREAD_DUAL Configures whether or not to enable the 2-bit mode of read-data (DIN) state in read operations.

0: Disable

1: Enable

(R/W)

SPI_FREAD_QUAD Configures whether or not to enable the 4-bit mode of read-data (DIN) state in read operations.

0: Disable

1: Enable

(R/W)

Continued on the next page...

Register 46.44. SPI_CTRL_REG (0x0008)

Continued from the previous page...

SPI_Q_POL Configures MISO line polarity.

0: Low

1: High

(R/W)

SPI_D_POL Configures MOSI line polarity.

0: Low

1: High

(R/W)

SPI_HOLD_POL Configures SPI_HOLD output value when SPI is in idle.

0: Output low

1: Output high

(R/W)

SPI_WP_POL Configures the output value of write-protect signal when SPI is in idle.

0: Output low

1: Output high

(R/W)

SPI_RD_BIT_ORDER Configures the bit order in read-data (MISO) state.

0: MSB first

1: LSB first

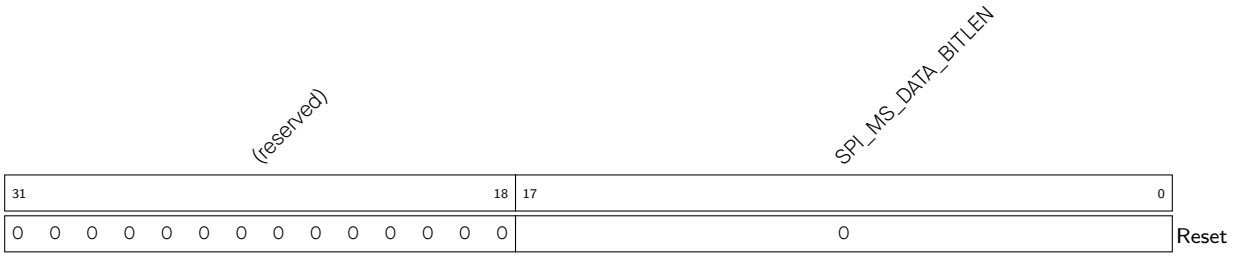
2: MSB first

3: LSB first

(R/W)

SPI_WR_BIT_ORDER Configures the bit order in command (CMD), address (ADDR), and write-data (MOSI) states.

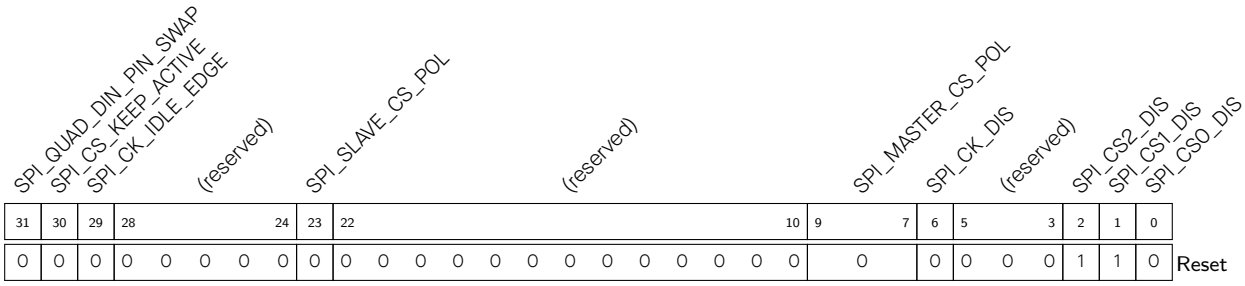
0: MSB first



1: LSB first

2: MSB first

3: LSB first



(R/W)

Register 46.45. SPI_MS_DLEN_REG (0x001C)

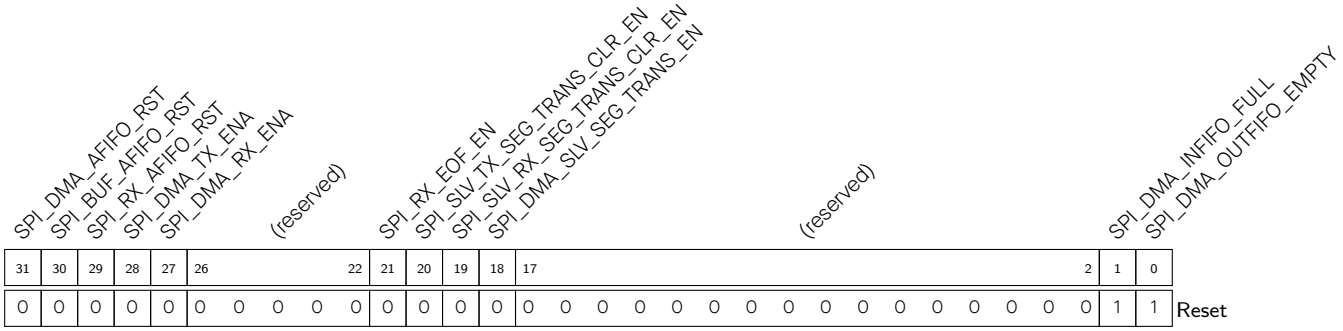
SPI_MS_DATA_BITLEN Configures the data bit length of SPI transfer in CPU-controlled master transfer. Or configures the bit length of SPI RX transfer in DMA-controlled slave transfer.
This value shall be (expected bit_num - 1).
(R/W)

Register 46.46. SPI_MISC_REG (0x0020)

SPI_QUAD_DIN_PIN_SWAP
SPI_CS_KEEP_ACTIVE
SPI_CK_IDLE_EDGE
(reserved)
SPI_SLAVE_CS_POL
(reserved)
SPI_MASTER_CS_POL
SPI_CK_DIS
(reserved)
SPI_CS2_DIS
SPI_CS1_DIS
SPI_CS0_DIS
31 30 29 28 24 23 22 10 9 7 6 5 3 2 1 0
0 0 0

Register 46.46. SPI_MISC_REG (0x0020)

Continued from the previous page...



SPI_QUAD_DIN_PIN_SWAP Configures whether or not to swap SPI Quad input pins.

0: Not swap

1: Swap SPI3_D with SPI3_Q, and SPI3_WP with SPI3_HD

(R/W)

Register 46.47. SPI_DMA_CONF_REG (0x0030)

SPI_DMA_OUTFIFO_EMPTY Represents whether or not the DMA TX FIFO is ready for sending data.

0: Ready

1: Not ready

(RO)

SPI_DMA_INFIFO_FULL Represents whether or not the DMA RX FIFO is ready for receiving data.

0: Ready

1: Not ready

(RO)

SPI_DMA_SLV_SEG_TRANS_EN Configures whether or not to enable DMA-controlled segmented transfer in slave half-duplex communication.

0: Disable

1: Enable

(R/W)

SPI_SLV_RX_SEG_TRANS_CLR_EN In slave segmented transfer, if the size of the DMA RX buffer is smaller than the size of the received data,

1: the data in all the following Wr_DMA transactions will not be received

0: the data in this Wr_DMA transaction will not be received, but in the following transactions,

- if the size of DMA RX buffer is not 0, the data in following Wr_DMA transactions will be received.

- if the size of DMA RX buffer is 0, the data in following Wr_DMA transactions will not be received.

(R/W)

SPI_SLV_TX_SEG_TRANS_CLR_EN In slave segmented transfer, if the size of the DMA TX buffer is smaller than the size of the transmitted data,

1: the data in the following transactions will not be updated, i.e. the old data is transmitted repeatedly.

0: the data in this transaction will not be updated. But in the following transactions,

- if new data is filled in DMA TX FIFO, new data will be transmitted. - if no new data is filled in DMA TX FIFO, no new data will be transmitted.

(R/W)

Continued on the next page...

Register 46.47. SPI_DMA_CONF_REG (0x0030)

Continued from the previous page...

SPI_RX_EOF_EN Configures the trigger source of GDMA_IN_SUC_EOF_CH*n*_INT_RAW.

0: GDMA_IN_SUC_EOF_CH*n*_INT_RAW is set by SPI_TRANS_DONE_INT event in a single transfer, or by an SPI_DMA_SEG_TRANS_DONE_INT event in a segmented transfer.

1: In a DAM-controlled transfer, if the bit number of transferred data is equal to (SPI_MS_DATA_BITLEN + 1), then GDMA_IN_SUC_EOF_CH*n*_INT_RAW will be set by hardware. (R/W)

SPI_DMA_RX_ENA Configures whether or not to enable DMA-controlled receive data transfer.

0: Disable

1: Enable

(R/W)

SPI_DMA_TX_ENA Configures whether or not to enable DMA-controlled send data transfer.

0: Disable

1: Enable

(R/W)

SPI_RX_AFIFO_RST Configures whether or not to reset RX AFIFO (i.e., spi_rx_afifo in Figure 46.5-3 and Figure 46.5-4), which is used to receive data in SPI master and slave transfer.

0: Not reset

1: Reset

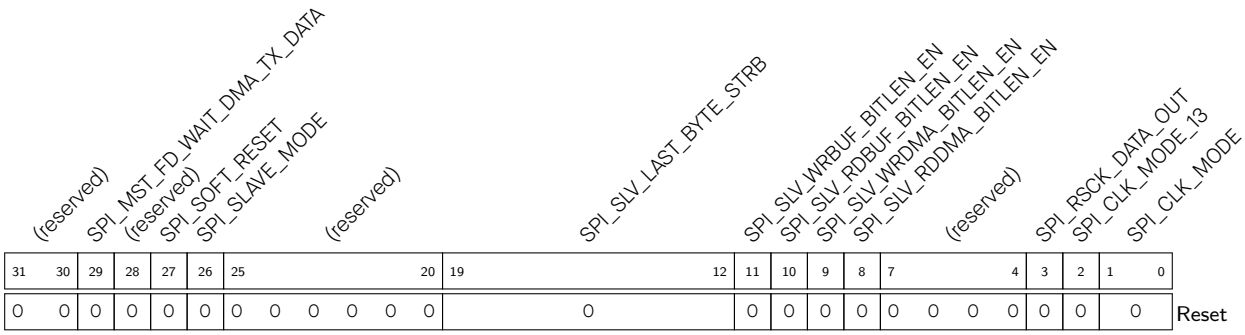
(WT)

SPI_BUF_AFIFO_RST Configures whether or not to reset BUF TX AFIFO (i.e., buf_tx_afifo in Figure 46.5-3 and Figure 46.5-4), which is used to send data out in SPI slave CPU-controlled transfer and master transfer.

0: Not reset

1: Reset

(WT)



SPI_DMA_AFIFO_RST Configures whether or not to reset DMA TX AFIFO (i.e., dma_tx_afifo in Figure 46.5-3 and Figure 46.5-4), which is used to send data out in SPI slave DMA-controlled transfer.

0: Not reset

1: Reset

(WT)

Register 46.48. SPI_SLAVE_REG (0x00E0)

SPI_CLK_MODE Configures SPI clock mode.

0: SPI clock is off when CS becomes inactive.

1: SPI clock is delayed one cycle after CS becomes inactive.

2: SPI clock is delayed two cycles after CS becomes inactive.

3: SPI clock is always on.

(R/W)

SPI_CLK_MODE_13 Configures clock mode.

0: SPI clock mode 1 and mode 3.See Table 46.7-2.

1: SPI clock mode 0 and mode 2. See Table 46.7-2.

(R/W)

SPI_RSCK_DATA_OUT Configures the edge of output data.

0: Output data at TSCK rising edge.

1: Output data at RSCK rising edge.

(R/W)

SPI_SLV_RDDMA_BITLEN_EN Configures whether or not to use SPI_SLV_DATA_BITLEN to store the data bit length of Rd_DMA transfer.

0: Not use

1: Use

(R/W)

SPI_SLV_WRDMA_BITLEN_EN Configures whether or not to use SPI_SLV_DATA_BITLEN to store the data bit length of Wr_DMA transfer.

0: Not use

1: Use

(R/W)

SPI_SLV_RDBUF_BITLEN_EN Configures whether or not to use SPI_SLV_DATA_BITLEN to store the data bit length of Rd_BUF transfer.

0: Not use

1: Use

(R/W)

Continued on the next page...

Register 46.48. SPI_SLAVE_REG (0x00E0)

Continued from the previous page...

SPI_SLV_WRBUF_BITLEN_EN Configures whether or not to use SPI_SLV_DATA_BITLEN to store the data bit length of Wr_BUF transfer.

0: Not use

1: Use

(R/W)

SPI_SLV_LAST_BYTE_STRB Represents the valid bits of the last received data byte in SPI slave full-duplex and half-duplex transfer.

(R/SS)

SPI_SLAVE_MODE Configures SPI work mode.

0: Master

1: Slave

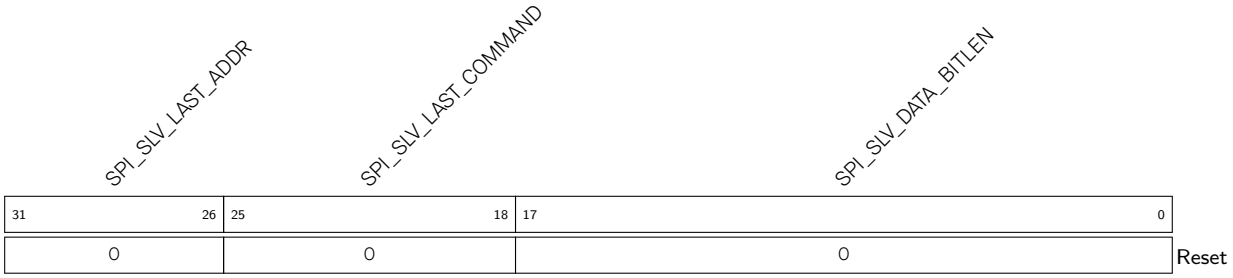
(R/W)

SPI_SOFT_RESET Configures whether to reset the SPI clock line, CS line, and data line via software.

0: Not reset

1: Reset

(WT)



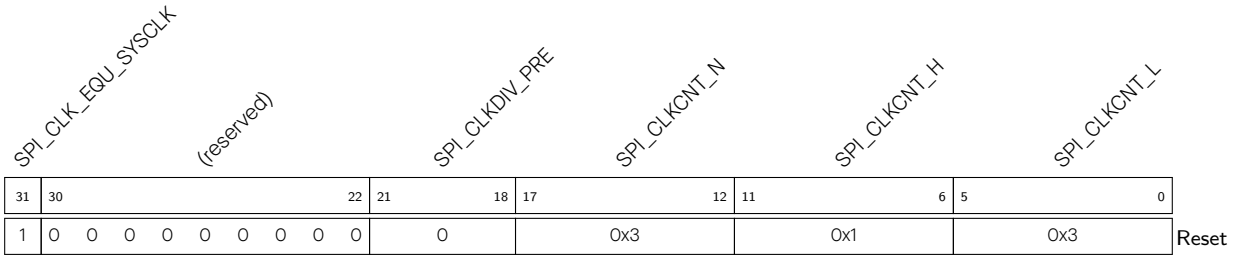
SPI_MST_FD_WAIT_DMA_TX_DATA Configures whether or not to wait DMA TX data gets ready before starting SPI transfer in master full-duplex transfer.

0: Not wait

1: Wait

(R/W)

Register 46.49. SPI_SLAVE1_REG (0x00E4)



SPI_SLV_DATA_BITLEN Configures the transferred data bit length in SPI slave full-/half-duplex modes.
(R/W/SS)

SPI_SLV_LAST_COMMAND Configures the command value in slave mode.
(R/W/SS)

SPI_SLV_LAST_ADDR Configures the address value in slave mode.
(R/W/SS)

Register 46.50. SPI_CLOCK_REG (0x000C)

SPI_CLKCNT_L Configures clock duty cycles, together with SPI_CLKCNT_H and SPI_CLKCNT_N.

In master transfer, this field must be equal to SPI_CLKCNT_N.

In slave mode, it must be 0.

Can be configured in CONF state.

(R/W)

SPI_CLKCNT_H Configures the duty cycle of SPI_CLK (high level) in master transfer.

It's recommended to configure this value to floor((SPI_CLKCNT_N + 1)/2 - 1). floor() here is to round a number down, e.g., floor(2.2) = 2.

In slave mode, it must be 0.

(R/W)

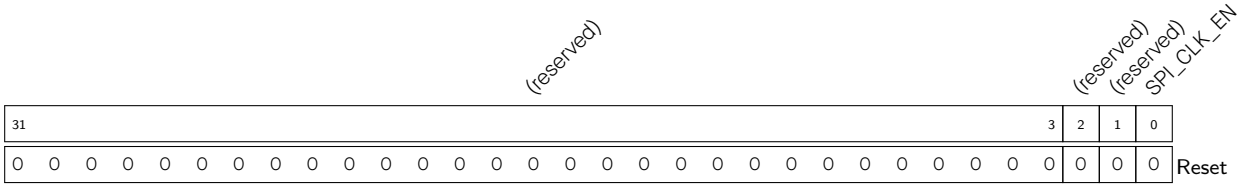
SPI_CLKCNT_N Configures the divider of SPI_CLK in master transfer.

SPI_CLK frequency is $f_{clk_spi_mst}$/(SPI_CLKDIV_PRE + 1)/(SPI_CLKCNT_N + 1).

(R/W)

SPI_CLKDIV_PRE Configures the pre-divider of SPI_CLK in master transfer.

(R/W)



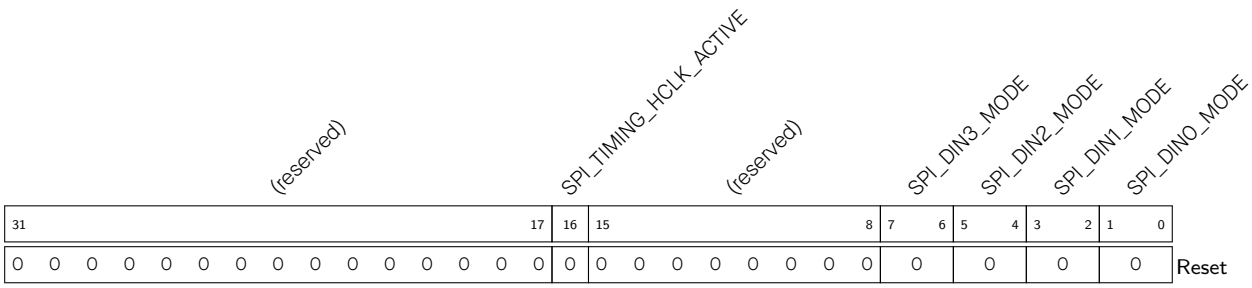
SPI_CLK_EQU_SYSCLK Configures whether or not the SPI_CLK is equal to clk_spi_mst in master transfer.

0: SPI_CLK is divided from clk_spi_mst.

1: SPI_CLK is equal to clk_spi_mst.

(R/W)

Register 46.51. SPI_CLK_GATE_REG (0x00E8)



SPI_CLK_EN Configures whether or not to enable clock gate.

0: Disable

1: Enable

(R/W)

Register 46.52. SPI_DIN_MODE_REG (0x0024)

SPI_DIN0_MODE Configures the input mode for SPI3_D signal.

0: Input without delay

1: Input at the (SPI_DIN0_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN0_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN0_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

(R/W)

SPI_DIN1_MODE Configures the input mode for SPI3_Q signal.

0: Input without delay

1: Input at the (SPI_DIN1_NUM+1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN1_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN1_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

(R/W)

SPI_DIN2_MODE Configures the input mode for SPI3_WP signal.

0: Input without delay

1: Input at the (SPI_DIN2_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN2_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

3: Input at the (SPI_DIN2_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

(R/W)

SPI_DIN3_MODE Configures the input mode for SPI3_HD signal.

0: Input without delay

1: Input at the (SPI_DIN3_NUM + 1)th falling edge of clk_spi_mst

2: Input at the (SPI_DIN3_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst rising edge cycle

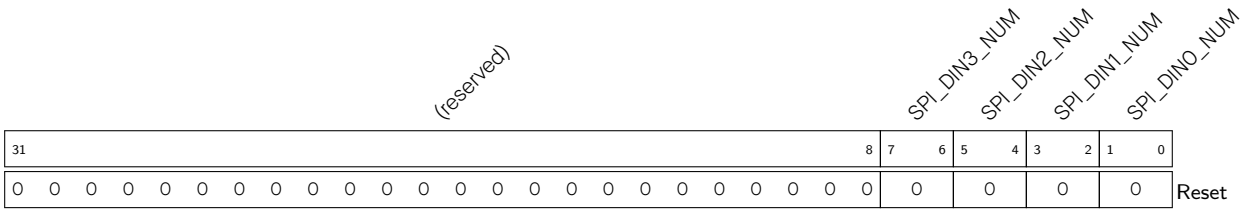
3: Input at the (SPI_DIN3_NUM + 1)th rising edge of clk_hclk plus one clk_spi_mst falling edge cycle

(R/W)

Continued on the next page...

Register 46.52. SPI_DIN_MODE_REG (0x0024)

Continued from the previous page...



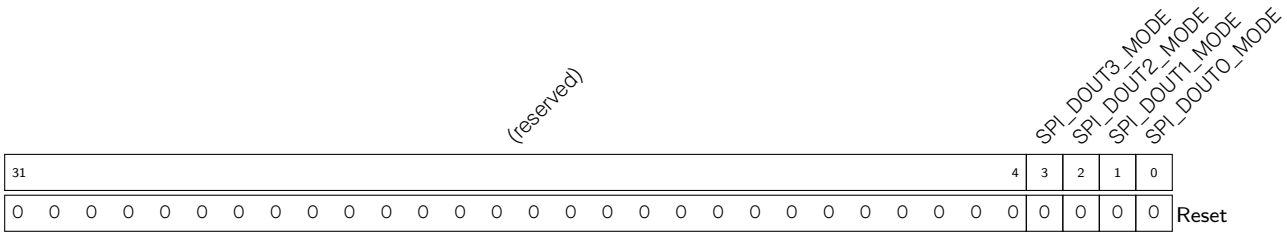
SPI_TIMING_HCLK_ACTIVE Configures whether or not to enable HCLK (high-frequency clock) in SPI input timing module.

0: Disable

1: Enable

(R/W)

Register 46.53. SPI_DIN_NUM_REG (0x0028)



SPI_DIN0_NUM Configures the delays to input signal SPI3_D based on the setting of SPI_DIN0_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
(R/W)

SPI_DIN1_NUM Configures the delays to input signal SPI3_Q based on the setting of SPI_DIN1_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
(R/W)

SPI_DIN2_NUM Configures the delays to input signal SPI3_WP based on the setting of SPI_DIN2_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
(R/W)

SPI_DIN3_NUM Configures the delays to input signal SPI3_HD based on the setting of SPI_DIN3_MODE.
0: Delayed by 1 clock cycle
1: Delayed by 2 clock cycles
2: Delayed by 3 clock cycles
3: Delayed by 4 clock cycles
(R/W)

Register 46.54. SPI_DOUT_MODE_REG (0x002C)

SPI_DOUT0_MODE Configures the output mode for SPI3_D signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

(R/W)

SPI_DOUT1_MODE Configures the output mode for SPI3_Q signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

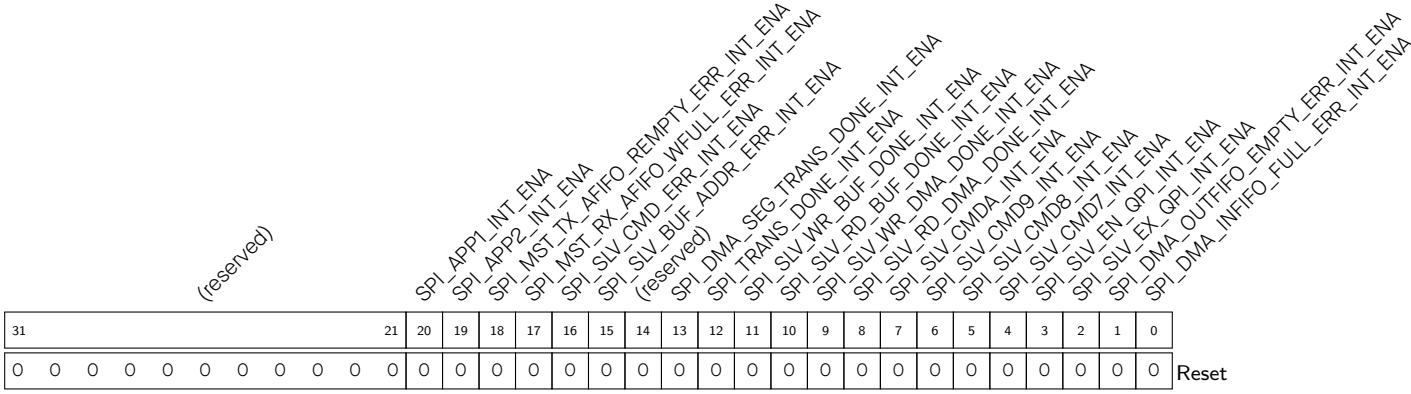
(R/W)

SPI_DOUT2_MODE Configures the output mode for SPI3_WP signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

(R/W)



SPI_DOUT3_MODE Configures the output mode for SPI3_HD signal.

0: Output without delay

1: Output with a delay of a SPI module clock cycle at its falling edge

(R/W)

Register 46.55. SPI_DMA_INT_ENA_REG (0x0034)

SPI_DMA_INFIFO_FULL_ERR_INT_ENA Write 1 to enable SPI_DMA_INFIFO_FULL_ERR_INT interrupt.
(R/W)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_ENA Write 1 to enable SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt.
(R/W)

SPI_SLV_EX_QPI_INT_ENA Write 1 to enable SPI_SLV_EX_QPI_INT interrupt.
(R/W)

SPI_SLV_EN_QPI_INT_ENA Write 1 to enable SPI_SLV_EN_QPI_INT interrupt.
(R/W)

SPI_SLV_CMD7_INT_ENA Write 1 to enable SPI_SLV_CMD7_INT interrupt.
(R/W)

SPI_SLV_CMD8_INT_ENA Write 1 to enable SPI_SLV_CMD8_INT interrupt.
(R/W)

SPI_SLV_CMD9_INT_ENA Write 1 to enable SPI_SLV_CMD9_INT interrupt.
(R/W)

SPI_SLV_CMDA_INT_ENA Write 1 to enable SPI_SLV_CMDA_INT interrupt.
(R/W)

SPI_SLV_RD_DMA_DONE_INT_ENA Write 1 to enable SPI_SLV_RD_DMA_DONE_INT interrupt.
(R/W)

SPI_SLV_WR_DMA_DONE_INT_ENA Write 1 to enable SPI_SLV_WR_DMA_DONE_INT interrupt.
(R/W)

SPI_SLV_RD_BUF_DONE_INT_ENA Write 1 to enable SPI_SLV_RD_BUF_DONE_INT interrupt.
(R/W)

SPI_SLV_WR_BUF_DONE_INT_ENA Write 1 to enable SPI_SLV_WR_BUF_DONE_INT interrupt.
(R/W)

Continued on the next page...

Register 46.55. SPI_DMA_INT_ENA_REG (0x0034)

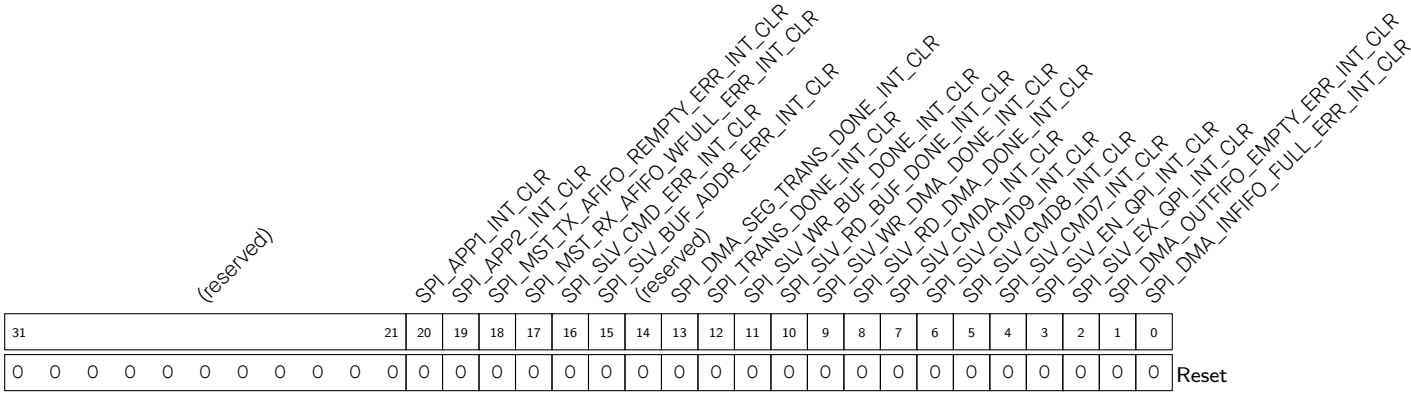
Continued from the previous page...

SPI_TRANS_DONE_INT_ENA Write 1 to enable SPI_TRANS_DONE_INT interrupt. (R/W)

SPI_DMA_SEG_TRANS_DONE_INT_ENA Write 1 to enable SPI_DMA_SEG_TRANS_DONE_INT interrupt. (R/W)

SPI_SLV_BUF_ADDR_ERR_INT_ENA Write 1 to enable SPI_SLV_BUF_ADDR_ERR_INT interrupt. (R/W)

SPI_SLV_CMD_ERR_INT_ENA Write 1 to enable SPI_SLV_CMD_ERR_INT interrupt. (R/W)



SPI_MST_RX_AFIFO_WFULL_ERR_INT_ENA Write 1 to enable SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt. (R/W)

SPI_MST_TX_AFIFO_REMPTY_ERR_INT_ENA Write 1 to enable SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt. (R/W)

SPI_APP2_INT_ENA Write 1 to enable SPI_APP2_INT interrupt. (R/W)

SPI_APP1_INT_ENA Write 1 to enable SPI_APP1_INT interrupt. (R/W)

Register 46.56. SPI_DMA_INT_CLR_REG (0x0038)

SPI_DMA_INFIFO_FULL_ERR_INT_CLR Write 1 to clear SPI_DMA_INFIFO_FULL_ERR_INT interrupt. (WT)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_CLR Write 1 to clear SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt. (WT)

SPI_SLV_EX_QPI_INT_CLR Write 1 to clear SPI_SLV_EX_QPI_INT interrupt. (WT)

SPI_SLV_EN_QPI_INT_CLR Write 1 to clear SPI_SLV_EN_QPI_INT interrupt. (WT)

SPI_SLV_CMD7_INT_CLR Write 1 to clear SPI_SLV_CMD7_INT interrupt. (WT)

SPI_SLV_CMD8_INT_CLR Write 1 to clear SPI_SLV_CMD8_INT interrupt. (WT)

SPI_SLV_CMD9_INT_CLR Write 1 to clear SPI_SLV_CMD9_INT interrupt. (WT)

SPI_SLV_CMDA_INT_CLR Write 1 to clear SPI_SLV_CMDA_INT interrupt. (WT)

SPI_SLV_RD_DMA_DONE_INT_CLR Write 1 to clear SPI_SLV_RD_DMA_DONE_INT interrupt. (WT)

SPI_SLV_WR_DMA_DONE_INT_CLR Write 1 to clear SPI_SLV_WR_DMA_DONE_INT interrupt. (WT)

SPI_SLV_RD_BUF_DONE_INT_CLR Write 1 to clear SPI_SLV_RD_BUF_DONE_INT interrupt. (WT)

SPI_SLV_WR_BUF_DONE_INT_CLR Write 1 to clear SPI_SLV_WR_BUF_DONE_INT interrupt. (WT)

Continued on the next page...

Register 46.56. SPI_DMA_INT_CLR_REG (0x0038)

Continued from the previous page...

SPI_TRANS_DONE_INT_CLR Write 1 to clear SPI_TRANS_DONE_INT interrupt. (WT)

SPI_DMA_SEG_TRANS_DONE_INT_CLR Write 1 to clear SPI_DMA_SEG_TRANS_DONE_INT interrupt. (WT)

SPI_SLV_BUF_ADDR_ERR_INT_CLR Write 1 to clear SPI_SLV_BUF_ADDR_ERR_INT interrupt. (WT)

SPI_SLV_CMD_ERR_INT_CLR Write 1 to clear SPI_SLV_CMD_ERR_INT interrupt. (WT)

SPI_MST_RX_AFIFO_WFULL_ERR_INT_CLR Write 1 to clear SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt. (WT)

SPI_MST_TX_AFIFO_REMPTY_ERR_INT_CLR Write 1 to clear SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt. (WT)

SPI_APP2_INT_CLR Write 1 to clear SPI_APP2_INT interrupt. (WT)

SPI_APP1_INT_CLR Write 1 to clear SPI_APP1_INT interrupt. (WT)

Register 46.57. SPI_DMA_INT_RAW_REG (0x003C)

SPI_DMA_INFIFO_FULL_ERR_INT_RAW The raw interrupt status of SPI_DMA_INFIFO_FULL_ERR_INT interrupt.
(R/WTC/SS)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_RAW The raw interrupt status of SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt.
(R/WTC/SS)

SPI_SLV_EX_QPI_INT_RAW The raw interrupt status of SPI_SLV_EX_QPI_INT interrupt.
(R/WTC/SS)

SPI_SLV_EN_QPI_INT_RAW The raw interrupt status of SPI_SLV_EN_QPI_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMD7_INT_RAW The raw interrupt status of SPI_SLV_CMD7_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMD8_INT_RAW The raw interrupt status of SPI_SLV_CMD8_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMD9_INT_RAW The raw interrupt status of SPI_SLV_CMD9_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMDA_INT_RAW The raw interrupt status of SPI_SLV_CMDA_INT interrupt.
(R/WTC/SS)

SPI_SLV_RD_DMA_DONE_INT_RAW The raw interrupt status of SPI_SLV_RD_DMA_DONE_INT interrupt.
(R/WTC/SS)

SPI_SLV_WR_DMA_DONE_INT_RAW The raw interrupt status of SPI_SLV_WR_DMA_DONE_INT interrupt.
(R/WTC/SS)

SPI_SLV_RD_BUF_DONE_INT_RAW The raw interrupt status of SPI_SLV_RD_BUF_DONE_INT interrupt.
(R/WTC/SS)

Continued on the next page...

Register 46.57. SPI_DMA_INT_RAW_REG (0x003C)

Continued from the previous page...

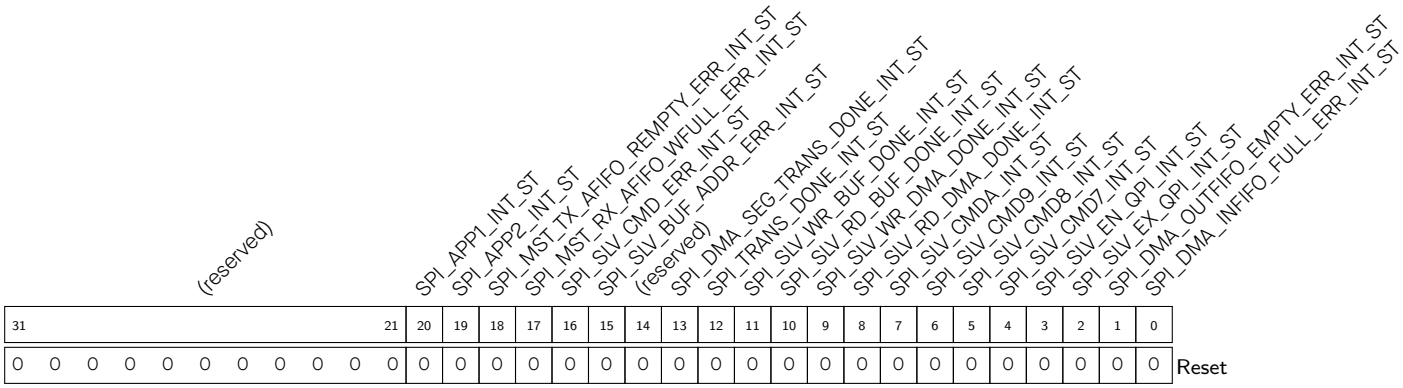
SPI_SLV_WR_BUF_DONE_INT_RAW The raw interrupt status of SPI_SLV_WR_BUF_DONE_INT interrupt.
(R/WTC/SS)

SPI_TRANS_DONE_INT_RAW The raw interrupt status of SPI_TRANS_DONE_INT interrupt.
(R/WTC/SS)

SPI_DMA_SEG_TRANS_DONE_INT_RAW The raw interrupt status of SPI_DMA_SEG_TRANS_DONE_INT interrupt.
(R/WTC/SS)

SPI_SLV_BUF_ADDR_ERR_INT_RAW The raw interrupt status of SPI_SLV_BUF_ADDR_ERR_INT interrupt.
(R/WTC/SS)

SPI_SLV_CMD_ERR_INT_RAW The raw interrupt status of SPI_SLV_CMD_ERR_INT interrupt.
(R/WTC/SS)



SPI_MST_RX_AFIFO_WFULL_ERR_INT_RAW The raw interrupt status of SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt.
(R/WTC/SS)

SPI_MST_TX_AFIFO_REMPTY_ERR_INT_RAW The raw interrupt status of SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt.
(R/WTC/SS)

SPI_APP2_INT_RAW The raw interrupt status of SPI_APP2_INT interrupt. The value is only controlled by the application.
(R/WTC/SS)

SPI_APP1_INT_RAW The raw interrupt status of SPI_APP1_INT interrupt. The value is only controlled by the application.
(R/WTC/SS)

Register 46.58. SPI_DMA_INT_ST_REG (0x0040)

SPI_DMA_INFIFO_FULL_ERR_INT_ST The interrupt status of SPI_DMA_INFIFO_FULL_ERR_INT interrupt.
(RO)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_ST The interrupt status of SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt.
(RO)

SPI_SLV_EX_QPI_INT_ST The interrupt status of SPI_SLV_EX_QPI_INT interrupt.
(RO)

SPI_SLV_EN_QPI_INT_ST The interrupt status of SPI_SLV_EN_QPI_INT interrupt.
(RO)

SPI_SLV_CMD7_INT_ST The interrupt status of SPI_SLV_CMD7_INT interrupt.
(RO)

SPI_SLV_CMD8_INT_ST The interrupt status of SPI_SLV_CMD8_INT interrupt.
(RO)

SPI_SLV_CMD9_INT_ST The interrupt status of SPI_SLV_CMD9_INT interrupt.
(RO)

SPI_SLV_CMDA_INT_ST The interrupt status of SPI_SLV_CMDA_INT interrupt.
(RO)

SPI_SLV_RD_DMA_DONE_INT_ST The interrupt status of SPI_SLV_RD_DMA_DONE_INT interrupt.
(RO)

SPI_SLV_WR_DMA_DONE_INT_ST The interrupt status of SPI_SLV_WR_DMA_DONE_INT interrupt.
(RO)

SPI_SLV_RD_BUF_DONE_INT_ST The interrupt status of SPI_SLV_RD_BUF_DONE_INT interrupt.
(RO)

SPI_SLV_WR_BUF_DONE_INT_ST The interrupt status of SPI_SLV_WR_BUF_DONE_INT interrupt.
(RO)

Continued on the next page...

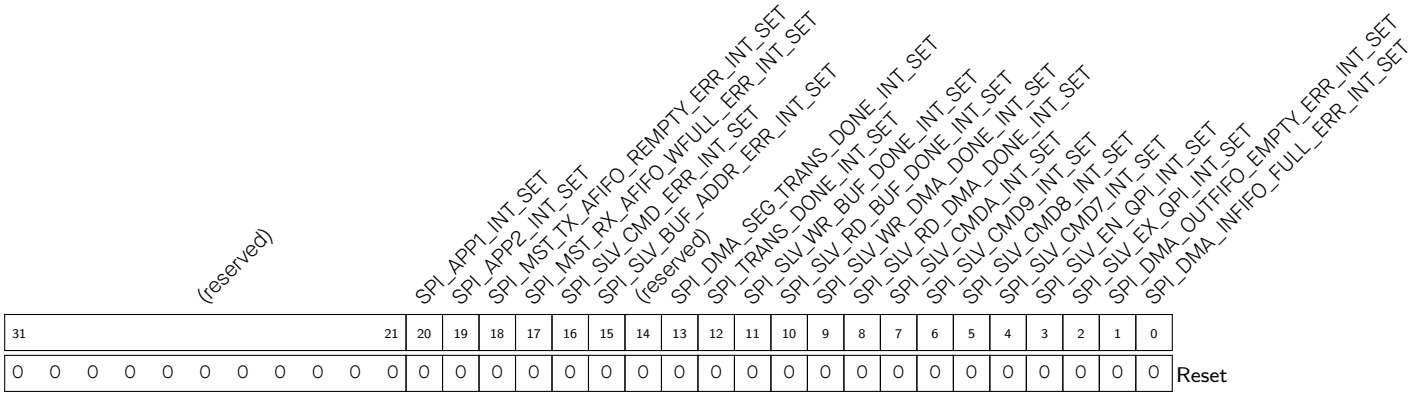
Continued from the previous page...

SPI_TRANS_DONE_INT_ST The interrupt status of SPI_TRANS_DONE_INT interrupt.
(RO)

SPI_DMA_SEG_TRANS_DONE_INT_ST The interrupt status of SPI_DMA_SEG_TRANS_DONE_INT interrupt.
(RO)

SPI_SLV_BUF_ADDR_ERR_INT_ST The interrupt status of SPI_SLV_BUF_ADDR_ERR_INT interrupt.
(RO)

SPI_SLV_CMD_ERR_INT_ST The interrupt status of SPI_SLV_CMD_ERR_INT interrupt.
(RO)



SPI_MST_RX_AFIFO_WFULL_ERR_INT_ST The interrupt status of SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt.
(RO)

SPI_MST_TX_AFIFO_REMPTY_ERR_INT_ST The interrupt status of SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt.
(RO)

SPI_APP2_INT_ST The interrupt status of SPI_APP2_INT interrupt.
(RO)

SPI_APP1_INT_ST The interrupt status of SPI_APP1_INT interrupt.
(RO)

Register 46.59. SPI_DMA_INT_SET_REG (0x0044)

SPI_DMA_INFIFO_FULL_ERR_INT_SET Write 1 to set SPI_DMA_INFIFO_FULL_ERR_INT interrupt. (WT)

SPI_DMA_OUTFIFO_EMPTY_ERR_INT_SET Write 1 to set SPI_DMA_OUTFIFO_EMPTY_ERR_INT interrupt. (WT)

SPI_SLV_EX_QPI_INT_SET Write 1 to set SPI_SLV_EX_QPI_INT interrupt. (WT)

SPI_SLV_EN_QPI_INT_SET Write 1 to set SPI_SLV_EN_QPI_INT interrupt. (WT)

SPI_SLV_CMD7_INT_SET Write 1 to set SPI_SLV_CMD7_INT interrupt. (WT)

SPI_SLV_CMD8_INT_SET Write 1 to set SPI_SLV_CMD8_INT interrupt. (WT)

SPI_SLV_CMD9_INT_SET Write 1 to set SPI_SLV_CMD9_INT interrupt. (WT)

SPI_SLV_CMDA_INT_SET Write 1 to set SPI_SLV_CMDA_INT interrupt. (WT)

SPI_SLV_RD_DMA_DONE_INT_SET Write 1 to set SPI_SLV_RD_DMA_DONE_INT interrupt. (WT)

SPI_SLV_WR_DMA_DONE_INT_SET Write 1 to set SPI_SLV_WR_DMA_DONE_INT interrupt. (WT)

SPI_SLV_RD_BUF_DONE_INT_SET Write 1 to set SPI_SLV_RD_BUF_DONE_INT interrupt. (WT)

SPI_SLV_WR_BUF_DONE_INT_SET Write 1 to set SPI_SLV_WR_BUF_DONE_INT interrupt. (WT)

SPI_TRANS_DONE_INT_SET Write 1 to set SPI_TRANS_DONE_INT interrupt. (WT)

Continued on the next page...

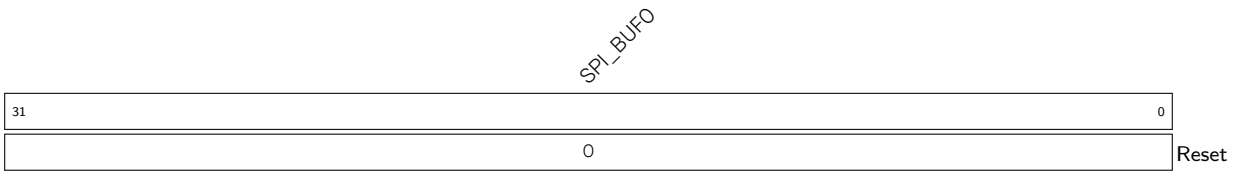
Register 46.59. SPI_DMA_INT_SET_REG (0x0044)

Continued from the previous page...

SPI_DMA_SEG_TRANS_DONE_INT_SET Write 1 to set SPI_DMA_SEG_TRANS_DONE_INT interrupt. (WT)

SPI_SLV_BUF_ADDR_ERR_INT_SET Write 1 to set SPI_SLV_BUF_ADDR_ERR_INT interrupt. (WT)

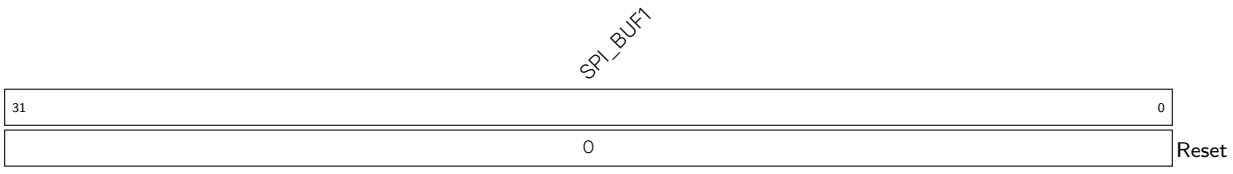
SPI_SLV_CMD_ERR_INT_SET Write 1 to set SPI_SLV_CMD_ERR_INT interrupt. (WT)



SPI_MST_RX_AFIFO_WFULL_ERR_INT_SET Write 1 to set SPI_MST_RX_AFIFO_WFULL_ERR_INT interrupt. (WT)

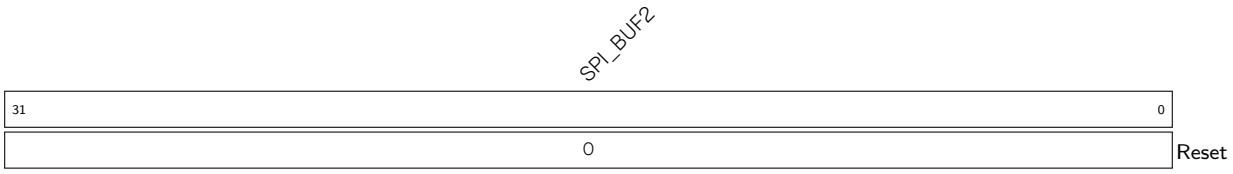
SPI_MST_TX_AFIFO_REMPTY_ERR_INT_SET Write 1 to set SPI_MST_TX_AFIFO_REMPTY_ERR_INT interrupt. (WT)

SPI_APP2_INT_SET Write 1 to set SPI_APP2_INT interrupt. (WT)



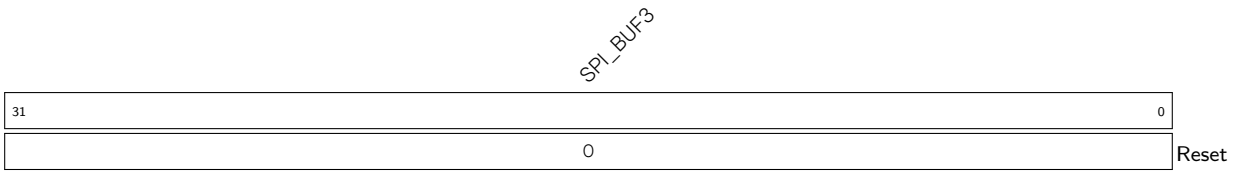
SPI_APP1_INT_SET Write 1 to set SPI_APP1_INT interrupt. (WT)

Register 46.60. SPI_W0_REG (0x0098)



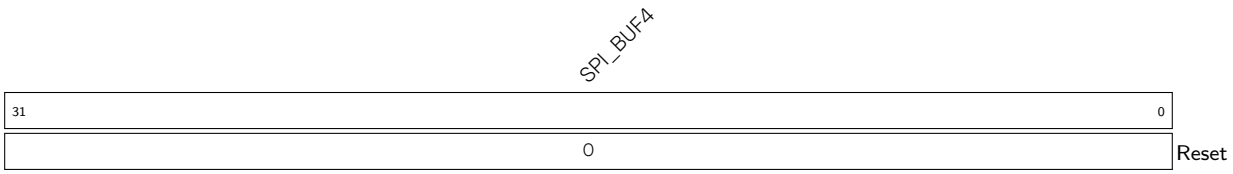
SPI_BUF0 32-bit data buffer 0. (R/W/SS)

Register 46.61. SPI_W1_REG (0x009C)



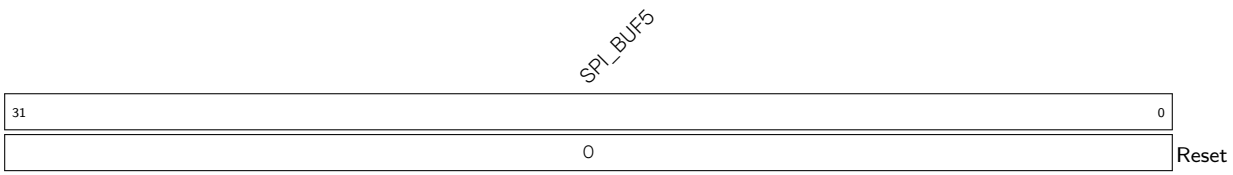
SPI_BUF1 32-bit data buffer 1. (R/W/SS)

Register 46.62. SPI_W2_REG (0x00A0)



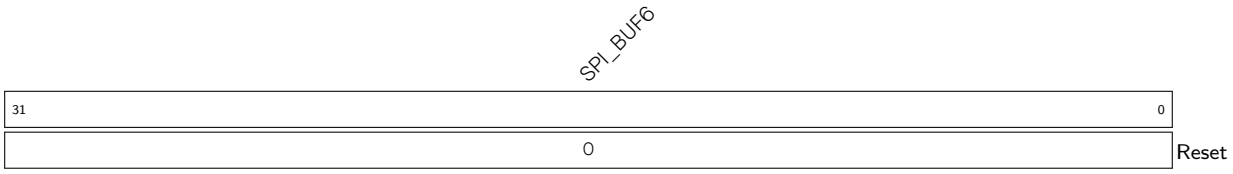
SPI_BUF2 32-bit data buffer 2.
(R/W/SS)

Register 46.63. SPI_W3_REG (0x00A4)



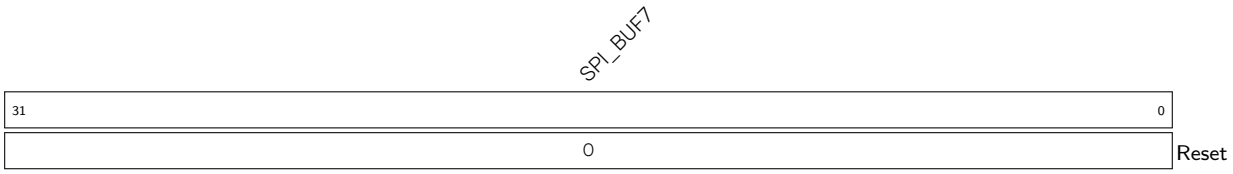
SPI_BUF3 32-bit data buffer 3.
(R/W/SS)

Register 46.64. SPI_W4_REG (0x00A8)



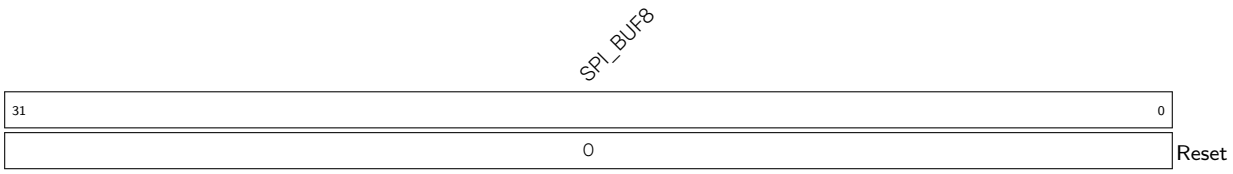
SPI_BUF4 32-bit data buffer 4.
(R/W/SS)

Register 46.65. SPI_W5_REG (0x00AC)



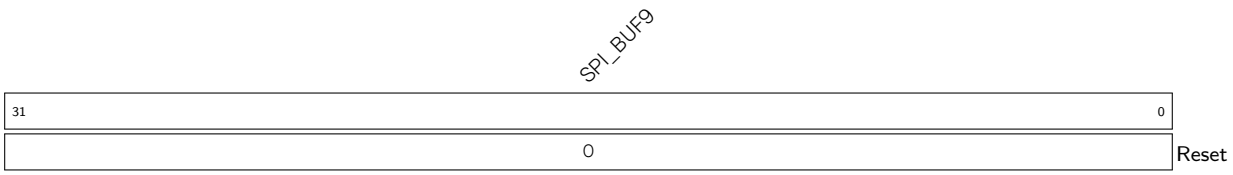
SPI_BUF5 32-bit data buffer 5.
(R/W/SS)

Register 46.66. SPI_W6_REG (0x00B0)



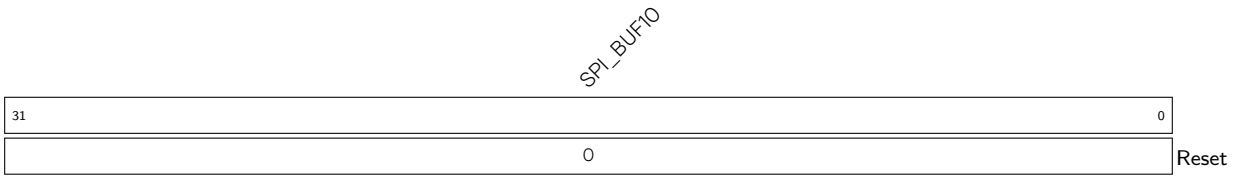
SPI_BUF6 32-bit data buffer 6.
(R/W/SS)

Register 46.67. SPI_W7_REG (0x00B4)



SPI_BUF7 32-bit data buffer 7.
(R/W/SS)

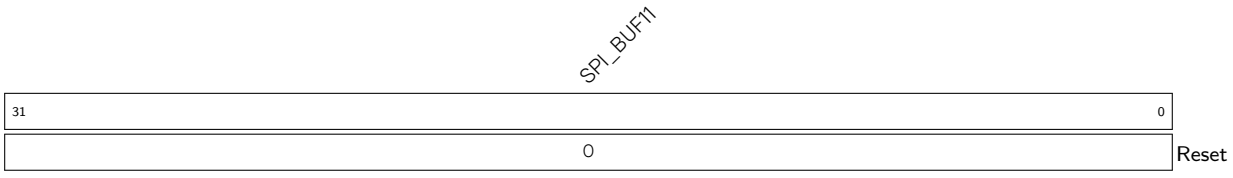
Register 46.68. SPI_W8_REG (0x00B8)



SPI_BUF8 32-bit data buffer 8.
(R/W/SS)

Register 46.69. SPI_W9_REG (0x00BC)

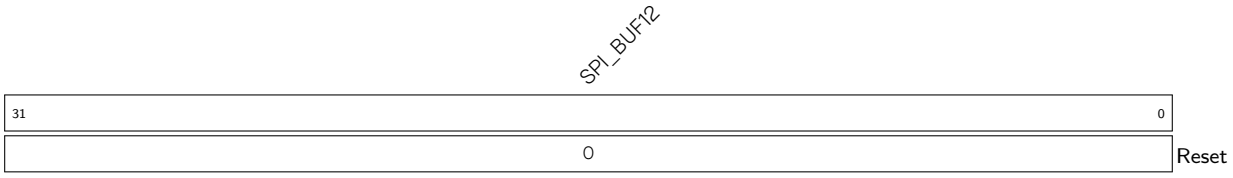
SPI_BUF9 32-bit data buffer 9.
(R/W/SS)



Register 46.70. SPI_W10_REG (0x00C0)

SPI_BUF10 32-bit data buffer 10.

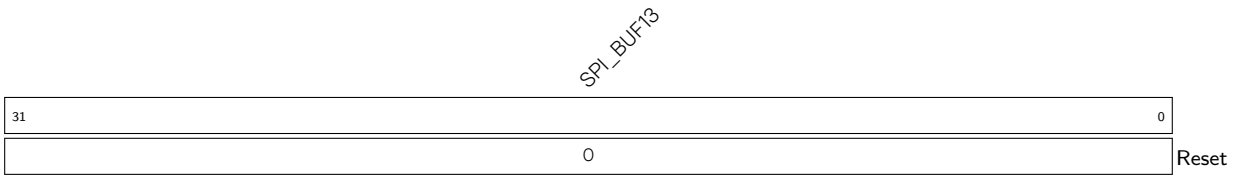
(R/W/SS)



Register 46.71. SPI_W11_REG (0x00C4)

SPI_BUF11 32-bit data buffer 11.

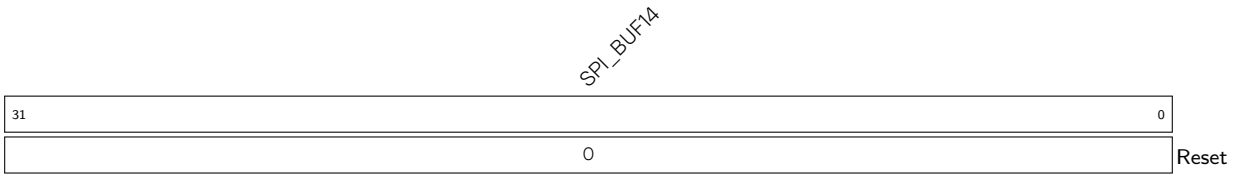
(R/W/SS)



Register 46.72. SPI_W12_REG (0x00C8)

SPI_BUF12 32-bit data buffer 12.

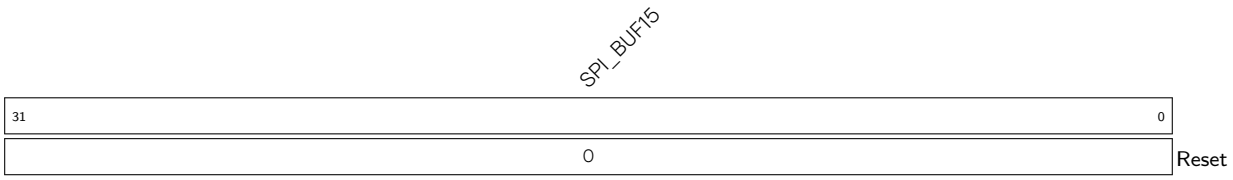
(R/W/SS)



Register 46.73. SPI_W13_REG (0x00CC)

SPI_BUF13 32-bit data buffer 13.

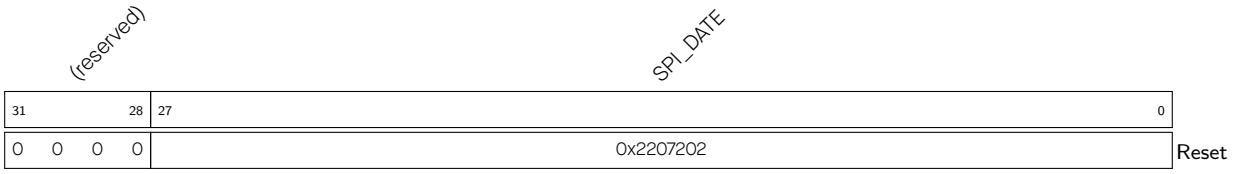
(R/W/SS)



Register 46.74. SPI_W14_REG (0x00D0)

SPI_BUF14 32-bit data buffer 14.

(R/W/SS)



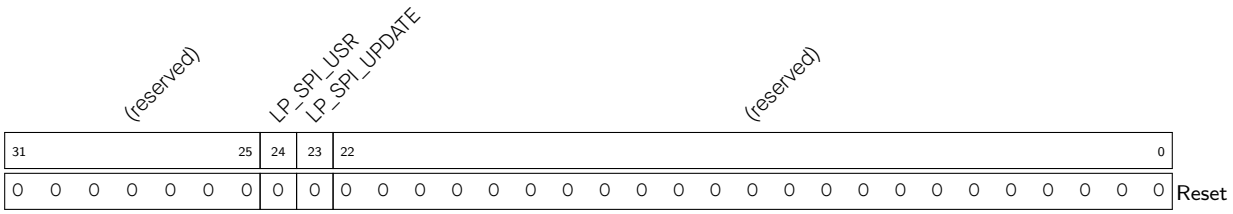
Register 46.75. SPI_W15_REG (0x00D4)

SPI_BUF15 32-bit data buffer 15.

(R/W/SS)

Register 46.76. SPI_DATE_REG (0x00F0)

SPI_DATE Version control register.



(R/W)

46.13.3 LP-SPI Register

The addresses in this section are relative to LP-SPI base address provided in Table 9.3-2 in Chapter 9 *System and Memory*.

For how to program reserved fields, please refer to Section *Programming Reserved Register Field*.

Register 46.77. LP_SPI_CMD_REG (0x0000)

LP_SPI_UPDATE Configures whether or not to synchronize SPI registers from APB clock domain into SPI module clock domain.

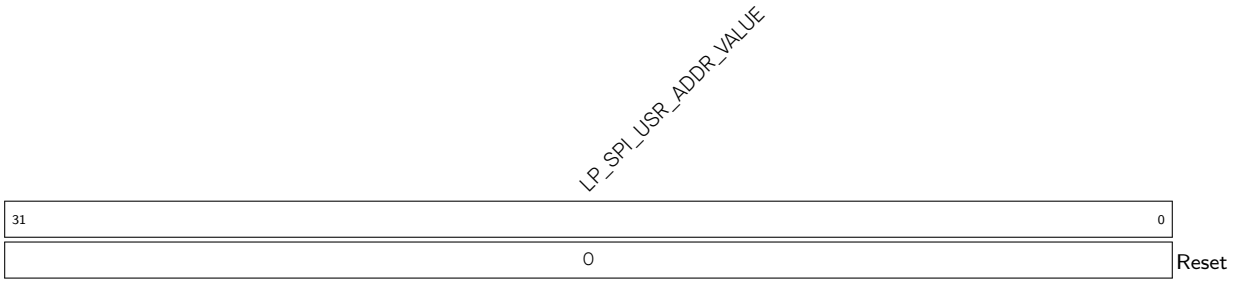
0: Not synchronize

1: Synchronize

This bit is only used in SPI master transfer.

(WT)

LP_SPI_USR Configures whether or not to enable user-defined command.

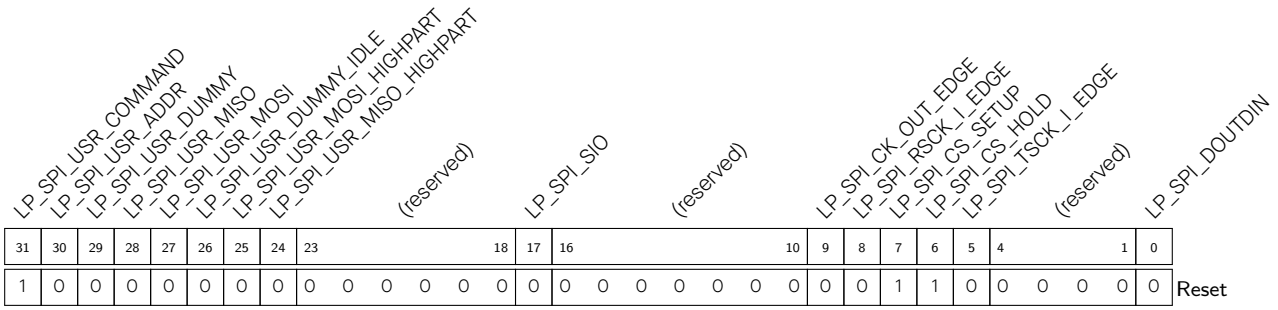


0: Not enable

1: Enable

An SPI operation will be triggered when the bit is set. This bit will be cleared once the operation is done.

(R/W/SC)



Register 46.78. LP_SPI_ADDR_REG (0x0004)

LP_SPI_USR_ADDR_VALUE Configures the address to slave.

(R/W)

Register 46.79. LP_SPI_USER_REG (0x0010)

LP_SPI_DOUTDIN Configures whether or not to enable full-duplex communication.

0: Disable

1: Enable

(R/W)
